PROCEEDINGS

IX International Conference IcETRAN

and LXVI ETRAN Conference,

Novi Pazar, Serbia, 6 - 9, June, 2022.

ЗБОРНИК РАДОВА

IX међународне конференције ИцЕТРАН

и LXVI конференције ЕТРАН,

Нови Пазар 6 - 9. јуна 2022. године

PROCEEDINGS IX International Conference IcETRAN and LXVI ETRAN Conference, Novi Pazar, Serbia, 6 - 9, June, 2022.

ЗБОРНИК РАДОВА IX међународне конференције ИцЕТРАН и LXVI конференције ЕТРАН, Нови Пазар 6 - 9. јуна 2022. године

Editor in Charge / Главни уредник
Vladimir Katić / Владимир Катић

Published by **/ ETRAN Society, Belgrade, Academic Mind, Belgrade**
Издавачи / **Друштво за ЕТРАН, Београд и Академска мисао, Београд**

Production / Израда
Academic Mind, Belgrade / Академска мисао, Београд

Place and year of publication / Место и година издања
Belgrade, 2022. / Београд, 2022.

Circulation / Тираж
300 copies / 300 примерака

ISBN 978-86-7466-930-3

ETRAN – Society for electronics, telecommunication, computing, automatics and nuclear angineering

ЕТРАН - Друштво за електронику, телекомуникације, рачунарство, аутоматику и нуклеарну технику

Kneza Milosa 9/IV, 11000 Belgrade / Кнеза Милоша 9/IV, 11000 Београд

Phone / Телефон: +381 (11) 3233 957

ORGANIZERS - ОРГАНИЗАТОРИ

ETRAN Society, Belgrade / Друштво за ЕТРАН, Београд

State University of Novi Pazar, Novi Pazar, Serbia / Државни универзитет у Новом Пазару, Нови Пазар, Србија

University of Priština temporarily settled in Kosovska Mitrovica, Faculty of Technical Sciences, Serbia / Факултет техничких наука Косовска Митровица - Универзитет у Приштини са привременим седиштем у Косовској Митровици

UNDER THE AUSPICES OF / ПОКРОВИТЕЉ

Ministry of Education, Science and Technological Development of the Republic of Serbia /

Министарство просвете, науке и технолошког развоја републике Србије

SUPPORTED BY / ПОДРШКА

IEEE – Institute of Electrical and Electronics Engineers, USA

Power Electronics Society of Serbia / Друштво за енергетску електронику Србије

CIRED Serbia / CIRED Србија

ЗБОРНИК РАДОВА/PROCEEDINGS

ИМПРЕСУМ/IMPRESUM

	ACOUSTICS/АКУСТИКА - (AKI/АК)	1
AKI1.1	Recent Advances on Perforated Panels for Sound Absorption Applications *Jesus Carbajo, Nicholas Xuanlai Fang and Sang-Hoon Nam*	2
AKI1.2	Real-time Speaker Independent Recognition of Bimodal Produced Speech *Boris Malčić, Vlado Delić, Jovan Galić and Nebojša Babić*	6
AKI1.3	Feature Analysis for Industrial Product Sounds Using Discrete Meyer Wavelet *Đorđe Damnjanović, Dejan Ćirić and Dejan Vujičić*	12
AK1.1	Multidisciplinarnost u istraživanju slike i zvuka u sakralnom prostoru *Jelena Erdeljan and Ljubica Vinulović*	18
AK1.2	Auralizacija sakralnih prostora i likovni programi: nove perspektive i mogućnosti istraživanja *Vuk Dautović and Jakov Đorđević*	21
AK1.3	Istraživanje zvučnog ambijenta srpskih sakralnih prostora kao višemedijskog fenomena *Miomir Mijić, Miloš Bjelić, Dragana Šumarac Pavlović, Tatjana Miljković and Filip Pantelić*	25
AK1.4	O ulozi akustičkih rezonatora u prostoru hrama Svetog Save u Beogradu *Dragana Šumarac Pavlović, Miomir Mijić, Jelena Erdeljan and Tatjana Miljković*	31
AK2.1	Optimizacija prostorne rezolucije mikrofonskog niza za merenje saobraćajne buke *Miodrag Stanojević, Miloš Bjelić and Tatjana Miljković*	37
AK2.2	Komparativna analiza akustičkih signala motora sa unutrašnjim sagorevanjem mapiranih u slike bazirane na spektrogramu *Marko Milivojčević, Emilija Kisić and Dejan Ćirić*	41
AK2.3	Koeficijent inharmoničnosti tonova harfe -Specifičnost i problemi automatske procene *Tatjana Miljkovic, Miloš Bjelić, Jelena Ćertić and Dragana Šumarac Pavlović*	46
AK2.4	Implementacija algoritama za kontrolu usmerenosti zvučničkog niza sa dva glavna loba na otvorenom hardveru *Tijana Đorđević, Stefan Aćimović and Miloš Bjelić*	52
AK2.5	Optimizacija pozicija zvučnika u zvučničkom nizu *Stefan Aćimović, Tijana Đorđević and Miloš Bjelić*	58
AK2.6	Realizacija sistema za aktivnu kontrolu buke u cevi na otvorenom hardveru *Marija Ratković, Nebojša Kolarić and Miloš Bjelić*	63
	ANTENNAS AND PROPAGATION/АНТЕНЕ И ПРОСТИРАЊЕ - (API/АП)	69
API1.1	Application of Microwave Imaging for Brain Diagnostics *Marija Nikolic Stevanovic, Darko Ninkovic, Tushar Singh, Branislav Ninkovic, Miodrag Tasic and Branko Kolundzija*	70
API1.2	Current distribution in a hollow circular conductor influenced by a parallel filament *Dragan Filipović and Tatijana Dlabač*	75
API1.3	Jamming a Drone - EM Simulation of Simple EW and EW Countermeasures Scenarios *Tomislav Milosevic*	80
API1.4	Simulation Study of Voxel-Based Head Phantom for Medical Microwave Imaging *Mladjen Stevanetic, Branko Kolundzija, Tushar Singh and Marija Nikolic Stevanovic*	85
API1.5	Radome Shape Impact on Automotive Radar Sensor Operating at 79 GHz *Nebojsa Pupavac and Miodrag Tasic*	90
API1.6	Implementing Gradient Model for Surface Roughness in WIPL-D *Milan Radović, Aleksandar Golubović and Miloš Jovičić*	95
API1.7	The Ability to Minimize a New Type of Moderate-Bandwidth Microwave Filter *Dušan Nešić and Tomislav Milošević*	99
AP1.1	Uopštenje izraza za transfer funkcije između antena u problemima inverznog rasejanja *Anja Kovačević, Marija Nikolić Stevanović and Antonije Đorđević*	102
	AUTOMATION/АУТОМАТИКА - (AUI/АУ)	106
AUI1.1	The Improved GM PHD algorithm for Multi- Target Radar Tracking *Zvonko Radosavljevic, Dejan Ivkovic and Branko Kovacevic*	107
AUI1.2	Four-Stage Recursive Least Squares Algorithm for CARARMA Systems *Nasar Aldian Shashoa, Ahmed J Abougarair, Bdulhakim Agll and Abdurrezag Elmezughi*	113
AUI1.3	Consensus on the Auxiliary Variables in Distributed Gradient-Based Temporal Difference Algorithms *Milos Stankovic, Marko Beko, Nemanja Ilic and Srdjan Stankovic*	118
AUI1.5	Arduino based online laboratory platform for digital control systems analysis and design *Vladimir Mitić, Vladimir Sibinović, Snežana Đorđević and Boban Veselić*	124
AUI2.1	Implementation of the New Curricula in Smart Products and Services Engineering *Marko Milojkovic, Dragan Antic, Sasa Nikolic and Nebojsa Jotovic*	129
AUI2.2	Denoising the open-loop step response using an encoder-decoder convolutional neural network *Natalija Đorđević, Nenad Džamić, Aleksa Stojić and Goran Kvaščev*	132

AUI2.3	Single Screw Extruder Temperature Control Using PLC and HMI in Cable Production Process *Igor Kocić, Saša Nikolić, Aleksandra Milovanović, Darko Mitić, Petar Đekić and Nikola Danković*	137
AU1.1	Upravljanje nivoom vode i pumpama upotrebom SMS poruka *Igor Kocić and Zoran Jovanović*	143
AU1.2	Application of Subtractive Clustering in Data Processing *Boris Barišić, Aleksandra Krstić, Sanja Vujnović and Željko Đurović*	148
	BIOMEDICAL ENGINEERING/БИОМЕДИЦИНСКА ТЕХНИКА - (BTI/БТ)	153
BTI1.1	AGILIS: Restoring Functional Grasping in Individuals with Tetraplegia using Epineural Electrodes *Christine Azevedo, Charles Fattal, Lucie William, Lucas Fonseca, Arthur Hiairrassary, David Andreu, Antoine Geffrier, Jacques Teissier and David Guiraud*	154
BTI1.2	A Device for Monitoring Physiological Parameters and Electrotactile Stimulation *Bojan Jorgovanović, Matija Štrbac, Miloš Kostić, Vojin Ilić and Nikola Jorgovanović*	156
BTI1.3	Deep Neural Network Approach for Artifact Detection in Raw ECG *Tanja Boljanić, Jovana Malešević and Goran Kvaščev*	160
BTI1.4	Inhibition Potency of Terpyridine Metal Complexes toward Penicillin-Binding Protein 1A *Svetlana Jeremić, Enisa Selimović, Milan Dekić and Tanja Soldatović*	164
BTI1.5	GT Analyzer - A Basic Tool for Handwriting Movement Data *Vladimir Džepina, Nikola Ivančević, Vera Miler-Jerković, Blažo Nikolić, Dejan Stevanović, Jasna Jančić and Milica Janković*	168
BTI1.6	Morphological parameters assessment with a depth camera based measurement system *Olivera Tomašević, Luka Mejić, Darko Stanišić and Nikolina Maravić*	173
	POWER ENGINEERING/ЕЛЕКТРОЕНЕРГЕТИКА - (EEI/ЕЕ)	178
EEI1.1	Overview of measuring methods and equipment for calibration of instrument transformers *Dragana Naumovic-Vukovic*	179
EEI1.2	Effects of cryptocurrency mining rig operation on power quality in LV distribution network *Vladimir Katic, Zoltan Corba and Aleksandar Stanisavljevic*	188
EEI1.3	Prediction of voltage dips characteristics in IEEE 13-bus test grid using harmonic footprint *Aleksandar Stanisavljević and Vladimir Katic*	194
EEI1.4	Optimal Power Dispatch in Distribution Networks with PV Generation and Battery Storage *Jordan Radosavljević, Miloš Milovanović, Nebojša Arsić, Andrijana Jovanović, Bojan Perović and Jovan Vukašinović*	199
EEI1.5	Modeling of High-Voltage Induction Machines with Fallen-out Magnetic Slot Wedges *Milica Banović, Kristina Vujkov, Mladen Terzić and Dejan Jerkan*	205
EEI1.6	Time-domain simulation of electric circuit with nonlinear hysteretic inductor *Srđan Divac and Branko Koprivica*	211
EEI1.7	A Comparative Analysis of Three-Phase Phase-Locked Loops for Grid-Connected Systems *Filip Bakić, Lazar Stojanović, Katarina Obradović and Emilija Lukić*	217
EEI2.1	Parameter estimation of induction motors using Wild Horse Optimizer *Jovan Vukašinović, Miloš Milovanović, Nebojša Arsić, Jordan Radosavljević, Saša Štatkić, Bojan Perović and Andrijana Jovanović*	222
EEI2.2	Damper Winding Inductances Calculation by Winding Function Approach *Aldin Kajević and Gojko Joksimović*	228
EE1.1	Inteligentni DTC algoritam sa automatskom reorganizacijom u zavisnosti od intenziteta ripla momenta *Марко Росић*	234
EE1.2	Primjena električnih vozila za smanjenje deficita snage u sistemu *Uroš Ognjenović, Saša Mujović and Lazar Šćekić*	240
EE1.3	Realizacija laboratorijskog sistema za bežični prenos energije *Dejan Janjić, Alenka Milovanović and Branko Koprivica*	246
EE1.4	Pravci istraživanja u elektroenergetici kroz tematsku orijentaciju radova sa skupova CIRED Srbija i ETRAN/IcETRAN *Zoran Simendić and Vladimir Katic*	251
	ELECTRIC CIRCUITS AND SYSTEMS AND SIGNAL PROCESSING/ЕЛЕКТРИЧНА КОЛА, ЕЛЕКТРИЧНИ СИСТЕМИ И ОБРАДА СИГНАЛА - (EKI/ЕК)	257
EKI1.1	A method for laser rangefinder reticle position calibration in a multi-sensor imaging system *Saša Vujić, Miloš Radisavljević, Dragana Perić and Branko Livada*	258
EKI1.2	Linear regression in RR-RT domain for cardiac cycle evaluation *Milan Milivojević, Ana Gavrovska and Dragi Dujković*	264
EKI1.3	Application of Bayes and knn classifiers in tumor detection from brain MRI images *Marta Mirkov and Ana Gavrovska*	268
EKI1.4	From puppet-master creation to false detection *Ana Pantelić and Ana Gavrovska*	273
EK1.1	Kvarcni kristalni filtar frekvencije 35.4 MHz zasnovan na trećem overtonu *Dragi Dujkovic, Ana Gavrovska, Lenkica Grubišić, Snežana Dedić-Nešić, Irini Reljin and Ivan Popovic*	278
EK1.2	Primena vremensko-frekvencijskih metoda kod analize spektra u kognitivnom radiju *Nenad Stojanovic, Milenko Andrić, Dimitrije Bujaković, Boban Bondzulic and Vladimir Ristić*	283
	ELECTRONICS/ЕЛЕКТРОНИКА - (ELI/ЕЛ)	289

ELI1.1	A Gigabit Ethernet Media Access Controller for TCP/UDP Radar Data Streaming and Visualization *Vukan Damnjanović and Vladimir Milovanović*	290
ELI1.2	ANN model for one day ahead Covid-19 prediction *Jelena Milojković, Miljana Milić and Vančo Litovski*	296
ELI1.3	Equivalent Electromechanical Model of a Composite Ultrasonic Transducer *Igor Jovanović and Dragan Mančić*	300
ELI1.4	Hardware Realization of Nearest Neighbour Search Algorithm over an In-Memory Pre-Stored k-d Tree *Aleksandar Kondić and Vladimir Milovanović*	304
	METROLOGY/МЕТРОЛОГИЈА - (MLI/МЛ)	310
MLI1.1	An Intercomparison of the Broadband Electrical Field Meter NARDA NBM 550 *Nenad Munić, Aleksandar Kovacević, Nenko Brkljač and Ljubiša Tomić*	311
MLI1.2	LiDAR measurements in Maritime transport safety and navigation of the deep seafloor *Dijana Džever and Marjan Urekar*	316
ML1.2	Dvokoračna segmentna linearizacija kao deo mernog lanca termopara *Dragan Živanović, Milan Simić, Milica Stojanović and Dragan Denić*	322
ML1.3	Poređenje merenja brzine vetra anemometrom sa lopaticama i ultrasoničnim anemometrom na vetroturbini *Robert Fajhner and Marjan Urekar*	328
ML1.4	Primena linearnog niza fotodetektora kod optičkih pseudoslučajnih pozicionih enkodera *Ivana Ranđelović, Dragan Denić, Goran Miljković and Aleksandar Jocić*	333
ML2.1	Ponovljivost rezultata merenja nivoa električnog polja EM smetnji *Aleksandar Kovačević and Nenad Munić*	337
ML2.2	Pregled elektrogastrografske metode *Jelena Đorđević Kozarov, Platon Sovilj, Marjan Urekar, Milan Šaš and Miroljub Pešić*	340
ML2.3	Sistem za merenje pritiska u konceptu Internet of Things *Tomislav Pap and Marjan Urekar*	344
ML2.4	Merno informacioni sistem za automatsko hranjenje kućnih ljubimaca *Maja Perić and Marjan Urekar*	347
ML2.5	Uređaj za pravilno sedenje baziran na merno-informacionim modulima *Jovana Jović and Marjan Urekar*	352
ML2.6	Merno-akvizicioni sistem za pravilno sedenje *Mario Volaš, Dragan Pejić and Marjan Urekar*	358
ML2.7	Razvoj softvera za merenje vremena reakcije na vizuelne i zvučne stimuluse *Milica Djordjevic, Djordje Novakovic and Marjan Urekar*	364
ML3.1	Projektovanje univerzalne razvojne ploče za merenje i regulaciju *Ninoslav Srdić, Marjan Urekar, Dragan Pejić and Platon Sovilj*	368
ML3.2	Merni sistem za detekciju padova zasnovan na akcelerometru, žiroskopu i GPS modulu *Sanja Mandić and Đorđe Novaković*	373
ML3.3	Merenje karakteristika i modelovanje Hamonovoh etalon otpornika u naizmeničnom režimu *Stefan Mirkovic, Dragan Pejic and Aleksandar Dimitrijevic*	378
ML3.4	Merni sistem za određivanje modula i faznog stava impedanse baziran na virtuelnoj instrumentaciji *Milan Šaš, Dragan Pejić, Nemanja Gazivoda, Đorđe Novaković and Bojan Vujičić*	382
ML3.5	Simulaciona analiza metode pogodne za metrološku karakterizaciju impedanse na niskim frekvencijama *Milan Šaš, Dragan Pejić, Nemanja Gazivoda, Đorđe Novaković and Bojan Vujičić*	386
	MICROELECTRONICS AND OPTOELECTRONICS, NANOSCIENCES AND NANOTECHNOLOGIES/МИКРОЕЛЕКТРОНИКА И ОПТОЕЛЕКТРОНИКА - (MOI/МО)	390
MOI1.1	Two Color Photodiodes Mounted on the Micromachined Carrier *Žarko Lazić, Milče Smiljanić, Dušan Nešić and Ljubiša Zeković*	391
MOI1.2	Optimization of electrodeposition parameters to improve composite hardness of nickel coatings on brass substrate for varying film thicknesses and applied indentation loads *Ivana Mladenović, Jelena Lamovec, Marko Obradov, Milena Rašljić Rafajilović, Vesna Radojević, Dana Vasiljević Radović and Nebojša Nikolić*	395
MOI1.3	Electrically Programmable Analog Device As An Ultraviolet Light Sensor *Stefan Ilić, Milija Sarajlić, Dana Vasiljević-Radović, Marko Andjelković, Alberto J. Palma, Russell Duane and Goran Ristić*	401
MOI1.4	Origin of the Open Circuit Voltage and Important Processes that Affect its Value in Organic Solar Cells *Teodora Pavličević, Jovana Gojanović, Nataša Ćirović and Sandra Živanović*	405
MOI1.5	Design Consideration for Low-Power Step-Up Converter *Jana Vračar, Milan Stojanović, Zoran Prijić, Aneta Prijić and Ljubomir Vračar*	411
MO1.1	Osnovi teorije diferencnih jednačina sa primenom na analizu svojstava nanostruktura *Jovan Šetrajčić, Vjekoslav Sajfert and Siniša Vučenović*	415
MO1.2	Difuzija optičkih pobuđenja u tankim molekulskim filmovima *Jovan Šetrajčić and Siniša Vučenović*	427
MO1.3	Indukovanje stanja sličnih topološkim kod dvoslojnih fosforenskih traka primenom normalnog električnog polja *Vladimir Arsoski and Milan Tadić*	433
MO1.4	Elektronska svojstva grafenskih nanotraka sa periodičnim defektima *Jovana Vlahović, Vladimir Arsoski, Milan Tadić and Milorad Milošević*	437

	MICROWAVE TECHNIQUE, TECHNOLOGIES AND SYSTEMS/МИКРОТАЛАСНА ТЕХНИКА, ТЕХНОЛОГИЈЕ И СИСТЕМИ - (MTI/MT)	441
MTI1.1	On Some Differences Between Wave Digital Models of Directional Couplers *Biljana Stošić, Nebojša Dončov and Marin Nedelchev*	442
MTI1.2	Doherty PA Linearization by Injection of the 2nd order Digitally Processed Signals for 5G FBMC modulation *Aleksandar Atanasković, Nataša Maleš-Ilić, Biljana Stošić and Djuradj Budimir*	448
MTI1.3	Planar Archimedean Spiral Antenna Resonant Frequency and Bandwidth Estimation using MLP Neural Network *Zoran Stanković, Maja Sarevska, Nebojsa Doncov and Ksenija Pesic*	452
MTI1.4	Analysis of Feeding Methods for High-Gain Crossed Slot Antenna Arrays *Marija Milijic and Branka Jokanovic*	457
MTI1.5	Cost-Effective Standing Wave Ratio Meter *Ana Ćupurdija and Slobodan Savić*	463
MT1.1	Automatizacija određivanja nivoa EM polja radio-difuznih predajnika na osnovu ITU-R P.1546 metode za visine h1 manje od 10 m *Miloš Radojković and Zlatica Marinković*	469
MT1.2	TLM modelovanje deformacija savijanja antene u biomedicinskim aplikacijama *Jugoslav Jokovic, Tijana Dimitrijević, Aleksandar Atanaskovic and Nebojsa Doncov*	473
	NEW MATERIALS IN ELECTRICAL AND ELECTRONIC ENGINEERING/НОВИ МАТЕРИЈАЛИ - (NMI/HM)	478
NMI1.1	Sintering and Phase transition of the ZnTiO3 nano powder dilatometric data deconvolution *Nebojša Labus, Milena Rosić, Smilja Marković, Maria-Vesna Nikolić and Srđan Matijašević*	479
NMI1.2	Study of the effect of microstructure and magnetic texture on major loop phenomenology using OOMMF *Mehrija Hasicic, Aphrodite Ktena and Jasna Hivziefendic*	487
NM1.1	Primeri primene fraktalne analize na karakterizaciju novih materijala *Sanja Aleksić, Branislav Ranđelović, Aleksandar Pantić, Neda Stanojević and Dušan Milošević*	492
NM1.2	Mikrostrukturna i dielektrična karakterizacija PLZT keramike *Vesna Paunović, Miloš Marjanović and Zoran Prijić*	498
NM1.3	Električne karakteristike BaTiO3 keramike dopirane antimonom *Aleksandra Stojković, Miloš Marjanović, Vesna Paunović, Aneta Prijić and Zoran Prijić*	503
NM1.4	Осетљивост магнетоимпедансног елемента CoFeSiB аморфне жице *Jelena Orelj and Nebojsa Mitrovic*	507
	NUCLEAR ENGINEERING AND TECHNOLOGY/НУКЛЕАРНА ТЕХНИКА - (NTI/HT)	512
NTI1.1	The stability and Quality Control of Instruments for Measurement of Ambient Dose Equivalent Rate *Jelena Krneta Nikolic, Marija Janković, Milica Rajacic, Ivana Vukanac, Dragana Todorovic and Natasa Sarap*	513
NTI1.2	Measurement using liquid scintillation spectrometer-quality control *Marija Janković, Nataša Sarap, Jelena Krneta Nikolić, Milica Rajačić, Dragana Todorović and Ivana Vukanac*	516
NTI1.3	E-Waste Glass in Radionuclide Immobilization *Tatjana Miljojcic, Ivana Jelic, Marija Sljivic Ivanovic and Slavko Dimovic*	519
NT1.1	UTICAJ FUZIONIH GENERATORA NA EFIKASNOST GASNOG ODVODNIKA PRENAPONA *Nemanja Aranđelović, Dušan P. Nikezić, Uzahir Ramadani, Ivan Lazović, Nikola Mirkov and Predrag V. Osmokrović*	524
NT1.2	Sektorski pristup u analizi bezbednosnih rizika upravljanja nuklearnim otpadom *Slavko Dimović, Milica Ćurčić and Nikola Zdolšek*	530
NT1.3	UTICAJ JONIZUJUĆEG ZRAČENJA NA KARAKTERISTIKE GASNIH ODVODNIKA PRENAPONA *Uzahir Ramadani, Dušan P Nikezić, Alija Jusić, Ivan Lazović and Nikola Mirkov*	537
	COMPUTING AND INFORMATION ENGINEERING/РАЧУНАРСКА ТЕХНИКА И ИНФОРМАТИКА - (RTI/PT)	543
RTI1.1	One Solution For Multimedia Subscription Using Blockchain *Igor Srdić and Djordje Glisic*	544
RTI1.2	Model-Driven Approach to Blockchain-Enabled MLOps *Nenad Petrović*	548
RTI1.3	Controllability of the multi-agent system modeled by the chain graphs with repeated degree *Milica Anđelić, Edin Dolićanin and Zoran Stanić*	554
RTI1.4	Distillation of Secret Keys using Speech Signals and Discussion through a Public Channel *Jelica Radomirović, Milan Milosavljević and Aleksandra Krstić*	558
RTI2.1	One solution for voice commands on Android based STB *Jovana Simić, Djordje Glisic and Uros Jokic*	562
RTI2.2	One solution for simulating conditional access in DTV Software on PC platform *Milan Petrović, Djordje Glisic and Uroš Jokić*	566
RTI2.3	One solution for testing embedded DTV software on the PC platform *Branka Ševa, Djordje Glisic and Uroš Jokić*	570
RTI2.4	Comparison of type-2 hypervisor performance on the example of VirtualBox, VMware Workstation player and MS Hyper-V	574

	Borislav Đorđević, Iva Jovičić, Nenad Kraljević and Valentina Timčenko	
RTI2.5	Comparison of file system performance in full virtualization with MS Hyper-V and KVM hypervisors *Borislav Đorđević, Miloš Piljić, Nenad Kraljević and Valentina Timčenko*	580
RTI2.6	A Review of Wazuh Tool Capabilities for Detecting Attacks Based on Log Analysis *Stefan Stanković, Slavko Gajin and Ranko Petrović*	585
RTI3.1	Infrastructure for Simulating n-Dimensional Simplicial Complexes *Dušan Cvijetić, Nenad Korolija and Marko Vojinović*	590
RTI3.2	Possibilities for Parallelizing Simplicial Complexes Simulation *Dušan Cvijetić, Nenad Korolija and Marko Vojinović*	595
RTI3.3	The Evolution of Big Data Analytics Solutions in the Could *Danko Miladinović, Jovan Popović and Nenad Korolija*	600
RTI3.4	Hybrid Manycore Dataflow Processor *Danko Miladinović, Miroslav Bojović, Vladisav Jelisavčić and Nenad Korolija*	606
RTI3.5	Service-Oriented Communication Between ADAS and IVI Domains in Automotive Solutions *Dušan Kenjić, Marija Antić and Dušan Živkov*	611
RT1.1	Утврђивање сличности софтверског кода *Zaharije Radivojević and Miloš Cvetanović*	617
RT1.2	Softversko rešenje za akviziciju i vizuelizaciju moždanih talasa *Ivan Tot, Boriša Jovanović, Dušan Bogićević, Tamara Gajić and Jordan Atanasijević*	626
RT2.1	Platforma za praćenje kvaliteta vazduha u gradu Čačak *Nikola Kukric, Bozidar Popovic, Slobodan Lubura and Zorana Mandić*	630
	ROBOTICS AND FLEXIBLE AUTOMATION/РОБОТИКА И ФЛЕКСИБИЛНА АУТОМАТИЗАЦИЈА - (ROI/PO)	634
ROI1.1	Mobile robot decision-making system based on deep machine learning *Aleksandar Jokić, Milica Petrović and Zoran Miljković*	635
ROI1.2	Method for Configuring Virtual Robot as an Integral Part of the Control System *Nikola Slavković, Saša Živanović, Zoran Dimić and Nikola Vorkapić*	639
ROI1.3	Low-cost real-time human motion capturing system *Milutin Nikolic, Lazar Milić, Milutin Studen and Mirko Raković*	645
ROI1.4	GAN-based Data Augmentation in the Design of Cyber-attack Detection Methods *Dušan Nedeljković and Živana Jakovljević*	651
ROI1.5	Comparison of SLAM algorithms on omnidirectional four wheel mobile robot *Slaven Petković, Lazar Milić, Milutin Nikolić, Mirko Raković and Dragiša Mišković*	657
ROI2.1	Natural Non-Invasive Human-Machine Interface Based on Hand Gesture Recognition *Jelena Rodić, Darko Golubović, Nikola Knežević and Kosta Jovanović*	663
RO1.1	Pozicioniranje Hvataljke ABB Kolaborativnom Robota Pomoću Kamere *Vojislav Vujičić and Ivan Milićević*	668
RO1.2	Upravljanje pasivnom krutošću završnog uređaja robota oblikovanjem elipsoida krutosti *Branko Lukić, Nikola Knežević and Kosta Jovanović*	672
RO1.3	Hijerarhijsko distribuirano upravljanje kolaborativnim industrijskim humanoidnim robotom podržano oblak-arhitekturom *Jovan Šumarac, Aleksandar Rodić and Ilija Stevanović*	678
	TELECOMMUNICATIONS/ТЕЛЕКОМУНИКАЦИЈЕ - (TEI/TE)	683
TEI1.1	On Pulse Shaping for Generalized Faster than Nyquist Signaling with and without Equalization *Jovan Milojkovic, Srđan Brkić and Jelena Ćertić*	684
TEI1.2	Performance simulation for LCR of MIMO Multi-branch SC Diversity System in α−μ fading and α-μ interference channel *Dejan Milic, Suad Suljović, Dejan Rančić, Nenad Petrović and Nenad Milošević*	688
TEI1.3	Location Privacy Improvements in Telecommunication Data Management Systems *Milan Simaković, Zoran Čiča and Dejan Drajić*	693
TEI1.4	Introducing IoT to Big Data Platform for Network Performance Monitoring *Milan Simaković, Zoran Čiča and Dejan Drajić*	698
TEI1.5	Reliability of Earth-Space Links under Deep Fades with Interleaved Reed-Solomon Codes *Srđan Brkić, Zoran Čiča, Andreja Radošević, Đorđe Sarač and Predrag Ivaniš*	702
TEI1.6	Effect of Phase Noise on Error Probability of MPSK Receiver over TWDP Channel - Simulation Study *Goran Djordjevic, Jarosław Makal, Bane Vasic and Bata Vasic*	707
TEI2.1	Initial Development of a Program for Drone Micro-Doppler Signature Modelling *Jovan Radivojević, Predrag Petrović, Aleksandar Lebl and Mladen Mileusnić*	711

Recent Advances on Perforated Panels for Sound Absorption Applications

Jesús Carbajo, Nicholas Xuanlai Fang and Sang-Hoon Nam

***Abstract*—Perforated panel sound absorbers have become one of the most promising passive noise control solutions not only because of their excellent sound absorption performance but also because of their high structural strength and durability. These features make them an interesting eco-friendly alternative to traditional porous fibrous media or foams, especially in those scenarios implying aggressive environmental agents (e. g. strong wind, heavy rain…) or severe working conditions (e. g. turbines, jet engines…). Many engineering applications of these systems can be found in practice ranging from noise barriers and room acoustics conditioning to the design of muffler devices and MRI scanners. This work briefly reviews the fundamentals of classical perforated panel sound absorbers and reports some recent advances in their use for sound absorption applications.**

***Index Terms*—Acoustics; sound absorption; perforated panels.**

I. Introduction

Noise pollution is a problem of major concern because of the harmful effects on human health and the negative impact on the environment. In this context, the scientific community together with industrial partners and public authorities are working together on the development of systems that let reduce noise. Among these, passive sound absorbers have become one of the most-extended solutions, being the perforated panel sound absorbers of great interest due to their improved structural features when compared to conventional porous media. Although generally used as a protective covering for such media, when backed by an air cavity the resulting panel system may work as an acoustic resonator for sound absorption itself. To improve the low-frequency absorption performance and absorption bandwidth of these resonators, many authors have proposed different configurations throughout the years. Maa [1] proposed the use of panels whose perforations are sub-millimetric in size resulting in the so-called Micro-Perforated Panel (MPP) sound absorbers. Subsequently, he analyzed their wideband capabilities by using double-layer MPP arrangements [2]. Some other examples are the study of perforated panels with viscous energy dissipation enhanced by orifice design carried out by Randeberg [3], taking advantage of the vibrational response of thin perforated panels [4], the use of multiple sizes of holes investigated experimentally by Miasa et al. [5], or the parallel arrangement of MPPs [6]. All of these and many other studies served to a great extent as a reference to further developments on this topic, a brief review of the fundamentals of classical perforated panel sound absorbers, and a summary of some recent works being the main aim of this work.

II. Classical Perforated Panel Sound Absorber

A perforated panel typically consists of a flat rigid surface with periodically arranged perforations such as circular holes or slits, the attenuation of sound being produced by viscothermal losses in these holes (i. e. viscous friction and thermal conduction in the inner air of the perforations). When backed by an air cavity and a rigid wall, a resonant sound absorber is achieved. Let us consider the schematic representation of a classical perforated panel sound absorber as that depicted in Fig. 1. The sound absorption performance of this perforated panel absorber for the case of circular perforations is mainly determined by the radius of the holes, R, the spacing between perforations, b, the panel thickness, d, and the backing air cavity depth, D. Note that the spacing between perforations can be directly related to the perforation rate in the case of periodically distributed perforations by $\phi = \pi R^2/b^2$. In brief, by reducing the radius of the holes the absorption bandwidth can be widened, whereas an increase in the panel thickness or the air cavity depth shifts the peak frequency to lower frequencies.

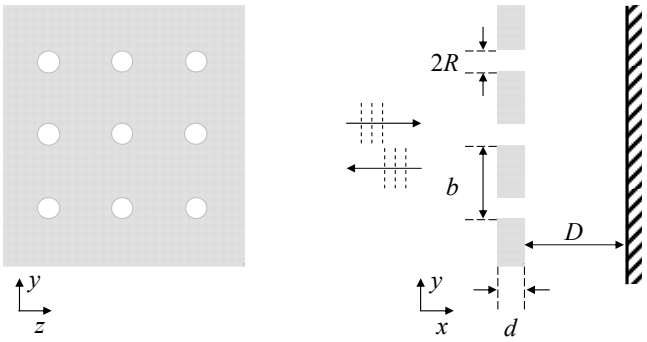

Fig. 1. Schematic representation of a classical perforated panel sound absorber. Left: frontal view. Right: lateral view.

Under plane wave incidence along the x-direction, the acoustic impedance Z of the resonator system is given by

 ISBN 978-86-7466-930-3

$$Z = Z_{PP} - jZ_0 \cot\left(k_0 D\right). \quad (1)$$

where Z_{PP} is the transfer impedance of the perforated panel and D is the backing air cavity depth, being Z_0 and k_0 the characteristic impedance and wavenumber in air, respectively.

Once the acoustic impedance of the resonator is obtained, it is straightforward to calculate its sound absorption coefficient as

$$\alpha = 1 - \left|\frac{Z - Z_0}{Z + Z_0}\right|^2 . \quad (2)$$

Much research has been dedicated to determining the transfer impedance of perforated panels throughout the years. Based on early works by Crandall [7] and Rayleigh [8] on sound propagation in narrow tubes, several authors have proposed theoretical models that let predict the acoustic behavior of the whole resonator system [9]. Some relevant contributions are the end correction terms suggested by Ingard [10] to account for the finite thickness of the panels, the formulas for MPPs proposed by Maa [1], or the derivation of an equivalent fluid model as that proposed by Atalla and Sgard [11]. Moreover, some works have analyzed the acoustic properties of perforated panels at high sound pressure levels [12] or orifices under grazing flow conditions [13]. Unfortunately, the above models may present some limitations for the analysis of complex configurations (e. g. a panel with non-uniform perforations). Nevertheless, the high development of computers over the last decades has paved the way for implementations based on numerical methods such as the Finite Element Method (FEM) that allow dealing with those cases. Some recent examples are the use of Computational Fluid Dynamics (CFD) models for the analysis of tapered perforations [14] or the adoption of a full linearized Navier-Stokes formulation for the analysis of a non-homogeneous distribution of the perforations [15].

On the other hand, the acoustic characterization of such absorbers is an essential task both to assess the validity of a predictive model and to analyze extra dissipation phenomena (e. g. the structural resonances). One of the most extended methods to determine their sound absorption coefficient is the transfer function method, whose measurement procedure can be found in the ISO 10534-2 standard [16]. Alternatively, a transfer matrix approach as that described in detail in the ASTM E2611-09 [17] can be used to derive their transfer impedance. Given that the estimation of these acoustic indicators using a prediction model depends on a set of geometrical parameters, it is also common to obtain the values of the latter by using an optimization procedure (e. g. the Nelder-Mead direct search method [18]) that let obtain the best fit between the measured data and the theoretical predictions.

III. Innovative Perforated Panel Sound Absorbers

Even though classical perforated panel sound absorbers may show an excellent sound absorption performance, apart from interesting aesthetical and structural features, there has been some representative research over the last years that not only show their great capabilities, but also the potential of these devices to be used in diverse scenarios. A representative selection of six of these research works is briefly outlined next.

A. Parallel-Arranged Extended Tubes (PPET)

Perforated Panels with Extended Tubes (PPET) have been reported to significantly improve the sound absorption in the low frequencies. The use of extended tubes not only let increase the "effective length" of the panel but also achieves a wider bandwidth when combining parallel-arranged PPETs with different cavities (see Fig. 2a). A theoretical investigation into the performance of the PPET was carried out by Li et al. [19], serving this analysis to obtain an optimal design for practical application in the low-frequency range (120-250 Hz). For this purpose, an optimization procedure based on the simulated annealing algorithm was used to derive a configuration of four parallel-arranged PPETs in a constrained space of 100 mm. Experimental validation of the proposed design was performed by manufacturing a prototype which was tested using an impedance tube setup, results showing a reasonable agreement when compared to predictions.

B. Coiled Coplanar Air Chamber

Most perforated panel sound absorbers have a total thickness comparable to the peak absorption wavelength, this being a drawback when designing absorbers for low frequencies. Li and Assouar [20] showed that by coiling up space into the air cavity of the perforated panel absorber an extremely low-frequency acoustic resonator can be achieved. The absorber system consisted of a metasurface composed of a perforated plate combined with a coiled air chamber formed with solid beams as depicted in Fig. 2b. Simulations based on fully coupled acoustic with thermodynamic equations and theoretical impedance analysis were carried out to further understand the underlying physic phenomena. The resulting metasurface possessed a deep subwavelength thickness down to a feature size of $\lambda/223$ achieving perfect sound absorption at 125.8 Hz for a total thickness of the system of 12.2 mm. Furthermore, perfect sound absorption was achieved at the design target frequency. The high efficiency of this type of structure and easy fabrication, when compared to labyrinthine metasurfaces, encourages their use in many applications.

C. Perforated Honeycomb-Corrugation

Tang et al. [21] showed that an ultra-lightweight sandwich panel with perforated honeycomb corrugation in its core as shown in Fig. 2c can be an excellent sound absorber. By using small perforations on the top face sheet and the corrugation of a sandwich panel in the inner cavity, an improvement in both the sound absorption within the frequency band 250-2000 Hz and the mechanical performance of the structure (stiffness and strength) was achieved. Additionally, a theoretical model for sound

 ISBN 978-86-7466-930-3

absorption was used to show that wideband sound absorption performance can be also achieved if multiple acoustic resonators are introduced. The resulting multi-functional structure showed to be promising for many engineering applications requiring lightweight constructions with both great acoustic and mechanical properties.

D. Compressed and Micro-Perforated Metal

As an alternative to typical perforated panels, Bail et al. [22] proposed a panel fabricated by compression and micro-perforation of a porous metal. The compressed and micro-perforated porous metal panel absorber let achieve better sound absorption than the un-compressed porous metal or a simply micro-perforated spring steel panel. A fourth-order polynomial function was proposed to express the superposition absorption effect resulting from the simultaneous action of the porous and micro-perforated structures. An analysis of the micro-morphology (see Fig. 2d) of the fabricated panel samples provided intuitive explanations of the improvement, which was attributed to the irregular micro-vias from the micro-pores to the micro-perforation.

E. Panel with Oblique Perforations

A perforated panel design that uses perforations aligned obliquely to the panel surface as illustrated in Fig. 2e was proposed in a recent work by the authors [23]. Similar to the PPET, an increase of the "effective length" of the panel allow both improving the low-frequency sound absorption and dealing with limiting space constraints common in many practical scenarios. In doing so, not only a frequency shift of 730 Hz of the resonance frequency of the absorber towards low frequencies can be achieved but also an increase in the peak absorption amplitude provided the geometrical characteristics of the panel are properly chosen. A simple predictive model that relies on the fluid-equivalent theory was developed to investigate the acoustic properties of these absorbers, modified expressions for the geometrical tortuosity and flow resistivity being proposed. Measurements in an impedance tube over additive manufactured samples confirmed previous assertions showing a good agreement when compared to prediction data. Unlike coiled or labyrinthine solutions avoids addressing the air cavity design, which may pose an advantage in terms of further development for practical purposes.

F. Graded spherical perforations

In a recent work by Sailesh et al. [24], the influence of spherical bubble perforations and their grading was investigated by preparing different samples with 3D printed biodegradable material. Both the sound absorption and sound transmission performance of these panel designs were assessed by using the impedance tube method and finite element numerical simulations (see Fig. 2f). Results for different sizes of the spherical bubbles and different types of patterns of graded perforations revealed an enhanced sound absorption performance in the low-frequency range up to 1000 Hz. The authors suggest that these solutions can be effectively used in soundproofing applications in the building and transportation sectors.

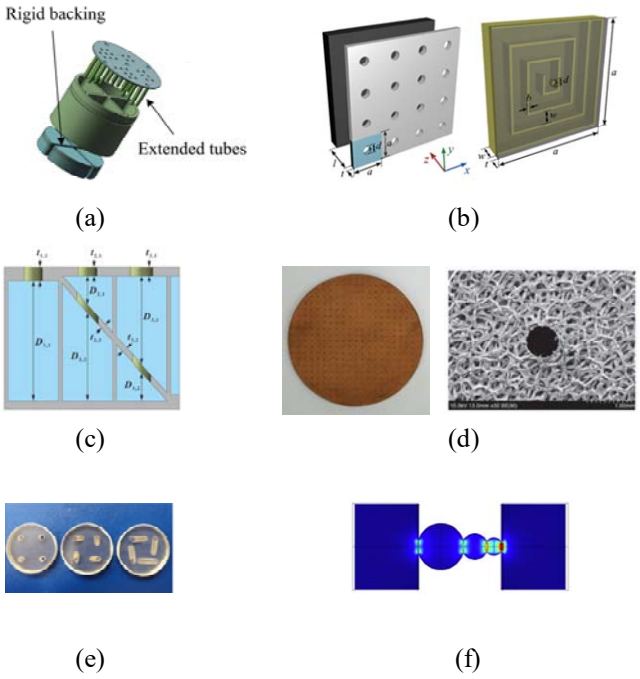

Fig. 2. Innovative perforated panel sound absorbers: (a) parallel-arranged extended tubes (PPET) [19]; (b) coiled coplanar air chamber [20]; (c) perforated honeycomb-corrugation [21]; (d) compressed and micro-perforated metal [22]; (e) panel with oblique perforations [23]; and (f) graded spherical perforations [24].

IV. Conclusion

In summary, perforated panel sound absorbers show higher durability and structural strength capabilities than conventional porous media. These advantages make these resonator systems provide a wide range of possibilities in many research fields and disciplines of engineering. On the other hand, the incessant development of additive manufacturing techniques poses a new scenario for the conception of innovative designs like those reviewed in this work. In this regard, it may turn out of great interest to also develop new characterization procedures and perhaps to define additional absorption performance indicators. All the same, there is still a need for cost-effective fabrication processes that ease these fabrication procedures to be more extensively adopted in practice. Extending these techniques into the acoustic materials industry will presumably be a challenge to be faced in the forthcoming years.

Acknowledgment

J. C. would like to thank the Organizing Committee of IcETRAN 2022 for the invitation to the Section of Acoustics and also express gratitude to dr. Dejan G. Ćirić for the proposal.

Real-time Speaker Independent Recognition of Bimodal Produced Speech

Boris Malčić, Vlado Delić, Jovan Galić and Nebojša Babić

***Abstract*—This paper presents the initial results in recognition of neutral speech and whispering in real-time, independent of a spea er. The speech database used for training is Whi- pe. The system for training and testing is based on the phin -4 recognition platform. The e periments in recognition showed average recognition accuracy of .2 (for normal speech) and .2 (for whisper). Compared to the recognition in controlled conditions, significant drop of the performance is observed in real-time recognition, for both speech modes.**

eywords— peech recognition; Whi- pe speech database; phin -4; whispered speech.

I. Introduction

Recent advances in automatic speech recognition (ASR) systems have brought many benefits in man-machine speech interaction. Despite good performance in controlled conditions, relatively high sensitivity in adverse conditions is the main reason for low robustness and poor use in real-life scenarios [1-2]. Speech technologies are intended for commonly used modes of speech, i.e. normally phonated speech (normal speech). Other speech modalities include shouted speech, louder speech, soft speech and whisper. The parameters for distinction of these 5 modes are sound pressure level (SPL), sentence duration and silence percentage, frame energy distribution and spectral tilt [3]. Whispered speech is pronounced as an alternative to neutral speech for a number of reasons: when someone does not like to disturb others, when loud speech is prohibited or unpleasant, when the information to speak is secret, when someone wishes to hide identity etc. Also, whispered speech can be produced due to health problems (laryngitis or rhinitis) [4]. Whisper as a speech mode is characterized by a lack of glottal vibration, noisy excitation of the vocal tract and in general, the changes of the vocal tract structure. Recent studies demonstrated performance gain in whispered speech recognition using data augmentation techniques [5-6], denoising autoencoders [7], as well as voice conversion [8].

The goal of the research study presented in this paper is to present initial results in real-time speaker independent recognition of bimodal produced speech (isolated words in neutral speech and whisper) for Serbian. The ASR system for training and testing is based on CMU Sphinx platform [9]. The remainder of this paper is organized in the following manner. In Section 2 a short overview of Hidden Markov Models (HMM) is given. Section 3 presents a speech database, the training of the ASR system and experiment setup for testing. In Section 4 we give results of experiments as well as its discussion, whereas concluding remarks and direction for future studies are stated in Section 5.

II. Hidden Markov Models

Modern ASR systems are inconceivable without Markov models that are combined with a model of a mixture of Gaussian distributions, or with deep neural networks that have become increasingly popular in recent times. The HMMs have become one of the most useful statistical methods for modeling speech signals [10]. Moreover, HMM is often defined by a parameter set $\mathbf{\Lambda} = (\mathbf{A}, \mathbf{B}, \boldsymbol{\pi})$ where are denoted: a transition probability matrix as $\mathbf{A} = [a_{ji}]$; an output probability matrix as $\mathbf{B} = [b_j(m)]$, $b_j(m) = P(X_t = o_m | x_t = j)$; and an initial state distribution matrix as $\boldsymbol{\pi} = [\pi_j]$. Furthermore, with a fully connected (ergodic) HMM, transition from any state to any other state is possible. On the other hand, due to the dynamic nature of the speech signal, in modern ASR systems, the serial structure dominates in which transition is possible only to a state with the index higher than the current one. An example of such structure is shown in Fig. 1 where the inactive states (null states) are shaded and located at the beginning and at the end of the sequence, while the output (ultimate) probabilities at the final moment $t = T$ (we observe a series of T feature vectors) are defined by $\eta_j = P(x_T = j), 1 \le j \le M, \eta_j + \sum_{i=1}^{M} a_{ji} = 1, \forall j$ for a certain state sequence $\boldsymbol{X} = \{x_1, x_2, \dots, x_T\}$.

In HMM-based speech recognizers, model parameters can be obtained using the Viterbi algorithm in training and the expectation maximization (EM) algorithm. Improved values are obtained by the EM algorithm using the method of Lagrange multipliers to determine the local extremum of a multivariate function. This procedure is called the iterative Baum-Welch (BW) training algorithm. Moreover, it is

 ISBN 978-86-7466-930-3

important to emphasize that the BW algorithm does not guarantee reaching a global maximum but only a local one, and the iterative procedure is repeated while the joint probability of training data increases.

In order to be able to apply the previous discrete HMM methodology for speech signal recognition, continuously distributed HMMs have been introduced where the probabilities of emitting discrete symbols are changed as a function of the probability density of observations. Since the probability density function of any random variable can be approximated by the sum of *N* Gaussian random variables, the multivariate Gaussian mixtures are used in HMM recognizers.

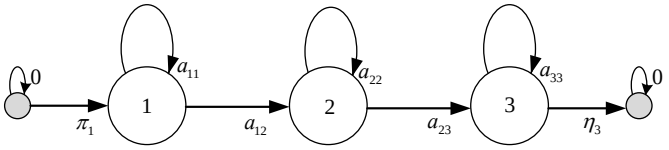

Fig. 1. An example of the serial left-right topology with 3 active states without the possibility of skipping a state

III. System for Recognition

A. Speech database

There are a relatively small number of languages with available speech databases created in modes other than neutral [11-13]. The Whi-Spe database was created for research activities needed for human-machine interaction in Serbian for bimodal produced speech [14]. In its initial form, the database contains recordings of 50 different words from 10 speakers (5 female and 5 male). The vocabulary of 50 words is divided in three groups: basic colors (6 words), numbers (14 words) and phonetically balanced words (30). Each word is repeated 10 times in both speech modes. Finally, the database includes 10.000 utterances (*wa* records) in a total duration of 2 hours. The sampling frequency of speech samples is 22050 Hz and 16 bits per sample (mono PCM *wa* format). More details about the database (recording, segmentation procedure, labeling and quality control) can be found in [14].

B. AS training system

The task of the automatic speech recognition system (ASR) is to extract words from the speech signal in the order in which they are spoken. The block diagram of the ASR system based on HMM is shown in Fig. 2. Moreover, in section III c. we present a graphical interface of our program implemented in Java, and based on Fig. 2. First, in the feature extraction block, the speech signal is transformed into a series of feature vectors. The task of the feature extraction block is also to eliminate various variations caused by changes in speakers, ambience or channels. The task of the recognizer is to find the sequence of words that (according to a predetermined criterion) best corresponds to what was actually said.

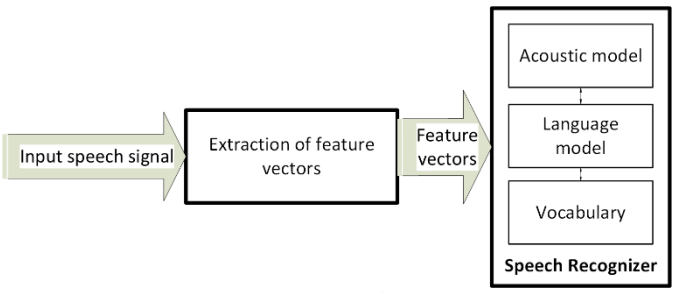

Fig. 2. The operation principle of a general ASR system

From a statistical point of view, the recognizer finds a string (i.e. $\widehat{W} = w_1, w_2, \dots, w_M$) of M words which maximizes a posteriori probability $P(W|X)$ where $\hat{X} = x_1, x_2, \dots, x_T$ is an array of T features. Namely, the language model describes the relationship between words taking into account the grammar of the language for which the recognizer is intended, while the description of the statistical point of view of speech behavior in the feature vector space is presented with an acoustic model. In ASR systems, the basic units for modeling are phonemes, and from their point of view in speech communications, the smallest acoustic unit that a person can perceive is a phoneme. In context-independent recognition, each phoneme is modeled independently, and that modeling unit is called a monophone. However, due to coarticulation, the pronunciation of a particular phoneme largely depends on neighboring phonemes, and then triphones (rarely biphones) are usually used, which are derived using the monophones in a way which takes into account the previous and next phonemes. When using the same, there is a need for a huge training database, which is also one of the main disadvantages of using triphones, and due to the relatively small Whi-Spe database used in this research paper, we only were able to train the acoustic model using the monophones.

Furthermore, let us now mention that speech recognition is divided into two phases: 1st phase of system training, 2nd phase of speech recognition or system testing. Common to both of these phases is that they need to perform feature vector extraction. In doing so, the feature vector should describe as adequately as possible the envelope of the amplitude spectrum of the spoken phoneme, because the information about the spoken phoneme is precisely contained in that envelope. In the training phase, we divided speech into frames (smaller segments) of 25 ms duration within which the speech signal can be considered quasi-stationary. Also, adjacent frames are shifted 10 ms to better track changes in the speech signal spectrum. The most commonly used features in speech recognition are the mel-frequency cepstral coefficients (MFCCs), and Fig. 3 presents the block diagram for the extraction of MFCC feature vectors.

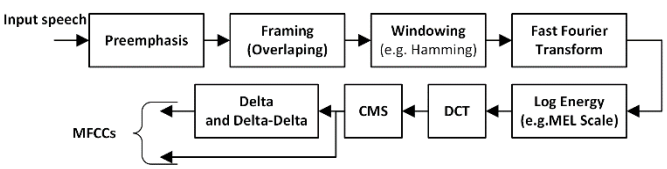

Fig. 3. Process for the MFCCs feature vector extraction

 ISBN 978-86-7466-930-3

Fig. 3. depicts that several steps need to be performed in the processing chain to extract MFCCs from the input speech signal. Some of these steps are Fast Fourier Transform (FFT) over speech signal frames. Next, the signal spectrum is passed through a filter bank (describing the operation of the basilar membrane) whose filters are distributed evenly on the mel-frequency scale. Furthermore, Discrete Cosine Transform (DCT) replaces inverse FFT and is used to calculate cepstral coefficients because the speech is a real signal and its amplitude spectrum is an even function. Then, to increase the robustness of the system, normalization with Cepstral Mean Subtraction (CMS) is performed, because by subtracting the mean value from Cepstral coefficients, a significant separation of excitation and transfer function of the vocal tract is achieved. This procedure is very useful in whisper recognition. Finally, with the last block in the processing chain on Fig. 3 we single out the dynamic features using which are better monitored the time characteristics of the speech signal, and that achieves less correlation between adjacent frames. For this purpose are used the so-called delta (Δ) features that represent the first derivative (rate of feature change) of static features, and also the delta-delta (ΔΔ) features that are obtained as a second derivative and represent the acceleration with which static features are changed.

In order to train the acoustic model for CMUSphinx, we followed in detail the procedure described in [15]. First, following the procedure all the necessary files (*an4.dic, an4.filler, an4.phone, an4 train.fileids, an4 train.transcription*) for training are created. For that purpose, the phonemes used in training the acoustic HMM for Serbian are presented in Table I. Next, in Table I phonemes {CC, CH, Dj, DZ, SH, ZH} are in Serbian {Ć, Č, Đ, Dž, Š, Ž}, and the notation Y is used for the phoneme SCHWA. Furthermore, an example of the phonetic transcription for only three words (of all 50 words in the Whi-Spe that are used in the process of training for the Serbian ASR system), is shown in Table II.

TABLE I
PHONEMES USED FOR MODEL TRAINING

A	B	C	CC	CH	D	Dj	DZ
E	F	G	H	I	J	K	L
Lj	M	N	Nj	O	P	R	S
SH	T	U	V	Y	Z	ZH	SIL

TABLE II
AN EXAMPLE OF PHONETIC TRANSCRIPTION FOR THREE WORDS

Word	Phonetic transcription
CRNA	C Y R Y N A
TRI	T Y R I
ZGRADE	Z G Y R A D E

Second, we prepared the directory **an4** (i.e. our appropriate directory where we created the *wa* subdirectory inside which are all *wa* records). In our case, 10,000 *wa* records are used from the training Whi-Spe database. After that, using the terminal, we positioned into the **an4**, and executed the command **sphin train -t an4 setup**.

The previous command created a subdirectories **an4** and **feat** in the directory **an4** and the subdirectory **feat** was not visible in the file system, but it was visible in the terminal which could be checked with the commands **ls** and/or **la**. Please note that in relation to the steps of the official instructions, it is important that in the **etc** directory (created previously) from our database (which we called **an4**) we store all the necessary files for training, namely: *an4.dic, an4.filler, an4.phone, an4 train.fileids, an4 train.transcription, sphin train.cfg*. Next, be sure to create a wav directory in the directory of the database (**an4**), and place in it all wav records. Furthermore, we need to modify the configuration file (**sphin train.cfg**) by replacing the following lines (paths) in the configuration file:

```
C G A DI home user Des top sphin -source an4 ;
C G P I T AI DI home user Des top sphin -source sphin train ;
```

Also, in the configuration file we need to set

```
(yes no) Train conte tually dependent models
C G CD T AI no ;
```

Moreover, this previously modified **sphin train.cfg**, and all other files from the **etc** file within **an4**, should be copied and moved to the **etc** folder within the folder **home user Des top sphin -source sphin train**. Finally, after all the previous preparation steps, we started the model training by calling **perl** scripts. Specifically, we go to the terminal in the **sphin train** folder which is inside the **sphin -source** directory (within that directory there are also **an4**, **sphin base** and **poc etsphin** directories which we prepared earlier). Next, we observed that differences in github's **sphin train** versions manifested by writing keyword **scripts** instead of the original **scripts pl** in the training commands, and by changing the numbers of **perl** scripts equivalent to those in the training internals sections [15], so for example instead of the command **perl scripts pl 1 .vector quantize slave. .pl** now it is necessary to write **sudo perl scripts 5.vector quantize slave. .pl**. The previous is mentioned because we pulled the edge CMU Sphinx toolkit packages from github, and not used the recommended (5prealpha) releases [16]. Finally, after being positioned in the **sphin train** directory, we executed the following commands in terminal for model training:

```
user ubuntu Des top sphin -source sphin train
sudo perl scripts .comp feat slave feat.pl
user ubuntu Des top sphin -source sphin train
sudo perl scripts .verify verify all.pl
```

 ISBN 978-86-7466-930-3

```
user ubuntu Des top sphin -source sphin train
sudo perl scripts 5.vector quantize slave. .pl
user ubuntu Des top sphin -source sphin train
sudo perl scripts 2 .ci hmm slave convg.pl.
```

After executing the last command, we got the parameters of the Context Independent (CI) trained model as in Fig. 4.

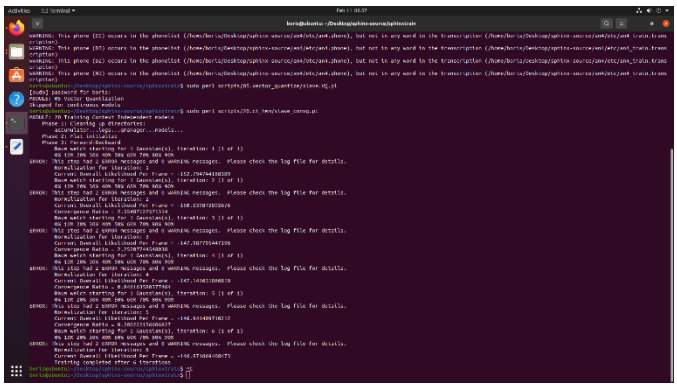

Fig. 4. An example of output **CI** training in the Ubuntu 20.04.3 LTS terminal

To sum up, we finally created new directories in **an4**, such as the **model parameters** directory within which is located directory **an4.ci cont** containing 7 files obtained during the training process, i.e.: **feat.params**, **mdef**, **mean**, **mi weights, noisedict, transition matrices**, **variances**. From the **feat.params** file is visible the number of filters in filterbank is 25. Then, as a feature vector, a 39-dimensional dynamic feature vector is used (13-static + Δ + ΔΔ). The number of Gaussian mixtures is 8. For each utterance, cepstral mean normalization (cmn) is performed. The number of monophones is 32 (of which 30 corresponding to the 30 phonemes in Serbian, then phoneme SCHWA and silence - SIL). As a result, the models of monophones are initialized with global mean value and variance (flat-start initialization). These all files in **an4.ci cont** represent the CI continuous HMM that will be used in the following section by the application for the process of testing.

C. AS recognition testing system

Fig. 5. shows the main window of the interface. Labeled with numbers, the components are as follows: 1. Main menu, 2. The list of words available in the model but left out, 3. The list of words chosen for the test, 4. Buttons for managing lists 2 and 3, 5. Most commonly used commands available in the main menu, 6. Output console, and 7. Console-related commands.

The main menu holds all options needed to run the test, load the language model, overview of the used grammar and management of extra words and sentences for the test. The application is packaged with the language model, but also any other compatible language model can be tested through the application. By default, the list of available words is displayed using the language model's dictionary.

When loading the custom model, the user can choose whether to use a grammar definition instead of relying on the language model.

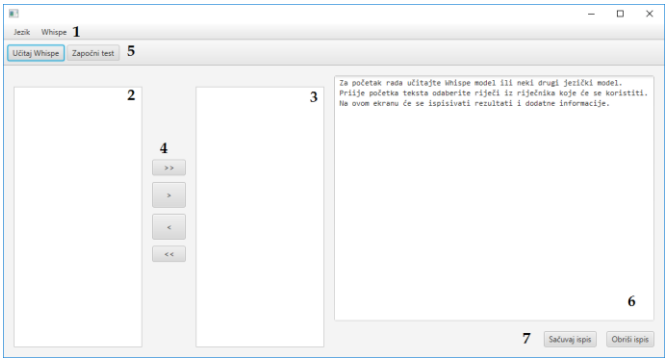

Fig. 5. The main window of the interface

As the list of available words loaded from the dictionary cannot match any but the most basic of grammars, the user can load sentences to use in the test. Each loaded sentence file is treated as a group of sentences where each sentence is one line in the text file. Each loaded file has the box (❒) icon next to the name to indicate that the selected keyword is actually a container of multiple test entries.

When the user wants to run a test, they have an option of shuffling and/or repeating the words multiple times. The user can also decide to save logs into a file instead of relying on the console for the test results. The console will show the results regardless of this setting. When performing many consecutive tests with the same settings, the user can instead provide the configuration through a file. When the file *testConfig.t t* is provided in the same directory as the application, the test settings step is skipped.

The test process screen is shown on Fig. 6. The test process aims to be as simple as possible. The left side of the window shows the instructions of what to pronounce. On each pronunciation, the next word or sentence is shown. The test can be stopped at any time for partial results. The right side of the window shows the test result logs. On each pronunciation, a line with a timestamp, the detected and the correct word will show. When the test is finished, the statistical result will also show, stating the overall accuracy. The console output can be saved or cleared at any time using the buttons below the console.

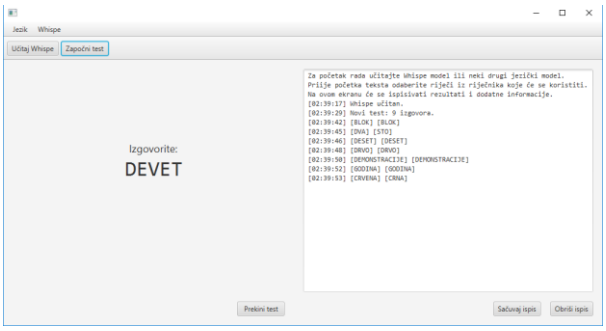

Fig. 6. The application window in the testing phase

 ISBN 978-86-7466-930-3

IV. RESULTS

The accuracy and correctness of speech recognition are tested on 10 people, i.e. 5 male testing examinees enumerated as {M1, M2, M3, M4, M5}, and 5 female examinees marked as {F1, F2, F3, F4, F5}. All the above respondents pronounced the words from Whi-Spe. The testing was performed in a room with SPL of 30-35 dB(A).

For this purpose, first the parameters of the HMM trained on the entire Whi-Spe for the normal speech, are loaded into the application, and then the testing scenario is repeated for the whisper speech. Exactly, these models are tested on all 10 examinees and this scenario is denoted as **full**. Then, we tested a new scenario denoted as **match** in which the parameters of HMMs were obtained by training only over part of the Whi-Spe (i.e. only on *female male* speakers in the database), and the obtained models for normal speech (n) and whisper (w) are tested only on 5 *female male* respondents, respectively. For all those models 8 Gaussian mixtures were used in the configuration file for the training. Next, for all different scenarios (*n full, n match, ..., w_match*), the obtained corresponding results for the accuracy (***Acc***), and the correctness (***rr***) are calculated in Table III and in Table IV, using the following expressions[17]

$$Corr[\%] = \frac{N-D-S}{N} \times 100\%, \quad (1)$$

$$Acc[\%] = \frac{N-D-S-I}{N} \times 100\%, \quad (2)$$

where: N is the total number of words in the reference transcriptions, is the number of deletion errors, S is the number of substitution errors, and I is the number of insertion errors in each of the tested HMMs. From Table III it is calculated the mean value of recognition accuracy (*Acc_n full*) of 86.4% with a mean absolute deviation (MAD) equal to 3.52% in the case of normal speech recognition on female examinees in the case of a full scenario (i.e. *n full*), while for the whisper speech the mean *Acc_w full* is 62.8% with the average correctness (*Corr_w full*) of 90.8%. Furthermore, from Table IV, the mean of *Acc_n match* is 88% (mean value of *Corr_n match* is 93.6%) with MAD = 4% for testing the male examinees of normal speech for the **matched** (i.e. trained on utterances of male speakers, and tested on male examinees) case.

TABLE III
RESULTS OF SPEECH RECOGNITION ON FEMALE EXAMINEES FOR DIFFERENT SCENARIOS

Examinee	F1	F2	F3	F4	F5
Acc_n full [%]	88	84	92	80	88
Acc_n match [%]	74	88	74	70	62
Acc_w full [%]	70	64	72	54	54
Acc_w match [%]	50	58	66	56	60
Corr_n full [%]	90	84	94	82	94
Corr_n match [%]	86	92	88	84	92
Corr_w full [%]	72	64	76	60	70
Corr_w match [%]	58	72	74	68	78

TABLE IV
RESULTS OF SPEECH RECOGNITION ON MALE EXAMINEES FOR DIFFERENT SCENARIOS

Examinee	M1	M2	M3	M4	M5
Acc_n full [%]	94	84	88	74	90
Acc_n match [%]	84	86	84	94	92
Acc_w full [%]	76	58	72	62	80
Acc_w match [%]	76	76	82	62	80
Corr_n full [%]	98	94	90	78	94
Corr_n match [%]	94	94	88	96	96
Corr_w full [%]	80	62	76	68	80
Corr_w match [%]	80	84	86	64	88

Next, in the matched case for recognizing males' whispers the mean correctness is 80.4% with MAD = 6.72% and word error rate (WER) of 24.8%. Of course, in the case of the larger (with more different speakers) training database it would be logical to get better testing results in the match case, but for our research the relatively small Whi-Spe database was only available. Moreover, there is an evident reduction in real-time recognition accuracy compared to the controlled conditions (quiet environment and same recording equipment) in closed set speaker independent recognition based on HMM where accuracy was 98.3% (for neutral speech) and 96% (for whisper) [18]. As well, recognition of whisper in real-time is with significantly lower success than recognition of neutral speech. As can be seen from results in Tables 3 and 4, average recognition rate (accuracy and correctness) is higher for male speakers, but this is not statistically confirmed, despite the same training database. Variations among different speakers are high for both speech modes. For the determination of statistically significant parameters which contribute to high deviation of performance among speakers, a higher number of speakers is needed.

V. CONCLUSION

Speech recognition of mode other than neutral is by all means a serious challenge for modern ASR systems. In this paper, the experiments on real-time speech recognition in normal and whisper mode for Whi-Spe speech database and HMM algorithm, are conducted. Obtained results suggest that for recognition in real world scenarios, the larger speech database is needed for training. Future studies will be focused on the analysis of data augmentation techniques in multimodal speech recognition. Finally, the further research will also be based on deep neural networks (DNNs) because using *n*-gram language model from randomly initialized DNN with lattice-free maximum mutual information is possible WER relative reduction around 25% with respect to the best HMMs based ASR system [19].

ACKNOWLEDGEMENT

This research was supported by the Science Fund of the Republic of Serbia, #6524560, AI-S-ADAPT Ministry of

Education, Science and Technological Development of Serbia: University of Novi Sad, Faculty of Technical Sciences (MPNTR - 451-03-68/2020-14/200156).

The authors would like to thank all examinees for participation in speech recognition tests.

Feature Analysis for Industrial Product Sounds Using Discrete Meyer Wavelet

Đorđe Damnjanović, Dejan Ćirić and Dejan Vujičić

***Abstract*—The process of wavelet decomposition into approximation and detail coefficients is used in many research fields, especially when signal de-noising is in focus. Extraction of features of different signal types is also an area where wavelets are often mentioned. Different wavelet families provide interesting results in feature analysis and further classification. In that regard, a wavelet that has attracted a significant interest is discrete Meyer. This paper presents the usage of discrete Meyer wavelet for feature analysis of industrial product sounds. More than 100 sounds of 6 different industrial products are tested. The most representative results are given here.**

***Index Terms*—Audio feature analysis; Discrete Meyer wavelet; Approximation coefficients; Detail coefficients; Industrial product sound.**

I. Introduction

Wavelets are often mentioned in literature as an algorithm that solved some problems in the Fourier transform [1-2]. If short time Fourier transform (STFT) and wavelet algorithms are compared, the window function are used in both cases for purpose of analysis and processing of signals. However, in the case of wavelets, window function is not of a fixed size. Width of the wavelet window can be changed as the transform is computed for every single spectral component, and that is the main difference in comparison with STFT [1-2].

Applicability of wavelets can be considered to be one of their advantages since a number of applications are made based on the wavelet algorithms. Some of them include echo cancelation, noise control, speech recognition, de-noising of audio and image signals, unknown system detection and others. Applications can be found in different fields, such as biomedical engineering, telecommunications, signal processing, computer engineering, etc [3-6].

The process of wavelet decomposition into approximation and detail coefficients (Fig. 1) is often used nowadays in feature extraction and analysis. Authors of this paper already presented the results of feature extraction method using wavelets for DC motor sounds in [7-9], where focus is on differences between non-faulty and faulty motors. In that regard, a lot of wavelet families are used, such as Haar, Daubechies, Coiflet, Symlet, biorthogonal, reverse biorthogonal and Meyer.

In the discrete wavelet processing, the decomposition process is done using the discrete wavelet transform (DWT), (see Fig. 1). This process is based on the use of low-pass (LP) and high-pass (HP) filters. Here, "A" stands for the approximation coefficients, "D" stands for the detailed coefficients and 2↓ is the down-sampling. Fig. 1 presents only decomposition up to level 2, but the whole process can be extended to a higher level of decomposition [4-5,10-11].

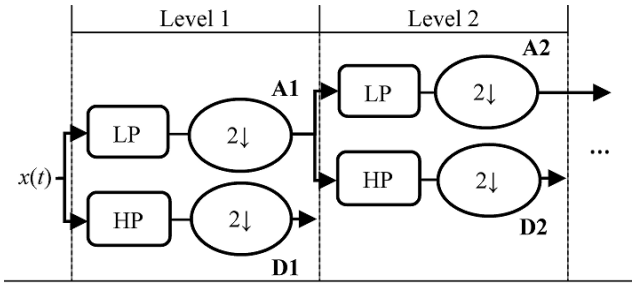

Fig 1. Block diagram of wavelet decomposition.

This paper presents usage of the discrete Mayer wavelet for the purpose of feature extraction from different industrial product sounds. More than 100 sounds organized into 6 different classes (categories) are tested: fan, gearbox, slider, toycar, toytrain and valve. Those sounds are taken from the DCASE 2021 challenge (task 2) [12]. The goal is to find certain similarities of the extracted features within the same class and certain differences among the classes in order to prepare the obtained features for future classification. The analysis is done in Matlab software package.

II. Meyer Wavelet

In 1985, Yves Meyer developed the first nontrivial orthogonal wavelet basis. This wavelet is in-group of orthogonal wavelets where are also Daubechies, Coiflet and Symlet wavelets. The main idea was to define wavelet and scaling function in the frequency domain using trigonometric functions. Both wavelet and scaling functions are presented in (1) and (2) [11,13-15]:

$$\hat{\psi}(\omega)=\frac{1}{\sqrt{2\pi}}e^{j\frac{\omega}{2}}\begin{cases}\sin\left(\frac{\pi}{2}v\left(\frac{3}{2\pi}|w|-1\right)\right) & \frac{2\pi}{3}\le|\omega|\le\frac{4\pi}{3}\\ \cos\left(\frac{\pi}{2}v\left(\frac{3}{4\pi}|w|-1\right)\right) & \frac{4\pi}{3}\le|\omega|\le\frac{8\pi}{3}\\ 0 & |\omega|\notin\left[\frac{2\pi}{3},\frac{8\pi}{3}\right]\end{cases} \quad (1)$$

Đorđe Damnjanović is with the University of Kragujevac, Faculty of Technical Sciences Čačak, Svetog Save St. 65, 32000 Čačak, Serbia (e-mail: djordje.damnjanovic@ftn.kg.ac.rs).

Dejan Vujičić is with the University of Kragujevac, Faculty of Technical Sciences Čačak, Svetog Save St. 65, 32000 Čačak, Serbia (e-mail: dejan.vujicic@ftn.kg.ac.rs).

 ISBN 978-86-7466-930-3

$$\hat{\varphi}(\omega)=\frac{1}{\sqrt{2\pi}}\begin{Bmatrix}1 & |\omega|\le\frac{2\pi}{3}\\ \cos(\frac{\pi}{2}v(\frac{3}{2\pi}|w|-1)) & \frac{2\pi}{3}\le|\omega|\le\frac{4\pi}{3}\\ 0 & |\omega|\ge\frac{2\pi}{3}\end{Bmatrix} \quad (2)$$

where the function v can be changed for the purpose of obtaining different wavelets, for example as done in (3) [12,14]:

$$v(a)=a^4(35-84a+70a^2-20a^3), a\in[0,1]. \quad (3)$$

The wavelet function, presented in (1), is symmetrical around point 1/2, while the scaling function (2) is symmetrical around the point 0 [12-14]. What is also important to mention is that the Meyer wavelet is an indefinitely differentiable with infinite support. In Fig. 2, the discrete Meyer wavelet function (which is often used in software packages) is presented.

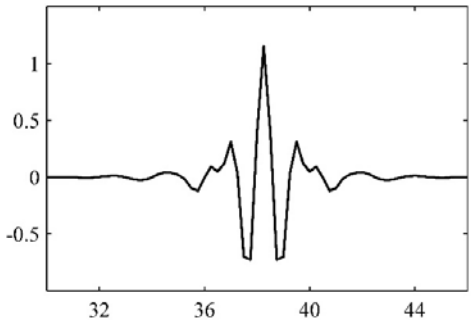

Fig 2. Discrete Meyer wavelet function.

III. Methods of Analysis

Within the task 2 (Unsupervised anomalous sound detection for machine condition monitoring under domain shifted conditions) of DCASE 2021 challenge [12], a number of sounds of 7 different industrial machines (products) - fan, gearbox, pump, slide rail (slider), toycar, toytrain and valve are available. For each of the mentioned products, there are three datasets – development, additional training and evaluation datasets. The development dataset is split into three subsets, and in overall these development datasets contain more than 4000 sound samples of normal and anomalous operating product modes.

Among those sounds from the development datasets, about 100 sound samples from 6 classes – from all classes mentioned above except pump (approximately around 17 sounds per product) are chosen here for initial analysis. All sounds are recorded using the sampling frequency of 16 kHz. Length of the recorded signals is 10 s, and they include both the sounds of a machine and its associated equipment as well as environmental noise [12]. In this paper, the following abbreviations will be used: fan-f, gearbox-g, slider-s, toycar-tc, toytrain-tt, valve-v.

At the very beginning, all chosen sounds are analyzed in the time and frequency domain. Then, segmentation process is applied. Size of segments is 50 ms. In this paper, the overlap between neighbor segments of 50% (25 ms) is chosen like in some other previous papers [7-9,16]. Size of segments and overlap can vary from research to research. In some studies, authors propose no overlap between segments [17-18].

After segmentation, the signals are decomposed using the discrete Meyer wavelet. This wavelet is a unique wavelet in the sense that there are no more variations, as for instance in the Coiflet wavelet family, where there are 5 different types in Matlab or in the Symlet wavelet having 45 types, etc [19]. The Meyer wavelet is chosen here having in mind the previous authors' researches [8-9] where this wavelet gave interesting results. The detail coefficients obtained through the wavelet decomposition with different levels of decomposition (from 1 up to 8) are used for further analysis

At each decomposition level and for every segment, the absolute values of the detail coefficients are calculated, and then the mean value of these absolute values is obtained. The set of the mean values of the details coefficients generated in the described way is used as a representative audio feature (wavelet-based feature). In some researches, such as [7-9,20-21], it is presented that the standard deviation can also be used, but authors of this paper showed previously, see [8-9], that the results based on the mean values and standard deviation are similar. This is why the standard deviation is omitted here.

The analysis is carried out in Matlab software package. When the wavelet decomposition is in focus, it is worthwhile to mention a few functions: *wavedec* for wavelet decomposition, *appcoef* and *detcoef* for obtaining the approximation and detail coefficients, *abs* and *mean* for calculating absolute and mean values, respectively.

A specific measure (quantity) named feature difference is introduced in certain isolated cases. It is calculated as the mean value of a difference between wavelet-based features for different industrial products taken from all segments and normalized by the mean feature value [8-9]. This measure is used to indicate more closely the numerical differences among the obtained features in addition to what is shown graphically.

IV. Results

The initial analysis starts with observation of signals in the time and frequency domain. In Fig. 3, six random audio signals (one from each type of the industrial products) are presented in the time domain. If the graphs are closely observed, it can be pointed out that differences between these signals are small. Thus, the time domain signals of fan and gearbox are very similar. The same is valid for the signals of slider, toycar and valve, although some more transients are present here. An exception is the signal of toytrain, which has a rather different shape and amplitude comparing to others. In the next four figures, lines associated to these products are plotted by the same color scheme as done in Fig. 3: red color for fan, blue color for gearbox, black color for slider, green color for toycar, magenta color for toytrain, cyan color for

 ISBN 978-86-7466-930-3

valve.

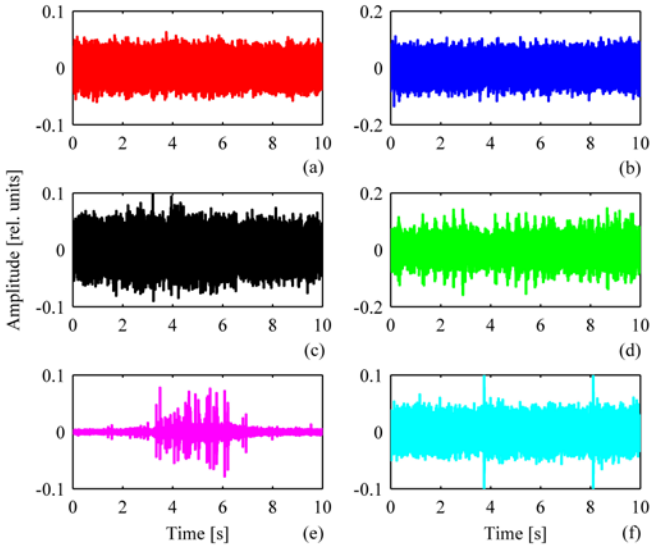

Fig 3. Audio signals (sounds) of industrial products in time domain: (a) fan, (b) gearbox, (c) slider, (d) toycar, (e) toytrain and (f) valve.

Spectra of the signals from Fig. 3 are presented in Fig. 4. In the frequency domain, the situation is rather different and differences between spectra are more prominent than in the time domain. Again, like in the time domain, the sound of toytrain product sound stands out from the others (see Fig. 4). The trend in spectra for all other products is similar in the frequency range above 125 Hz, where the maximum deviation of any spectra of these products is not greater than approximately 10 dB. On the other hand, the spectrum of toycar shows a significant rolloff below 125 Hz, which is not the case with spectra of other products.

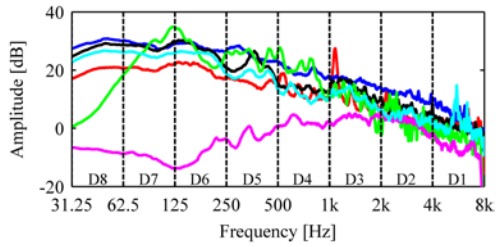

Fig 4. Spectra of audio signals (sounds) of industrial products (the same colors are used as in Fig. 3).

The results obtained in the frequency domain indicate a very favorable trend of what could happen when the signal decomposition by the discrete Meyer wavelet is done. In Fig. 4, the areas from D1 to D8 (from right to left) are also indicated. Those areas are related to the frequency ranges of the detail wavelet coefficients after decomposition at a particular level. Thus, the frequency range from 4 kHz to 8 kHz is correlated with the detail coefficients at the decomposition level 1 (D1). At the next decomposition level, the lower frequency range (up to 4 kHz) is split into two halves, so that the detail coefficients at the decomposition level 2 (D2) are extracted from the frequency range from 2 kHz to 4 kHz. This trend continues through the next decomposition levels [9] up to the last one, which is here the level 8. For all 8 decomposition levels, the related frequency ranges are given in Table I.

The illustration of the product sound characteristics in both time and frequency domain is given through the spectrograms presented in Fig. 5. The trend seen in the spectra given in Fig. 4 of the level reduction with frequency is also visible in the spectrograms. However, here some unique time-stamps of the signals are stressed, such as fluctuation in time of the slider or non-stationary amplitude of the toytrain.

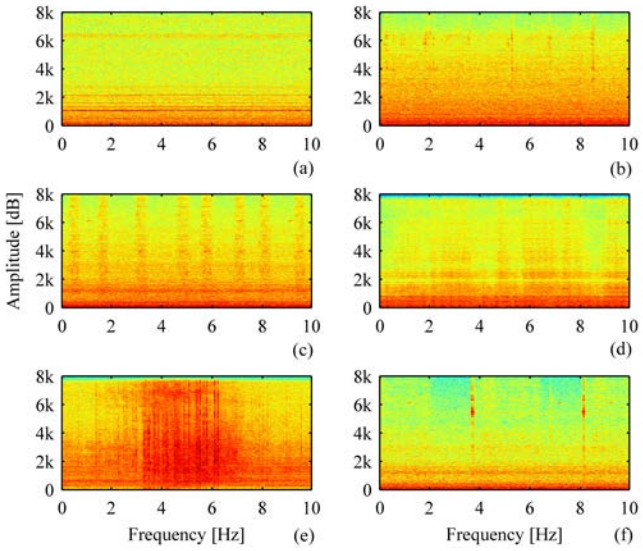

Fig 5. Spectrograms of audio signals (sounds) of industrial products: (a) fan, (b) gearbox, (c) slider, (d) toycar, (e) toytrain and (f) valve.

TABLE I
DEPENDENCE OF THE WAVELET DECOMPOSITION LEVEL TO THE FREQUENCY RANGE

Decomposition level	Frequency range
1	4 kHz – 8 kHz
2	2 kHz – 4 kHz
3	1 kHz – 2 kHz
4	500 Hz – 1 kHz
5	250 Hz – 500 Hz
6	125 Hz – 250 Hz
7	62.5 Hz – 125 Hz
8	31.25 Hz – 62.5 Hz

After analysis in the time and frequency domain, the chosen signals are decomposed using the discrete Meyer wavelet. Fig. 6 presents the values of the extracted wavelet-based feature for all six products, that is, signals whose time and frequency representations are given in Figs. 3, 4 and 5. All signals are segmented, wavelet decomposed and then the mean value of the absolute values of the obtained detail coefficients is calculated for each particular segment. At each decomposition level, some differences between the wavelet-based features (detail coefficients) of different products can be observed.

 ISBN 978-86-7466-930-3

These differences are smaller for some decomposition levels and comparing certain products, while they are larger at some other levels and for some other products. Also, the stationarity of the features of different products is not the same, and it might be used as one more parameter for differentiating the products. The previously mentioned emphasizes the need to make a more detailed analysis between the signals and the detail coefficients (wavelet-based features).

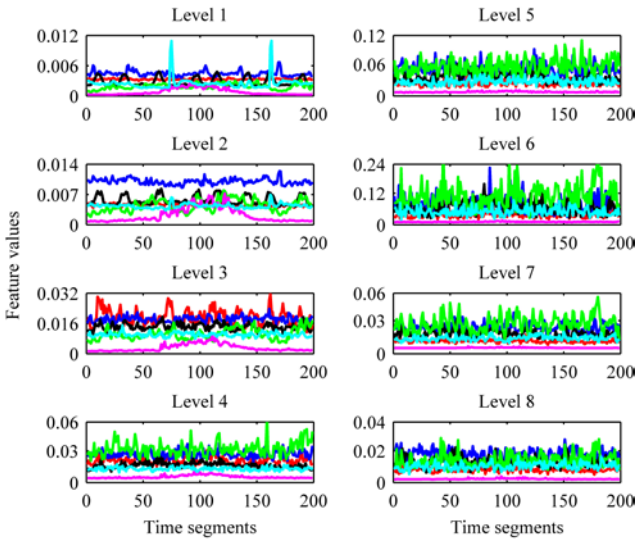

Fig 6. Wavelet-based features generated from the detail coefficients obtained after applying discrete Meyer wavelet to segmented signals and using the decomposition levels from 1 to 8.

In Tables II and III, the numerical values of the feature difference measure are summarized, where indexes in the numerical values represent the level of decomposition from which that specific case is obtained. These differences can be used to consider more closely the relations between particular products. Table II presents the feature differences between the products belonging either to the same class or different classes, where these differences are prominent. On the other hand, Table III presents the feature differences between the products where the differences are rather small when the products belong to the same class, but also when the products belong to different classes.

TABLE II
PROMINENT DIFFERENCES BETWEEN INDUSTRIAL PRODUCT SOUNDS REGARDING THE FEATURE DIFFERENCE MEASURE

Diff.	f	g	s	tc	tt	v
f	0.79_1	1.12_2	1.15_2	1.35_7	1.76_8	1.01_2
g	1.12_2	0.86_4	1.13_1	1.32_1	1.84_6	1.24_4
s	1.15_2	1.13_1	0.76_2	1.31_6	1.91_6	0.85_1
tc	1.35_7	1.32_1	1.31_6	0.84_2	1.91_7	1.36_6
tt	1.76_8	1.84_6	1.91_6	1.91_7	1.06_5	1.73_8
v	1.01_2	1.24_4	0.85_1	1.36_6	1.73_8	1.03_3

TABLE III
SMALL DIFFERENCES BETWEEN INDUSTRIAL PRODUCT SOUNDS REGARDING THE FEATURE DIFFERENCE MEASURE

Diff.	f	g	s	tc	tt	v
f	0.007_8	0.005_2	0.009_3	0.008_1	0.24_2	0.004_5
g	0.005_2	0.002_2	0.001_7	0.005_2	0.84_3	0.002_4
s	0.009_3	0.001_7	0.001_6	0.03_2	0.71_2	0.001_2
tc	0.008_1	0.005_2	0.03_2	0.005_7	0.53_2	0.001_2
tt	0.24_2	0.84_3	0.71_2	0.53_2	0.001_1	0.5_2
v	0.004_5	0.002_4	0.001_2	0.001_2	0.5_2	0.007_8

Analyzing Table II, it can be concluded that the smallest feature difference is obtained within the same class, that is going along the diagonal except for the product valve denoted as “v”, which has slightly smaller values for fan and slider meaning that this feature of the valve is more similar to the feature of those two products - fan and slider. But, in other products, it can be clearly seen that the features are much more similar within the class than between the classes.

The trend seen in Table II can not be seen in Table III where the features differences are rather small independently whether the compared products belong to the same class or different classes. The only exception is the product toytrain that has considerably larger feature differences when the product is compared to other product belonging to other classes. All these trends seen in the feature difference measure are in line with the noticed specific properties of spectra of these products.

Fig. 7 presents the feature differences from Tables II and III in the plot format. Differences having moderate values (called prominent differences) are given by blue curves, while small differences are given by red curves. Here, Fig. 7(b) presents only 6 cases randomly extracted from Tables II and III used to illustrate prominent and small differences between the classes. The values for prominent differences are smaller within the same class, Fig. 7(a) and diagonal elements of Table II, in comparison with the values between the classes, Fig. 7 (b). On the other hand, the values for small differences are rather small independently whether are calculated within the same class or between the classes except for the toytrain as discussed above. The latter shows that the differences of the wavelet-based feature between the classes can be small in some extreme cases representing minority of all cases.

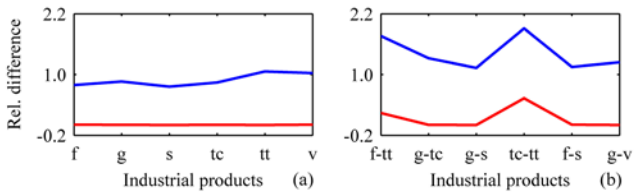

Fig 7. Differences between wavelet-based features (values of the feature difference measure): (a) prominent (blue) and small (red) differences between signals from same class, (b) prominent (blue) and small (red) differences between signals from different classes (products).

It is beneficial to look at the differences in the obtained detail coefficients (wavelet-based features) from different

 ISBN 978-86-7466-930-3

angles. As in all other cases of the wavelet-based features presented here, these features are obtained by applying the discrete Meyer wavelet to each signal segment. Fig. 8 presents prominent differences in the detail coefficients at some decomposition levels between the signals from same class (the same product type). The level of decomposition and class are indicated in the title of each graph, as it is also done for next figures of the same type. The blue curve is related to the first signal (product), while the red curve is related to the second signal (product). The presented differences are obvious, like the ones given in Table II.

A rather specific situation is presented for the toycar in Fig. 8, where the detail coefficients of these two toycar signals differ in a part of the segments (part of the signal), while this is not the case in the rest of the segments (rest of the signal) where the differences are negligible.

The opposite case is given in Fig. 9 presenting the negligible differences between the detail coefficients obtained from the signals belonging to the same class (the same type of industrial product). This figure can be used as a graphical confirmation of the results listed in Table III.

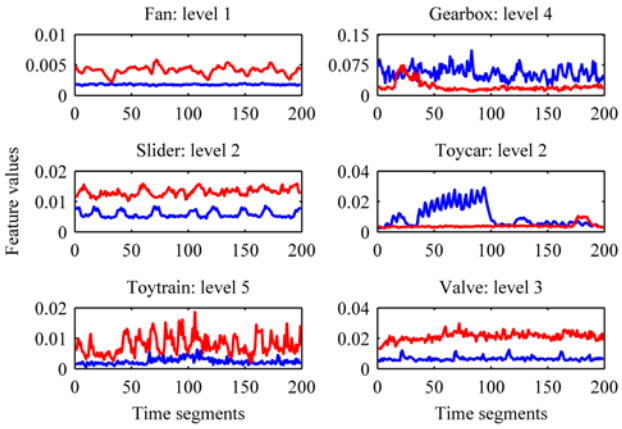

Fig 8. Wavelet-based features generated from the detail coefficients after applying discrete Meyer wavelet to segmented signals obtained for signals from the same class (type of industrial product); the case where the differences are obvious.

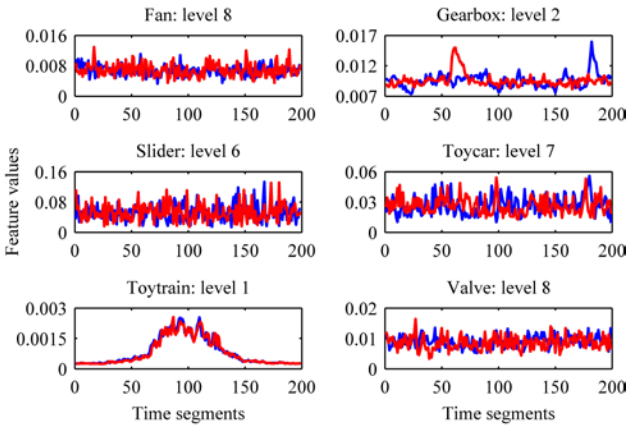

Fig 9. Wavelet-based features generated from the detail coefficients after applying discrete Meyer wavelet to segmented signals obtained for signals from the same class (type of industrial product); the case where the differences are negligible.

Fig. 10 presents some illustrative examples of the wavelet-based features - detail coefficients at particular levels of decomposition where the differences between the signals from different classes (types of industrial products) are obvious. Those difference are rather prominent, and they are greater than differences seen between the products belonging to the same class. Smaller differences between the detail coefficients (wavelet-based features) for signals from different classes (types of industrial products groups) are shown in Fig. 11. The found differences could not be considered to be negligible. They are smaller than those given in Fig. 10, but greater than those given in Fig. 9. What is also worth mentioning is that these wavelet-based features have some specific behavior along the time axis. For some of the classes (product types), such as the toytrain and toycar, it is not an easy task to find small differences between the wavelet-based features. These signals are not as stationary in time as other signals, and this is why their wavelet-based features show significant fluctuations of values along the time axis, that is, going through the segments.

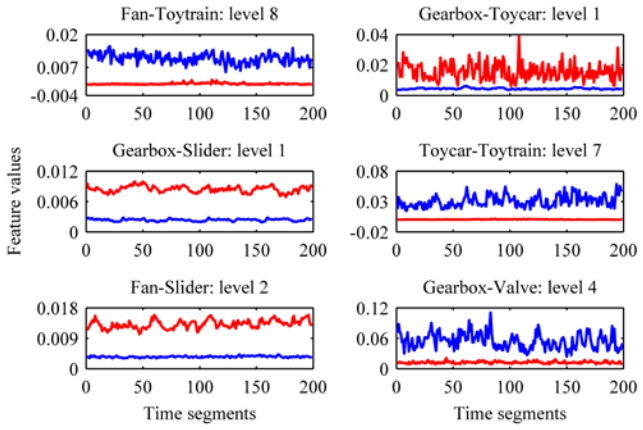

Fig 10. Wavelet-based features generated from the detail coefficients after applying discrete Meyer wavelet to segmented signals obtained for signals from different classes (types of industrial products) (extracted illustrative examples); the case where the differences are obvious.

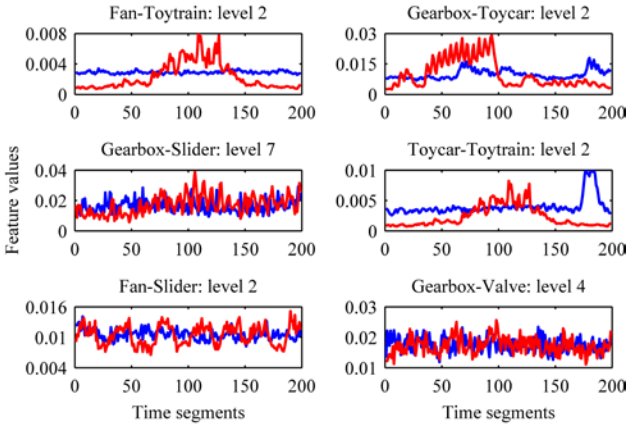

Fig 11. Wavelet-based features generated from the detail coefficients after applying discrete Meyer wavelet to segmented signals obtained for signals from different classes (types of industrial products) (extracted illustrative examples); the case where the differences are small.

 ISBN 978-86-7466-930-3

Analyzing Figs. from 8 to 11, it can be concluded that the presented prominent differences between the wavelet-based features are related to the cases when the feature curves differ from each other, while the negligible differences are related to the cases where the feature curves are overlapped (or close to each other) in the majority of time segments.

V. Conclusion

Wavelets represents a technique that is more and more popular nowadays in diverse application including audio feature extraction. Since there are a number of different wavelet families, it is a rather difficult task to select the most appropriate one for a particular purpose. This paper presents usage of the discrete Meyer wavelet in signal decomposition to approximation and detail coefficients, where the latter are used as the wavelet-based features. The goal is to get relevant audio features able to provide a large enough distinction among industrial products based on sound they generate.

More than 100 sound samples of industrial products (machines) belonging to six different classes are used in this study. The decomposition of every sound using the discrete Meyer wavelet goes from level 1 to level 8. All signals are first segmented, where the overlap between two segments is 50% of the segment length.

In this phase of the research, only manual numerical and graphical analysis is performed. The results show that the detail coefficients used as a wavelet-based feature provide a significant difference between the classes (types of industrial products) in majority of cases. Certain differences exist even between the sound samples from the same class, but typically they are smaller than the ones between the classes. Some illustrative examples showing small differences both within the same class and between different classes are identified and presented. This confirms that even when different industrial products are analyzed, it is possible to get very similar characteristics in the time and frequency domain, but also in the domain of audio features (in this case wavelet-based feature). This is why a more detailed analysis of statistics of the extracted wavelet-based features will be done in the next phase of the research.

Acknowledgment

This study was supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia (the results are parts of the Grant No. 451-03-68/2022-14/200132 with University of Kragujevac - Faculty of Technical Sciences Čačak and University of Niš - Faculty of Electronic Engineering) as well as by the Science Fund of the Republic of Serbia, 6527104, AI-Com-in-AI.

I. UVOD

Novija istraživanja vizuelne kulture tj. slike (*imago*), prevazilaze tradicionalne okvire ikonografskih pa i ikonoloških studija, koje su, izvesno, značajno doprinele njenom proučavanju. Ona danas uključuju široki opseg materijala koji se proučava kao što su predmeti vizuelne kulture, efemerni spektakli, film, televizija, opera, pozorište, multimedijalne instalacije, video igre, a oslanjaju se na metode i istraživačke postupke velikog broja disciplina – od istorije umetnosti preko studija kulture, performativnosti, do muzikologije i etnolmuzikologije, te psihologije muzike i kognitivnih neuro-nauka.

Knjiga profesorke Bisere Penčeve, profesorke istorije vizantijske umetnosti sa univerziteta Stenford (SAD), *Ikone uka* (u originalu *Icons of Sound*: *oice, Architecture, and Imagination in Medie al Art*), predstavlja zbornik tekstova od izuzetnog značaja za proučavanje performativnosti tj. odnosa između slike i zvuka u sakralnom prostoru srednjovekovne crkve [1]. Eseji autora govore o višegodišnjim istraživanjima u okviru projekta profesorke Penčeve koji ona vodi od 2008. godine na Stenford Univerzitetu. Ključ istraživanja odnosa i slike i zvuka leži u multidisciplinarnom i interdisciplinarnom pristupu. Na projektu je okupljen tim vodećih stručnjaka iz različitih naučnih oblasti kao što su istorija umetnosti,etnologija, istorija liturgike, muzikologija, digitalne tehnologije i inženjerstvo, a posebno inženjeri koji se bave pitanjem akustike [2]. Njihova zajednička istraživanja doprinela su formiranju krajnjeg cilja projekta a to je kako umetnost i slika postaje oživotvorena putem zvuka i glasa. Merenja zvuka u crkvi Svete Sofije u Carigradu doprinela su jasnijem razumevanju na koji način se zvuk kretao kroz prostor crkve i kako se u vidu „vodopada“ odbijao od pojedinih tačaka u crkvi, na koji način je to oživljavalo mozaike i ono što je najvažnije, kako je to sadejstvo slike i zvuka imalo uticaj na doživljaj vernika [3]. Istraživanja na ovom projektu pokazala su da je putem zvuka slika prestajala da bude dvodimenzionalna i da je oživljavala pred očima vernika. Angažovanje profesionalnog hora Kapela Romana čiji su pojci pojali iz originalnih sačuvanih srednjovekovnih notnih zapisa omogućilo je ovom timu stručnjaka da rekreira autentičan akustični ambijent srednjovekovnih sakralnih prostora, pre svega sakralnog prostora Svete Sofije. Današnja dostignuća digitalne tehnologije omogućila su da se izvođenje liturgije i različitih služni služenih na originalnom grčkom jeziku snimi i postavi na youtube kako bi se ljudi mogli da osete deo autentične srednjovekovna atmosfere [4]. Istraživanja predstavljena u radovima obuhvataju izuzetno veliku geografsku širinu, od srednjovekovne Francuske, Španije i Italije do Vizantije i Jermenije. Hronološki raspon obuhvaćen u radovima je od 9. do 16. veka.

II. METOD

Metodologija studije vizuelne kulture kombinovana je sa metodologijom studija muzikologije, istorije liturgike, etnologije i inženjeringa s obzirom na to da su njihovi rezultati a posebno rezultati muzikologije i inženjeriga opipljivi i empirijski ih je moguće izmeriti i zabeležiti [1]. Rezultati obrađeni u okviru ove knjige su čistoća zvuka, rasipanje zvučne energije, jačina zvuka i njegova reverberacija. Merenje, prikupljanje i obrada ovih podataka omogućilo je kreiranje akustičnog modela odabranih sakralnih prostora i stvaranje njihove auralne atmosfere, kao što je to slučaj sa Svetom Sofijom. Ova istraživanja omogućena su upravo uključivanjem hora Kapela Romana koji je pojao određene originalne srednjovekovne službe od kojih su neke od njih posebno pisane za Svetu Sofiju. Merenja su vršena tokom njihovog pojanja i istraživači su mogli da utvrde kojom brzinom zvuk putuje kroz prostor crkve, koja mu je jačina u određenim tačkama prostora kao i koliko traje revebreracija [3]. Ovakva istraživanja nisu mogla da budu obavljena bez uključivanja inženjera čija je uska specijalnost akustika. Njihova istraživanja spojena sa vizuelnom kuluturom su istoričari umetnosti, muzikolozi i istoričari liturgike stavili u

kontekst i dali su im interpretaciju kako bi rekonstruisali i oživeli prošlost.

III. GLAVNI REZULTATI

Knjiga je podeljena na tri „neopipljiva“ aspekta koji su međusobno povezani. To su liturgijski glas (liturgijsko pojanje), zvučni identitet prostora i reverberacija. Ova tri aspekta zajedno čine auralnu dimenziju sakralnog prostora koja komunicira sa slikama na zidu [2]. Tehnička merenja jačine zvuka i njegove reverberacije omogućila su da se rekonstruiše autentična atmosfera srednjovekovnih sakralnih prostora. Digitalni zapisi omogućili su da se ljudi bliže upoznaju sa akustikom srednjovekovnih prostora od kojih je danas veliki broj „gluv“ prostor s obzirom na to da se tu više ne vrše službe ili su oni pretvoreni u muzeje ili džamije kao što je to danas slučaj sa velikim brojem vizantijskih crkava. Sva istraživanja povezana su sa krajnjom svrhom liturgijskog pojanja i slika svete istorije u crkvi, a to je spasenje kroz realno Božije prisustvo koje se ogleda upravo u zvuku i slici. U ovom doživljaju su pored cula sluha, ogromnu ulogu imala i druga ljudska čula kao i ljudska psiha i moć imaginacije. Nekoliko radova fokusirano je na sferu imaginalnog i taktilnog, kao ključne aspekte za rekonstrukciju korelacije zvuka i slike a u cilju da se spasenje definiše u pojmu auralnosti koji omogućava da se Bog čuje [2].

Kroz radove se istražuje odnos između zvuka, umetnosti i arhitekture i njihovi zajednički uticaj na ljudsku imaginaciju i doživljaj sakralnog prostora [1,5]. Ključno pitanje ovih radova je koju je ulogu zvuk imao u pojanju u sakralnom prostoru i njegovom oblikovanju kao i u percepciji metafizičkog i aktiviranju veze između fizičke slike i imaginacije. Još od vremena autora iz ranog srednjeg veka kao što je Sveti Benedikt hor monaha koji poje predstavljao je odraz hora anđela. Pojanje u okviru sakralnog prostora simboliše prisustvo anđela kao i Boga koji prebiva u okviru crkve ili manastira. Na ovaj način su vernici istovremeno slušajući pojanje i gledajući slike ostvarivali kontakt sa Bogom.

Francisko Prado–Vilar jedan od autora posebno se u svom radu fokusirao na moć imaginacije i ulogu koji zvuk kako imaginarni tako i realni ima u tome [6]. Predmet njegovog istraživanje je takozvani Porta Francigena, severni portal hodočasničke crkve Santijago de Kompostela koji se nalazi u Galiciji na severu današnje Španije. Ova crkva u kojoj se čuvaju mošti Svetog Jakova Zavedejeva jednog od dvanaest Hristovih učenika u srednjem veku je pored Jerusalima i Rima predstavljao jednu od najvažnijih hodočasničkih tačaka i krajnji cilj hodočasnika na zapadu. Svoju pažnju je posebno fokusirao na mermerni stub. Na njemu su u vidu friza duž celog stuba u nekoliko registra predstavljene scene iz Odiseje. U pitanju je antička scena *Nostos* koja priča priču o Odisejevom povratku kući na rodnu Itaku i poteškoćama koje su zadesile Odiseja i njegovu posadu tokom putovanja. Na stubu je posebno istaknut Odisejev susret sa sirenama i morskim nemanima Scilom i Haribdom na uzburkanom moru. Stub je nekada činio sastavni deo severnog portala koji je predstavljao glavni ulaz za hodočasnike koji su dolazili na poklonjenje moštima Svetog Jakova. Predstave sa stuba komunicirale su sa scenama koje su se nalazile na timpanonu portala. To su Stvaranje Adama i Adamov izgon iz Raja kao i Blagovesti Bogorodici. Autor posebno ističe moć taktilnog u ljudskoj imaginaciji, s obzirom na to da su hodočasnici mogli da dodirnu stub i uzborkane talase mora koji su isklesani na njemu i na taj način da evociraju šum i miris mora. U tome im je umnogo pomagao prirodni ambijent i prirodni zvukovi jer se sama crkva nalazi na obali Atlantskog okeana. Realni šum i miris okeana bili su okidači za kontemplaciju vernika pred ovim portalom na kojem je noseća tema putovanje kući, koje u hrišćanskoj interpretaciji predstavlja putovanje čoveka u porazi za iskupljenjem čoveka, njegovo pomirenje i susret sa Bogom i povratak u Raj. U rekreaciji ovog susreta čoveka i Boga ključnu ulogu imao je zvuk vode, kiše i vetra koji je oživljavao Božiji glas i njegovo realno prisustvo u scenama na portalu. Ljudska čula zajedno sa slikom i zvukom kako prirodnim tako i imaginarnim oblikuje sakralni prostor u kojem se pred očima vernika prepliću realno i metafizičko.

IV. ZAKLJUČAK

Uloga zvuka imala je ključnu ulogu u aktivaciji slike kreirajući na taj način sakralnu dramu u kojoj su uslgu imali pojci, svečtenici, slike na zidovima crkava i vernici koji su prosustvovali liturgiji i drugim sakralnim obredima za koje su pisane posebne službe. Odnos zvuka, slike i osvetljenja oživljavao je sakralni prostor u kojem prebiva Bog i Božija sila. Zvučna atmosfera srednjovekovnih crkava stvaranja je kroz pojanje i molitve. Slike i osvetljenje prostora predstavljale su neizostavni deo ove atmosfere. Tokom merenja utvrđeno je da su se određeni tonovi sa određenim slogovima odbijali od određenih tačaka na mozaicima ili freskama [3]. Na ovaj način su dodatno davali život ovim slikama. U sadejstvu zvuka sa osvetljenjem stvaran je pokret i tako su vernici pred svojim očima videli žive, oživotvorene svetitelje i postajali su realni svedoci svete istorije koja je predstavljena na zidovima crkve u vidu mozaika ili fresaka. Ova međusobna povezanost zvuka, slike i osvetljenja predstavlja štimung jednog sakralnog prostora.

ABSTRACT

The multidisciplinary approach to the research in the field of study of visual culture has been prevalent over the last two decades. A combination of methods of various fields of research such as art history, ethnology, liturgical history, musicology, digital technologies and engineering, and in particular electrical and acoustical engineering, has contributed to a more encompassing understanding of the relation between image and sound in the shaping of the sacral space of medieval churches. The volume *Icons of Sound oice, Architecture and Imagination in Medie al Art* edited by Bissera Pentcheva offers insight into years of research in the field of correlation between image and sound and their role in the process of recreating authentic medieval acoustical (aural) ambiences and bringing the past back to the present.

ultidisciplinary approach in the study of image and sound in sacral space

Auralizacija sakralnih prostora i likovni programi: nove perspektive i mogućnosti istraživanja

Vuk Dautović, Jakov Đorđević

***Apstrakt*—Doživljaj prisustva svetosti bio je gotovo pretpostavljeno čulno iskustvo za srednjovekovne ljude. Poslednjih decenija istraživanja uloge svetla, mirisa i performativnih aspekata likovnih programa u dočaravanju prisustva svetosti unutar srednjovekovnih crkava omogućila su nove perspektive u razumevanju sakralne vizuelne kulture. Interdisciplinarna grupa naučnika okupljena oko projekta *Soundscapes of Byzantium* doprinela je jasnijem uvidu o važnosti zvuka kada je reč o oblikovanju vizantijskih sakralnih prostora istraživanjem auralizacije osam crkava u Solunu. Ne samo da je potvrđeno kako su promene u arhitekturi i likovnim programima išle paralelno sa promenama u bogosluženju i pojanju već je utvrđena i veza između likovnih programa i akustičkih karakteristika crkava.**

***Ključne reči*—auralizacija; sakralni prostor; obred; likovni program; multidisciplinarnost; zvučna slika.**

I. Uvod

Pozitivistička podela na jasno definisane i kruto odvojene discipline odavno se pokazala nedovoljnom za sticanje saznanja iza kojih stoje složenija pitanja o ljudskoj prirodi, kreativnom delovanju i svetu imaginarnog. Pristup svetosti i doživljaj svetog već decenijama privlače pažnju naučnika koji nominalno ne pripadu isključivo krugu antropologa. Tako se istorija religioznog slikarstva pomerila od jednostavnog objašnjenja likovnih izvedbi njihovim svođenjem na „Bibliju za nepismene“, a istorija arhitekture sakralnih zdanja od potrebe za hronološkim praćenjem promena arhitektonskih formi kvalitativno okarakterisanih kroz prizmu napretka i stagnacije. Štaviše, kada je konkretno reč o crkvama, istraživanja poslednjih godina donose sve više rezultata koji opravdavaju novu perspektivu njihovog posmatranja kao multimedialnih instalacija. Pored osnovne funkcije pružanja mesta kolektivne molitve, crkve su podizane i oblikovane sa namerom da vernicima obezbede manifestaciju prisustva svetosti i čulno učešće u njoj.

Grupa naučnika okupljena na projektu *Soundscapes of Byzantium*, imajući u vidu da glas predstavlja osnovno sredstvo molitve, postavila je kao svoj osnovni predmet istraživanja ulogu zvuka u kreiranju sakralnih prostora Vizantijskog carstva. Ovaj interdisciplinarni tim predvođen Šeron Gerstel (profesorka vizantijske umetnosti i arheologije na Univerzitetu u Kaliforniji, Los Anđeles) i Krisom Kiriakakisom (direktor Imersivne audio laboratorije na Univerzitetu Južne Kalifornije) odabrao je osam srednjovekovnih crkava u Solunu kao polaznu tačku svog ispitivanja [1]. Budući da je reč o gradu sa drevnom istorijom koji i danas čuva mesta hrišćanske molitve još od kasnoantičkog razdoblja, Solun je pružio priliku za analizu akustičkih svojstava crkava različitih perioda hiljadugodišnjeg carstva, a time i razmatanje nove pretpostavke uslovljenosti promena u arhitekturi i slikarstvu uvođenjem novina u crvenom bogosluženju i stilu pojanja [1, 2].

II. Pristup istraživanju

Istraživanje sprovedeno u okviru projekta *Soundscapes of Byzantium* počiva na merenju impulsnih odziva na različitim mestima unutar crkava. Odabir odgovarajućih pozicija za izvore zvuka i mikrofone za snimanje određivan je na osnovu nekoliko kriterijuma: 1) položaju specifičnih arhitektonskih formi koje potvrđeno doprinose oblikovanju posebnih akustičkih efekata; 2) pozicijama određenih likovnih predstava koje nagoveštavaju vezu sa crkvenim pojanjem; 3) mestima koja su posebno izdvojena u vizantijskim bogoslužbenim knjigama kao tačke odigravanja specifičnih obrednih radnji. Kako bi se postigla što objektivnija kvalifikacija, merenja su ponavljana svakog dana u isto vreme, obraćajući pažnju na eventualne promene prouzrokovane različitim temperaturama i vlažnošću prostora. Sprovedena analiza dobijenih podataka omogućila je razmatranje auralne atmosfere svake sakralne građevine ponaosob, ali i komparativno sagledavanje svih osam solunskih crkva. Takođe je pridata pažnja utvrđivanju čistoće zvuka i varijacijama koje uvodi izgovorena reč u odnosu na otpevan ton, kao i razlikama koje donosi izvedba soliste nasuprot horskom pevanju. Budući da je reč o pokušaju rekreiranja originalne estetike zvučne slike i njene sinergije sa likovnim programom i arhitektonskim karakteristikama prostora, psihoakustička razmatranja predstavljala su kranji cilj analize. Prikupljeni podaci upoređeni su sa opservacijama pojaca angažovanih na projektu baš kao i pažljivo pozicioniranih slušalaca. Najzad, empirijsko sagledavanje i pojedinačne impresije omogućile su novu perspektivu za preispitivanje opisa akustičkih doživljaja zabeleženih u vizantijskim izvorima [1-3].

 ISBN 978-86-7466-930-3

Ovim merenjima prethodila su jasno formulisana metodološka stanovišta koja su na teorijskom planu pripremila i uporedila različita znanja o shvatanju zvuka i njegovoj ulozi u oblikovanju verske stvarnosti. Pošavši od premise da je savremeni čovek izložen brojnim auditivnim doživljajima i da su muzika i zvuk prisutniji od tišine, za razliku od čoveka vizantijskog doba koji se sa muzikom i pevanjem u najveličajnijem vidu mogao sresti tokom bogosluženja u samim crkvama ali i tokom molitvenih procesija koje su hristijanizovale spoljni prostor, te tokom kojih su svi senzorni aspekti bili jednako važni, udruživši vizuelnost, auditivno i olfaktorno u performativnom činu krsnog hoda ili litije. Konačno sama crkva shvaćena je kao muzički instrument odnosno „rezonantna kutija“ koja zvuku kroz svoja akustička stvojstva daje konačan pečat [3, 5].

Teorijsko poznavanje tumačenja auditivnog, pre svega teoloških spisa i patristike istočne crkve uporedo je posmatrano sa akustičkim mogućnostima solunskih crkava shvatanih kao odraz „nebesa na zemlji“. Upravo je veza sa mističnom teologijom istočne crkve i poznavanje angelologije kao teološke discipline koja se bavi karakterom i prirodom bestelesnih nebesnih sila u fokus stavila zvuk kao neposredni emanator nevidljivog sveta, što potvrđuju brojni istorijski izvori. Važna ideja na kojoj počiva recepcija zvuka bogosluženja jeste učenje po kome se nebeska i zemaljska liturgija odvijaju istovremeno i jedinstveno na beskonačnom broju oltara. Pisanje savremenika, Solun XIV veka opisuje kao „još jedno nebo“, što je značajna polazišna osnova pri tumačenju akustičkih osobenosti njegovih hramova. Izvođenje crkvenih himni svetiteljima i pevanje psalama, karakteristični za svakodnevicu srednjevekovnog razdoblja pružali su u javnim manifestacijama pobožnosti priliku za „kolektivan emocionalni odušak“ naročito vezano za praznike povezane sa Hristovim Vaskrsenjem, te su glasnost i jauci jednako oblikovali auditivni svet medijevalnih ljudi. U tom smislu i sam grad koji je mogao biti prepešačen u vremensmom okviru od 45 minuta postaje svojevrstan muzički instrument ili rezonator u njemu proizvedenog kolektivnog zvuka [3] .

Znanja o vizantijskoj liturgici, i sve promene koje se tiču poretka molitava i pesama koje se tokom bogosluženja izvode jesu od značaja za šire tumačenje povezanosti likovnih programa i vizuelizacije izvođenja crkvenih pesama ili još detaljnije pojedinih trenutaka u liturgiji na njima prikazanih. Upravo je smeštanje određenih molitava poput *Trisvete pesme* u izabrani segment unutar sakralne topografije hrama stvaralo mogućnost da kroz načine komponovanja ali i akustička svojstva odbijanja zvuka efekte udvojenih glasova ili „anđeoskih horova“ [3, 5].

Naglašavanje muzike i auditivnog bilo je postignuto kreiranjem paralelnih narativnih scena u kojima su anđeli obučeni poput đakona sa ripidima i svicima izvodili određene molitve bivajući veza sa mističnom stvarnošću koja verniku iznova nudi „multimedijalni“ doživljaj bogosluženja. Ovakve slike javljaju se u brojnim umetničkim medijima od veza preko bogoslužbenih predmeta od metala i sveth slika, pojačavajući značaj vizuelno-auditivnog polja. Pomenuta uporišta u kulturno istorijskoj praksi vizantijskog sveta, himnografiji, liturgici te istoriji muzike i istoriji vizantijske umetnosti stavljena su u službu posmatranja crkvenog prostora kao akustičkog sistema koji prima glas kao zvučni impuls emitujuću zvuk koji je modifikovan akustičkim svojstvima same građevine. Upravo je kroz multidisciplinarnost ove vrste izvršena demonstracija načina na koje društveno-humanističke i tehničke nauke mogu doprineti polju episteme otvarajući unutar njega nove perspektive.

III. NOVE PERSPEKTIVE

Uvođenje sve većeg broja svetiteljskih figura sa svitcima na kojima se čitaju odlomci stihova crkvene poezije, baš kao i pojava doslovne vizualizacije sastava crkvenog pesništva u vidu složenih kompozicionih rešenja i ciklusa, samo su neke od karakteristika oblikovanja likovnih programa crkava kasnijih epoha Vizantijskog carstva. Navedene predstave sa svojim naslikanim tekstovima neretko su korišćene za obeležavanje posebno važnih obrednih tačaka u hramu sa ciljem definisanja emocionalnog iskustva vernika koji prisustvuje službi. Gotovo dramski iscenirani prizori često su praćeni rečima zahvalnosti, tugovanja, radosti ili strahopoštovanja i njihovim čitanjem vernik bi ih prisvajao postajući učesnik u ritualnom rekreiranju događaja iz svete istorije prilikom liturgije. Monumentalna kompozicija Oplakivanja Hrista u crkvi Svetog Pantelejmona u Nerezima brižljivo dočarava ekspresije bola na licima aktera scene, podstičući empatiju posmatrača. Sa druge strane, figure svetih himnografa pod freskom drže u rukama poetske sastave čije čitanje ne samo da nagoveštava teološke premise ovog događaja već verbalizuje i poželjne emocionalne odgovore vernika. Međutim, budući da je reč o performativnim tekstovima, odnosno onima koji su čitani ili pevani naglas makar jednom u toku liturgijske godine, ispisane reči bile bi animirane glasom. Predstave svetih himnografa u crkvi u Nerezima nalaze se u severnoj pevnici i bile su delimično zaklonjene grupom pojaca koji su sa tog mesta pevali za vreme službe, uznoseći stihove svitaka u molitvenoj pesmi [4]. U paraklisu Hrista Hore u Carigradu, funerarnoj kapeli namenjenoj čuvanju uspomene na tu sahranjene preminule, zapadni travej nosi kupolu sa pandantifima na kojima su prikazani sveti sastavljači stihova čitanih prilikom komemorativnih službi [4]. Reči njihovih svitaka mogle su da se čuju prilikom izvedbe navedenih obreda. Stoga, likonvi programi vizantijski crkava mogli su da ukažu na konkretne prostorne tačke namenjene izvedbi pojanja, ali i na prirodu molitve, „režirajući“ pozicije okupljenih kao i njihov duhovni doživljaj [4, 5].

Kada je reč o „animiranju“ naslikanih figura, zanimljivo ispitivanje proizašlo je iz akustičke analize u crkvi Svetog Nikole Orfanosa u Solunu. Severni krak ophodnog broda originalno je bio zatvoren zidom sa zapadne strane obrazujući zasebnu kapelu prislonjenu uz jezgro crkve. Bogorodičin akatist, likovni ciklus sačinjen od ilustracija stihova himne posvećene Hristovoj majci, nekada je pokrivao sve zidove kapele izuzev istočnog zida. Danas su kompozicije Akatista

 ISBN 978-86-7466-930-3

opstale jedino na južnom zidu i to u registru koji teče neposredno iznad dva prolaza u glavnu crkvu – njen oltarski prostor i naos. Kako je reč o vizualizaciji pesničkog sastava, članove tima *Soundscapes of Byzantium* zainteresovao je odnos izvedbe pojaca i slike. Prva analiza bazirana je na ispitivanju akustičkih svojstava prostora na osnovu pojanja u samom severnom kraku ophodnog broda. Činjenica da je nekadašnja kapela izgubila originalni zid sa zapadne strane svakako je doprinela potpunoj promeni prvobitnog akustičkog okruženja i pokazalo se da je „nedostatak rezonancije podjednako nezadovoljavajuć i za pojce i slušaoce“ [4]. Premda je teško utvrditi originalnu zvučnost kapele, eksperiment pozicioniranja jednog pojca okrenutog prema istoku sa zapadne strane oltarske pregrade glavne crkve (mesta sa kojeg bi kretalo pojanje u pojedinim trenucima liturgijske službe), pokazao je da je svakako postojala svest o promišljanju akustičkih svojstava u sprezi sa osmišljavanjem likovnog programa. Istočni prolaz koji povezuje kapelu i crkvu pojačao je jačinu glasa koji je dolazio u kapelu. Na osnovu opisa iskustva prisustva bogosluženju iz izvora i dosadašnjih istraživanja kontemplativnog stanja monaha pred slikom, ukazala se mogućnost specifične zamisli pri planiranju programa: namera da se stvori utisak kao da pojanje dolazi od naslikanih figura Akatista koje su i prikazane kako pesmom proslavljaju mladog Hrista na prestolu nad lučnim prolazom [4].

Ovakve „zvučne slike“, odnosno predstave koje bi bile animirane glasom, prema istraživanju projekta *Soundscapes of Byzantium*, obeležavale su posebna mesta namenjena okupljanju kongregacije u okviru odgovarajuće službe. Nad ulazom u središnji deo naosa crkve Svetih Apostola u Solunu iz severnog kraka ambulatorijuma, koji je funkcionisao kao kapela Svetog Jovana Krstitelja, naslikana je kompozicija Božićnog tropara. Monumentalna freska obavija gornji deo lučnog prolaza prikazujući anđele koje se u pesmi spuštaju kroz otvorene nebeske vratnice i monahe koji poju podeljeni u dve grube pri dnu kompozicije (sa obe strane ulaza u naos). Kako su vizantijski pojci bili podeljeni u desnu i levu pevnicu, navedena predstava ne samo da je obeležavala mesto izvedbe službe na božićnom jutrenju, nakon čega bi svi ušli u naos, već je nudila i model okupljenima, poistovećujući posmatrače sa akterima scene. Slika je mogla da se čuje, a glasu je pružana vizija više duhovne stvarnosti gde su nebeske sile saučestvovale u obredu [4, 5].

Projekat *Soundscapes of Byzantium* uložio je posebne napore da razmotri da li je mistično tumačenje liturgije kao zajedničke službe neba i zemlje moglo da bude i doslovno opaženo čulom sluha putem postignutih akustičkih efekata [3]. Kupole, apside i svodovi, pored činjenice da prema stepenovanju svetosti predstavljaju prostore najviše sakralnosti, takođe su pojačavali i usmeravali glasove. Akustička svojstva apside doprinosila su čujnosti glasa sveštenika okrenutog prema istoku, a važnost prostora kupole i kao najrezonantnijeg dela crkve ogleda se u vizantijskim liturgijskim priručnicima koji daju instukcije da se posebni delovi službe upravo tu odigravaju [5]. Sprovedena akustička merenja na različitim pozicijama unutar solunskih crkava i psihoakustička razmatranja pružila su nove poglede kada je u pitanju sama percepcija. Zahvaljujući postojanju galerije sa pogledom na naos, crkva Proroka Ilije omogućila je uvud i u razlike prisustva bogosluženju kada se vernik nalazi na uzvišenom mestu. Utisak da je zvuk na galeriji čistiji i jasniji potvrđen je poređenjem impulsnih odziva. Iz toga proističe da su galerije, budući namenjene osobama višeg dostojanstva, omogućavale, pored neometanog pogleda na naos, i privilegovaniji položaj za slušanje [1]. Međutim, testiranjem zvuka solunskih crkva uočeni su i posebno zanimljivi akustički obrasci koje su pojci opisali kao prisustvo „bestelesnih glasova“ [3]. Prema opisu, čuli su melodijsku liniju za oktavu višu istovremeno sa sopstvenim pojanjem. Zapravo, u akustičkom smislu, ono što su čuli bio je prvi oberton iz niza kao posledicu reverberacije građevine. Zabeležen doživljaj sličan je vizantijskim teološkim opisima zajedničkog služenja liturgije nebeskih sila sa vernicima na zemlji [3].

IV. Zaključak

Premda je sagledavanje originalne auralizacije drevnih zdanja otežano zbog njihovih kasnijih prepravki, dogradnji i oštećenja, pri čemu je čest gubitak izvornog materijala sa svojim prirodnim svojstima reflektovanja i upijanja zvuka ostavio trajne posledice [2, 4], grupa predvođena Šeron Gerstel i Krisom Kiriakakisom donela je veoma važne rezultate i postavila dragocene smernice za buduća istraživanja. Komparativna ispitivanja osam crkava u Solunu potvrdila su visoku svest o važnosti akustike pri oblikovanje sakralnih prostora u Vizantijskom carstvu. Štaviše, promene u planu, obliku i likovnim programima vizantijskih crkava išle su paralelno sa promenama u bogosluženju i pojanju kao neraskidivi splet koji je trebalo da ostvari multisenzorno iskustvo učešća u svetosti [1, 2]. Nije slučajno da se novi tip pojanja sa mnoštvom ukrasa i težnjom ka apstrakciji pojavio u XIII veku – periodu kada počinju da se slikaju raskošne kompozicije inspirisane crkvenim pesništvom [1, 4, 5]. Projekat *Soundscapes of Byzantium* doneo je važan materijal za dalja komparativna istraživanja crkava na drugim područjima koja bi u budućnosti mogla da daju još detaljniji i dublji uvid u duhovne potrebe, kreativnost i svet imaginarnog srednjovekovnih ljudi, ali i da odrede preciznije karakteristike verske kulture na području Evrope.

ABSTRACT

The presence of the sacred was experienced by the senses in the Middle Ages. In the last decades, the research on the role of light, smell, and the performative aspects of pictorial programs in evoking the presence of holiness within the medieval churches provided new perspectives in understanding the sacral visual culture. The interdisciplinary group of scientists gathered around the project Soundscapes of Byzantium contributed to better insight into the importance that sound had in fashioning Byzantine sacred spaces by researching the auralization of the eight churches in Thessaloniki. It is not only attested that changes in architecture went hand in hand with the changes in liturgical rite and chanting but the connection between pictorial programs and acoustical characteristics of the churches has also been shown.

Auralization of sacral spaces and pictorial programs: new perspectives and possibilities of research

Istraživanje zvučnog ambijenta srpskih sakralnih prostora kao višemedijskog fenomena

Miomir Mijić, Miloš Bjelić, Dragana Šumarac Pavlović, Tatjana Miljković, Filip Pantelić

***Apstrakt* — Istraživanje zvučnih ambijenata u istorijskom kontekstu iznedrilo je posebnu oblast akustike nazvanu arheoakustika. Pored mnogih značajnih istorijskih objekata, tema takvih istraživanja bile su povremeno i akustičke karakteristike verskih prostora. Sintezom akustičkih, istorijskih i teoloških činjenica o srpskim sakralnim prostorima dolazi se do zaključka da je njihov koncept višemedijska tema u kojoj je zvuk samo jedna, mada važna komponenta. Da bi se dao smisao mogućnostima koje savremena akustička analiza može pružiti u tumačenju sakralnih prostora neophodno je izaći iz okvira fizike i posmatrati sadejstva zvuka sa ostalim korišćenim medijima kao što su slikarstvo, arhitekura, muzika, koreografija, svetlost. Ovaj rad razmatra mesto i ulogu akustike u kontekstu mogućih multidisciplinarnih istraživanja srpskih sakralnih prostora. Fokus se usmerava na nekoliki karakterističnih inženjerskih tema: na korelaciju impulsnih odziva i fizičkih formi sakralnih prostora, na auralizaciju zvučnog polja u njima kako bi se omogućilo izmeštanja istraživanja u laboratorijske uslove, na uticaj akustičkog ambijenta sa pozicije pojaca i sveštenika, kao i na akustičku karakterizaciju šireg fizičkog ambienta iz kojeg vernici ulaze u domen sakralnog prostora i u koji se iz njega vraćaju.**

Ključne reči* — akustički ambijent; arheoakustika, crkve, impulsni odziv, sakralni prostor, *stage support

I. UVOD

Jednom prigodom neko je zanimljivo primetio da je istorija sve do dvadesetog veka zapravo bila nema. Zvuk je oko čoveka oduvek nastajao, ali i nestajao u istom trenutku, ostajući dostupan samo neposredno prisutnim oko mesta gde se javio. Zbog toga se istorijsko proučavanje nužno fokusiralo na artefakte koji traju u vremenu, na građevine, predmete i zapise, dok su zvuci koji su pratili život ljudi, kao i informacije koje su ti zvukovi nosili, ostali trajno nedostupni. Tek sa audiotehnikom, koja se pojavljuje na prelazu iz devetnaestog u dvadeseti vek, i njenim razvojem čovečanstvo i civilizacija počinju da ostavljaju reativno trajne zvučne otiske koji o minulim događajima i ljudskim odnosima svedoče na svoj način i pružaju dodatne informacije [1].

S razvojem novih tehničkih mogućnosti, neumitno se postepeno javilo zanimanje za akustičke fenomene i u istorijskom kontekstu, što je učinilo da se s vremenom izdvoji nova multidisciplinarna oblast nazvana „arheoakustika“. Njena najširа definicija kaže da se „arheoakustika bavi odnosima između ljudi i zvuka kroz istoriju“ [2]. Ilustrativna je i definicija koja naglašava upravo njenu multidisciplinarnost, i po kojoj se arheoakustika bavi „akustikom na arheološkim lokalitetima u različitim kulturama koristeći i kombinujući u svom pristupu fiziku, antropologiju i arhitekturu“ [3]. U tom kontekstu su i akustičke karakteristike srpskih crkvenih prostora povremeno bivale predmet istraživanja [4-10].

Pregledom naslova publikovanih radova u akustičkoj literaturi saznaje se da je arheoakustika došla u fokus istraživača krajem dvadesetog veka. To se može objasniti činjenicom da poslednje dekade prošlog veka koincidiraju sa eksplozivnim razvojem računara i raznih softverskih alata od značaj za tu oblast: za simulaciju zvučnog polja, za snimanje i analizu impulsnog odziva prostora, a kasnije i za auralizaciju. Postalo je jednostavno da se za razne istorijski značajne prostore dobije detaljna akustička karakterizacija. Ta mogućnost potoji čak i za prostore koji danas više ne postoje, samo ako su njihova geometrija i materijalizacija dovoljno detaljno dokumentovane.

U obilju danas dostupnih tehničkih mogućnosti nametnula se ideja traganja za širim smislom koju mogu dobiti izmerene ili izračunate akustičke informacije o prostoru, a koje su po pravilu predstavljene „autističnim“ numeričkim podacima. Naime, zvuk se uvek pojavljuje u nekom kontekstu i nosi informacije o tome koje čulo sluha čoveka dekoduje. Zvučne informacije se neumitno povezuju sa ostalim perceptivnim inputima koji se istovremeno stiču u moždanim centrima, pa je doživljaj čovekovog okruženja rezultat multisenzorske percepcije. U takvom kontekstu zvuk pod određenim okolnostima može dobiti jedan širi i složeniji smisao.

Možda najintrigantniji fenomen pojave zvuka javlja se u sakralnim prostorima. Crkvena služba koja se u njima odvija, sa vizuelnim dimenzijama prizora i narativom koji ih prati, tipičan su primer višemedijske forme koja kod ljudi aktivira mulitisenzorsku percepciju. U sakralnom prostoru zvuk je u sprezi sa drugim primenjenim medijima: slikarstvom, arhitekturom, svetlošću, muzikom, koreografijom. Da je u pitanju višemedijski efekat dokazuje, na primer, jasna razlika između doživljaja pri slušanja snimka nekog pojanja emitovanog s kućnog sistema za reprodukciju zvuka u atmosferi dnevne sobe i slušanja istog pojanja uz fizičko prisustvo službi u nekoj crkvi.

 ISBN 978-86-7466-930-3

Razlika u doživljaju koja je u navedenom primeru prilično jasna objašnjava fenomen multisenzorske percepcije u sakralnim prostorima. Višemedijsku prirodu pravoslavne crkvene službe istoričari su razmatrali dokazujući da je u tome evidentno združeno dejstvo monumentalnog slikarstva na zidovima, zvuka pojanja i specifičnog akustičkog odziva prostora crkve koji nastaje pri takvoj zvučnoj pobudi [11]. Šaron Gerstel u jednom svom članku konstatuje: "U ovoj maloj crkvi zvuk pojanja, reči koje se izgovaraju i sakralne slike povezane su na neočekivani i sofisticiran način" [12]. Specifične efekte produžene reverberacije i mešanje različitih zvukova koji nastaju u atmosferi crkvene službe neki istoričari su prepoznavali kao „mešanje nebeskih i ljudskih glasova" [13].

U tehničkom domenu višemedijska priroda crkvene službe može se prepoznati kao najraniji pojavni oblik multimedijalnih događaja. Danas je savremena tehnologija, pogotovo ona najsofisticiranija, u multimedijalnim produkcijama prebacila poentu na tehnički spektakl, a ponekad i na spektakl tehnologije po sebi, ali sâm koncept događaja osmišljenog da podstakne multisenzorsku percepciju očigledno potiče od davnina.

Zvučna dimenzija crkvene službe zasniva se na ljudskom glasu i nekim specifičnim zvukovima koji prate određene radnje kao što su zvukovi posuda sa tamjanom, zvona, klepala. Neki istraživači srednjeg veka ukazuju da su Vizantinci bili pod uticajem zvuka i naglašavaju moguće psihološke dimenzije raznih zvučnih fenomena. U literaturi je zabeležen stav da je prijem zvuka kod publike bio faktor koji je uticao na organizaciju oslikavanja i postavljanje slika tematski povezanih sa pojanjem u određenim zonama crkve [13].

Sa aspekta fiziološke i psihološke akustike čulo sluha čoveka u predmodernom dobu bilo je isto kao i danas. To je suviše kratak vremenski period da bi evolucija unela neke fiziološke promene, što daje za pravo da se zaključci savremenih istraživanja primene i na tumačenja reakcija ljudi suočenih sa višemedijskim delovanjem sakralnih prostora u srednjem veku. Uprkos postepene promene karaktera zvučnih ambijenata, pre svega značajnom povećanju ukupnog nivoa buke u životnoj sredini nastalom od početka industrijskog doba, čulo sluha je centralno svojstvo ljudskog iskustva danas kao što je bilo i za srednjovekovnog čoveka.

Istraživanje zvučne komponente ambijenta sakralnih prostora ne može se odvojiti od njihove višemedijske prirode. To zahteva postavljanje pravih pitanja koja ne smeju biti rezultat isključivo inženjerskih shvatanja teme. Traganje za odgovorima otvara nekoliko važnih istraživačkih putanja. Prvo, to je utvrđivanje osnovnih karakteristika akustičkog odziva prostorija koji čine deo sakralnih prostora i njihovog odraza na subjektini doživljaj slušalaca. Za postojeće prostore do tog saznanja se može doći neposrednim snimanjem impulsnih odziva, a za prostore koji su vremenom devastirani ili potpuno uništeni do toga se može doći metodama simulacije zvučnog polja (ako postoje zapisi sa dovoljno informacija o njihovoj geometriji i materijalizaciji).

Drugo, to je stvaranje baze snimaka onoga što ljudi slušaju tokom službe, snimljenih na različitim mestima u crkvama različitih veličina i formi. Glavni cilj toga je stvaranje mogućnosti da se u laboratorijskim uslovima primenom auralizacije analizira priroda auditornih doživljaja u okvirima sakralnih prostora.

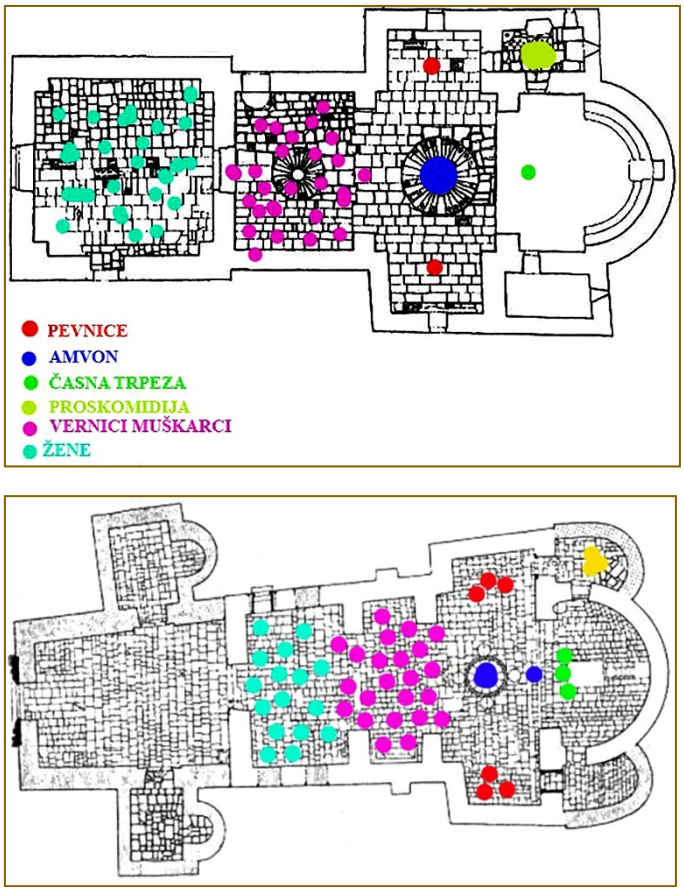
Treće, postoji izvestan uticaj zvučnog ambijenta na one koji pevaju, sveštenike, pojce i horove. U kontroli njihovog pevanog glasa oni se prilagođavaju onome kako sebe čuju, što zavisi od akustičkog odziva prostora. Povratna sprega koja neumitno postoji upravlja kontrolom glasa, a u ovom slučaju verovatno i na vokalnu interpretaciju.

Najzad, širi obuhvat sakralnih prostora, to jest ambijent u kome se nalaze verski objekti, ima neke svoje akustičke karakteristike. Tokom dolaska ljudi u crkvu one možda imaju ulogu u njihovoj pripremi za kompleksni doživljaj službe, a takođe predstavljaju ono što ih u zvučnom smislu dočekuje nakon završetka službe.

U ovom radu su detaljnije razmatrane četiri opisane istraživačke putanje u arheoakustičkom pristupu sakralnim prostorima i njihove veze sa tangentnim naučnim oblastima u kojim se analiziraju iste teme.

II. Imulsni odzivi sakralnih prostora

Od samog nastanka moderne akustike pre stotinak godina istraživanja su bila usmerena na pokušaje da se procesi u prostorijama na neki način numerički karakterišu, a sve sa ciljem da se u nekom sledećem koraku utvrde veze između dobijenih brojeva i dimenzija koje u subjektivnom doživljaju zvuka i estetike zvučne slike prepoznaje slušalac. Najveći zamah u tom domenu dalo je istraživanje koncertnih i operskih sala i pokušaji da se inženjerski izmerene veličine, što znači numerički pokazatelji, povežu sa subjektivnim doživljajem estetike onoga što slušalac čuje u sali tokom muzičkih izvođenja [14,15]. Saznanja o tome koja su stečena do danas predstavljaju dobru osnovu za istraživanje sakralnih prostora u kojima je zvuk element crkvene službe, i gde čulo sluha takođe na svoj kompleksan način vrednuje ono što prima.



Osnovni prikaz procesa u kome zvuk iz nekog izvora stiže do slušaoca je impulsni odziv prostora u kome se taj proces dešava. Zato prvi korak u istraživanju sakralnih prostora podrazumeva utvrđivanje karaktera impulsnog odziva u crkvama od interesa. Definicija impulsnog odziva podrazumeva da su u prostoru definišu pozicije izvora zvuka i prijemnika, a to su slušaoci. Njihove pozicije su relativno precizno određene liturgikom i arhitekturom crkve. Dva primera njihovih pozicija prikazani su na slici 1. Uzeti su primeri crkve Preobraženja u manastiru Pridvorica (12. vek) i crkve Vaszesenja Gospodnjeg u manastiru Mileševa (13. vek). Vidi se da postoji jasna podela na zonu u kojoj se nalaze potencijalni slušaoci i relativno lokalizovane pozicije izvora zvuka: pevnice, amvon i časna trpeza. To u izvesnom smislu pojednostavljuje pristup snimanju impulsnih odziva i svodi taj istraživački korak na relativno ograničen broj parova tačaka izvor zvuka – prijemnik zvuka.

III. Auralizacija ambijenta sakralnih prostora

Auralizacija je termin koji je uveden kao analogija pojmu vizuelizacije, pa se može slikovito reći da je to „renderovanje" zvučnog polja [16]. Taj proces podrazumeva reprodukciju zvuka pomoću slušalica, jer je koncept zasnovan na pripremi binauralnih signala. Cilj auralizacije je da se kod slušaoca u laboratorijskim uslovima generiše auditorni događaj kakav bi

 ISBN 978-86-7466-930-3

doživeo u različitim prostorima kada bi se u njima fizički nalazio, slušajući pri tome zvučne sadržaje koji se mogu proizvoljno birati. Auralizacija omogućava rekonstrukciju onoga što se čuje u nekom prostoru bez potrebe da se u njemu fizički nalazi, i što je u istraživačkom smislu posebno važno, da se to preslušava proizvoljan broj puta.

Sl.1. Osnova crkve Preobraženja u manastiru Pridvorica (gore) i crkve Vaznesenja u manastiru Mileševa (dole) sa naznačenim tačkama od značaja za snimanje impulsnih odziva.

Za auralizaciju je potrebno raspolagati binauralno snimljenim impulsnim odzivima prostora koji se želi predstaviti, a to znači sa signalima impulsnog odziva registrovanim na pozicijama levog i desnog uva neposredno prisutnog slušaoca. Takvi odzivi su označeni kao impulsni odzivi glave (HRTF – Head Related Transfer Function). Oni se u praksi dobijaju snimanjem impulsnog odziva pomoću veštačke glave ili pomoću takozvanih binauralnih mikrofona.

Veštačka glava je uređaj koji se izrađuje od tvrde gume ili sličnih materijala, i u geometrijskom smislu ima sve atribute ljudske glave [17]. Njene dimenzije i oblik kopiraju osnovnu formu prosečne ljudske glave utvrđene statistički, s posebno detaljno modelovanim ušnim školjkama. U unutrašnjosti veštačke glave, na poziciji ušiju, nalaze se mikrofoni čiji izlazni signali predstavljaju zvučne pritiske koji se javljaju na levom i desnom uvu slušaoca. Tako dobijeni signali sadrže u sebi uticaj glave kao prepreke, što je neophodno čulu sluha za dekodovanje prostornih dimenzija zvučnog polja. Veštačka glava se postavlja na stativ na poziciji gde se želi registrovati signal.

Binauralni mikrofoni su minijaturni mikrofoni koji se postavljaju u uši poput slušalica kakve se koriste uz mobilne telefone. Kao i veštačka glava, oni daju signale koji odgovaraju onome što deluje na uši slušaoca kada se nalazi u nekom zvučnom polju. Razlika je samo u tome što se glava pravi prema statistički utvrđenim dimenzijama i sa pojednostavljenom geometrijom lica, a binauralni mikrofoni daju signale koji su personalizavani, jer se pri snimanju nalaze na realnoj osobi.

Pobuda prostora pri snimanju impulsnog odziva vrši se neusmerenim zvučnikom postavljenim na odabranoj poziciji realnog izvora zvuka, to jest sveštenika ili pojca. Preko njega se reproduku posebno pripremljeni veštački signali koji su označeni kao MLS i *sweep*, i koji su napravljeni numerički. Kroz odgovarajuću numeričku proceduru iz takvog procesa dobija se signal impulsnog odziva za odabrani par tačaka izvor zvuka – prijemnik, to jest zvučnik i veštačka glava.

U istraživanju sakralnih prostora, a posebno u multidisciplinarnom pristupu njihovoj višemedijskoj prirodi, auralizacija može biti značajan istraživački alat, posebno u slučaju istraživanja istovremenog dejstva više medija na čoveka. Takav alat se može koristiti u dva važna domena. Prvo, beleženjem akustičkog odziva u prostorima od interesa moguće je u laboratorijskim uslovima auralizacijom stvoriti kod slušaoca auditorni utisak kakav bi bio kada bi se nalazio u tom prostoru. Pri tome, moguće je napraviti binauralne snimke sa bilo kojim muzičkim i drugim signalima, kao što su glas sveštenika, pojanja sa pevnica, zvuk zveckanja kadionice ili sve zajedno. Napravljeni snimak može se reprodukovati proizvoljan broj puta i u proizvoljnim trenucima u laboratoriji ili na nekom drugom mestu.

Drugo, pomoću softverskih alata za modelovanje zvučnog polja moguće je akustički odziv, to jest HRTF, dobiti simulacijom prostora koji odavno više ne postoje. Za takav postupak potrebno je raspolagati sa dovoljno detaljnim grafičkim prikazima objekta, to jest arhitektonskim crtežima dobijenim nekim prethodnim istraživanjima, i informacijama o materijalizaciji svega što je u njegovom enterijeru izloženo zvučnom polju.

Korišćenje mogućnosti auralizacije u istraživanju sakralnih prostora zahteva, pored ostalog, i razradu jedne teorijske teme iz domena obrade signala. Naime, postoje okolnosti u kojim se slušaoci kreću kroz prostor, kao na primer tokom raznih procesija. U literaturi je nagoveštено da se u crkvama mogu očekivati promene karaktera akustičkog odziva po prostoru, što je na neki način potrebno predstaviti i u auralizaciji. Za takve namene potreban je algoritam za kontinualnu promenu HRTF po trajektoriji kojom se slušalac kreće pri zadatim položajima izvora zvuka. S obzirom da se snimanje impulsnog odziva po definiciji obavlja za nepomičan izvor zvuka i mikrofona dok traje sekvenca snimanja (interval vremena koji je potreban za određeni broj ponavljanja sekvenci MLS ili *sweep* signala), jasno je da se može raspolagati samo sa snimcima HRTF u diskretnom skupu parova tačaka. Za kvalitetnu auralizaciju onoga što se čuje pri kretanju kroz prostor crkve potrebno je istraživati mogućnosti morfinga, a to znači interpolacije oblika binauralnih impulsnih odziva za bilo koju kombinaciji položaja

 ISBN 978-86-7466-930-3

izvora zvuka i slušaoca, a na osnovu snimaka HRTF u konačnom broju tačaka duž zadate trajektorije.

IV. Uticaj akustičkog ambijenta crkve na pevanje

U literaturi iz oblasti arheoakustike inicirano je pitanje doživljaja sopstvenog glasa onih koji pevaju u crkvama [11,13]. Primećeno je da u tradicionalnim formama pravoslavnih crkava postoji razlika u karakteru doživljaja zvuka kada se peva sa različitih pozicija. Ukazano je da promena položaja pevača ima ulogu u ukupnom doživljaju ambijenta kod slušalaca, ali da takođe postoji povratno dejstvo na doživljaj sopstvenog glasa onog ko peva. Tako na primer, u literaturi se za jednu crkvu konstatuje da je „nedostatak rezonance uznemiravao i pevače i slušaoce“ [11].

Sa takvim informacijama iz literature jasno je da istraživanje zvučnog ambijenta sakralnih prostora neminovno zahteva i analizu njihovih akustičkih karakteristika sa aspekta onoga što čuju pevači, to jest sveštenici, pojci i hor. To utiče na formiranje njihovog pevanog glasa, kao i na celovit pevački izraz. Tema za istraživanje u tom domenu treba da bude korelacija između arhitektonskih odlika crkve, njene veličine i forme, i subjektovnog doživljaja sopstvenog glasa pevača na različitim pozicijama u njoj.

I u ovom domenu istraživanja se mogu koristiti saznanjima iz akustičke teorije koncertnih i operskih sala. U postupcima za njihovo objektivno ocenjivanje definisan je i koristi se parametar nazvan „podrška“ i označava se sa ST (*Stage support*). On numerički odslikava u kojoj meri ambijent svojim odzivom deluje na izvor zvuka nekom formom povratne sprege i tako pomaže u formiranju i kontroli zvuka koji se stvara, pevanog ili pomoću muzičkog instrumenta. Postupak njegovog izračunavanja je standardizovan [18]. Dobija se iz impulsnog odziva snimljenog u postavci kada se zvučnik nalazi na mestu gde bi se nalazio izvora zvuka (u koncertnim salama to je na bini a u crkvama su to uobičajene pozicije sveštenika, pojaca i hora), a merni mikrofon se nalazi na rastojanju 1 m od akustičkog centra zvučnika. U karakterizaciji podrške najčešće se koristi takozvana „rana podrška“ ST_{Early} koja po definiciji predstavlja odnos u decibelima reflektovane energije koja stiže u prvih 100 ms i energije direktnog zvuka, pa je:

$$ST_{Early} = 10log\left[\frac{\int_{0.020}^{0.100} h^2(t)dt}{\int_{0}^{0.010} h^2(t)dt}\right]$$

gde je $h(t)$ signal snimljenog impulsnog odziva, a $t = 0$ trenutak stizanja direktnog zvuka u njemu. Prema tome, postoji teorijski aparat i merna procedura da se istraživanje usmeri u tom pravcu. Za koncertne sale definisana je optimalna vrednost, preciznije donji prag koji vrednosti ST_{Early} mora da prebaci da bi prostor bio zadovoljavajući za izvođače. Za okolnosti kakve postoje u crkvama tek predstoji utvrđivanje optimalnih vrednosti ovog parametra. Za to su potrebna merenja ST_{Early} i ankete među pevačima o njihovim utiscima u kojoj bi oni vredovali različite pozicije za pevanje.

V. Zvučni ambijent prostora u kome se nalaze sakralni objekti

Sastavni deo doživljaja sakralnih prostora je i zvuk ambijenta u širem smislu u kome se taj prostor nalazi. Realno je pretpostaviti da postoji razlika kada se nakon doživljaja službe izađe u bučnu ulicu sa mnoštvom zvučnih nadražaja koji privlače pažnju, što je upobičajeno u gradskim sredinama i uopšte u naseljima, i kada je to ambijent prirode kao u slučaju manastira i njihovog okruženja. Mesta gde je pozicionirana većina manastira još uvek okružuje manje-više očuvani mir i ambijent prirode.

Nesumnjivo je da takve ambijente karakteriše relativna tišina. Apsoluta tišina ne postoji, pa čulo sluha uvek registruje neke prisutne zvukove. Činjenica da su zvukovi takvih ambijenata vrlo niskih apsolutnih nivoa, otvara još i pitanje mikrofona s kojim bi se mogli registrovati za potrebe njihove naknadne analize. Za kvalitene uzorke signala tihih ambijenata neophodno je raspolagati s mikrofonima vrlo niskog nivoa sopstvenog šuma što, moguće je, izlazi iz okvira standardne opreme za audio snimanja.

Snimci ambijenata iz očuvanih okruženja omogućili bi da se u laboratorijskim uslovima ambijent ekstremne tišine, kakav postoji u anehoičnim i semianehoičnim prostorijama koje se uobičajeno koriste za psihoakustičke testove, obogati zvučnim sadržajem prirodne „tišine“ manistirskih ambijenata.

U evropskim naseljima tokom prethodnih vekova zvuci koje su ljudi slušali bili su različiti od današnjih. Promene su nastupile sa industrijskom revolucijom koja je donela motore i mehaničke sprave čiji rad generiše buku. Ipak, razlika je mnogo dublja od ekoloških tema o kojim se danas intenzivno govori. Dok danas ljudi pokušavaju da pobegnu od gradske buke, za stanovnike ranih gradova zvuk je služio kao ključni izvor informacija. Formirao je semiotički sistem, prenoseći vesti, pomažući ljudima da se lociraju u vremenu i prostoru i čineći ih delom „audijalne zajednice“ [2]. Zvuk je pomogao da se izgradi identitet i da se struktuiraju odnosi među ljudima. Evolucija ovog informacionog sistema odražava promene u društvenoj i političkoj organizaciji i u odnosu prema vremenu i urbanom prostoru. Zbog toga je u istraživanju istorijske dimenzije zvučnog ambijenta sakralnih prostora potrebno uložiti napor da se u izvesnoj meri rekonstruišu mogući ambijenti u kojima su se oni mogli nekada nalaziti.

VI. Problem rekonstruisanih crkava

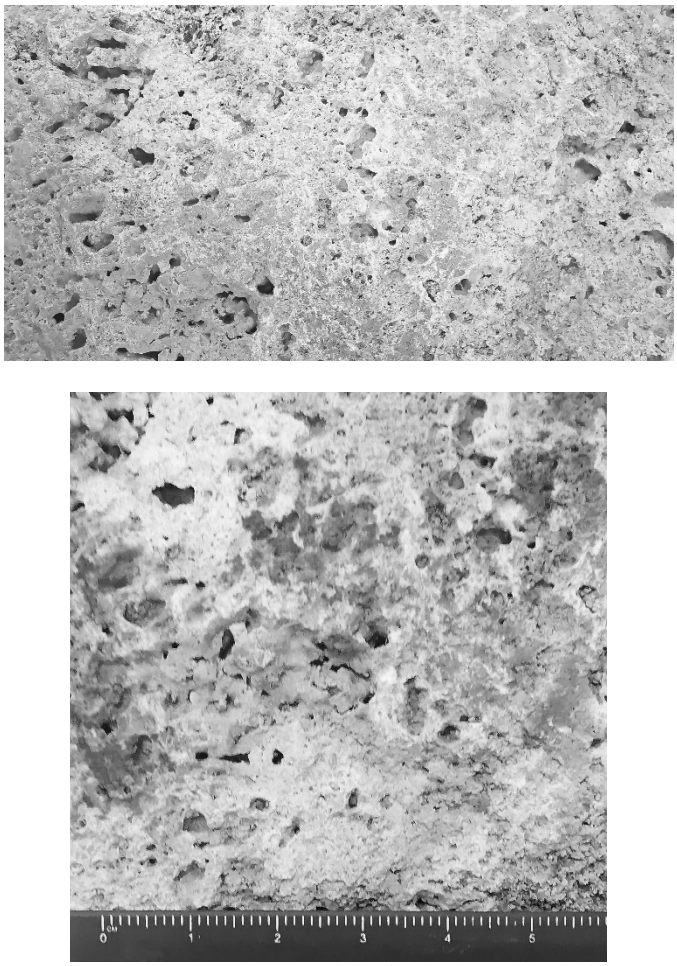
U istraživanjima akustičkog aspekta srpskih sakralnih prostora izvestan problem može nastati u crkvama koji su u relativno novije vreme rekontruisane. Materijali koji se pri tome koriste ili autorski stav onoga ko vodi rekonstrukciju mogu promeniti akustičke uslove u njima. To dalje može usmeriti današnja istraživanja u pogrešnom smeru jer je ambijent akustički izmenjen.

Primer toga može se videti u crkvi manastira Žiča. Prema kazivanju onih koji imaju auditivna iskustva sa tim prostorom pre i posle građevinskih intervencija, u crkvi su se nakon rekonstrukcijen u izvesnoj meri promenile akustičke karakteristike. Na žalost, nema rezutata akustičkih merenja iz perioda pre toga, ali se kroz diskusiju došlo do zaključka da je uzrok takve promene novi malter koji je upotrebnjen prilikom rekonstrukcije.

 ISBN 978-86-7466-930-3

Naime, crkve su sa aspekta akustičkog dizajna specifični prostori, jer u njima nema izrazito apsorpcionih površina, osim naroda koji se u njima okupi za vreme službe. Sve unutrašnje površine u crkvama su akustički „tvrde“, po pravilu malterisane radi oslikavanja, osim poda koji je pokriven kamenom. Takve tvrde površine dominantno određuju prepoznatljiv akustički odziv crkvenih prostora. Prema podacima iz literature, koeficijent apsorpcije malterisane površine na masivnom zidu je vrlo mali i može se očekivati da je u intervalu $\alpha = 0{,}05\text{-}0{,}07$ [19]. U odsustvu površina sa intenzivnom apsorpcijom, male varijacije vrednosti koeficijenta apsorpcije, čak samo na nivou druge decimale, mogu se značajnije odraziti na akustički odziv prostora.

Jednostavna numerička ilustracija može objasniti značaj karaktera maltera u crkvama. Zapremine starih srpskih crkava su u najvećem broju slučajeva u intervalu od 500 m^3 do 3000 m^3 [7]. Veće crkve su vrlo retke, dok manje od 500 m^3 nemaju očekivani akustički ambijent karakterističan za crkve. Uzimajući 1000 m^3 kao približnu sredinu tog intervala posmatranog u logaritamskoj razmeri i koristeći Sabinov obrazac za izračunavanje vremena reverberacije može se dobiti gruba procena kakvu promenu u akustičkom odzivu unosi promena maltera sa koeficijentom apsorpcije 0,05 na malter čija je vrednost 0,07. Pri tome su obe vrednosti veoma male u odnosu na vrednosti koeficiejnta apsorpcije ostalih materijala koji se koriste u zgradama. U proračunu se polazi od pretpostavke da je vreme reverberacije tog hipotetičkog crkvenog prostora 2 s, što je ranije utvrđeno kao estetski optimum za pravoslavni crkvenu službu [5,7]. Na osnovu toga je procenjena i rezidualna apsorpcija zvuka koju unose svi drveni predmeti, tkanine i druga uobičajena oprema enterijera u crkvama



Pojednostavljen akustički proračun pokazuje da će se vreme reverberacije samo promenom prirode maltera i njegove poroznosti, to jest povećanjem njegovog koeficijenta apsorpcije sa 0,05 na 0,07, smanjiti sa vrednosti 2 s na vrednost 1,7 s. To je promena koja se zapaža slušanjem. Realno je pretpostaviti da se vrednost koeficijenta apsorpcije maltera u srkvama može kretati i u širim granicama od ovih koje su usvojene u pojednostavljenom proračunu, pa se mogu dobiti i veće promene akustičkog odziva.

Prikazani proračun je krajnje aproksimativan, ali ukazuje na veliki značaj maltera za akustički odziv u okolnostima kada malterisane površine čine dominatnu apsorpciju u prostoriji, kao što je to u crkvama. U literaturi nisu nađeni podaci o apsorpcionim svojstvima starih maltera kakvi se nalaze u istorijski značajnim srpskim sakralnim građevinama. To je svakako jedna od tema koje zaslužuju detaljniju analizu i sasvim sigurno merenja na terenu. Problem u tome koji treba istraživački rešiti je što ne postoji standardizovani merni postupak za *in situ* merenja koeficijenta apsorpcije koji bi se mogao direktno primeniti. Posebno što se zahteva merenje izuzetno malih vrednosti.

Još jedan karakterističan slučaj od značaja za istraživanje zvučnog ambienta srpskih sakralnih prostora nalazi se u crkvi manstira Gradac, sazidanoj u 13. veku. Ona je izgrađena od poroznog kamena čije je nalazište u lokalnoj sredini. Fotografije površine jednog primerka tog kamena prikazana je na slici 2. Ovaj materijal zbog svoje poroznosti nesumnjivo ima značajno veći koeficijent apsorpcije od masivnog malterisanog zida kakav je uobičajen u crkvama. Ne postoje podaci o merenju apsorpcije ovakvog kamena, pa je to svakako još jedna tema za istraživanje.

Crkva manastrira Grdac bila je u stanju polurazrušenosti do njene rekonstrukcije. Princip koji je usvojen pri obnovi je da se svi novoizgrađeni delovi ne malterišu kako bi se jasno naglasila razlika između originalnog i novog [20,21]. Zbog toga je relativno velika unutrašnja površina crkve ostala sa vidljivim poroznim kamenom kao sa slike 2. Subjektivni utisak u prostoru ove crkve je akustička prigušenost neuobičajena za takve ambijente.

Slučajevi kao što je crkva manastira Gradac nakon njene rekonstrukcije očigledno ne odslikava očekivane akustičke karakteristike sakralnog prostora. Možda upravo takva crkva može biti pogodna za neka istraživanja u domenu višemedijske prirode u okolnostima redukovanog akustičkog sadržaja.

Sl.2. Izgled strukture kamena od koga je sačinjena unutrašnja površina crkve manastira Gradac: gore – izgled površine; dole – detalj sa razmernikom u cm da se može proceniti veličina poroznosti

VII. ZAKLJUČAK

Celovito istraživanje zvučnog ambijenta srpskih sakralnih prostora u kojima nastaju multisenzorski doživljaji zahteva saradnju istraživača iz svih domena njihove višemedijske prirode. Ono u toj kompleksnosti pokreće nekoliko sasvim novih pitanja iz domena akustike prostorija i psihoakustike za

 ISBN 978-86-7466-930-3

čije je odgovore neophodan iskorak iz inženjerske rutine i uključivanje u multidisciplinarno posmatranje sakralnih prostora. U radovima istoričara postoji dovoljno naznaka za preciznije definisanje mogućih ciljeva istraživanja, a teorijske osnove iz oblasti akustike i obrade signala omogućavaju da se ostvari kvalitetativni pomak u metodologiji istraživačkog rada.

Primena auralizacije otvara nove mogućnosti za pouzdanije sagledavanje kompleksnih uticaja sakralnih prostora na prisutne ljude. Posebno je značajna činjenica da auralizacija omogućava premeštanje istraživanja u laboratoriju, gde je moguće postići kontrolu pobude i ponavljanje ispitivanja proizvoljan broj puta. Posebno je istraživački zanimljiv eventualni povratni uticaj akustičkog ambijenta na pevače, što bi dalo objašnjenja za neke pojave ranije konstatovane u istorijskoj literaturi.

ABSTRACT

The study of soundscape in the historical context has given rise to a new field of acoustics called archaeoacoustics. In addition to many important historical buildings, the topic of such research was the acoustic characteristics of religious spaces, too. The synthesis of acoustic and historical facts about Serbian sacral spaces led to the conclusion that their concept is a multimedia topic in which sound is only one, although important component. In order to give meaning to the complex acoustic analysis results, one has to look beyond physics and recognize the interactions of sound with other applied media such as painting, architecture, music, light. This paper considers the place and role of acoustics in the context of possible multidisciplinary research of Serbian sacral spaces. The focus is on several characteristic topics: the correlation of impulse responses and physical forms of sacral spaces, the auralisation of the sound field in them to enable the relocation of research to laboratory ambient, the impact of the acoustic environment on the position of priests and chanters, as well as acoustic characterization the physical ambience from which people enter the sacred space and into which they come back.

Research of the Serbian sacral space soundscape as a multimedia phenomenon

O ulozi akustičkih rezonatora u prostoru hrama Svetog Save u Beogradu

Dragana Šumarac Pavlović, Miomir Mijić, Jelena Erdeljan, Tatjana Miljković

***Apstrakt*— Akustički rezonatori su naprave od davnina korišćene u crkvama sa idejom da se pomoću njih na neki način kontroliše zvučni odziv prostora. Projekat hrama Svetog Save u Beogradu svojevremeno je predvideo ugradnju 476 posebno dizajniranih rezonatora da bi se umanjila očekivana reverberacija u njegovoj velikoj zapremini od 117.000 m^3. Tokom izrade mozaika kojim je oslikan hram tako veliki broj rezonatorskih otvora relativno velikog prečnika otežavao je montažu kamenih elemenata mozaika. Zbog toga se nametnulo pitanje njihove nužnosti i svrsishodnosti u hramu i pokrenuto je istraživanje realne efikasnosti ugrađenih rezonatora i rizika koje nosi njihovo eventualno zatvaranje. Tadašnja analiza je malo proširena i ukupni rezultati do kojih se došlo prikazani su u ovom radu.**

***Ključne reči* — akustički odziv; akustički rezonatori; crkve, Hram Svetog Save.**

I. UVOD

Nesumnjivo najznačajniji sakralni objekat u Srbiji je hram Svetog Save. Izgrađen je na vrhu Vračarskog brda u Beogradu, pa zahvaljujući svom položaju, ali i fizičkoj monumentalnosti, dominira Beogradom i vidljiv je s velikog dela teritorije grada. Navodi se da je Hram po zapremini glavnog molitvenog prostora najveća aktivna pravoslavna crkva na svetu [1]. Njegova zapremina, preciznije unutrašnji vazdušni prostor, zauzima oko 117.000 m^3.

Aktivnosti na izgradnji hrama započete su još 1895. godine kada je u Beogradu osnovano „Društvo za podizanje hrama Svetog Save na Vračaru“. Društvo je 1905. godine raspisalo arhitektonski konkurs za idejno rešenje hrama. Zanimljivo je da su svi prispeli radovi, a prispelo ih je samo 5, odbačeni kao nedovoljno dobri. Nakon I svetskog rata Društvo je obnovilo rad i 1926. godine raspisan je novi konkurs. Kao najuspešniji proglašen je rad arhitekte Bogdana Nestorovića, pa je Društvo 1930. godine poverio izradu projekta arhitektama Nestoroviću i Aleksandru Deroku. Izgradnja hrama je konačno započela 15. septembra 1935. godine.

Od početka građevinskih radova do nemačke okupacije 1941. godine izgrađeni su temelji hrama i podignuti zidovi visine od 7 do 11 m. Stariji beograđani pamte takvo njegovo stanje sa poluizgrađenim zidovima od opeke. S Drugim svetskim ratom „Društvo za izgradnju hrama“ je prestalo da postoji.

Nastavak gradnje hrama započet je 1984. godine, a za novog arhitektu hrama imenovan je arhitekta Branko Pešić. Gradnja objekta je u građevinskom smislu završena 2004. godine. Međutim, radovi na unutrašnjem uređenju i dekoraciji dovršeni su značajno kasnije, da bi se otvaranje hrama ozvaničilo tek nedavno, krajem 2021. godine nakon završetka oslikavanja mozaikom i finalizacije većine prostora u hramu (iako se u njemu još uvek odvijaju građevinski i instalaterski radovi).

Svakako je zanimljivo da su u projektovanju hrama tokom osamdesetih godina dvadesetog veka projektanti razmatrali i akustičke aspekte. Kao akustički konsultant angažovan je Stevan Milosavljević. Tokom rada na projektu doneta je odluka da se kontrola akustičkog odziva prostora hrama realizuje pomoću akustičkih rezonatora, svakako imajući u vidu brojne informacije o njihovom postojanju u srednjovekovnim crkvenim prostorima. Neki od radova koji obrađuju tu temu pobrojani su u spisku literature na kraju ovog rada [2-9]. Činjenica je da radovi o rezonatorima u crkvama koji se mogu naći u raznorodnoj literaturi većim delom nisu inženjerski, preciznije akustičarski. Postoje brojni radovi koji su rezultat analiza koje su sprovodili arheolozi, istoričari umetnosti, arhitekte i drugi autori iz oblasti tangentnih sa akustikom.

Ideja o rezonatorima kao sredstvu za kontrolu akustičkog odziva u hramu inicirala je u vreme projektovanja opsežnu studiju o kojoj je pisao D.Kalić [10]. Dimenzije rezonatora prikazane u njegovom radu određene su na osnovu prethodno usvojene odluke o potrebnim rezonantnim frekvencijama u zadatom prostoru. Rezonatori imaju formu betonskih kocki sa okruglim otvorom na prednjoj strani. Primenjena su dva tipa rezonatora, manji i veći. Veći rezonatori imaju dužinu stranice 1,1 m i proračunom utvrđenu rezonatnu frekvenciju 125 Hz, a manji su sa stranicom 55 cm i proračunom utvrđenom rezonantnom frekvencijom 250 Hz. U hramu je projektom predviđeno ukupno 476 takvih rezonatora. Njihove pozicije su vidljive na fotografiji prikazanoj na slici 1. Rezonatori su postavljani u površine gornje zone hrama, u kupoli i svim bočnim svodovima, očigledno prema realnim mogućnostima ugradnje takvih relativno velikih kutija u građevinske strukture. Naime, na tim delovima građevinske konstrukcije hrama postoji dvostruka betonska ljuska. To je omogućilo da prisustvo nezavisnih celina kakve su kutije rezonatora ne ugrožavaju statiku objekta. Bliski poled na dva rezonatora u ugrađenom stanju prikazan je na slici 2.

 ISBN 978-86-7466-930-3

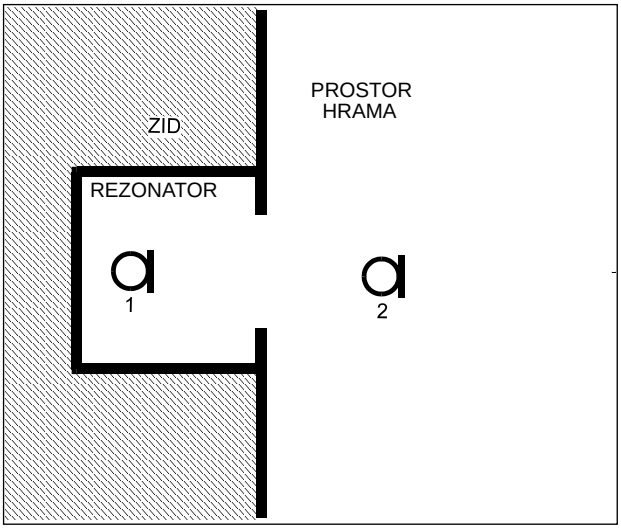
Sl.1. Gore - izgled unutrašnjosti hrama pre postavljanja mozaika sa vidljivom otvorima rezonatora oko kupole (fotografia je napravljena 2010. godine, to jest pre postavljanja mozaika); dole – označene pozicije dvostrukih betonskih struktura kupole i svodova vidljive u preseku u koje su ugrađeni rezonatori.

Oslikavanje hrama, a posebno odluka da se za to koristi mozaik kao tehnika, otvorilo je neke praktične probleme koji očigledno nisu uzeti u obzir pri projektovanju takve akustičke obrade prostora. Problemi su posledica činjenice da na unutrašnjim površinama hrama prostoje brojni, relativno veliki otvori rezonatora. Oni su potencijalno remetili strukuru slika, ali i komplikovali montažu teških obloga sa pripremljenim kamenim elementima mozaika. Zbog toga je pokrenuto pitanje provere svrsishodnosti i realnih dometa rezonatora u kontroli veoma duge reverberacije prostora hrama i procene akustičkog rizika koji nastaje ako se rezonatori eliminišu prekrivanjem njihovih otvora.

Sl.2. Bliski pogled na dva rezonatora u kupoli - levo je manji, a desno veći rezonator.

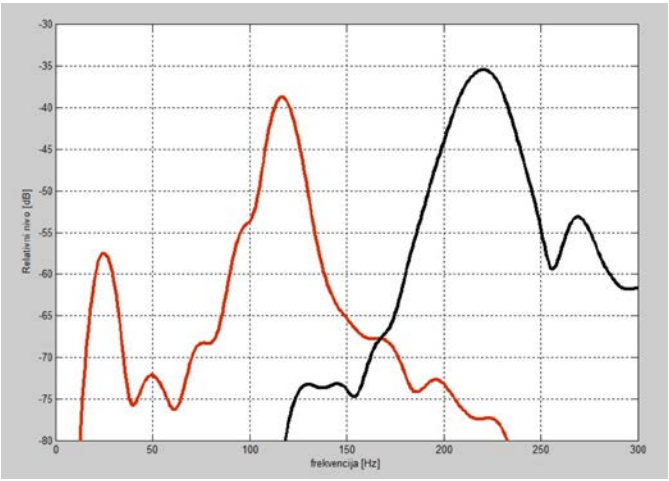
Da bi se razrešile nedoumice oko uticaja rezonatora i montaže mozaika inicirano je posebno istraživanje. Njegov cilj je bio da pomogne u donošenju strateških odluka u konačnom dovršavanju hrama. Istraživanje je obavljeno tokom 2010. godine, a u njemu su učestvovali članovi stručnog tima Laboratorije za akustiku Elektrotehničkog fakulteta u Beogradu. U analizama su korišćeni rezultati merenja akustičkog odziva hramu u zatečenom stanju i u njegovom numeričkom modelu pomoću rej-trejsing simulacije. Za sagledavanje novih aspekata analiziranog problema utrađene su u novije vreme neke dodatne analize. Rezultati su prikazani u ovom radu.

II. KARAKTERISTIKE UGRAĐENIH REZONATORA



Prvi korak u istraživanju na temu mogućeg doprinosa ugrađenih rezonatora na akustički odziv hrama uključilo je proveru njhovih realno postignutih rezonantnih frekvencija. Podaci o tome prikazani u projektu dobijeni su proračunima koji uvek nose moguću grešku zbog nesavršenosti matematičkih modela [11-14]. S tim ciljem je organizovano *in situ* merenje rezonantnog odziva urađenih rezonatora.

Za tu namenu iskorišćena je dizalica sa platformom koja je u to vreme postojala u hramu i korišćena je za potrebe građevinskih radova. Dizalica je vidljiva na desnoj strani fotografije sa slike 1. Ona je omogućila da se ostvari dovoljno približavanje jednoj grupi rezonatora u kupoli i postavljanje zvučnog izvora i mernih mikrofona. S obzirom na njihovu poziciju u hramu, merenja su izvršena na rezonatorima koji su bili dohvatni sa platforme dizalice i prikazani su na slici 1.

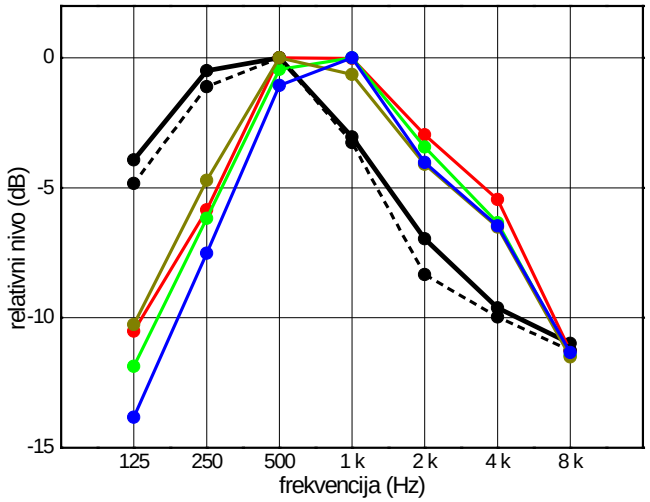


Metodologija merenja rezonantnih svojstava ugrađenih rezonatora ilustrovana je na slici 3. Koncept merenja njihove rezonantne frekvencije i propusnog opsega ranije je razvijen za potrebe detaljne analize izvesnog broja rezonatora izvađenih iz srednjovekovnih srpskih crkava [15]. Za tu namenu korišćen je priručni širokopojasni izvor zvuka pozicioniran u zoni otvora ispitivanih rezonatora. Zvučni signal je registrovan sa dva merna mikrofona – jedan se nalazio u blizini otvora rezonatora i registrovao je pobudu rezonatora iz prostora hrama, a drugi je bio u unutrašnjosti rezonatora i u njemu registrovao odziv na

 ISBN 978-86-7466-930-3

primenjenu pobudu. Na osnovu razlike signala iz mikrofona u ove dve tačke dobijena je relativna promena nivoa zvuka po frekvencijama u rezonatoru, a koja nastaje kao posledica rezonantnog procesa. Dobijene rezonatne krive za dva tipa rezonatora ugrađena u hramu prikazane su na slici 4.

Sl.3. Šematski prikaz postupka merenja rezonantne frekvencije ugrađenih rezonatora: 1 – mikrofon u rezonatoru, 2 – mikrofon u prostoru ispred rezonatora



Sl.4. Odzivi dva tipa rezonatora ugrađena u kupoli hrama; odzivi su snimljeni metodologijom prikazanom na slici 2: crvena linija – veći rezonator, crna linija – manji rezonator.

Sa slike 4 se vidi da je snimljeni odziv analiziranih rezonatora na spoljašnju zvučnu pobudu karakterističan za rezonantni proces, Jasno se vidi da je njihova selektivnost relativno uska. Rezonantna frekvencija većeg rezonatora je bliska 125 Hz, kao što je bilo predviđeno projektom, a propusni opseg je oko 10 Hz. Rezonantna frekvencija manjeg rezonatora je oko 220 Hz (projektom je predviđeno 250 Hz), a propusni opseg je oko 20 Hz. To ukazuje da se njihov uticaj na zvučno polje može očekivati samo u okvirima njihovih propusnih opsega vidljivih na dijagramu. Činjenica je da se opseg delovanja rezonatora može širiti korišćenjem nekog apsorpsionog materijala, ali proširivanje selektivnosti rezonantnog procesa neumitno smanjuje eventualni efekat apsorpcije zvuka na rezonantnoj frekvenciji. Rezultat merenja sa slike 4 pokazuje da je sa aspekta akustičkog odziva u prostoru hrama eventualni dobitak takvom modifikacijom upitan.

III. KARAKTERISTIKE ZVUČNE POBUDE KOJA SE JAVLJA U HRAMU

Potencijalni doprinos ugrađenih rezonatora u akustičkom odzuvu hrama, sa njihovim izmerenim rezonatnim odzivima, zavisi od zvučnih sadržaja koji se pojavljuje tokom službi. Da bi se to razjasnilo izvršena je frekvencijska analiza uzoraka zvučnih signala koji se pojavljuju tokom službe u srpskim pravoslavnim crkvama, i kojim se pobuđuje njihov prostor. Za analizu su uzeti liturgijsko pevanje hora i pojanje sa pevnice. Da bi rezultati takve analize bili primenjivi moraju se posmatrati izvorni akustički signali koje emituju glasovi kao zvučni izvori, to jest bez uticaja ambijenta koji promenama u frekvencijskom i vremenskom domenu utiče na karakter zvuka koji se čuje. Zbog toga su upotrebljeni snimci bliski anehoičnim, napravljeni u jednom ranijem istraživanju, pa su primenjeni i za potrebe ove analize. Pojanja su snimljena u crkvenom prostoru, ali sa vrlo bliskim mikrofonima. Na taj način je u dobijenom signalu potisnut uticaj ambijenta karakterističnog za crkve. Pevanje hora je snimljeno u relativno maloj prostoriji za probe koja je prigušena izvesnom količinom apsorpcionog materijala. Dugovremeni spektri šest uzoraka takvih signala prikazani su na slici 5.

Sl.5. Dugovremeni spektri segmenata liturgije koju peva hor i pojanja grupe pojaca: crne linije – pojanje sa pevnice, obojene linije – pevanje hora.

Dijagrami sa slike 5 pokazuju karakter zvuka kojim se uobičajeno pobuđuje prostor pravislavnih crkava za vreme službe. Spektri u kome dominiraju muški glasovi, kao što je pojanje sa pevnice, imaju maksimum spektra u oktavi na 500 Hz, dok je u pevanju mešovitog hora maksimum energije u oblasti oktava sa centralnim frevencijama na 500 Hz i 1 kHz, i sa opadanjem relativnog nivoa ka višim i nižim frekvencijama.

Upoređujući dugovremene spektre sa slike 5 sa rezonantnim svojstvima akustičkih rezonatora prikazanim na slici 4, zaključuje se da su oni podešeni na frekvencije ispod oblasti u

 ISBN 978-86-7466-930-3

kojoj se nalazi maksimum energije glasova, a to znači maksimum zvučne pobude crkvenog prostora tokom službe. Takav zaključak je apostrofiran i u ranijem istraživanju akustičkih rezonatora pronađenih u srednjovekovnim srpskim crkvama [15]. Ovakva činjenica ograničava moguće auditivne efekte koje oni mogu ispoljavati u srpskim pravoslavnim crkvama, pa i u hramu Svetog Save.

IV. MERENJE U HRAMU PRE POSTAVLJANJA MOZAIKA

Da bi se utvrdilo realno stanje akustičkog odziva prostora hrama sa ugrađenim rezonatorima organizovano je merenje akustičkog odziva. Merenje je sprovedeno u dve seanse tokom 2010. godine. Bilo je to u fazi izgradnje hrama, kada je objekat u ugrađevinskom smislu bio završen, a pre početka većih radova na oslikavanju i ukrašavanju. Merenja su vršena tokom noći kada u njemu nije bilo posetilaca. Od dodatnih elemenata u hramu kojh neće biti u njegovom finalnom stanju tom prilikom su postojale skele u jednom delu prostora, manja količina građevinskog materijala ograđenog mrežama koja ih štiti i dizalica vidljiva na slici 1. Pod u to vreme nije bio popločan.

Merenje akustičkog odziva je izvršeno direktnom metodom, što znači da je za pobudu korišćen izvor impulsnog zvuka. U prostoru koji ima tako veliku zapreminu to je bio jedini dostupan način za njegovu pobudu neusmerenim zračenjem. Rezultat merenja vremena reveberacije prikazan je na slici 6, dobijen usrednjavanjem za nekoliko prijemnih i predajnih mesta u hramu.

Sl.6. Rezultat merenja vremena reverberacije u hramu u fazi pre postavljanja mozaika.

Sa dijagrama na slici 6 može se uočiti nekoliko karakterističnih činjenica.

1. I pored postojanja rezonatora prostor hrama na nižim frekvencijama ima veliku vrednost vremena reverberacije, čak do 12 s u oktavi na 250 Hz. Vrednosti oko 10 s su konstatovane i u drugim tako velikim prostorima, kao na primer u Beogradskoj areni čija je unutrašnja zapremina oko 300.000 m^3 [16]

2. U hramu ne postoje površine koje bi mogli doprineti povećanoj apsorpciji na niskim frekvencijama. To bi teorijski mogle biti sve površine koje deluju kao mehanički rezonatori: drvene obloge, površine sa gipsanim pločama i slično. Činjenica je da u hramu postoje relativno velike površine vrata, podaščane zone i površine slične materijalizacije koje mogu u nekoj maloj meri doprineti apsorpciji najnižih frekvencija, ali je to po ukupnoj kvadraturi minorno u datoj zapremini. Zbog toga je pad vrednosti vremena reverberacije u oktavi na 125 Hz očigledna posledica delovanja rezonatora. Pa ipak, i pored svih tih uticaja vrednost vremena reverberacije je relativno velika, čak 9 s.

3. Uticaj rezonatora se u oktavi na 250 Hz iz nekih razloga ne primećuje, iako dijagram sa slike 3 pokazuje da je oko polovina od njhovog ukupnog broja podešena na frekvenciju koja se nalazi upravo u tom opsegu. Razlog tome može biti suviše uzak propusni opseg rezonatora u odnosu na ukupnu širinu oktave na 250 Hz koja je oko 170 Hz (od oko 180 Hz do oko 350 Hz). Njegov doprinos sa delovanjem u opsegu širine od samo 20 Hz očigledno se ne primećuje u usrednjenoj oktavnoj vrednosti vremena reverberacije.

4. Modelovanje funkcije usamljenog rezonatora ugrađenog u masivnom zidu pokazuje da je maksimalno moguća vrednost ekvivalentne apsorpcione površine koju on ispoljava [17]:

$$A = \frac{\lambda_0^2}{2\pi} \text{ [m}^2\text{]}$$

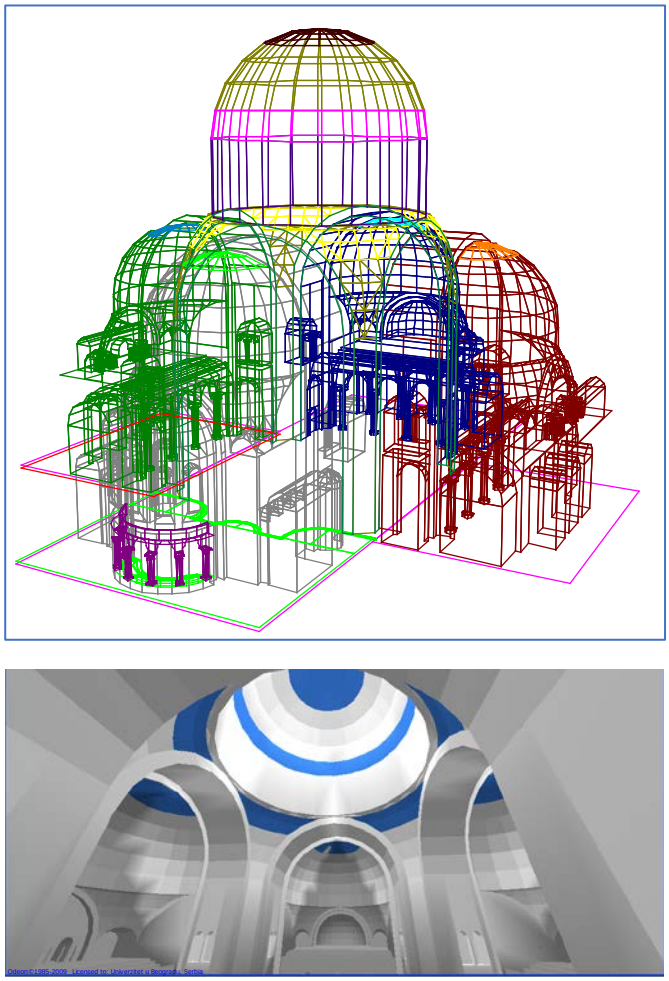
Ova vrednost se dostiže samo ako je dizajn rezonatora optimalan. To znači da će udeo rezonatora u ukupnoj apsorpciji prirodno da opada sa frekvencijom. To može biti objašnjenje manje vidljivosti uticaja rezonatora na vreme reverberacije u oktavi na 250 Hz u odnosu na oktavu na 125 Hz.

5. Monotoni pad vrednosti vremena reverberacije na višim frekvencijama jasno je određen uticajem disipacije u vazduhu, jer u enterijeru hrama nema poroznih materijala koji bi uneli takvu apsorpciju. To znači da je kriva vremena reverberacije u toj oblasti frekvencija u izvesnoj meri promenljiva u funkciji promene vlažnosti i temperature vazduha, ali da ima očekivani monotoni pad ka višim frekvencijama počev od oktave 250 Hz.

V. ANALIZA MOGUĆEG DOPRINOSA REZONATORA U HRAMU SIMULACIJOM ZVUČNOG POLJA

Da bi se procenila mogućnost predikcije efekta ugrađenih rezonatora u prostoru hrama sprovedena je analiza proračunima. Za to su primenjena dva pristupa:

- simulacijom zvučnog polja u softverskom modelu njegove unutrašnjosti pomoću rej-trejsing analize i
- pomoću statističkog modela zvučnog polja koristeći poznatu Sabinovu formulu za vreme reverberacije u prostoriji.



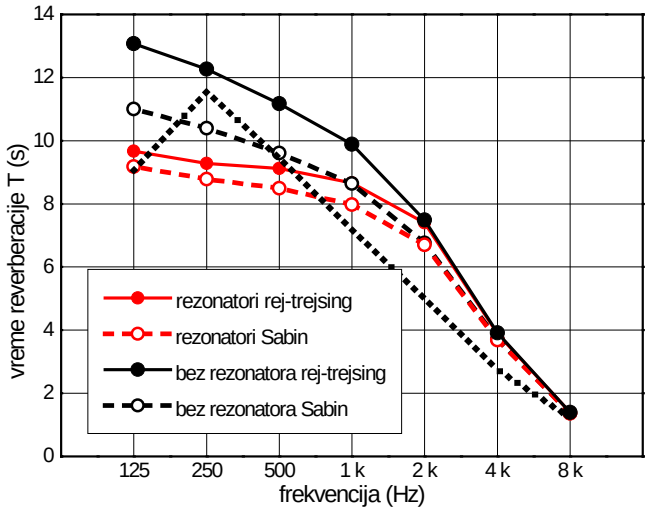
Za potrebe rej-trejsing simulacije napravljen je model unutrašnjosti hrama čiji je izgled prikazan na slici 7. Unutrašnjim površinama dodeljene su procenjene vrednosti koeficijenta apsorpcije koristeći podatke iz literature [18]. Za potrebe proračuna posebno je izvršena procena vrednosti koeficijenta apsorpcije površina sa ugrađenim reznonatorima, tačnije izračunavanje njihove apsorpcione površine, da bi se to primenilo u ovim modelima.

Rezultat proračuna vremena reverberacije metodom rej-trejsinga i Sabinovom formulom prikazan je na slici 8. Radi

 ISBN 978-86-7466-930-3

poređenja, na dijagramu je ucrtan i rezultat merenja sa slike 6. Na osnovu ovih rezultata može se izvesti nekoliko važnih zaključaka.

1. U oktavi na 125 Hz izmerena vrednost vremena reverberacije poklapa se sa rezultatom proračunom za obe primenjene metode modelovanja.



Sl.7. Izgled softverskog modela unutrašnjosti hrama u kome je izvršeno modelovanje zvučnog polja metodom *rej-trejsing*: gore – žičani model, dole – model sa unetom materijalizacijom gde je vrednost koeficijenta apsorpcije kodovana bojama.

2. U oktavi na 250 Hz izmerena vrednost vremena reverberacije se približno poklapa sa vrednostima izračunatim za slučaj hrama bez rezonatora. Preciznije, izmerena vrednost je između vrednosti dobijenih Sabinovom formulom i rej-trejsing simulacijom za slučaj bez rezonatora.

3. Na višim frekvencijama proračuni po obe metode premašuju izmerene vrednosti. To može biti posledica dva faktora: razlike u proceni disipacije u vazduhu i činjenice da u nedovršenom hramu neke površine ipak imaju izvesnu poroznost koja može imat uticaja na apsorpciju viših frekvencija, a što nije moglo biti sagledano u primenjenim proračunima.

VI. Merenja u završenom prostoru hrama

Da bi se zaokružila slika o mogućim efektima rezonatora na akustički odziv hrama potrebno je izvršiti finalno merenje akustičkog odziva u njemu. Uslovi za takvo merenje su se steki tek nedavno, nakon finalizacije oslikavanja i nekih drugih bitnih detalja. Time su svi otvori ugrađenih rezonatora zatvoreni masivnim slojem materijala od koga je načinjen mozaik. Nažalost, sticajem raznih okolnosti organizacione prirode to merenje još uvek nije izvršeno.

Sl.8. Rezultati proračuna vremena reverberacije u hramu za slučaj sa i bez uticaja ugrađenih rezonatora: proračuni su urađeni na dva načina: metodom rej-trejsing i pomoću Sabinove formule; tačkasto je ucrtan rezultat merenja u hramu.

VII. Zaključak

Iz analize uticaja akustičkih rezonatora u hramu Svetog Save u Beogradu proizašlo je nekoliko zaključaka koji se odnose na tu temu, ali i na šire aspekte akustike.

1. Pokazalo se da su rezonantne frekvencije primenjenih rezonatora ispod oblasti frekvencija gde se dominantno nalazi najveći dao energije glasova horskog pevanja i pojanja. To potvrđuje ranije zaključke koji su prizašli iz studije akustičkih rezonatora u srednjovekovnim srpskim crkvama.

2. Rezultati sprovedenih proračuna i njihovo poređenje sa rezultatima merenja u izgrađenom hramu pokazuju da postoji problem tačnosti modelovanja zvučnog polja i predikcije akustičkog odziva tako velikih prostora kao što je hram Svetog Save (117.000 m^3). Očigledno je da u projektovanju to zahteva posebnan istraživački pristup. Sličan zaključak je već ustanovljen prilikom projektovanja Beogradske arene [16].

3. U veoma velikim prostorima kao što je hram nemoguće je da se služba odvija bez primene sistema za ozvučavanje. Naime, ne postoje sredstva akustičkog dizajna prihvatljiva u kanonizovanom crkvenom prostoru koja bi mogla da vreme reverberacije svedu na optimalnu meru za takve ambijente (2-3 s) [7].

4. Savremena tehnologija daje mogućnost primene vrlo usmerenih zvučničkih sistema kakvi su danas uobičajeni u sistemima za ozvučavanje, koji kombinovani sa bliskim mikrofonima na sveštenicima i pojcima omogućavaju minimizaciju uticaja akustičkog ambijenta na ono što će se čuti

 ISBN 978-86-7466-930-3

na pozicijama slušaoca. Na taj način danas je u izvesnom smislu eliminisana neophodnost podešavanja vremena reverberacije u vrlo velikim verskim prostorima kakav je hram, što se odražava i na eventualnu ideju o primeni rezonatora.

ABSTRACT

Acoustic resonators are elements that have long been used in churches with the idea of using them to control the acoustic response of the worship space. The project of the Saint Sava temple in Belgrade included the installation of 476 specially designed resonators in order to reduce the expected reverberation. During the construction of the mosaic with which the temple was painted, such a large number of resonators with relatively large diameter of opening made it difficult to assemble the stone elements of the mosaic. Due to that, the question of their necessity and purposefulness in the temple arose. So, the research of the built-in resonators' real acoustic efficiency in the temple and the acoustical risk of their termination was initiated. The paper describes the results of the research and the achieved conclusions.

On the role of acoustic resonators in the temple of Saint Sava in Belgrade

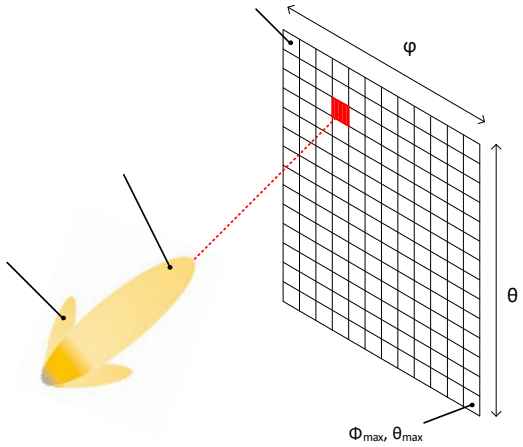
Optimizacija prostorne rezolucije mikrofonskog niza za merenje saobraćajne buke



Miodrag Stanojević, Miloš Bjelić, Tatjana Miljković

***Apstrakt* — Merenje saobraćajne buke mikrofonskim nizom omogućava određivanje ugaone raspodele incidentne energije buke na fasadi zgrada. Jedan od osnovnih parametara koji se zadaje u ovakvom merenju jeste ugaona rezolucija kojom se vrši odabiranje u prostornom domenu. S obzirom na računsku kompleksnost algoritma za prostorno-vremensku obradu signala mikrofonskog niza, optimizacija minimalne potrebne prostorne rezolucije omogućava značajno skraćivanje procesa izračunavanja. Merenja prikazana u ovom radu vršena su na četiri lokacije u urbanoj sredini. Lokacije se razlikuju u broju saobraćajnih traka, tipu saobraćaja, udaljenosti objekata, itd. Pretpostavka koja se istražuje u ovom radu jeste da je minimalna potrebna rezolucija mikrofonskog niza različita za svaku od ovih lokacija, i da je dominantno određena morfologijom urbane lokacije. Merenja su vršena mikrofonskim nizom koji čine 24 omnidirekciona mikrofona. Geometrija mikrofonskog niza je optimizovana za merenje saobraćajne buke.**

***Ključne reči* — mikrofonski niz, rezolucija, saobraćajna buka**

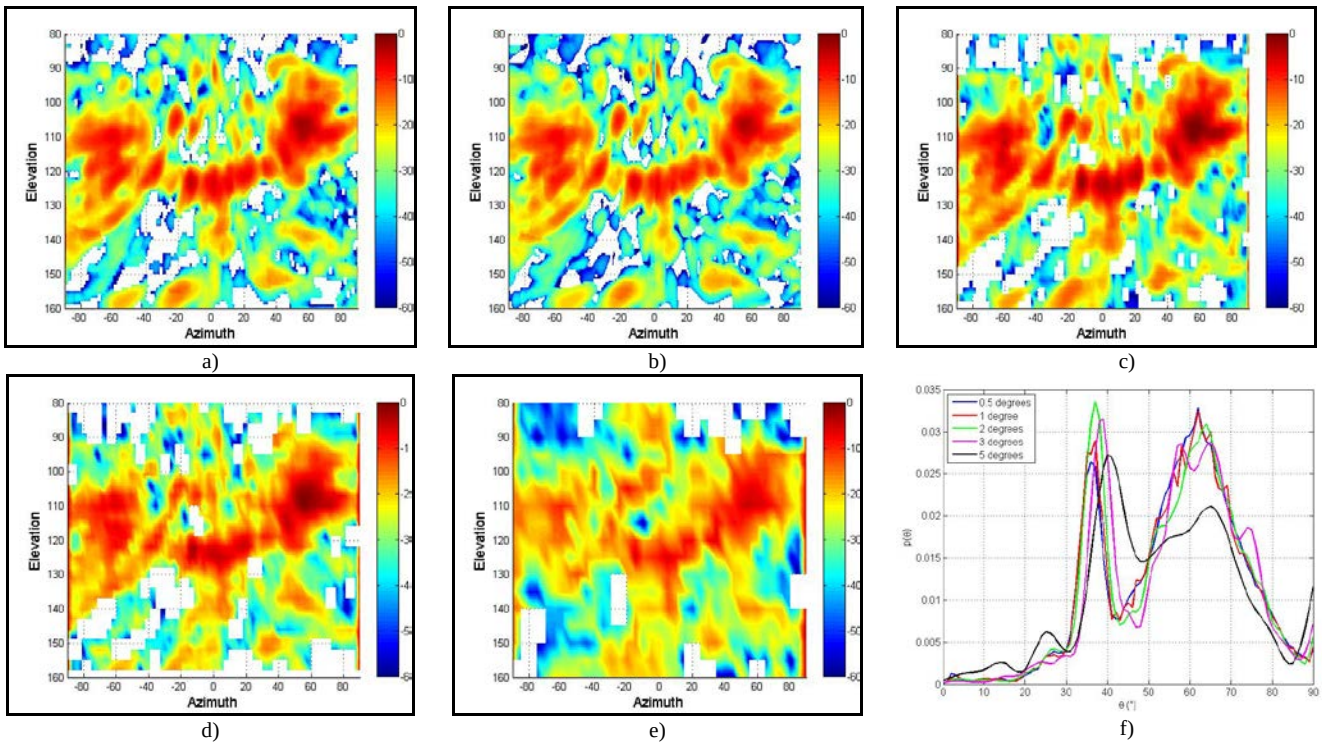
I. Uvod

Merenje izvora zvuka mikrofonskim nizom omogućava eksperimentalno utvrđivanje ugaone raspodele incidentne energije [1]. Prilikom tumačenja rezultata ovakvih merenja neophodno je uzeti u obzir fizička ograničenja mikrofonskog niza, odnosno *beampattern* koga karakterišu dva ključna parametra: širina glavnog loba i potisnutost bočnih lobova. Ova dva parametra su frekvencijski zavisna i određena prvenstveno rasporedom mikrofona, odnosno geometrije mikrofonskog niza. Mikrofonski niz koji je korišćen za merenja prikazana u ovom radu je dvodimenzionalni niz sa 24 omnidirekciona mikrofona čija je geometrija optimizovana za frekvencijski opseg u kom se nalazi saobraćajna buka [2]. Algoritam za eksperimentalno određivanje ugaone raspodele incidentne energije polazi od određivanja doprinosa zvučne energije iz pojedinačnih tačaka zamišljene ekvidistantne mreže tačaka na koju je podeljen prostor ispred mikrofonskog niza. Određivanje doprinosa energije podrazumeva virtuelno usmeravanje glavnog loba mikrofonskog niza i pomeranje od tačke do tačke i merenje energije izlaznog signala. Virtuelno usmeravanje mikrofonskog niza (*beamsteering)* vrši se nakon usnimavanja 24-kanalnog signala mikrofonskog niza.

Sl. 1. Usmeravanje mikrofonskog niza – *beamsteering*. Zamišljeni grid tačaka skeniranja određenih azimutom (φ) i elevacijom (θ).

Imajući u vidu navedene nesavršenosti mikrofonskog niza (konačna širina glavnog loba i postojanje bočnih lobova koji nisu zanemarljivi), dobija se mapa prostorne raspodele energije koja predstavlja konvoluciju stvarne raspodela izvora zvuka i odziva mikrofonskog niza, stoga se ovakav rezultat naziva „prljava mapa“. Ova mapa služi kao osnov za dalju obradu koja podrazumeva set dekonvolucionih procedura koje imaju za cilj da dobijeni rezultat očiste od uticaja mikrofonskof niza. Dekonvolucioni algoritam koji se koristi u ovom istraživanju je DAMAS2 [3,4,5]. Nakon toga se moguće je odrediti gustinu verovatnoće energije po prostornim uglovima u odnosu na liniju upravnu na ravan fasade, koja služi za proračun izolacione moći pregrade.

Vremenski najzahtevniji postupak u opisanoj proceduri jeste dobijanje „prljave mape“. Razlog za to je iterativni postupak izračunavanja energetskih doprinosa koji podrazumeva izračunavanje za svaki par azimut-elevacija. S obzirom da je kompleksnost ovog procesa $O(n^2)$, smanjivanje rezolucije odabiranja donosi velike uštede u vremenu potrebnom za izračunavanje.



Pretpostavka koja se istražuje u ovom radu je da minimalna potrebna rezolucija zavisi od karakteristika urbane lokacije na kojoj se vrši merenje: da li je kanjon ulica, udaljenost saobraćajnih traka od fasade objekta (tzv. udaljenost ravni skeniranja *r*), postojanje raskrsnica i sl. Pretpostavlja se da će dominantan uzrok razlike u minimalnoj potrebnoj rezoluciji na različitim lokacijama biti različita udaljenost ravni skeniranja od fasade objekta na kojoj je postavljen mikrofonski niz. Međutim, istražena je eventualna zavisnost minimalne potrebne rezolucije od drugih parametara lokacije.

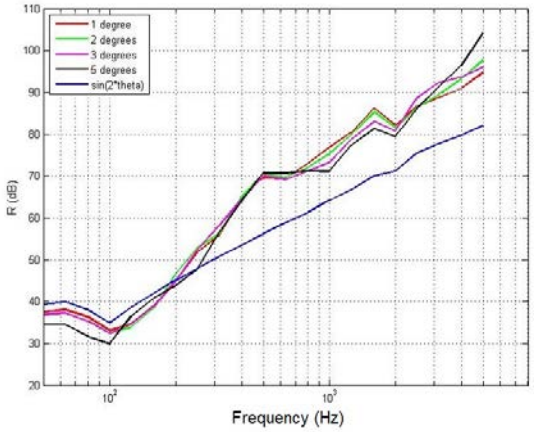
 ISBN 978-86-7466-930-3

a) b) c) d) e) f)



Sl. 2. Raspodela incidentne energije po azimutu i elevaciji za događaj prolaska automobila za različite ugaone rezolucije (pomeraje po azimutu i elevaciji): a) $\Delta\varphi=\Delta\theta=0.5^o$, b) $\Delta\varphi=\Delta\theta=1^o$, c) $\Delta\varphi=\Delta\theta=2^o$, d) $\Delta\varphi=\Delta\theta=3^o$ i e) $\Delta\varphi=\Delta\theta=5^o$. Funkcija gustine verovatnoće incidentne energije za različite ugaone rezolucije.

Cilj istraživanja jeste dobijanje formule za određivanje minimalne potrebne rezolucije kojom se ulazi u proračun za datu lokaciju, kako bi se postigla maksimalna efikasnost algoritma i skratilo vreme izračunavanja.

II. METODE

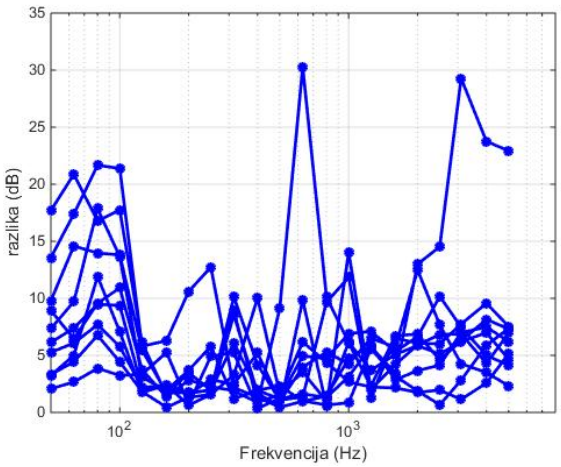
Na slici 2 prikazana je raspodela energije po azimutu i elevaciji za jedan prolazak automobila ispred fasade objekta, za različite vrednosti prostorne rezolucije odabiranja. Na slici f) prikazana je gustina verovatnoće incidentne energije po prostornim uglovima u odnosu na normalu na površinu fasade. Funkcija gustine verovatnoće prikazana je za jedan frekvencijski bin širine 1 Hz opseg oko centralne frekvencije 1000 Hz. Iz oba prikaza se može zaključiti da smanjivanje rezolucije do $\Delta\phi=\Delta\theta=3^o$ ne unosi značajnu grešku u određivanju funkcije gustine verovatnoće incidentne energije. Kako bi se sagledao uticaj na krajnji rezultat, neophodno je izvršiti analizu nad svim frekvencijskim binovima, odnosno proračunati prediktovanu vrednost izolacione moći fasadne pregrade koja je izložena buci sa ovakvom raspodelom [6].

Na slici 3 prikazana je proračunata prediktovana vrednost izolacione moći fasadne pregrade od betona debljine 20 cm. (Parametri pregrade $d=0.20$ m, $msp=2500$ kg/m^3, $c_l=3500$ m/s, $\eta_i=0.006$). Prikazane su frekvencijski zavisne vrednosti izolacione moći za rezolucije 1,2,3 i 5 stepeni, kao i teoretska vrednost proračunata za oblik raspodele incidentne energije $sin(2\theta)$. Na slici se može uočiti da su proračunate vrednosti u određenim frekvencijskim opsezima i do 8 dB za različite vrednosti ugaone rezolucije. Međutim, kada se posmatraju jednobrojne vrednosti izolacione moći (Tabela 1), uočava se da je razlika između različitih rezolucija sa kojima se ulazi u proračun zanemarljiva. U svim slučajevima izolaciona moć proračunata na osnovu realnih raspodela energije podmašuje teoretsku vrednost u frekvencijskom opsegu oko frekvencije koincidencije, a premašuje u opsegu iznad oko 300 Hz. Jednobrojne vrednosti izolacione moći proračunate na osnovu realnih raspodela energije premašuju teoretsku vrednost u svim slučajevima.

Sl. 3. Izolaciona moć fasadne pregrade za različite vrednosti ugaone rezolucije. Struktura pregrade – beton 20 cm.

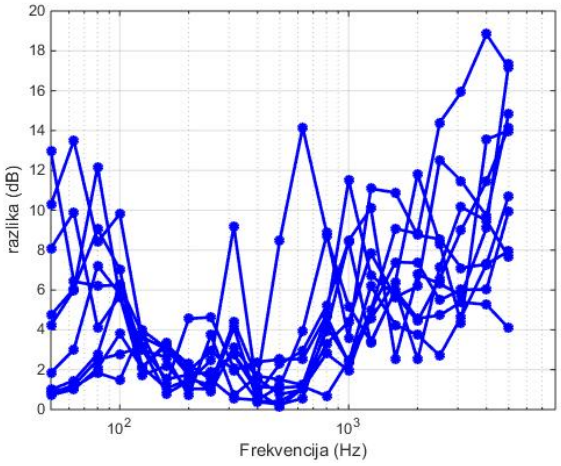
$\Delta\phi=\Delta\theta$	R'_w (dB)
1°	60
2°	60
3°	59
5°	59
$p(\theta)=sin(2\theta)$	58

Tabela 1. Jednobrojne vrednosti izolacione moći fasadne pregrade za različite vrednosti ugaone rezolucije. Struktura pregrade – beton 20 cm.



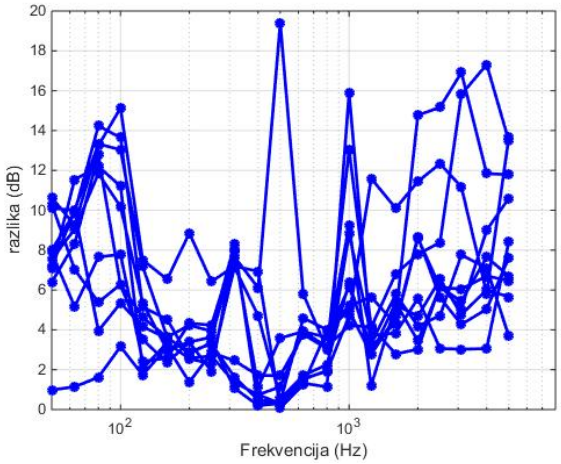
Prikazano poređenje izvršeno je na bazi jednog događaja na jednoj lokaciji u gradskoj sredini. Kako bi se izveli generalni zaključci analiza je proširena na veći broj lokacija, događaja i tipova događaja.

 ISBN 978-86-7466-930-3

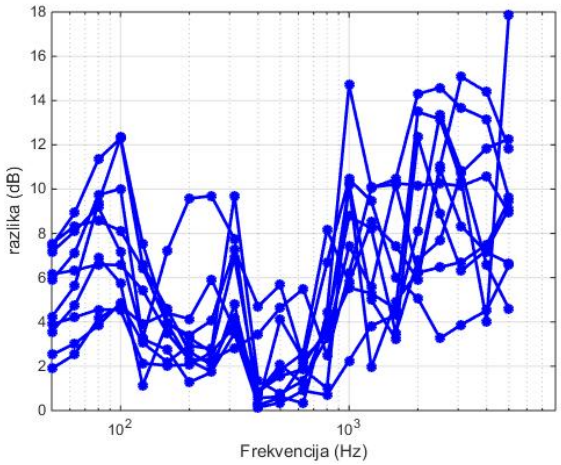


U prethodnim istraživanjima pokazano je da se prostorna raspodela energije na lokaciji može utvrditi analizom ključnih događaja, te da je globalna raspodela energije na lokaciji funkcija raspodela pojedinačnih događaja [7]. Stoga je analiza prikazana u ovom radu sprovedena nad setom od 10 ključnih događaja za četiri različite lokacije u gradskoj sredini. Pet događaja koji su predstavljaju pomeranje dominantnog zvučnog izvora na lokaciji (saobraćaj – automobili, trojelbusi autobusi) i pet događaja koji predstavljaju ambijentalni fon prisutan na lokaciji bez dominantnih izvora zvuka koji se izdvajaju po energiji.

III. Rezultati



Na slici 4 je prikazana razlika između maskimalne i minimalne dobijene vrednosti izolacione moći po frekvencijama za 10 događaja na lokaciji Bulevar Kralja Aleksandra.



Sl. 4. Varijabilnost proračunate vrednosti izolacione moći za različite prostorne rezolucije. Lokacija – Bulevar Kralja Aleksandra

Sl. 5. Varijabilnost proračunate vrednosti izolacione moći za različite prostorne rezolucije. Lokacija – Cara Nikolaja II

Sl. 6. Varijabilnost proračunate vrednosti izolacione moći za različite prostorne rezolucije. Lokacija – Ilije Garašanina

Sl. 7. Varijabilnost proračunate vrednosti izolacione moći za različite prostorne rezolucije. Lokacija – Molerova

IV. Diskusija

Zahvalnica

Ovaj rad je realizovan u okviru projekta TR 36026 koga finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

Measurements of the traffic noise using microphone arrays enables the determination of angular distribution of the incident energy on a building façade. One of the parameters which are set in such measurements is the spatial resolution. Considering high computational complexity of space-time algorithms for array signal processing, the optimization of required spatial resolution can reduce the computation process significantly. The measurements shown in this paper were performed on four urban locations. The locations differ in the number of traffic lanes, traffic types, distances to the surrounding buildings, etc. This paper examines the assumption that the minimal required resolution of the microphone array is different for each location, and is dominantly determined by the urban location morphology. The measurements were performed with a microphone array comprised of 24 omnidirectional microphones. The geometry of the microphone array is optimized for traffic noise measurements.

Microphone array spatial resolution optimization for traffic noise measurements

Komparativna analiza akustičkih signala motora sa unutrašnjim sagorevanjem mapiranih u slike bazirane na spektrogramu

Marko Milivojčević, Emilija Kisić, Dejan Ćirić

***Apstrakt*—Motori sa unutrašenjm sagorevanjem kao i druge vrste motora i mašina pri svom radu generišu zvuk. On se karakteriše specifičnim svojstvima zavisno od vrste motora, moda rada, kao i stanja samog motora. Na osnovu zvuka moguće je izvući značajne informacije o motoru, uključujući i detekciju pogonskog goriva (benzina ili dizela). U tom kontekstu, u ovom radu je izvršena analiza akustičkih signala motora sa unutrašnjim sagorevanjem posle njihovog prebacivanja (mapiranja) u odgovarajuće slike i to spektrogram, hromagram, gamatonegram i tempogram. Kako sve ove slike imaju formu klasičnog spektrograma, one se u literaturi nazivaju slike bazirane na spektrogramu ili slične spektrogramu. Cilj analize je da se izvrši međusobno poređenje navedenih slika i da se ustanovi koja od njih najbolje prikazuje razliku između signala motora koje pokreće benzin i dizel gorivo. Analiza je izvršena nad bazom od 350 snimljenih signala kako bi se u nastavku istraživanja koristeći izabranu metodu mapiranja signala u slike izvršila klasifikacija pogonskog goriva sa što većom tačnošću pomoću tehnika dubokog učenja.**

***Ključne reči*—Akustičke karakteristike, audio zapis, vremenski domen, motori sa unutrašnjim sagorevanjem, spektrogram, hromagram, gamatonegram, tempogram.**

I. Uvod

Sa razvojem modernih tehnologija i naprednih tehnika dubokog učenja, problemi automatizovane klasifikacije ili detekcije, kao što je prepoznavanje govora ili akustičkih signala, mogu se veoma uspešno rešiti ukoliko se izabere adekvatan algoritam mašinskog učenja i ukoliko se formira kvalitetna baza podataka na osnovu koje će se sistem obučiti.

Kada je reč o akustičkim signalima, njihovo prepoznavanje predstavlja veoma kompleksan zadatak i za čoveka, pre svega zbog nemogućnosti svih slušaoca da identično čuju odgovarajući signal što je uslovljeno različitim auditivnim karakteristikama svakog od slušaoca. Problem postaje još složeniji uzimajući u obzir da je na osnovu primljenog signala potrebno izvršiti klasifikaciju ili detekciju događaja upotrebom prethodno stečenog iskustva. "Treniranjem sluha", posebno u istom (radnom) okruženju, je moguće postići tačniju procenu događaja. Primena automatske klasifikacije/detekcije akustičkih signala za određenu vrstu događaja bi eliminisala nesavršenost čovekovog slušnog aparata, kao i elemente individualne subjektivnosti i manuelnog izvršavanja postupka klasifikacije/detekcije.

Činjenica da motori sa unutrašnjim sagorevanjem generišu zvuk prilikom svog rada, kao i da se taj zvuk perceptivno razlikuje u zavisnosti od pogonskog goriva, a sa dodatnom potrebom da se pogonska goriva klasifikuju iz ekoloških razloga [1], poslužila je kao motiv za razvoj sistema automatske klasifikacije baziran na audio snimcima rada motora.

U cilju realizacije jednog ovakvog sistema bilo je potrebno razviti akvizicioni sistem za prikupljanje audio signala. Ovi signali će formirati bazu uzoraka na osnovu koje će se sistem obučiti nekim od algoritama mašinskog, odnosno dubokog učenja. Pomenuti akvizicioni sistem za snimanje uzoraka koristi mikrofon pozicioniran u oblasti ispod motornog prostora putničkog vozila [2, 3] pošto se detektuje prisustvo vozila iznad mikrofona. Nakon toga, dodatnom obradom u vremenskom domenu vrši se izdvajanje režima praznog hoda motora. Kako je u režimu praznog hoda motora slušanjem utvrđena najveća razlika između pogonskih goriva, dodatna obrada je poslužila da se u banci uzoraka nađu samo audio zapisi takvog režima rada motora, pri čemu je detaljan prikaz postupka izdvajanja željenog režima rada motora prikazan u prethodnim fazama ovog istraživanja [4].

U ovom radu je izvršena komparativna analiza signala iz baze uzoraka mapiranjem signala u slike na bazi spektrograma. Osnovni motiv za analizu akustičkih signala mapiranih u slike bazirane na spektrogramu je visoka uspešnost klasifikacije na osnovu signala predstavljenih na ovaj način, videti na primer [5]. Krajnji cilj ovog istraživanja je izdvajanje onog prikaza koji daje dovoljno malu razliku unutar istog pogonskog goriva motora (benzin ili dizel), a ujedno najveću razliku između pogonskih goriva kako bi se u budućoj klasifikaciji pravilno formirala hijerarhija obeležja na osnovu kojih će se vršiti klasifikacija.

Rad je podeljen u više poglavlja. Karakteristični slučajevi prikupljenih audio signala i metode njihove obrade su prikazani u poglavlju gde je opisana metodologija. U poglavlju gde su opisani rezultati prikazani su karakteristični signali mapirani u slike u obliku spektrograma, hromagrama, gamatonegrama i tempograma. Zaključci komparativne analize dobijenih prikaza su sumirani u poglavlju koje sledi,

II. METODOLOGIJA

Prikupljanjem audio signala generisanih radom motora sa unutrašnjim sagorevanjem u realnim uslovima formirana je baza od 350 uzoraka. Preslušavanjem baze i analizom vremenskog oblika signala izdvojen je po jedan karakterističan signal rada benzinskog i jedan signal rada dizel motora u režimu praznog hoda radi lakše ilustracije i predstavljanja rezultata.. Kao predstavnici svojih klasa ova dva signala su uporedno analizirana i mapirana u slike bazirane na spektrogramu. Vremenski oblici analiziranih uzoraka su prikazani na Sl. 1.

Sl.1. Vremenski oblik audio signala benzinskog i dizel motora

A. Spektrogram

Jedna od tehnika za mapiranje akustičkih signala u sliku koja je korišćena u ovom radu je ona koja kao rezultat daje spektrogram. Ovakva vrsta slike je veoma pogodna reprezentacija signala, zato što se pomoću nje signal predstavlja u tri dimenzije: na horizontalnoj osi prikazuje se vreme, na vertikalnoj osi prikazuje se frekvencija, dok se amplituda predstavlja skalom boja. Spektrogram se može zamisliti kao grupa spektara signala poređanih jedan do drugog, gde je jačina spektralnih komponenti predstavljena intenzitetom boje. Spektrogram zapravo predstavlja kratkovremensku brzu Furijeovu transformaciju (eng. *short time fast Fourier transform*- STFT) [6], i računa se kao brza Furijeova transformacija (eng. *fast Fourier transform*-FFT) na pomerajućem prozoru podataka.

Osnovna ideja kod spektrograma jeste da se ceo signal podeli na segmente (okvire, odnosno frejmove, eng. *frame*) sa preklapajućim kratkovremenskim prozorima i da se zatim primeni FFT na svaki segment. Korišćenje spektrograma je veoma važno kod signala koji su kvazi-stacionarni, odnosno kod signala kod kojih postoji stacionarnost, ali samo na dovoljno kratkim odsečcima signala. Zbog toga, umesto standardne Furijeove transformacije koja transformiše signal iz vremenskog domena u frekvencijski domen (spektar), kod obrade akustičkih signala se uglavnom koristi vremenski kratkotrajna Furijeova transformacija. Njena glavna prednost jeste da se spektralna analiza sprovodi nad kratkim odsečcima signala kod kojih je zadovoljen uslov stacionarnosti.

Izdvajanje takvih odsečaka se sprovodi primenom vremenskih prozora, koji su različiti od nule samo za konačan skup indeksa. Množenjem ulaznog signala sa takvim vremenskim prozorom postavljenim na željeno mesto u signalu, dobija se novi signal takođe beskonačnog trajanja, ali čiji su uzorci jednaki nuli za sve indekse signala koji se nalaze izvan primenjenog vremenskog prozora.

Neka je akustički signal dužine N odmeraka označen kao $s[n]$. Spektrogram akustičkog signala predstavlja funkciju i vremena i frekvencije što se može zapisati kao:

$$STFT[f,t]=\sum_{n=0}^{N-1} s[n]\cdot w[n]e^{-j2\pi fn} \quad (1)$$

gde f predstavlja frekvenciju, n vremenski argument spektrograma, a $w[n]$ je prozorska funkcija.

U ovom radu za računanje spektrograma signala korišćena je *stft* funkcija u okviru biblioteke *librosa* u programskom jeziku *Python*. Podela signala na segmente (okvire) je već implementirana unutar funkcije. Potrebno je definisati širinu prozora W, zatim korak analize K (odnosno veličinu preklapanja prozora), kao i broj tačaka M u kojima se računa Furijeova transformacija. Drugim rečima, funkcija *stft* deli akustički signal na preklapajuće okvire (gde se definiše širina prozora i veličina preklapanja), zatim za svaki od okvira računa FFT u onom broju tačaka koji se zada, a na spektrogramu se mogu pročitati informacije o vremenu, frekvenciji i amplitudi željenog signala. U ovom radu za širinu prozora je izabrano W=2048, preklapanje prozora je K=512, a broj tačaka za računanje Furijeove transformacije je M=2048. Izabrana prozorska funkcija je *Hann*-ova prozorska funkcija.

B. Hromagram

Hromagram (hroma spektar) predstavlja veoma moćnu reprezentaciju audio signala u kojoj se ceo spektar projektuje na 12 binova koji predstavljaju 12 različitih polutonova (ili hroma) muzičke oktave [1].

Pošto se u muzici note koje su udaljene za tačno jednu oktavu doživljavaju kao posebno slične, poznavanje raspodele hroma čak i bez apsolutne frekvencije (tj. originalne oktave) može dati korisne muzičke informacije o zvuku, odnosno može otkriti uočenu muzičku sličnost koja nije vidljiva u originalnim spektrima.

Hromagram se dobija preslikavanjem diskretnih vrednosti dobijenih kratkotrajnom brzom Furijeovom transformacijom (STFT) audio signala u 12 hroma, odnosno prelaskom iz domena diskretnih frekvencija u domen diskretnih veličina hroma.

C. Gamatonegram

Spektrogram je tradicionalna vremensko-frekvencijska vizualizacija, ali zapravo ima nekih važnih razlika u odnosu na to kako se zvuk analizira od strane ljudskog uva. Najznačajnija razlika je to što frekvencijski podopsezi uva postaju širi na većim frekvencijama, dok spektrogram ima

 ISBN 978-86-7466-930-3

konstantan propusni opseg na svim frekvencijama, odnosno u svim frekvencijskom opsezima (kanalima). Kako bi se ovo ograničenje prevazišlo može se koristiti *Gama-spektrogram*, zasnovan na primeni gamatone filtara, odnosno *gamatonegram* [8].

Gamatone filteri su dizajnirani tako da modeluju frekvencijski selektivne kohlea aktivacione odzive ljudskog unutrašnjeg uva [9], pri čemu izlaz filtra simulira frekvencijski odziv bazilarne membrane. *Gamatone* filtar je linearni filtar opisan impulsnim odzivom koji je proizvod gama raspodele i sinusoidalnog tona. Impulsni odziv filtra dat je sledećom jednačinom:

$$g[k] = k^{P-1}T^{P-1}e^{-2bkT\pi}\cos(2fkT\pi + \theta) \qquad (2)$$

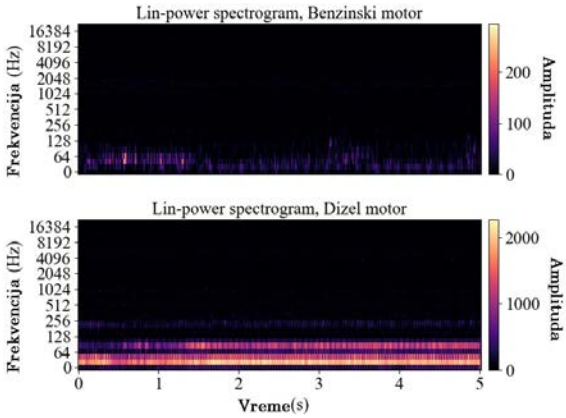
gde je k vreme, P je red filtra, T je perioda odabiranja, b je propusni opseg filtra, f je centralna frekvencija, a je θ faza nosioca. *Gamatone* filtri se koriste za modelovanje ljudskog slušnog sistema i sastoje se od niza filtara propusnika učestanosti. Banka *gamatone* filtara je formulisana kao ERB (eng. *equivalent rectangular bandwidth*) skala [10] na sledeći način:

$$ERB = 24.7(4.37\cdot 10^{-3} f + 1) \qquad (3)$$

Kako bi se generisao gamatonegram u ovom radu korišćen je toolbox razvijen od strane Ellis at al. [8], primenjen u programskom jeziku Python. Prvo je akustički signal transformisan u STFT spektrogram, kao što je gore opisano. Zatim je primenjeno *gamatone* ponderisanje $COE[F_{gam},F]$ na STFT kako bi se dobio gamatonegram:

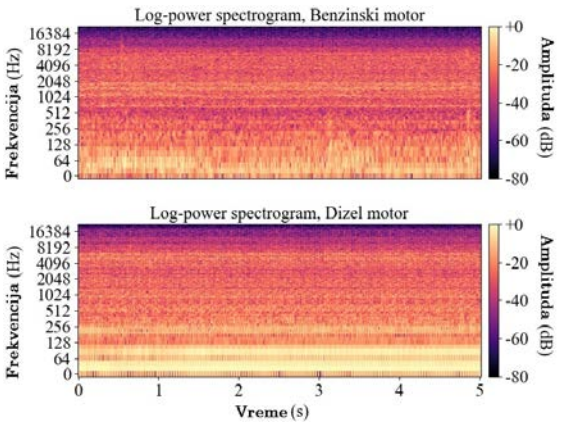
$$GAM[F_{gam},T] = COE[F_{gam},F]\times STFT[F,T] \qquad (4)$$

gde je F_{gam} rezolucija gamatonegrama (GAM spektrograma) i predstavlja broj gamatone filtara [11]. U ovom radu je broj gamatone filtara 64.



D. Tempogram

Slično spektrogramu, tempogram se definiše kao vremenska-tempo reprezentacija, odnosno tempo datog signala koji zavisi od vremena [12]. Tempogram signala je reprezentacija koja sadrži informaciju o lokalnom tempu za svaki frejm audio sigala. Postoje dva tipa tempograma: Furijeov tempogram i autokorelacioni tempogram. Furijeov tempogram konvertuje frekvenciju u tempo (eng. *beat per minute* - BPM) naglašavajući harmonike, dok autokorelacioni tempogram konvertuje vremensko kašnjenje (sekunde) u tempo, ističući subharmonike. U ovom radu korišćen je ciklični tempogram pomoću *libros*-a biblioteke u Python programskom jeziku. Ciklični tempogram se dobija iz Furijeovog i autokorelacionog tempograma [12].



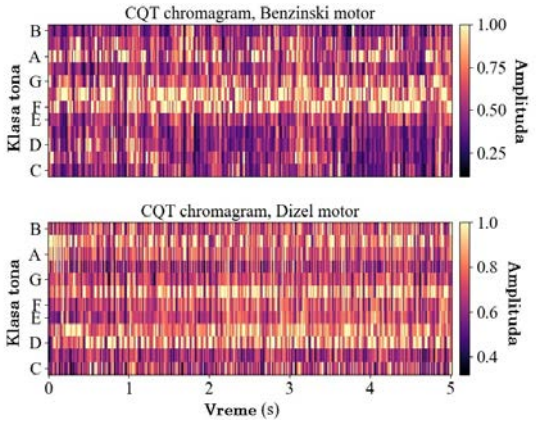
III. REZULTATI ANALIZE

Kako je akvizicioni sistem razvijen tako da kao krajnji rezultat prikupljanja audio zapisa izdvaja i čuva samo režim praznog hoda motora, predmet analize nisu bili signali sa promenljivim režimom rada. Primenom predstavljenih metoda za analizu iz prethodnog poglavlja, mapiranje signala je realizovano na karakterističnim signalima dobijenim radom benzinskog i dizel motora isključivo u režimu praznog hoda čiji su vremenski oblici prikazani na Sl. 1.

Na Sl. 2. je prikazan spektrogram gde je nivo signala predstavljen u linearnoj razmeri, dok je na Sl. 3. takođe prikazan spektrogam istih signala pri čemu je snaga signala predstavljena u logaritamskoj razmeri.

Sl. 2. Spektrogrami signala u linearnoj razmeri (*lin-power* spektrogrami)

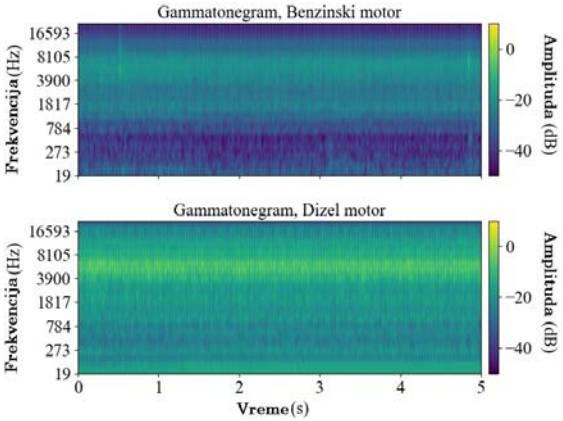
Sl. 3. Spektrogrami signala u logaritamskoj razmeri (*log-power* spektrogrami)



Analizom signala prikazanih u vidu spektrograma sa linearnom razmerom na Sl. 2. može se uočiti višestruka razlika signala između motora na benzin i dizel. Spektrogram benzinskog motora ima gotovo desetostruko niži nivo signala, dok spektrogram dizel motora pored višeg niva signala poseduje i izražene komponente na višim frekvencijama u odnosu na benzinski motor. Kod dizel motora se može uočiti neprekidnost spektrograma, posebno na osnovnoj učestanosti rada motora.

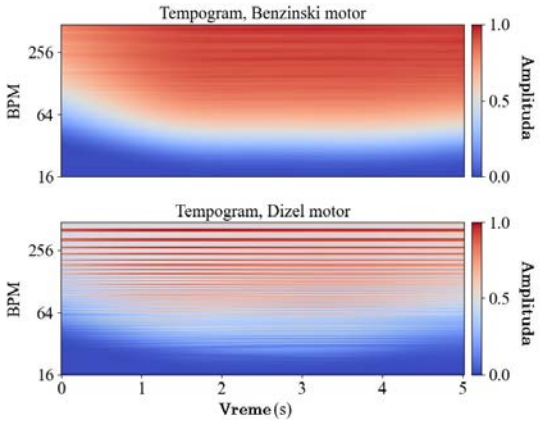
Prikazom ova dva signala u vidu spektrograma sa logaritamskom razmerom dobija se detaljniji prikaz spektralne raspodele signala, sl. 3. Na ovoj slici se takođe može uočiti viši nivo signala i veća gustina spektra dizel motora na nižim učestanostima. Pored ove osobine signala dobijenog radom dizel motora, koji odgovara percepciji slušaoca, da ovaj tip

 ISBN 978-86-7466-930-3



motora radi „dublje“, može se uočiti ravnomernija „popunjenost“ spektra sve do visokih frekvencija, dok se kod benzinskog motora posebno na približno 500 Hz može uočiti niži nivo signala. Kod signala generisanog radom benzinskog motora je i u oblasti visokih učestanosti, preko 10 kHz nivo signala niži, što odgovara percepciji slušaoca da prilikom dugog izlaganja buci dizel motora dolazi ranije do zamaranja slušaoca. Ova karakteristika generisanog zvuka se može potvrditi i analizom zvučne izolacije koja se ugrađuje na identičan tip putničkog vozila pokretanog različitim motorima, gde je zvučna izolacija dizel motora u najvećem broju slučajeva zbog komfora bolje izvedena.

Rezultat primene funkcija za određivanje hromagrama za izabrane karakteristične signale rada benzinskog i dizel motora u praznom hodu je prikazan na Sl. 4. Na dobijenom prikazu može se uočiti da je kod dizel motora zastupljenost različitih visina tj. klasa tonova kroz čitav opseg od svih dvanaest klasa, gotovo uniforman, pri čemu su najistaknutije klase D, D#, F# i A#, dok su kod benzinskog motora izražene klase F, F#, G i A. Na osnovu ovakvog prikaza signala moguće je uočiti da su kod benzinskog motora zastupljenije osnovne klase tonova dok su kod dizel motora zastupljenije povišene/snižene klase tonova.



Sl. 4. Hromagram benzinskog i dizel motora

Primenom gamatone filtara prilikom proračuna spektrograma za posmatrane signale dobijen je gamatonegram koji je prikazan na Sl. 5. Na prikazanom gamatonegramu jasno je moguće uočiti razliku između dva pogonska goriva. Kod dizel motora nivoi signala su viši na svim frekvencijama, a posebno je istaknut opseg 4-8 kHz, kao i opseg niskih frekvencija gde se nalazi osnovna učestanost rada motora. Kod benzinskog motora je moguće uočiti veoma nizak nivo signala u opsegu ispod 1 kHz i iznad 10 kHz. Kako je gamatonegram posebno prilagođen ljudskom uvu, dobijeni prikazi odgovaraju percepciji „glasnijeg“ dizel motora bez obzira na mereni nivo signala instrumentom.

Sl. 5. Gamatonegram benzinskog i dizel motora

U okviru analize izabranih audio signala posebna pažnja je posevećena percepciji slušaoca koja se odnosi na utisak veće ili manje ujednačenosti rada motora odnosno doživljaja tempa rada motora. Rezultat proračuna tempograma u vremenu prikazan je na Sl. 6. Na prikazanom tempogramu su razlike između benzinskog i dizel motora veoma jasno vidljive. Kod dizel motora tempogram je jasno definisan kao posledica koncentracije energije signala u okolini odgovarajućih učestanosti, dok kod benzinskog motora postoji uniformna raspodela amplituda kroz čitav opseg frekvencija.

Sl. 6. Tempogram benzinskog i dizel motora

IV. ZAKLJUČAK

Primenom akvizicionog sistema prilagođenog prikupljanju audio zapisa generisanih radom motora sa unutrašnjim sagorevanjem, prikupljeno je 350 uzoraka. Izvršeno je izdvajanje isključivo režima praznog hoda, kao režima u kome je slušaocu najjednostavnije da samo na osnovu zvuka utvrdi razliku između pogonskih goriva. Prikupljeni uzorci su analizirani u cilju pronalaženja i reprezentacije razlika koje bi omogućile primenu automatske klasifikacije upotrebom mašinskog i/ili dubokog učenja.

Prikupljanje uzoraka i klasifikacija se realizuju u realnim uslovima, što je stvorilo potrebu da se pronađu parametri na osnovu kojih će biti moguće razlikovati pogonska goriva bez obzira na okolnu buku. U ovom radu je korišćen metod mapiranja audio signala u slike bazirane na spektrogramu.

 ISBN 978-86-7466-930-3

Odgovarajućim odabirom tipa prikaza kao i parametara izračunavanja dobijene su slike na kojima je moguće jasno uočiti razlike između pogonskih goriva.

U poglavlju rezultati su dati uporedni prikazi za benzinski i dizel motor na primeru dva karakteristična audio signala. Prikazani spektrogrami signala daju uočljivu razliku kako za prikaz u linearnoj tako i za prikaz u logaritamskoj razmeri, pri čemu prikaz u logaritamskoj razmeri daje mogućnost detaljnije analize nivoa signala po frekvencijama (Sl. 2 i 3). Za oba prikaza dizel motor ima veću energiju skoncentrisanu na nižim učestanostima. Mapiranjem signala u hromagram takođe su dobijene jasno uočljive razlike u pogledu pogonskih goriva (Sl. 4). Na osnovu hromagrama uočljivo je da dizel motor generiše zvuk gotovo podjednako zastupljen na svim klasama tonova, pri čemu su više istaknute klase povišenih/sniženih tonova u odnosu na benzinski motor gde su istaknutije kase osnovnih tonova. Generisanjem gamatonegrama moguće je uočiti razliku koja se pre svega odnosi na nivo signala u čitavom opsegu, koji je kod dizel motora evidentno viši (Sl. 5). Izračunavanjem tempograma (Sl. 6) moguće je kod dizel motora uočiti jasnu koncentraciju energije za odgovarajuće nivoe tempa, dok je kod benzinskog motora tempogram gotovo uniforman.

Dobijene razlike za izdvojene parametre pružaju mogućnost binarne klasifikacije pogonskih goriva što predstavlja nastavak ovog istraživanja i budući rad za koji je bilo neophodno izvršiti ovakvu analizu.

ZAHVALNICA

Ovaj rad je realizovan zahvaljujući gospodinu Neđi Petijeviću ispred firme Novi Dom doo u Beogradu koji je omogućio pristup ulaznoj rampi podzemne garaže uz poštovanje svih bezbednosnih procedura. Ovaj rad je podržan od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije, evidencioni broj 451-03-68/2022-14/200102.

ABSTRACT

Internal combustion engines as well as other types of engines and machines generate sound during their operation. It is characterized by specific properties depending on the type of engine, operating mode, as well as the condition of the engine itself. Based on the sound, it is possible to extract important information about the engine, including the detection of fuel (gasoline or diesel). In that regard, in this paper, the analysis of acoustic signals of internal combustion engines is performed after their mapping into the appropriate images, namely spectrogram, chromagram, gammatonegram and tempogram. As all these images have the form of a classical spectrogram, they are called in the literature images based on a spectrogram or similar to a spectrogram. The aim of the analysis is to compare the above images and to determine which of them best shows the difference between the signals of the engine that runs on gasoline and diesel fuel. The analysis is performed on a database of 350 recorded signals, so that in the continuation of the research, using the selected method of mapping the signals into images, the fuel classification will be performed with the highest possible accuracy using deep learning techniques.

Comparative analysis of acoustic signals generated by internal combustion engines mapped into spectrogram-based images

Koeficijent inharmoničnosti tonova harfe – Specifičnost i problemi automatske procene

Tatjana Miljković, Miloš Bjelić, Jelena Ćertić, Dragana Šumarac Pavlović

***A stra t*— vaj rad bavi se ara terizacijom tona harfe i predstavlja nastavak istraživanja vezanih za ara terizaciju tonova žičanih instrumenata. ara terizacija tona harfe bazirana je pre svega na proceni oeficijenta inharmoničnosti. Inharmoničnost je svojstvo tonova žičanih instrumenata i ogleda se u odstupanju fre vencija parcijala od vrednosti celobrojnih umnožaka osnovne frekvencije. Preciznost automats og određivanja oeficijenta inharmoničnosti otežano je postojanjem "fantoms ih" parcijala oji su posledica različitih fizičkih procesa oji zavise od konstrukcije instrumenta, načina pobude, ao i materijala od kojih su žice napravljene. ao posledica onstru cije instrumenta i načina zatezanja žice, od harfe su veoma izraženi višestruki pikovi u spektru koji otežavaju automatsko izračunavanje koeficijenta inharmoničnosti. oeficijent je procenjen uz pomoć P D algoritma i upoređen sa vrednostima oje su procenjene uz pomoć namenski napravljenog alata za manuelnu procenu. rednosti oeficijenata za harfu upoređeni su sa vrednostima oeficijenta kod klavira i čembala.**

***Ključne reči*—Inharmoničnost parcijala, harfa, procena spe tra, „fantoms i" parcijali**

I. UVOD

Muzički ton karakteriše diskretan spektar sa harmonijski raspoređenim komponentama na celobrojnim umnošcima osnovne frekvencije. Jedna od specifičnosti tonova žičanih instrumenata je pojava inharmoničnosti parcijala koja se ogleda u odstupanju frekvencija parcijala od harmonijskog niza. Ovo svojstvo je prisutno kod svih žičanih instrumenata, ali je kod nekih manje ili više izraženo. Konstrukcija instrumenta, dužina žice, materijal od koga je žica napravljena, način okidanja žice, kao i način pričvršćivanja i zatezanja dovode do različitih fizičkih procesa koji za posledicu imaju odstupanje frekvencija modova od pravilnog harmonijskog niza.

Druga osobina spektra tonova žičanih instrumenata je prisustvo parazitnih diskretnih komponenti koji su posledica više različitih faktora: sprezanja oscilovanja susednih žica, sprezanja oscilovanja žice sa drugim rezonantnim sistemima, kao i nelinearne pojave koje prouzrokuju pojavu takozvanih „fantomskih" parcijala [1-3]. U slučaju harfe koja je predmet analize u ovom radu, veoma su izraženi skoro svi nabrojani faktori koji kao posledicu imaju dodatne komponente u spektru tonova koje su tema brojnih istraživanja [1-5].

Usled transverzalnih vibracija javljaju se nelinarnosti u procesu oscilovanja koji kao posledicu imaju pojavu takozvanih „fantomskih" parcijala [3, 6]. Fantomski parcijali se pojavljuju kao zbirovi inharmoničnih parcijala nižeg reda ili kao dvostruke vrednosti parnih harmonika. Posledica dodatnih pikova u spektru u okolini inharmoničnih modova prouzrokuje amplitudsku modulaciju anvelope harmonika koja utiče na boju zvuka. Kod različitih žičanih instrumenata postoje manje ili više izraženi pojedini efekti koji utiču na formiranje prepoznatljive boje zvuka određenog instrumenta. Navedeni artefakti spektra dodatno usložnjavaju njegovu prirodu, što za posledice ima komplikacije prilikom procene koeficijenta inharmoničnosti.

U cilju karakterizacije tonova žičanih instrumenata na osnovu koeficijenta inharmoničnosti neophodno je obuhvatiti ceo registar instrumenta. S obzirom da se registri instrumenata razlikuju, kao i da ih čini mnoštvo tonova uglavnom od 80 do 100, potrebno je izvršiti automatizaciju procesa procene koeficijenta inharmoničnosti. U literaturi postoje različite metode i algoritmi za procenu koeficijenta inharmoničnosti [7,8,9]. Uglavnom se automatska procena koeficijenta inharmoničnosti zasniva na proceni diskretnih inharmonijskih parcijala u spektru. Procena takvih parcijala iz spektra tona često je otežana zbog prisustvu brojnih izraženih spektralnih komponenti u blizini inharmoničnih parcijala. U ovom radu razmatrani su specifičnosti automatske procene koeficijenata inharmoničnosti, kao i problemi koji su doveli do otežane realizacije automatske procene.

Rad je organizovan kako sledi. U drugom poglavlju rada prikazana je konstrukcija i način proizvođenja tonova različitih tonskih visina, kao i karakteristike spektra i vremenskog razvoja pojedinih parcijala tonova hafre. U trećem poglavlju prikazana su dva postupka za procenu koeficijenta inharmoničnosti. Jedan postupak zasniva se na automatskoj proceduri zasnovanoj na PFD (*Partial Fre uency e iation*) algoritmu sa procenom spektra na bazi AR (*Auto egressi e*) modela, a drugi postupak baziran je na manuelnoj proceni na bazi namenski napravljenog alata. U IV poglavlju prikazani su i diskutovani eksperimentalni rezultati proračuna koeficijenta inharmoničnosti za kompletan registar tonova harfe. Procena je izvršena za sve tri pozicije pedala kao i uporedna analiza automatskog i manuelnog postupka procene. Procenjene vrednosti koeficijenta inharmoničnosti za harfu upoređene su sa vrednostima dobijenim za klavir i čembalo koji su analizirani u prethodnim istraživanjima.

II. OSNOVNE KARAKTERISTIKE HARFE

A. onstrukcija harfe

Harfa je instrument u obliku trostranog okvira, visokog oko 180 cm, sa nizom žica razapetih u uspravnoj ravni. Okvir harfe se sastoji iz 5 osnovnih delova. Osnovu instrumenta čini postolje, koje se još naziva pedalijera, jer su u njegovim stepenastim prorezima smešteni pedale za preštimavanje žica. Uspravno na postolju stoji šuplji stub, kroz čiju unutrašnjost prolaze čelične poluge koje povezuju pedale sa gornjim delom mehanizma za preštimavanje. Drugi krak okvira čini rezonantno telo, koje je takođe šuplje. Zaobljena strana rezonatora je okrenuta nadole i uglavom se izgrađuje od bukovog ili javorovog drveta.

Treću stranu okvira čini drveni vrat. Kroz vrat su provučene čivije – metalni zavrtnji koji drže gornje krajeve žica. Same žice su zakačene s leve strane, a sa desne strane se čivije mogu, posebnim ključem, zatezati ili otpuštati, čime se podešava osnovno štimovanje žica. Zajednicu sa vratom čini most, u kome se između dve mesingane ploče, nalazi gornji deo mehanizma za preštimavanje žica. Poluge ovog mehanizma, koje su kroz stub harfe povezane s pedalama u postolju, pokreću 90 bakarnih koturića postavljenih u dvostrukom nizu na spoljnoj levoj strani mosta. Svaki koturić ima po dva mala klina između kojih prolazi žica, a svaku žicu zahvataju po dva takva koturića [10]. Najniže dve do tri žice nemaju ove koturiće. Njihovi tonovi su vrlo retko u upotrebi, pa se pre sviranja štimovanje ključem podesi na onu tonsku visinu koja će biti potrebna. Na slici 1 prikazan je opisani sitem za preštimavanje žica na harfi. Takođe, na slici 1 se može uočiti kako se u postolju harfe nalaze 3 stepenasta proreza, koje označavaju da se pedale harfe mogu postaviti u 3 različita položaja.

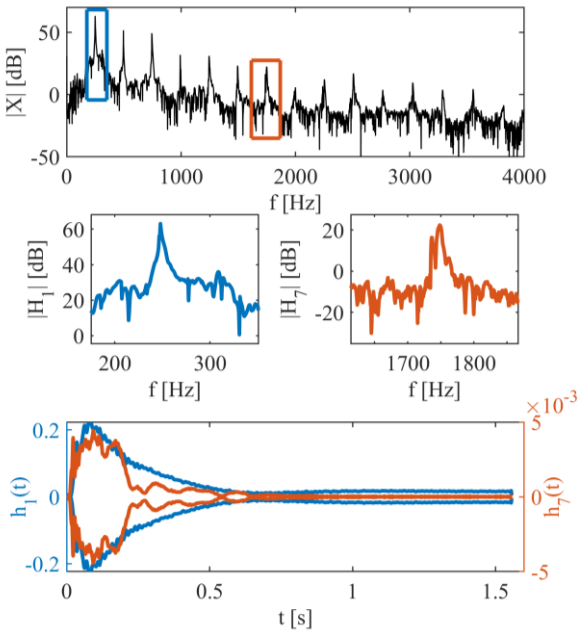
Sl. 1 Sistem preštimavanja žice na harfi; a) položaj 1 – otvorena žica, b) položaj 2 – jedanput skraćena žica, c) položaj 3 – dvaputa skraćena žica [10]

U gornjem položaju pedala je opuštena i ne deluje na gornji mehanizam, tako da klinovi koturića ne dotiču žicu i ona slobodno osciluje celom svojom dužinom. Ako se pedala pritisne i zakači u srednji položaj, taj se pritisak polugama prenosi do gornjeg od dva koturića i okreće ga za toliko, da njegovi klinovi zahvate žicu. U tom slučaju, njena aktivna dužina je skraćena, pa žica daje ton viši od osnovnog štimovanja za pola stepena. Pomeranjem u donji položaj, pedala pokreće, posredstvom poluga, i donji koturić, pa njegovi klinovi još više skrate dužinu žice i povise joj ton još za pola stepena. Opisanim postupkom, se iz svake žice mogu izvući po 3 tona različite visine. Time se postiže znatna ušteda u broju žica, što je za spretnost sviranja od velike važnosti.

Jedna pedala mehanizmom zahvata istovremeno žice istoimenih tonova u svim oktavama (npr. G1, G2, G3, G4 itd.) i zahvaljujući preštimavanju njihove hromatske varijante. Time je broj pedala sveden na 7. Oni su raspoređeni naspram leve i desne noge svirača i nose ime žica, koje kroz sve oktave, zahvataju [10]. Osnovno štimovanje harfe je dijatonski Ces-dur. Za ostvarenje te lestvice moraju sve žice da osciluju slobodno, celom dužinom, odnosno sve pedale moraju biti u gornjem položaju. Ako su sve pedale u srednjem položaju, dobija se C-dur, a donji položaj svih pedala daje Cis-dur. Kombinacijom različitih položaja pojedinih pedala može da da i bilo koju drugu lestvicu, osim naravno hromatske.

Tonski opseg harfe zahvata šest i po oktava: to je pri gornjem položaju pedala, od Ces1 do Ges7. Sa po 7 žica u okviru oktave, ukupan broj žica iznosi 46 ili 48. Orjentacija svirača u tolikom nizu žica olakšana je time, što su sve C žice obojene crveno, a sve F žice plavo. Dvanaest najnižih (najdužih) žica do As2 koje se još nazivaju bas žice imaju čelično jezgro, omotano metalnom niti; sledeći opseg od As2 do Es6 su žice od creva, i na kraju opsega od Fes6 do Ges7 žice su izgrađene od najlona.

B. remenske i spektralne karakteristike tono a harfe



Harfa spada u žičane muzičke instrumente, gde se ton proizvodi trzanjem žice. Tako se i u spektru tonova harfe uočavaju pojave koje su karakteristične za žičane instrumente. Jedan od efekata je inharmoničnost koja se ogleda u odstupanju položaja parcijala od frekvencija koje su celobrojni umnožak osnovne frekvencije. Međutim, u spektru harfe, uočavaju se i druge pojave koje se ne mogu objasniti inharmoničnošću a koje otežavaju sistematsku, automatsku analizu karakteristika harfe kao tipa instrumenta i parametre koji bi opisali svaki pojedinačan instrument i omogućili objektivno poređenje instrumenata. Pojave kojima se može objasniti prisustvo artefakata u spektru signala harfe opisane su u literaturi i definišu se :

- kao posledice nelinearnosti [3,6] usled koje se javljaju komponente u spektru koje predstavljaju zbir harmonika.
- kao posledice pobuđivanja i drugih žica osim žice koja se okida [1,2] usled koje se „čuju“ i pri analizi spektra i vide komponente koje po frekvenciji odgovaraju parcijalima neke druge žice ili žica. Ova pojava opisana je posebno za hrafu i posledica je konstrukcije samog instrumenta.

Obe pojave mogu dovesti do toga da se u spektru signala pojave komponente, koje su po frekvenciji bliske nekom od osnovnih inharmoničnih parcijala. Pomenute komponente dovode do amplitudske modulacije parcijala. Na slici 2 prikazan je spektar jednog tona harfe sa detaljnijim prikazom spektra prvog i sedmog parcijala, kao i njihove vremenske obvojnice. Komponente su izdvojene primenom namenski napravljene banke filtara [11] na čijem su izlazu dostupni

 ISBN 978-86-7466-930-3

uskopojasni signali pojedinačnih parcijala. Sa slike 2 se može uočiti da u okolini sedmog harmonika postoji izražena dodatna spektralna komponenta koja menja anvelopu pacijala i dovodi do toga da se anvelopa sedmog parcijala značajno razlikuje od tipične anvelope čiji je predstavnik anvelopa prvog parcijala. U okviru ovog rada, pojave dodatnih komponenti u spektru su razmatrane jer ograničavaju mogućnost za automatsku procenu koeficijenta inharmoničnosti, o čemu će biti više reči u poglavljima III i IV.

Sl. 2 Spektar tona Ces4 odsviranog na harfi sa prikazom vremenske obvojnice prvog i sedmog parcijala

III. METODOLOGIJA ODREĐIVANJA KOEFICIJENTA INHARMONIČNOSTI

Nastanak zvuka kod žičanih instrumenata potiče od vibriranja žice. U zavisnosti od načina na koji se žica pobuđuje na vibriranje razlikujemo 3 podgrupe žičanih instrumenata (gudačke, trzane i udarne žičane instrumente). Bez obzira na različite podgrupe žičanih instrumenata, za sve tipove žičanih instrumenata kod kojih zvuk nastaje udarom žice ili njenim okidanjem, karakteristična je pojava inharmoničnosti parcijala. Izučavanjem prirode i fizičkih uzroka inharmoničnosti izvedena je zakonitosti po kojoj se može odrediti frekvencija inharmonijskih parcijala :

$$f_k = kf_0\sqrt{1+k^2B}, \qquad (1)$$

gde je k redni broj harmonika, f_0 osnovna frekvencija tona, a B koeficijent inharmoničnosti [12]. Za svaki ton postoji jedinstven koeficijent inharmoničnosti B koji u izvesnoj meri na istom instrumentu varira sa promenom tonskih visina.

Procena B zasniva se na proceni spektra i u literaturi su predloženi različiti algoritmi za njegovu automatsku procenu. [7,8,9]. U ovom radu za automatsku procenu koeficijenta inharmoničnosti B razmatran je PFD algoritam [13]. Kako su automatskom procenom dobijene vrednosti B koje neočekivano variraju sa promenom tonskih visina, paralelno je izvršena procena B uz pomoć namenski napravljenog alata za manuelnu procenu.

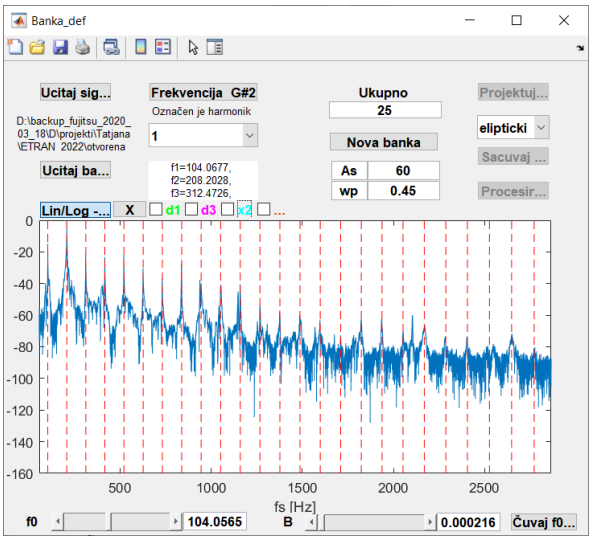
A. Automatska procena koeficijenta inharmoničnosti na osno u PF algoritma

PFD algoritam se može razmatrati kao algoritam koji se izvršava u dve etape. U prvoj etapi algoritma je neophodno izvršiti procenu spektra signala i odrediti prvih k frekvencija parcijala analiziranog tona. Grupa Finskih naučnika koja je predložila PFD algoritam kao algoritam za automatsku procenu B, procenu spektra tona bazirala je na DFT (*iscrete Fourier Transform*) metodi [13].

U prethodnim radovima pokazani su nedostaci takve metode za procenu spektra tonova[14,15]. Zbog navedenih nedostataka kao metod za procenu spektra predložen je AR model [15].

AR modelovanje podrazumeva da se na osnovu segmenata signala procene koeficijenti modela. Znajući koeficijente modela, za signale kod kojih su spektralne komponente izražene moguće je izvršiti procenu frekvencija spektralnih komponenti. Detaljni opis primenjenog AR modela prikazan je u radovima [16]. Krajnji rezultat metode AR modelovanja je procenjivanje frekvencija spektralnih komponenti na osnovu položaja dominantnih polova.

Druga etapa PFD je iterativni postupak koji se zasniva na izračunavanju devijacije frekvencije parcijala, gde se proračunava razlika niza frekvencija parcijala dobijenih iz procene spektra i odgovarajućeg niza frekvencija parcijala dobijenih na osnovu jednačine (1) za vrednost B u tekućoj iteraciji. Na osnovu trenda devijacije frekvencije, potrebno je doneti odluku da li se vrednost koeficijenta B smanjuje ili povećava [13]. Nakon određenog trenda devijacije moguće je modifikovati vrednost koeficijenta B polaznog tona. Minimizacijom krive devijacije postiže se konvergencija algoritma. Konačni rezultat cele procedure predstavlja jednobroja vrednost koeficijenta inharmoničnosti B za posmatrani ton.



B. Procena koeficijenta inharmoničnosti pomoću specijali o anog alata

Sa ciljem da se detaljnije sagleda priroda spektra tonova realizovan je specijalizovani alat za analizu tonova muzičkih instrumenata. Alat je nastao kao unapređenje ranije realizovane komplementarne filtarske banke [11]. Razvijanje alata je sprovedeno u MATLAB okruženju kao grafički interfejs (slika 3). Osnovne karakteristike alata koje su implementirane odnose se na sledeće kontrole: učitavanje signala, filtriranje namenski projektovanom bankom usklađenom sa karakteristikama spektra, određivanje osnovne frekvencije signala i definisanje pozicije parcijala u odnosu na zadatu vrednost B (prema formuli (1)), kao i uskopojasno filtriranje prema definisanim frekvencijama inharmonijskih parcijala**.** Uz pomoć dva klizača vrši se manuelno podešavanje koeficijenta inharmoničnosti B, za zadati broj parcijala.

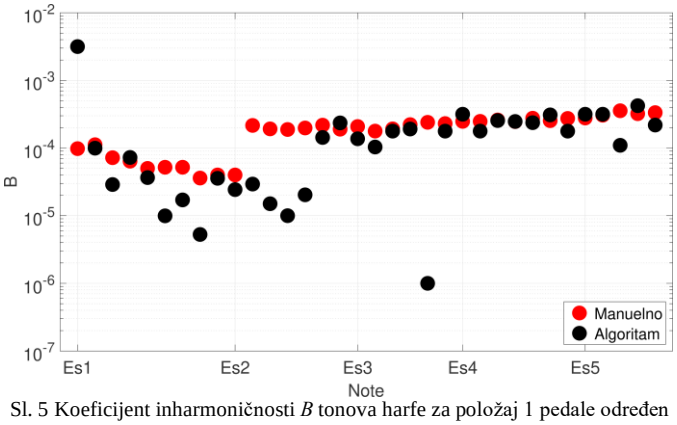
Na slici 3 dat je prikaz interfejsa specijalizovanog alata, gde je učitan signal ton As2 odsviranog na harfi. Na prikazanom logaritamskom spektru, isprekidanim crvenim linijama čiji je

 ISBN 978-86-7466-930-3

broj određen brojem upisanim u polje „ukupno“ obeležene su pozicije parcijala tona. Pomeranjem klizača f_0 i B menjaju se pozicije isprekidanih crvenih linija. U cilju što bolje procene koeficijenta B neophodno je pozicionirati isprekidane crvene linije tako da odgovaraju vrhovima spektralnih komponenti parcijala analiziranog tona. Vrednosti f_0 i B za koje se isprekidane linije najbolje poklapaju sa spektralnim komponentama tona proglašavamo za procenjene vrednosti osnovne frekvencije i koeficijenta inharmoničnosti analiziranog tona.

Sl. 3 Prikaz interfejsa alata za analizu pojedinačnih tonova muzičkih instrumenata

Detaljnijim uvidom u spektar posmatranog tona (slika 4) u opsegu od 1000 do 2000 Hz, može se uočiti postojanje spektralnih komponenti veoma frekvencijski bliskih parcijalima odsviranog tona. Pored postojanja udvojenih parcijala, još jedan od neregularnih spektralnih artefakta tona As2 jeste pojava veoma amplitudski izražene spektralne komponente između 2000 i 2200 Hz, koji se nalazi tačno na polovini između 19og i 20og harmonika tona As2. Navedeni fenomeni koji se pomoću specijalizovanog alata mogu uočiti u spektru tona otežavaju automatizaciju procene koeficijenta inharmoničnosti za ceo opseg tonova harfe.



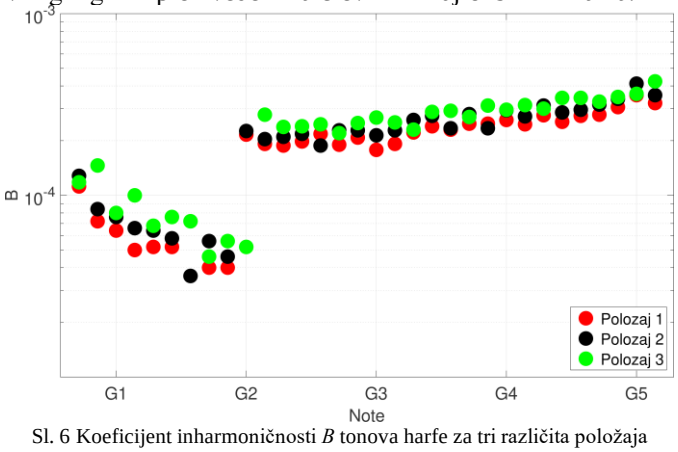
Sl. 4 Deo spektra tona As2 odsviranog na harfi

IV. Eksperimentalni rezultati i diskusija

U prethodnom poglavlju izložene su dve metodologije za određivanje koeficijenta inharmoničnosti, automatska procena na osnovu PFD algoritma i procena pomoću specijalizovanog alata. Krajnji rezultat obe metodologije jeste vrednost koeficijenta inharmoničnosti za celokupni opseg harfe. Bazu čini 141 snimak tonova odsviranih na harfi. Snimljeni tonovi pokrivaju celokupni registar harfe, odnosno svih 47 žica su pobuđene za sva 3 položaja pedale. Tonovi harfe snimljeni su u prostorijama Fakulteta muzičke umetnosti u Beogradu.

A. omparacija re ultata koeficijenta inharmoničnosti algoritmom i pomoću alata

Uticaj dve metodologije na procenu koeficijenta inharmoničnosti najbolje se može uočiti poređenjem trenda krive koeficijenta B. Na slici 5 dat je grafik koeficijenta inharmoničnosti B za tonove harfe odsvirane za položaj 1 pedale, odnosno za slučaj kada je žica otvorena. Koeficijenti inharmoničnosti su dobijeni na osnovu dve metofologije, pomoću PFD algoritma i manuelno, odnosno pomoću specijalizovanog alata. Za tonove iz srednjeg i višeg registra harfe koeficijenti B procenjeni na osnovu dve metodologije se ne razlikuju previše, dok za slučaj tonova iz nižeg registra dolazi do uočljivog razilaženja u vrednostima i to za red veličine. Glavni razlog za lošiju procenu koeficijenta inharmoničnosti na osnovu algoritma leži u kompleksnosti spektra tona harfe koji se odlikuje sa udvojenim parcijalima čije su vrednosti i frekvencijski i amplitudski veoma bliske, te se sam algoritam u odabiru spektralnih komponenti parcijala tona odluči za pogrešan.

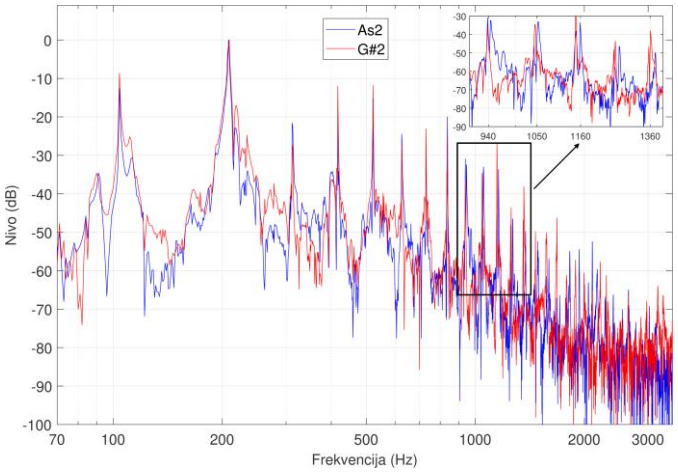


Sl. 5 Koeficijent inharmoničnosti B tonova harfe za položaj 1 pedale određen algoritmom i pomoću specijlizovanog alata

B. Procena koeficijenta inharmoničnosti za različite položaje pedala harfe

Na slici 6 prikazani su koeficijenti B tonova odsviranih na harfi za sva tri položaja pedale. Trend krive koeficijenta B očuvan je za sva tri položaja pedale. Za razliku od trenda krive koeficijenta B koji je očuvan razlike u vrednostima koeficijenta B za tonove iz nišeg registra u odnosu na vrednosti koeficijenta B za tonove iz srednjeg i višeg registra postoji. Procenjene vrednosti koeficijenta B kreću se u rasponu od $3{\cdot}10^{-4}$ do $2{\cdot}10^{-3}$. Veće vrednosti B označavaju veću inharmoničnost, odnosno veće odstupanje inharmonijskih frekvencija u odnosu na očekivane frekvencije harmonijskog niza. Na osnovu skoka u vrednosti koeficijenta

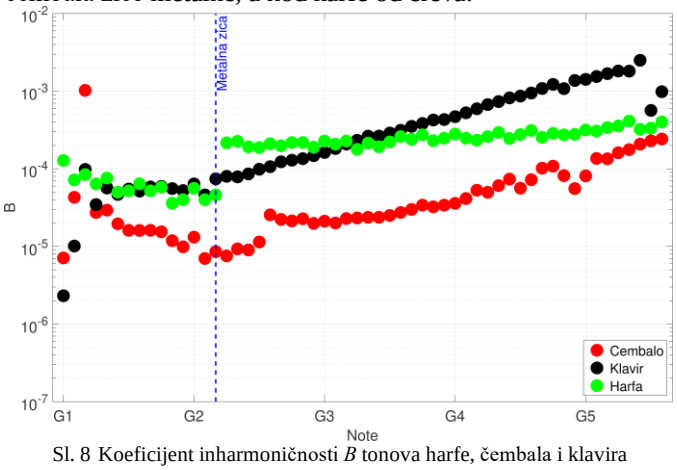
 ISBN 978-86-7466-930-3



inharmoničnosti možemo zaključiti da na samu vrednost koeficijenta inharmoničnosti utiče značajno materijal od kojeg je žica napravljena, s obzirom da su tonovi iz nižeg registra proizvedeni na metalnim žicama, dok su tonovi iz srednjeg i višeg registra proizvedeni na crevnim i najlonskim žicama.

Sl. 6 Koeficijent inharmoničnosti *B* tonova harfe za tri različita položaja pedale

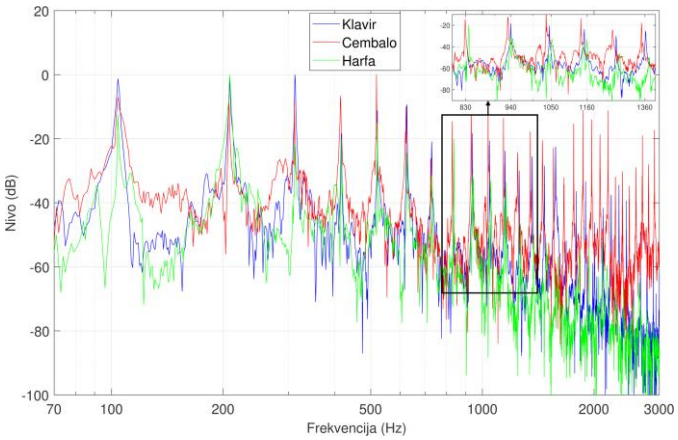
Još jedan od fenomena harfe kao muzičkog instrumenta se može uočiti iz krive koeficijenta inharmoničnosti prikazanog na slici 6. Iako postoje tonovi koji su enharmonski parovi (tonovi jednakih tonskih visina, ali različite notacije npr. Gis i As) njihovi koeficijenti inharmoničnosti se međusobno razlikuju. Razlog za razlike u vrednostima koeficijenta *B* se krije upravo u fizici nastanka tona. Iako su to tonovi istih osnovnih frekvencija, da bi se na harfi dobio ton As pedala se nalazi u položaju 1, žica je otvorena i kao takva osciluje, dok za slučaj tona Gis pedala se nalazi u položaju 3 i pomoću mehanizma sa dva koturića žica je skraćena na dva mesta za razliku od žice kada se pedala nalazi u položaju 1. S obzirom na fizičko skraćivanje žice, menjaju se i granični uslovi oscilovanja žice. Opisane razlike za enharmonski par tonova As2 i Gis2 mogu se uočiti i u prikazima njihovih spektara. Na slici 7 dat je prikaz tonova As2 i Gis2 odsviranih na harfi. Sa slike se može uočiti da na frekvencijama od 1000 Hz parcijali tonova As2 i Gis2 se razilaze za par Hz, što za posledicu ima različite vrednosti koeficijenta inharmoničnosti.



Osim razilaženja u frekvenciji inharmonijskih parcijala dolazi do pomeranja i „fantomskih“ parcijala koji su zavisni od osnovnih inharmonijskih parcijala.

Sl. 7 Prikaz spektra tonova As2 i Gis2 odsviranih na harfi

C. Poređenje procenje rednosti koeficijenta inharmoničnosti a tono e harfe, klavira i čembala



Koeficijent inharmoničnosti predstavlja kako kvalitativan tako i kvantitativan atribut tona žičanih muzičkih instrumenata. Sa ciljem opisivanja razlike između različitih klasa žičanih instrumenata izvršeno je poređenje koeficijenta inharmoničnosti tonova klavira, čembala i harfe. Na slici 8. prikazani su procenjeni koeficijenti inharmoničnosti za opseg tonova koji je zajednički za sva tri instrumenta, odnosno za tonove iz opsega od G1 do C6. S obzirom da se kod harfe ne može postići potpuna hromatika, kao kod klavira i čembala, pri izračunavanju koeficijenta inharmoničnosti tonova harfe, tonovi su birani tako da se njihove osnovne frekvencije slažu sa osnovnim frekvencijama tonova klavira i čembala. Takođe, koeficijenti *B* tonova harfe prikazani na grafiku određeni su pomoću specijalizovanog alata, a ne automatskom procedurom pomoću PDF algoritma. Na osnovu slike se može zaključiti da je trend krive koeficijenta inharmoničnosti za sva tri instrumenta očuvan. Vrednosti koeficijenta *B* tonova harfe iz nižeg registra se poklapaju sa vrednostima koeficijenta *B* klavira, što se objašnjava činjenicom da su žice od istog materijala, čak i poredive dužine. Takođe, činjenica da se u srednjem i višem registru vrednosti koeficijenata *B* harfe razlikuju i od koeficijenata *B* čembala i klavira može se opravdati različitim materijalom žice, gde su kod klavira i čembala žice metalne, a kod harfe od creva.

Sl. 8 Koeficijent inharmoničnosti *B* tonova harfe, čembala i klavira

Posledice različitih vrednosti koeficijenta inharmoničnosti za tonove klavira, čembala i harfe mogu se uočiti uporednom analizom spektra tonova pomenutih instrumenata. Na slici 9 dat je prikaz spektra tona iste frekvencije odsviranih na klaviru, čembalu i harfi. Na osnovu spektra signala može se uočiti da iako su tonovi istih frekvencija pozicije njihovih parcijala se razlikuju, što doprinosi različitim vrednositma koeficijenta inharmoničnosti. Takođe, poređenjem spektara tonova za tri navedena instrumenta može se zaključiti da je broj izraženih parcijala kod tona harfe manji u odnosu na broj izraženih parcijala klavira i čembala. Ta činjenica direktno utiče na vrednosti koeficijenata inharmoničnosti, s obzirom da se njegova vrednost procenjuje na osnovu frekvencija parcijala tonova, gde spektralno bogatstvo parcijala doprinosi niže procenjenoj vrednosti koeficijenta inharmoničnosti, a njihovo odsustvo utiče na povećanje procenjene vrednosti koeficijenta inharmoničnosti.

Sl. 9 Prikaz spektra tonova iste frekvencije odsviranih na klaviru, čembalu i harfi

V. ZAKLJUČAK

U ovom radu razmatran je koeficijent inharmoničnosti tonova harfe kroz prizmu automatske procene i specifičnosti koje prati data problematika. Formirana je baza snimaka koja se sastoji od 141 tonova odsviranih na harfi. Harfa je izabrana kao instrument u cilju proširivanja prethodnog istraživačkog rada i upotpunjavanja do sada formirane baze tonova žičanih muzičkih instrumenata. Koeficijent inharmoničnosti je računat na osnovu automatske procedure pomoću modifikovanog PFD algoritma. Pokazano je da za pojedine tonove iz nižeg registra harfe dobijene vrednosti koeficijenta inharmoničnosti na osnovu automatske procedure nisu dobro procenjene. Iz tog razloga realizovan je specijalizovani alat za analizu audio signala, pomoću koga se manuelnom inspekcijom može proceniti koeficijent inharmoničnosti tonova žičanih instrumenata. Novonastali specijalizovani alat otvara nove istraživačke mogućnosti, gde će nastavak istraživanja podrazumevati savladavanje problema automatske procene. Pored toga, kreirani alat otvara mogućnosti za proširivanje samog istraživanja dodavanjem mogućnosti ne samo analize tonova žičanih muzičkih instrumenata, već i njihove sinteze.

ZAHVALNICA

Ovaj rad je realizovan u okviru projekta TR36026 koji finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije. Zahvaljujemo se profesorki dr um. Mileni Stanišić na pomoći pri formiranju baze snimaka neophodnoj za ovo istraživanje.

ABSTRACT

This paper deals with the characterization of harp tones and presents continuation of research related to the string instruments characterization. The characterization of the harp tone is based primarily on the estimation of the inharmonicity coefficient. Inharmonicity is a property of the tones of string instruments and is reflected in the deviation of the partial frequencies from the integer multiple of the fundamental frequency. The accuracy of the automatic determination of the inharmonicity coefficient B is hampered by the existence of "phantom" partials which are consequences resulting from different physical processes that depend on the construction of the instrument, the excitation method, as well as the materials from which the strings are made. As a consequence of the instrument construction and the way the string is tightened, in harp multiple peaks in the spectrum are very pronounced, which makes it difficult to automatically calculate inharmonicity coefficient. The coefficient B was estimated using the PFD algorithm and compared with the values estimated using a purpose-built tool for manual estimation. The coefficient B values of the harp were compared with the values of the coefficient B of piano and harpsichord.

Inharmonicity coefficient of harp tones - pecificity and problems of automatic estimation

Implementacija algoritama za kontrolu usmerenosti zvučničkog niza sa dva glavna loba na otvorenom hardveru

Tijana Đorđević, Stefan Aćimović, Miloš Bjelić

***A stra t*— ovom radu pri azana je implementacija softverski usmerenih zvučničkih sistema. Softverski i hardvers i implementirani usmereni zvučnički sistemi, osim što povećavaju nivo zvu a u zadatom pravcu, takođe dovode i do smanjenja reverberacije. U implementaciji korišćeni su zvučnički niz i procesor na kome se izvršavaju tri različita algoritma za obradu signala. Prvo rešenje podrazumeva usmeravanje zvuka ka jednoj zadatoj tački, a drugo i treće rešenje podrazumevaju usmeravanje zvuka ka dvema tačkama koje su proizvoljno zadate. Akcenat rada je na drugom i trećem rešenju koja se koriste u slučajevima kada želimo da obezbedimo pokrivanje dva pravca u auditorijumu. Pored tri nezavisna algoritma u radu je pri azana i simulacija pomoću koje je moguće predvideti dijagrame usmerenosti u sva tri slučaja. Rezultati algoritma vantifi ovani su merenjem dijagrama usmerenosti po 1 oktavnim frekvencijskim opsezima. Biće pomenuti detalji implementacije i pojedinosti na oje treba obratiti pažnju prili om rada sa hardvers om platformom ela. radu su izložena poboljšanja koja su dobijena korišćenjem dva, umesto jednog snopa zvu a.**

***Ključne reči*—hardvers a platforma ela, dijagram usmerenosti, softverska kontrola usmerenosti, zvučnički niz.**

I. UVOD

Sa napretkom sistema za ozvučavanje i sa povećanjem zahteva korisnika sve je više istraživanja u oblasti softverski usmerenih zvučničkih sistema. Istorijski gledano pre ovih sistema nastali su sistemi koji su se na terenu podešavali tako što se od nekoliko zvučnika napravi niz koji je zakrivljen. Zakrivljenje niza omogućavalo je da se signali fazno usklade i da se maksimalna energija emituje u zadatom pravcu. Iako se ovi sistemi i danas koriste u mnogim aplikacijama, njihova nefleksibilnost je veliki problem. Potencijalno rešenje ovog problema može biti procesiranje signala koji se emituju na pojedinačnim zvučnicima. Glavna prednost ovih sistema je to što se usmeravanje zvuka može postići bez fizičkog pomeranja zvučnika. Promena željene tačke ka kojoj se fokusira zvuk može se uraditi bez menjanja položaja zvučnika. Zbog toga su ovi sistemi pogodni i za daljinsku kontrolu.

Tijana Đorđević – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: dt213283m@student.etf.bg.ac.rs).

Stefan Aćimović - Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: as213306m@student.etf.bg.ac.rs).

Miloš Bjelić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: bjelic@etf.rs).

Softverski usmereni zvučnički sistemi promenama kašnjenja signala za pojedinačne zvučnike usmeravaju zvuk ka željenoj tački. Ukoliko se signal ne procesira, maksimum će biti u osi koja je normalna na zvučnik, a pomenutim procesiranjem maksimum se pomera u željenom pravcu. Problem koji nastaje prilikom usmeravanja zvuka u jednom pravcu je izrazito jak bočni lob. Bočni lob se u mnogim slučajevima gotovo i ne razlikuje od glavnog loba. Na veličinu i širinu bočnog loba se ne može uticati, ona zavisi od frekvencije na kojoj se zvuk šalje, kao i rasporeda zvučnika na zvučničkom nizu. Teško je napraviti optimalnu geometriju zvučničkog niza koja bi za sve frekvencije podjednako dobro potiskivala bočne lobove U ovom radu će biti prikazana rešenja za softversko usmeravanje zvuka u jednom pravcu kao uvod u rešenja koja prikazuju pokrivanje dva pravca.

Do sada je u literaturi bilo pomena o implementaciji jednog loba [1]. U radu su prikazani dijagrami usmerenosti za 1/3 oktavne opsege čije su centralne frekvencije: 630 Hz, 1250 Hz, 2500 Hz i 4000 Hz. Takođe, neka istraživanja su se bavila i implementacijom algoritma za pokrivanje dva pravca [2], međutim, opseg signala koji je posmatran je ultrazvučni. Budući da će se ovi algoritmi koristiti za ozvučavanje, merenja u radu su izvršena u zvučnom opsegu. Za fokusiranje zvuka neophodan je zvučnički niz. Zvučnički nizovi se sastoje od nekoliko zvučnika raspoređenih na različite načine. Korišćeni su zvučnici koji su postavljeni duž y-ose i fokusiraju zvuk ka tački na željenoj visini. Zvučnički nizovi mogu biti sastavljeni od zvučnika sa različitim karakteristikama usmerenosti. Karakteristika pojedinačnih zvučnika utiče na formiranje dijagrama usmerenosti zvučničkog niza. Zvučnici koji se koriste u eksperimentu su kardioidni i to je neophodno implementirati u simulaciji.

Okosnicu ovog rada predstavlja implementacija sistema koji pokriva dva auditorijuma. Za ovu namenu dizajnirana su dva rešenja. Ideja prvog rešenja je da se polovina zvučnika koristi za usmeravanje signala ka jednoj tački, a druga polovina za usmeravanje signala ka drugoj tački. Budući da se za usmeravanje signala koristi samo polovina zvučnika, lobovi dijagrama usmerenosti će biti širi nego u slučaju kada usmeravanje vršimo sa svim zvučnicima. Drugo rešenje otklanja ovaj problem tako što koristi svih 8 zvučnika. Njegov glavni lob dijagrama usmerenosti za jedan pravac se praktično poklapa sa glavnim lobom u prvom slučaju kada se zvuk usmerava samo u jednom pravcu. U radu će biti prikazano poređenje rešenja kroz merne rezultate, kao i kroz simulaciju.

 ISBN 978-86-7466-930-3

Budući da se ovakvi sistemi koriste za ozvučavanje prostora neophodno je da oni rade u realnom vremenu. Ograničenje koje donosi ovaj zahtev je složenost algoritma. Poželjno je da algoritam bude što jednostavniji i da se odgovarajući parametri sistema prilikom izvršavanja algoritma na hardveru uzimaju iz memorije.

Primena pomenutih algoritama može biti u sistemima za ozvučavanje koncertnih sala, bioskopa i drugih objekata gde je neophodno pokrivanje dva pravca (parter i galerija). Takođe, moguće je da zvučnički niz bude ugrađen u TV i da u kućnim uslovima imitira *surround* sisteme.

II. METODOLOGIJA

U nastavku će biti prikazana tri različita rešenja za softversko usmeravanje zvučnika. Kao što je pomenuto, osim algoritma koji će se izvršavati na procesoru razvijena je i simulacija za proveru rešenja. Simulacija se sastoji od programa koji generiše jedinični impuls za svaki pojedinačni zvučnik. Signal se posmatra u nekoj tački na mestu prijema i zbog toga je potrebno uračunati kašnjenje i slabljenje usled pređenog puta. Takođe, neophodno je uračunati i usmerenost pojedinačnih zvučnika koja zavisi od ugla, te signal sa svakog pojedinačnog zvučnika pomnožiti sa tom vrednošću. Ukupan signal u nekoj tački računa se kao zbir signala sa svih zvučnika. Da bi se dobio signal po 1/3 oktavnim opsezima neophodno je na kraju filtrirati ukupan signal.

A. smera anje zvuka ka jednoj tački u prostoru

Prvo rešenje podrazumeva usmeravanje ka jednoj tački u prostoru. Da bi se ovo realizovalo neophodno je signale koji dolaze na ulaze Bela platforme obraditi i fazno uskladiti. Fazno usklađivanje ovih signala se vrši tako što se na različitim zvučnicima primeni različito kašnjenje. Kašnjenje zavisi od pozicije zvučnika i tačke ka kojoj se signal usmerava.

Računanje kašnjenja biće detaljno obrazloženo za ovo rešenje, a za ostala dva rešenja će biti pomenuta ograničenja i izmene. Na slici 1 prikazan je zvučnički niz i usvojeni koordinatni sistem. Centar koordinatnog sistema je sredina zvučničkog niza. Ugao φ je ugao između -ose i prave koja spaja koordinatni početak i tačku A. Tačka A predstavlja tačku u kojoj je potrebno fokusirati zvuk. Rastojanje između tačke A i koordinatnog početka je D. Koordinate tačke A računaju se na osnovu sledećih izraza:

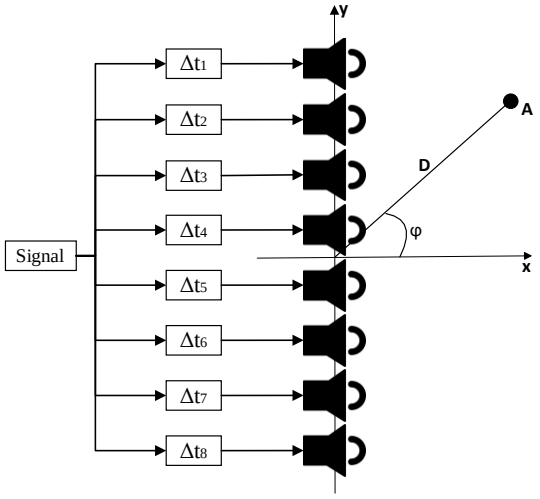
$$_A = \cdot\cos(\varphi) \quad (1)$$

$$y_A = \cdot\sin(\varphi) \quad (2)$$

Rastojanje između tačke A i zvučnika *i* računa se na sledeći način:

$$r_i = \sqrt{\left(_A - _i\right)^2 + \left(y_A - y_i\right)^2} \quad (3)$$

gde su $_i$ i y_i koordinate pojedinačnih zvučnika.

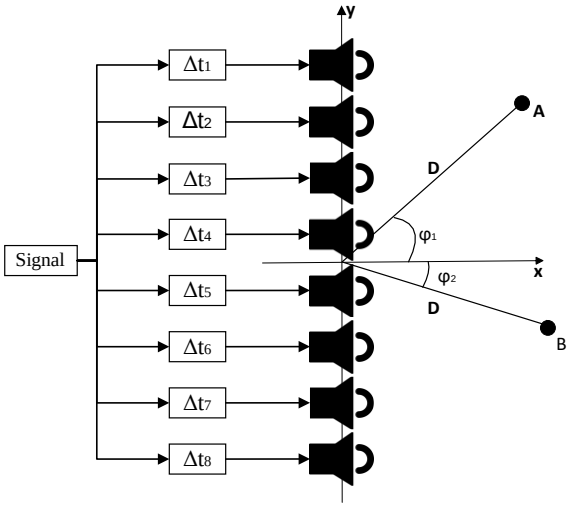


Ukoliko fazno ne uskladimo pojedinačne zvučnike, signal sa zvučnika 1 će prvi stići do tačke, a potom redom signali sa zvučnika 2, 3 itd. Kako bi se fazno uskladili signali neophodno je primeniti kašnjenja na svakom signalu. Kašnjenja se računaju prema sledećem izrazu:

$$\Delta t_i = \frac{r_{\max} - r_i}{c} \quad (4)$$

$$r_{\max} = \max\{r_i\}, i = 1, 2...N \quad (5)$$

gde je N ukupan broj zvučnika, u ovom slučaju 8, a c brzina prostiranja zvuka u vazduhu.



Problem prvog rešenja predstavljaju bočni lobovi. Prilikom usmeravanja signala veliki deo snage signala biva emitovan kroz bočni lob. Naredna rešenja zasnivaju se na dodavanju još jedne tačke ka kojoj će zvučnik usmeravati signal. Na ovaj način moguće je pokriti dva željena pravca zvukom. Primena se može naći u pokrivanju objekata koji se sastoje iz partera i balkona.

Sl. 1. Blok šema zvučničkog sistema za usmeravanje signala u jednom pravcu

B. smera anje uka ka d ema tačkama u prostoru sa odvojenim zvučnicima

Drugo rešenje podrazumeva da se signali na prva četiri zvučnika i poslednja četiri zvučnika posebno obrađuju. Ovaj sistem prikazan je na slici 2.

Sl. 2. Blok šema zvučničkog sistema za usmeravanje zvuka ka dvema tačkama sa odvojenim zvučnicima

Zvučnici označeni brojevima od 1 do 4 emituju zvuk ka tački A, a zvučnici označeni brojevima od 5 do 8 emituju

 ISBN 978-86-7466-930-3

zvuk ka tački B. Moguće je proizvoljno podesiti uglove φ_1 i φ_2, a oba ugla su iz opsega [-90˚,90˚]. Poželjno je da φ_1 bude veći od φ_2, jer je na taj način slabljenje signala minimalno, pošto je rastojanje između zvučnika i prijemnih tačaka minimalno. Kašnjenja se računaju pomoću izraza (5) sa razlikom kod r_{ma}. Maksimalna razdaljina računaće se pojedinačno za zvučnike označene sa 1 do 4 i pojedinačno za zvučnike označene sa 5 do 8.

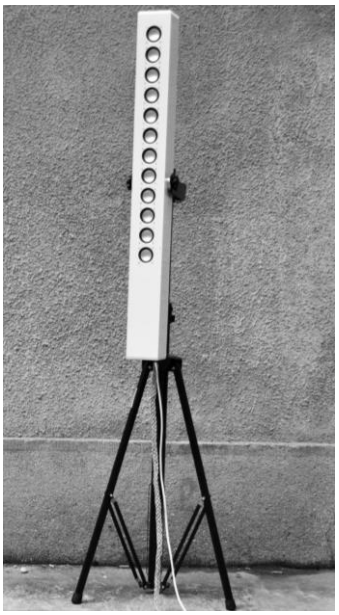
Prilikom implementacije se umesto 8 zvučnika koristi samo 4 za usmeravanje ka jednoj tački. Posledica ovoga su značajno širi glavni lobovi nego u prvom slučaju. Ovaj problem pokušavamo da prevaziđemo u narednom rešenju tako što umesto 4 koristimo svih 8 zvučnika za obe tačke.

C. Usmeravanje zvuka ka dvema tačkama u prostoru sa kombinovanim zvučnicima

U ovoj implementaciji koristiće se 8 zvučnika (slika 3) koji se usmeravaju ka dve nezavisne tačke.

Sl. 3. Blok šema zvučničkog sistema za usmeravanje zvuka ka dvema tačkama sa kombinovanim zvučnicima

Signali sa ulaza Bela platforme se obrađuju za svaku tačku pojedinačno, nakon čega se signali sabiraju za svaki pojedinačni zvučnik. Kašnjenja se računaju pomoću izraza (5), tako što se prvo posmatraju rastojanja do tačke A, a potom do tačke B. Ovim postupkom dobijamo 2 seta kašnjenja, posebno za tačku A i posebno za tačku B. Ova kašnjenja se nezavisno primenjuju na ulazni signal, potom se zakašnjeni signali sabiraju. Klipovanje se javlja kada je signal koji se prosleđuje funkciji *analogWrite* veći od 1 ili manji od 0. Prilikom sabiranja neophodno je skalirati signale sa faktorom 0.5 kako ne bi došlo do klipovanja na Bela platformi. Faktor skaliranja iznosi 0.5 jer se sabiraju dva signala u opsegu [0,1].



III. EKSPERIMENTALNA POSTAVKA

Prilikom realizacije ovog sistema korišćeni su: zvučnički niz, hardverska platforma Bela i računar. Signal se iz izvora audio signala vodi se na ulaz hardverske platforme Bela. U njoj se ulazni signal multiplicira 8 puta i svaka kopija se dalje nezavisno procesira i prosleđuje na odgovarajući pojačavač, a odatle na zvučnik.

A. Zvučnički ni

Zvučnički niz koji je korišćen sastoji se od *Genius* SP-D150 zvučnika. On sadrži 12 zvučnika sa kardioidnom karakteristikom usmerenosti. Prilikom eksperimenta biće korišćeno samo 8 zvučnika jer je to maksimalan broj audio izlaza kod audio ekspandera na hardverskoj platformi Bela. Zvučnici se nalaze na rastojanju od 6 cm. Unutar zvučničke kutije su osim zvučnika smešteni i pojačavači. Pojačavači se napajaju iz jednosmernog izvora za napajanje napona 9 V. Frekvencijska karakteristika jednog zvučnika koji je ugrađen u sistem je približno ravna na frekvencijama većim od 300 Hz [3].

Pre samog eksperimenta neophodno je sprovesti kalibraciju zvučnika. Potrebno je normalizovati nivoe signala tako da svi zvučnici za istu pobudu emituju isti nivo signala. Na slici 4 prikazan je zvučnički niz.

Sl. 4. Zvučnički niz

B. ard erska platforma Bela

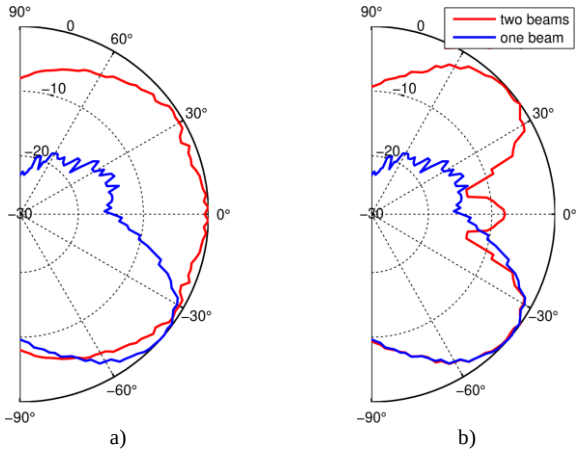
Hardverska platforma Bela je *open source single-board* uređaj za obradu signala. Bela se sastoji od platforme Beagle-Bone i namenske nadploče Bela. BeagleBone platforma je Linux kompatiblni sistem čiji je centralni deo ARM Cortex-A8 procesor sa 512MB RAM-a. Glavna prednost pri korišćenju Bele je malo kašnjenje koje će omogućiti da se reprodukcija zvuka odvija u realnom vremenu. Hardverska platforma Bela ima 2 stereo ulaza i 2 stereo izlaza za audio signal, zbog čega je neophodno koristiti audio ekspander [4]. Audio ekspander je dodatak koji povećava broj audio ulaza i izlaza. Na slici 5 prikazana je hardverska platforma Bela sa audio ekspanderom. Audio ekspander ima dodatne priključke na koje je moguće dovesti audio signal koji će nakon obrade biti prosleđen na analogne ulaze hardverske platforme Bela. Pre početka rada neophodno je povezivanje pojedinih pinova na audio ekspanderu. Konektori obezbeđuju vezu između audio ulaza ekspandera i analognih ulaza hardverske platforme Bela. Audio ulazi ekspandera su povezani sa

 ISBN 978-86-7466-930-3

analognim ulazima hardverske platforme Bela, te će se ovom signalu pristupati uz pomoć funkcija *analog ead* , *analogWrite* i *analogWrite nce* .

Sl. 5. Hardverska platforma Bela sa audio ekspanderom

Korišćenje 8 audio izlaza uvodi dodatno ograničenje kada je u pitanju frekvencija odabiranja. Umesto 44.1 kHz, frekvencija odabiranja biće 22.05 kHz. Bela platforma podržava objektno-orijentisanu paradigmu. Jezik u kome je pisan algoritam je C++. Poznato je da su jezici C/C++ daleko brži od ostalih zbog mogućeg direktnog pristupa memoriji i njenim registrima. Ovo doprinosi brzini izvršavanja algoritma na hardverskoj platformi Bela koja je ključna za *real-time* sisteme. Jezici koji se mogu koristiti su *Csound* i *SuperCollider*, a grafički interfejs se može pisati u *a aScript*-u.



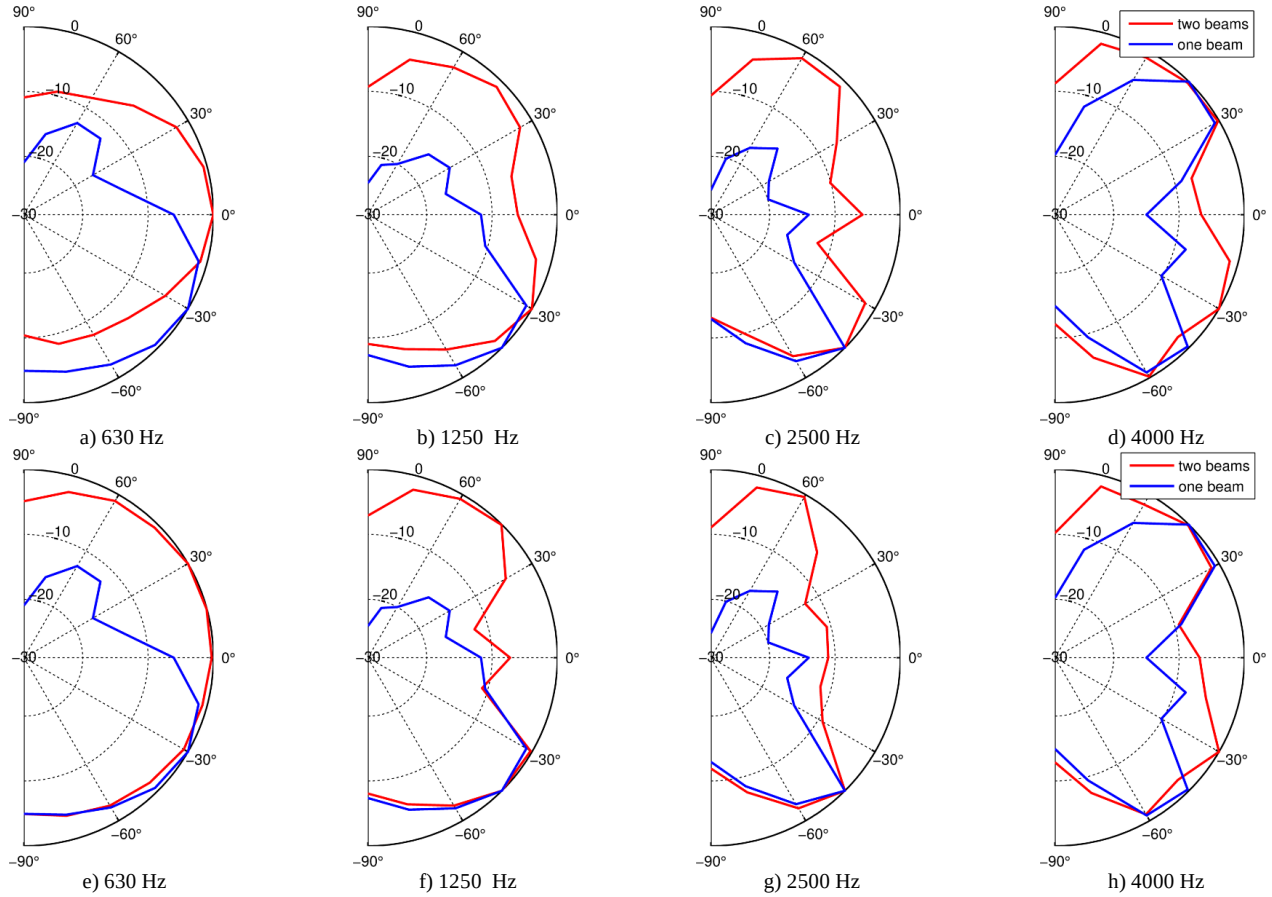
Ukoliko se u softveru ne izabere opcija za korišćenje audio ekspandera signal će biti u opsegu [0,1] i imaće jednosmernu komponentu od približno 0.44 V. To je posledica toga što Bela signale sa audio ekspandera čita kao analogne, a ne kao audio. Podešavanjima parametara na samoj platformi moguće je podesiti da ekspander automatski skalira signal sa [0, 1] na [-1, 1] i eliminiše jednosmernu komponentu.

Hardverska platforma Bela obrađuje blok po blok ulaznog signala i šalje ga na izlaz. Ovo Belu čini sistemom za obradu signala u realnom vremenu. Signal koji se pojavi na pinovima automatski se smešta u bafer, odakle biva iščitan uz pomoć pomenutih funkcija za analogne signale.

IV. Eksperimentalni rezultati

Na slici 6 prikazani su rezultati simulacije za 1/3 oktavni frekvencijski opseg sa centralnom frekvencijom 1250 Hz za različite algoritme implementirane u ovom radu. Sa slike 6 a) se jasno vidi problem širine lobova kod rešenja u kom se koriste odvojeni zvučnici za formiranje dva glavna loba. Na slici 6 b) je rešenje sa kombinovanim zvučnicima kod koga možemo uvideti da rešava pomenuti problem.

Merenje je izvršeno u anehoičnoj sobi na Elektrotehničkom fakultetu. Za eksperiment je korišćen neusmereni merni mikrofon [5]. Snimane su vertikalna i horizontalna karakteristika usmerenosti zvučničkog niza. Mikrofonom je meren nivo zvuka u tačkama na zamišljenoj kružnici poluprečnika . Rezolucija merenja je 15˚.



Sl. 6. Vertikalni dijagram usmerenosti zvučničkog niza na frekvenciji 1250 Hz za algoritam: a) sa odvojenim zvučnicima, b) sa kombinovanim zvučnicima.

Signal koji se šalje na procesor je MLS (Maximum-Length Sequence) sekvenca [6]. Poznato je da zvučnički nizovi kod kojih su zvučnici raspoređeni samo po jednoj dimenziji nisu u stanju da usmeravaju zvuk van te dimenzije. U eksperimentu zvučnik je postavljen vertikalno, te on nije u stanju da usmerava zvuk horizontalno. To je potvrđeno i u eksperimentima, horizontalni dijagram usmerenosti se ne menja korišćenjem algoritama za prostorno-vremensku obradu signala.

Na slici 7 prikazani su rezultati merenja pomenutih algoritama za različite opsege. Na slikama od a) do d) prikazani su dijagrami usmerenosti na različitim frekvencijama za prvo i drugo rešenje. Plavom bojom označeni su dijagrami usmerenosti za prvo, a crvenom bojom za drugo rešenje. U prvom rešenju signal se usmerava ka jednoj tački u prostoru koja se nalazi na rastojanju 2 m od centra zvučničkog niza i pod uglom od -45˚. Drugo rešenje predstavlja usmeravanje zvuka ka dve tačke sa odvojenim zvučnicima. Tačke se nalaze na rastojanju od 2 m pod uglovima od -45˚ i 45˚. Na slikama od e) do h) prikazani su dijagrami usmerenosti za prvo i treće rešenje. Plavom bojom je označen dijagram usmerenosti prvog, a crvenom trećeg rešenja. Treće rešenje podrazumeva usmeravanje signala ka dve tačke u prostoru sa svih 8 zvučnika. Tačke prema kojima se usmerava su identične kao i za prethodni slučaj.

Posmatrajući dijagrame usmerenosti za prvo rešenje dolazimo do određenih zaključaka. Merenja pokazuju da je zbog velike talasne dužine usmeravanje signala na niskim frekvencijama jedva primento. Na višim frekvencijama usmeravanje signala se povećava, ali se povećava i veličina bočnih lobova. Sa slika se može videti da su u opsegu 4000 Hz glavni i sporedni bočni lob gotovo jednaki. Usmeravanje signala ka jednoj tački dovelo je do neželjenog usmeravanja signala ka još jednoj tački u prostoru. Na ovaj način gubi se deo energije, budući da se ne emituje u željenom pravcu. Izgled bočnog loba zavisi od frekvencije i rastojanja između zvučnika na zvučničkom nizu, te na to ne možemo uticati.

 ISBN 978-86-7466-930-3

Sl. 7. Vertikalni dijagram usmerenosti zvučničkog niza u slučaju usmeravanja zvuka ka jednoj tački (plava boja) i u slučaju usmeravanja zvuka ka dvema tačkama sa odvojenim zvučnicima na frekvencijama a) 630 Hz b) 1250 Hz c) 2500 Hz i d) 4000 Hz i u slučaju usmeravanja zvuka ka dvema tačkama sa kombinovanim zvučnicima na frekvencijama e) 630 Hz f) 1250 Hz g) 2500 Hz i h) 4000 Hz

Drugo i treće rešenje pokazuju da je moguće istovremeno softverski uticati na pravce u kojima će se signal emitovati. Ova rešenja su primenjiva u situacijama kada želimo da direktnim zvukom pokrijemo više različitih auditorijuma. Kao i kod prvog rešenja na nižim frekvencijama usmerenost je relativno mala, a na višim frekvencijama se uočava jasna pojava dva loba pod uglovima od -45˚ i 45˚. Problem koji se javlja kod drugog rešenja jeste velika širina lobova na visokim učestanostima. Do smanjenja usmerenosti dovodi korišćenje samo polovine zvučnika. Treće rešenje koje je pomenuto rešava ovaj problem. Korišćenje svih osam zvučnika daje mogućnost boljeg usmeravanja signala. Možemo primetiti da su u ovom slučaju lobovi uži u odnosu na prethodni slučaj. Takođe, lobovi u ovom rešenju se gotovo podudaraju sa širinom glavnog loba iz prvog rešenja.

V. Zaključak

Rezultati koji su dobijeni prikazuju da je moguće softverskom obradom signala upravljati širinom i pozicijom snopova signala. Pokazano je da je moguće dodati još jedan nezavisni snop signala bez kvarenja već postojećeg snopa. Takođe, rešen je problem koji se javlja prilikom korišćenja polovine zvučnika za usmeravanje zvuka ka dvema tačkama. Značaj dobijenih rezultata leži u činjenici da su ova rešenja primenjiva u praksi. Rezultati eksperimenata pokazuju dobro poklapanje sa rezultatima simulacije, čime je potvrđena validnost simulacionog modela.

Budući rad će obuhvatati rešenja kod kojih će se drugačije računati kašnjenja. Moguće je za konkretnu geometriju niza i konkretan frekvencijski opseg naći optimalna kašnjenja pomoću optimizacionog algoritma. Kašnjenja bi se razlikovala u zavisnosti od uslova koji bi se postavio. Neki od uslova bi mogli biti da odnos glavnih i bočnih lobova bude minimalan ili da širina lobova bude minimalna.

Na samom početku rada pomenuto je da je nemoguće u potpunosti eliminisati bočne lobove jer oni nisu samo posledica frekvencije na kojoj se signal šalje, već i geometrije niza. Još neka poboljšanja postojećih rešenja mogla bi se ogledati u tome da je moguće odrediti kojih 8 od 12 zvučnika je optimalno koristiti na zvučničkom nizu da bi se smanjio uticaj bočnih lobova. Takođe, problem bočnih lobova je moguće rešiti optimalnim rasporedom zvučnika na zvučničkom nizu, odnosno menjanjem geometrije niza.

Zahvalnica

Ovaj rad je realizovan u okviru projekta TR 36026 koga finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

This paper presents the implementation of software-oriented speaker systems. Software and hardware implemented directional speaker systems, in addition to increasing the sound level in a given direction, also lead to a reduction in reverberation. The implementation used a speaker array and a processor on which three different signal processing algorithms are executed. The first solution involves directing the sound to one set point, and the second and third solutions involve directing the sound to two points that are arbitrarily set. The emphasis of the paper is on the second and third solutions used in cases when we want to provide coverage of two directions in the auditorium. In addition to three independent algorithms, the paper also presents a simulation that can be used to predict directional diagrams in all three cases. The results of the algorithm were quantified by measuring the directivity diagrams in 1/3 octave frequency bands. The details of the implementation and the details to pay attention to when working with hardware Bela platform will be mentioned. The paper presents the improvements obtained by using two, instead of one sound beam.

Implementation of spea er array directional control algorithms with two main lobes on open hardware

Optimizacija pozicija zvučnika u zvučničkom nizu

Stefan Aćimović, Tijana Đorđević, Miloš Bjelić

Abstract— **Optimizacioni algoritmi sve više nalaze primenu o raznim oblastima, kako nauke, tako i života. Uz analizu softverske kontrole usmerenosti zvučničkog sistema javila se i potreba za optimizacijom već postojećih rešenja. U ovom radu prikazano je kako se na više načina može doći do rešenja 2D optimizacione funkcije, gde se najbolje rešenja bira iz niza dovoljno dobrih. radu je pri azan algoritam za prostorno-vremensku obradu signala koji omogućava upravljanje dijagramom usmerenosti u verti alnoj ravni. Poboljšanje postojećih rezultata izvršeno je uz pronalaženje linearne pozicije 1 zvučnika u zvučničkom stubu, tako da njegov dijagram usmerenosti bude što usmereniji za određeni prostorni ugao i da je odnos glavnog i bočnih lobova što veći. a ove rezultate oristili su se parametri u vidu dva oeficijenta oji su dovoljno dobro opisivali kvalitet rešenja, tako što se svako rešenje smeštalo u funkciju, a nalaženje najboljih se sprovodilo preko Pareto fronta. Popunjavanje tačaka, odnosno rešenja dodatno se ubrzalo sa genetičkim optimizacionim algoritmom koji je u znatno manje iteracija doveo do jedna o dobrog rešenja kao i metod slučajnog generisanja potencijalnog rešenja.**

Ključne reči — **algoritmi, obrada signala, optimizacija, pareto front, genetički algoritam, softverska kontrola, usmerenost, zvučnički niz.**

I. UVOD

Zvučnički sistemi koji se koriste u sistemima za ozvučavanje treba da prenesu zvučni sadržaj do slušalaca koji se nalaze u određenom delu prostora. Zvučna energija koja odlazi u deo prostora na kome nema slušalaca na otvorenom prostoru predstavlja gubitak, a u prostorijama ima negativne posledice na percepciju zvuka jer dodatno pobuđuje reverberacioni proces. Zbog toga se u sistemima za ozvučavanje koriste usmereni zvučnički sistemi da bi se najveći deo zvučne snage slao u prostor gde se nalaze slušaoci. Usmereni zvučnički sistemi podrazumevaju da se grupa zvučnika nalazi na jednoj lokaciji i da su koncentrisani u jedinstven sistem. U ovu grupu zvučničkih sistema, na primer, spadaju takozvani *ine array* sistemi, kod kojih se usmerenost postiže tako što je zvučnička skupina zakrivljena, to jest pojedinačni zvučnici se nalaze na različitim udaljenostima od mesta prijema [1].

Zvučnički nizovi čiji se dijagram usmerenosti obradom signala usmerava postaju sve popularniji i tema su ovog rada. Ideja rada je razmatranje načina kako da se gubitak zvučne energije minimizira. Rešenje koje se razmatra u ovom radu je optimizacija pozicija 16 zvučnika, koji stoje u istoj osi, ali na različitim rastojanjima. U sličnim radovima iz ove oblasti predstavljena su uglavnom rešenja sa uniformnom raspodelom zvučnika ili sa jednostavnijom računicom koja je vezana za liniju kašnjenja i odgovarajuću raspodelu zvučnika. Metod nalaženja najboljih pozicija zvučnika u zvučničkom stubu svodi se na tehnike optimizacije 2D funkcije i nalaženja skupa pogodnih rešenja koja zajedno čine pareto front. Baš zbog prirode problema koja zahteva da se dve stvari optimizuju, a koje su zavisne. Pareto front se uveo kao potencijalni alat za rešavanje ovog problema. U ovom radu je služio kao kriterijum za ocenjivanje skupa rešenja od kojih je odabrano ono najpovoljnije. Pošto Pareto front daje skup (front) rešenja gde je svako podjednako dobro, komparativnom metodom je utvrđeno koje rešenje je dovoljno dobro za predstavljeni problem [2].

Od celog fronta bira se jedino rešenje, tako da najmanje šteti uslovima optimizacije. Uslovi su da je odnos glavnog i bočnog loba što veći (što bi značilo da je gubitak energije manji) i da je širina glavnog loba što manja (odnosno da je što više moguće usmeriti zvučnički niz po svim oktavnim opsezima i za sve zadate uglove).

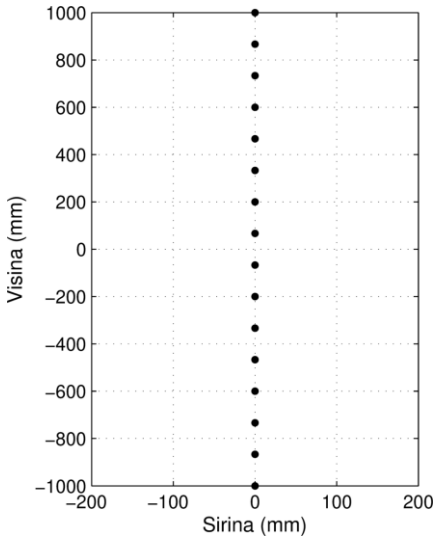
Metode optimizacije koje su se koristile u ovom radu jesu slučajno generisanje rešenja u pareto front, kao i genetički algoritam [3]. Oba algoritma se svode na skupinu koeficijenata koji na neki način opisuju trenutno rešenje i koliko dobro ono zadovoljava oba gore pomenuta uslova, zatim se od najboljih mogućih rešenja, koja su sastavljena u front, odabira najbolje moguće. Ovakvo rešenje proverava se za sve uglove od značaja, kao i da li se može fizički realizovati, odnosno da nema preklapanja jednog zvučnika preko drugog. Uglovi od značaju su nam oni uglovi koji se koriste i kada se fizički usmeravaju nizovi zvučnika na većim ili manjim prostorima, okvirna granica može biti od 30° do 60°. Metode provere svode se na poređenje već postojećih rešenja sa uniformnom raspodelom zvučnika, kao i na prethodna dobijena rešenja, kako preko algoritma, tako i preko drugih radova iz literature.

II. METODOLOGIJA

A. Zvučnički niz i dijagram usmerenosti

Za definisanje problema optimizacije potrebno je uvesti element koji je povoljan, tako da se lako može vršiti obrada nad njim u softverskom, a i da se rezultat može primeniti i u

Stefan Aćimović - Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: as213306m@student.etf.bg.ac.rs).



Tijana Đorđević – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: dt213283m@student.etf.bg.ac.rs).

Miloš Bjelić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: bjelic@etf.rs).

 ISBN 978-86-7466-930-3

hardverskom delu sistema. Metodologija koja je primenjena u ovom radu jeste menjanje relativnih pozicija svih 16 zvučnika, zatim računanje dijagrama usmerenosti koji se posle delom pretvara u koeficijente koji su služili za dalju optimizaciju.

Na slici 1 prikazana je pozicija zvučnička u uniformnom raspodelom pozicija zvučnika. Dimenzija zvučničkog niza koja je definisana u ovom radu je 2 metra. Na osnovu poznatih pozicija zvučnika i poznavanja njihovog dijagrama usmerenosti moguće je dobiti dijagram usmerenosti zvučničkog niza [4]. Adekvatnom obradom signala za pojedinačne zvučnike moguće je izvršiti usmeravanje glavnog loba u dijagramu usmerenosti za željeni prostorni ugao. Na slici 2 prikazan je izgled dijagrama usmerenosti uniformnog niza za određeni prostorni ugao [5].

Sl. 1. Raspored zvučnika za uniformnu geometriju zvučničkog stuba

Sl. 2. Dijagram usmerenosti uniformnog zvučničkog niza za prostorni ugao - 30° i 1/3 oktavni frekvencijski opseg 1250 Hz

Bočni lobovi predstavljaju problem u smislu gubitka energije, jer je cilj imati što usmereniji glavni lob [6], a idealno bi bilo da bočni lobovi budu maksimalno potisnuti. Kod uniformne raspodele zvučnika jasno se može videti da energija koju ima bočni lob samo oko 10 dB manja u odnosu na glavni lob za frekvencije već oko 1000 Hz, što se i vidi na Sl. 4. Sa povećavanjem frekvencije glavni i bočni lob postaju jednaku. Svaki rezultat koji za cilj ima da smanji odnos glavnog i bočnog loba čak i za 1 dB može se smatrati kao povoljnim rešenjem, jer je početna tačka odnosa lobova na nuli. Uz algoritme optimizacije dokazano je u radu da se bočni lob može smanjiti čak i do 10 dB.

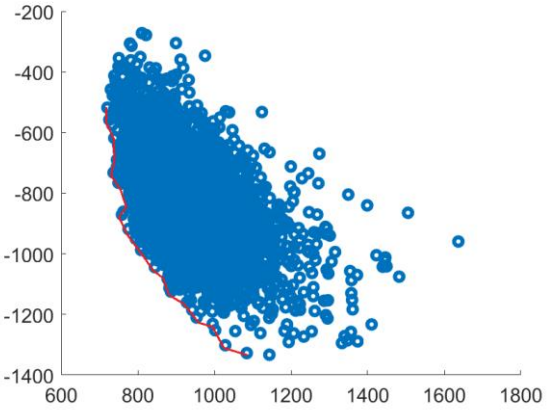
B. Pareto front i slučajno generisana geometrija

Kod pristupa slučajnog generisanja pozicija zvučnika u zvučničkom nizu pozicije su generisane iz skupa [-1, 1] metar, što su maksimalne dimenzije zvučničkog niza. Na osnovu dobijene geometrije izračunava se dijagram usmerenosti, usmeren za odrešeni prostorni ugao. Zatim je na osnovu dobijenog dijagrama moguće izračunati koeficijente sa kojima se opisuje širina glavnog loba, odnosno njegova usmerenost, kao i odnos glavnog i najvećeg bočnog loba. Koeficijenti se izračunavaju na osnovu sledećeg izraza:

$$\alpha = \begin{cases} 0.5 * \ [n],\ n \in \left[0, \frac{1}{3} * end\right] \\ [n],\ n \in \left[\frac{1}{3} * end, end\right] \end{cases}$$
$$\beta = \begin{cases} [n],\ n \in \left[0, \frac{1}{3} * end\right] \\ 0.5 * \ [n],\ n \in \left[\frac{1}{3} * end, end\right] \end{cases} \quad (1)$$

gde su α i β koeficijenti kojima se opisuju frekvencijski koraci od po 50 Hz za odnos glavnog i bočnog loba, kao i usmerenost glavnog loba respektivno. Ovde se jasno vidi da postupak optimizacije zapravo zavisi od dva parametra koja nisu nezavisne, već zajedno prave potencijalnu skupinu rešenja koja se može predstaviti u 2D površi. Za rešavanje ovog problema uveden je Pareto front.

Pareto front (koji se takođe naziva Pareto granica ili Pareto skup), koristi se u višedimenzionoj optimizaciji i predstavlja skup svih Pareto efikasnih rešenja. Koncept se široko koristi u inženjerstvu. Omogućava se ograničenje pažnje na skup efikasnih izbora, te je umesto da se razmatra čitav opseg svakog parametra, pravljenje kompromisa u okviru ovog skupa jedna od stvari koje su neizbežne i neophodne.



Pareto front se može lako opisati kao pomoć u odabiru velikog niza kolača od kojih svaki ima određenu vrednost koliko je ukusan i koliko kalorija vredi. Te dve vrednosti su povezane i ne mogu se nezavisno menjati, obično što je kolač ukusniji, to više kalorija ima. Pareto front nam služi da od gomile kolača odaberemo nekoliko ili jedan koji će biti dovoljno sladak i imati onoliki broj kalorija koji možemo da pojedemo a da se ne osećamo loše. Za taj broj kalorija pareto nam sigurni može tvrditi da smo izabrali najslađi kolač i obrnuto, za kolač odabrane slatkoće nam može tvrditi da od ostalih kolača iste slatkoće, mi smo definitivno izabrali onaj sa najmanje kalorija.

Koeficijenti koji su primenjeni ovde dobijeni su empirijski gde se uz nekoliko eksperimenata dobilo saznanje o tome koji

 ISBN 978-86-7466-930-3

je skup frekvencija više, a koji je manje važan za određivanje najbolje moguće pozicije zvučničkog niza.

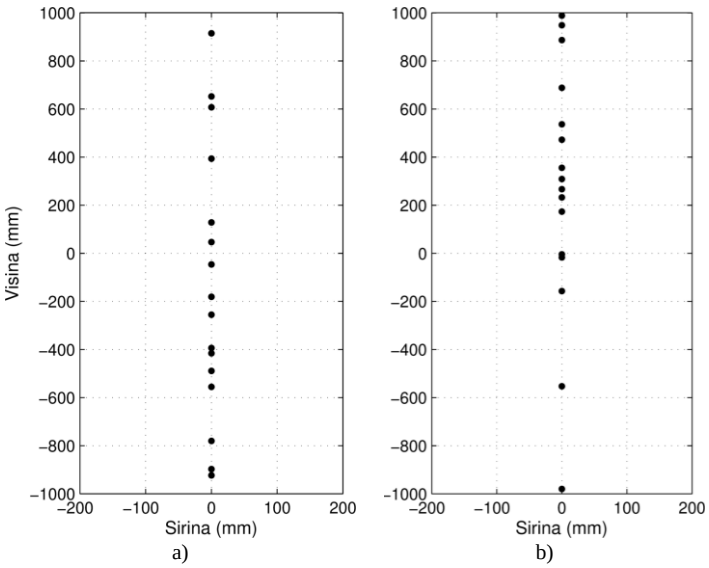
Na slici 3 prikazan je skup rešenja koji se dobiju bilo za slučajno generisanje zvučničkog niza ili uz genetički algoritam. Svaka tačka predstavlja rezultat jedne geometrije koja se uz formulu koeficijenata stavlja na 2D *scatter* rezultat. Crvena linija predstavlja Pareto front odnosno sva rešenja koja su podjednako dobra. Cilj nam je da vrednosti na obe ose budu što manje, ali se uglavnom smanjivanjem jedne vrednosti povećava ona druga [7]. Za rešenja koja su povoljna ovom radu uzimao se kriterijum gde je značajnije imati smanjenje od 1 dB bočnog loba nego povećanje usmerenosti glavnom loba za 1˚. Apsica predstavlja rezultate koeficijenta koji opisuje usmerenost glavnog loba, dok ordinata predstavlja rezultate odnosa bočnog i glavnog loba. Na ovom primeru bi neko potencijalno rešenje bilo više prema desnoj strani Pareto fronta.

Sl. 3. Pareto front koji prikazuje povezanost oba uslova, širinu glavnog loba i odnos glavnog i bočnog loba zajedno sa koeficijentima.

C. Genetički algoritam

Koeficijenti primenjeni u ovom pristupu dobijeni su empirijski gde se uz nekoliko eksperimenata dobilo saznanje o tome koji je skup frekvencija više, a koji je manje važan za određivanje najbolje moguće pozicije zvučničkog niza. Pored slučajne raspodele rešenja koristio se modifikovani genetički algoritam, čiji su osnovni principi uvek isti, ali se za ovaj problem algoritam u nekim delovima razlikuje od klasičnog pristupa. Genetički algoritam veoma je popularan optimizacioni algoritam i njegova rasprostranjenost i primena je velika. Od NASA antene koja prikuplja i šalje zrake određenih frekvencija sa najmanjim gubicima do svih omiljenih stvari koje možete staviti u kofer za avion, a da one ne prevaziđu određenu težinu [8].

Jasno je da se genetički algoritam koristi za traženje optimalnog rešenja od gomile ponuđenih uz dodatne uslove. Osnovni koraci genetičkog algoritma su sledeći:



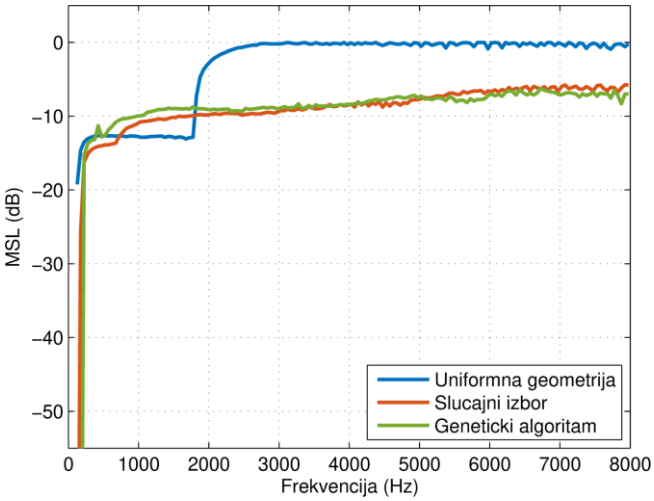
- Nulta generacija (skup genoma)
- Fitnes funkcija
- *Crosso er* funkcija
- Odabir novih genoma
- Mutacija (opciono)
- Nova generacija

Algoritam radi po gore pomenutim tačkama, gde je nulta generacija zapravo populacija slučajno izabranih distanci zvučnika zvučničkog niza. Sam početak je isti kao i za generisanje slučajnih pozicija zvučnika. Fitnes funkcija ovde je predstavljena na način koliko dobro jedan genom, odnosno raspodela zvučničkog niza daje rezultat u vidu tačke pareto fronta. Svaki zvučnički niz nulte generacije prolazi kroz ovu funkciju. Nakon toga se odabiraju dva najbolja iz generacije i šalju se na *crosso er* funkciju. Jedinke, odnosno zvučnički nizovi koji se šalju na *crosso er* funkciju nazivaju se roditelji, a njihovi rezultati ukrštanja, deca. Roditelji se ukrštaju tako što se na slučajnom mestu prepolovi zvučnički niz i od tog mesta se zameni sa drugim rediteljem, isto tako se dešava i za drugog roditelja.

Nakon ovih rezultata odabiraju se ostali genomi koji će na neki način učestvovati u sledećoj generaciji. Tehnika koja je rađena u ovom radu jeste tehnika turnira, gde se nasumično biraju dva genoma, te onaj sa boljom fintes funkcijom ide u turnir, postupak se ponavlja, te se onda dva pobednika vode na *crosso er* funkciju, njihova deca se šalju u novu generaciju. Neki genomi generisani su ponovo slučajno i dodati u novu generaciju. Nakon toga postoji i opciona mutacija koja sa malom verovatnoćom menja jedan deo jednog slučajnog broja genoma, odnosno poziciju jednog od zvučnika u celom zvučničkom nizu. Tako se dobija nova generacija i ceo postupak se ponavlja ponovo kao i za nultu generaciju genoma.

III. REZULTATI I DISKUSIJA

Na slici 4 su prikazani rezultati slučajnog rasporeda zvučnika i rasporeda zvučnika dobijenog genetičkim algoritmom.



Sl. 4. Raspored zvučnika na osnovu rezultata algoritma: a) Slučajni raspored i b) Genetički algoritam

Na osnovu prikazanih geometrija izračunati su parametri pomoću kojih je moguće proceniti kvalitet rešenja: odnos glavnog i maksimalnog bočnog loba (MSL) i širina glavnog loba (BW). Ovi parametri izračunati su za frekvencijski opseg

 ISBN 978-86-7466-930-3

od interesa i za prostorni ugao od -30 stepeni za glavni lob. Na slici 5 je prikazana frekvencijska zavisnost parametra koji predstavlja odnos glavnom i najvećeg bočnog loba.

Kod pristupa rešavanja gde su se pozicije zvučničkog niza sasvim slučajno generisale dobijene su znatno niže vrednosti bočnih lobova, za gotovo ceo frekvencijski opseg. Isti slučaj daje i genetički algoritam, što je bio cilj. U odnosu na uniformnu raspodelu jasno se vidi da slučajno generisanje daje daleko bolje rezultate za bilo koji frekvencijski opseg, a da time nije narušilo usmerenost glavnog loba, što znači da definitivno postoji kombinacija rasporeda zvučnika u zvučničkom nizu koja se može i hardverski realizovati, isti rezultat u odnosu na uniformnu raspodelu zvučnika vidi se i sa genetičkim algoritmom. Sa slike 5 se vidi da se za slučajno generisanje nešto bolji odnos lobova vidi na nižim frekvencijama, dok kod viših dominira genetički algoritam. Oba rešenja se mogu smatrati za dobrim, jer je razlika ovih rešenja između 1 dB do 2 dB u nekim frekvencijskim opsezima. Važna napomena je ta da je za generisanje rešenja slučajne raspodele bilo potrebno preko 200000 iteracija algoritma, dok se sličan rezultat postigao sa 1500 iteracija genetičkim algoritmom.

Sl. 5. Frekvencijska zavisnost nivoa bočnih lobova zvučničkog niza

Sl. 6. Frekvencijska zavisnost nivoa bočnih lobova zvučničkog niza

Zvučnički niz dobijen slučajnim generisanjem pozicija zvučnika predstavlja daleko bolje rešenje od uniformne raspodele pozicija. Ovakvo rešenje može se dobiti uz veliki broj različitih rešenja i svođenja rezultata na front, bez ikakve dodatne optimizacije, koja bi ta rešenja dalje poboljšavala. Već sa ovim pristupom može se pokazati da za 16 zvučnika, sa kardioidnom usmerenosti postoje rešenja softverskog usmeravanja zvučnika takva da je u svim oktavnim opsezima od važnosti odnos glavnog i bočnog loba iznosi približno 10 dB. Prednost uniformne raspodele zvučnika je ta što na različitim uglovima usmerenosti ona daje jako malu širinu glavnog loba, što se može videti na prikazanom grafiku. Rešenje koje je dobijeno slučajnim generisanjem rešenja, ne samo da je bolje u smislu odnosa lobova, nego je i zadržalo visok nivo usmerenosti glavnog loba na svim frekvencijskim opsezima. Kao jedna od mera za izbor povoljnog rešenja bio je i kriterijum da je razlika bočnog i glavnog loba od dodatnih 2 dB znatno bitnija nego smanjenje usmerenosti glavnog loba za 2°.

Rezultati dobijeni genetičkim algoritmom su veoma slični rezultatima slučajne raspodele, samo što postoji jedna važna razlika razlika koja se ogleda u vremenu izvršavanja algoritma. Vreme koje je bilo potrebno računaru da dođe do optimalnog rešenja sa slučajnom raspodelom bilo je tri dana, dok je genetički algoritam došao do jednako dobrog rešenja za sat vremena.

IV. ZAKLJUČAK

Dobijeni rezultati jasno prikazuju da su rešenja dobijena optimizacijom na oba načina daleko bolja od polaze situacije. Sa softverskom simulacijom je pokazano da se na različite načine može doći do rešenja koje u većini delova frekvencijskog spektra od značaja uspeva da suzbije bočni lob za čak 10dB, a da pritom ne šteti povećanju širine glavnog loba.

Budući radovi koji se zasnivaju na modernijim metodama optimizacije stoje na raspolaganju. Potrebno je uvesti dodatna ograničenja na algoritam, tako da se definitivno omogući i hardverska realizacija rešenja. Pored biranja najbolje pozicije zvučnika u zvučničkom nizu, takođe se javlja mogućnost da se odabiraju i najoptimalnija kašnjenja sa istim i sličnim algoritmima sa kojima se dolazilo do gore pomenutih rešenja.

Zbog fizike problema, na niskim frekvencijama je jako teško dodatno usmeriti glavni lob, a da to ne utiče na povećanje odnosa glavnog i bočnog loba, pogotovo na višim frekvencijama. Takođe se vidi i da se bočni lobovi nikada ne mogu potpuno suzbiti, te se gubitak energije može samo optimalno smanjiti. Ovaj rad samo otvara novo poglavlje u kome je optimizacija ponovo našla svoju primenu, a ostavlja skup mogućnosti i ideja kojima se ovakvi problemi mogu dodatno razložiti i potencijalno još bolje i efikasnije rešiti.

ZAHVALNICA

Ovaj rad je realizovan u okviru projekta TR 36026 koga finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

Optimization algorithms are increasingly being applied in various fields, both science and life. Along with the analysis of the software control of the direction of the speaker system, there was also a need to optimize the already existing solutions. In this paper, it is shown how the solution of the 2D optimization function can be reached in several ways, where the best solutions are chosen from a series of good enough ones. The paper presents an algorithm for spatial-temporal signal processing that enables control of the direction diagram in the vertical plane. For these results, parameters in the form of two coefficients were used, which described the quality of the solution well enough. Each solution was placed in a function, and finding the best was carried out via the Pareto front. Filling in the points, ie the solution, was additionally accelerated with the genetic optimization algorithm, which in significantly fewer iterations led to an equally good solution as the method of random generation of a potential solution.

Realizacija sistema za aktivnu kontrolu buke u cevi na otvorenom hardveru

Marija Ratković, Nebojša Kolarić, Miloš Bjelić

***A stra t*— A C (Acoustic oise Control) sistemi su neophodni u prostorijama gde se traži eliminisanje neželjenih zvu ova. ovom radu bavili smo se simulacijom i implementacijom na hardveru A C sistema u cevi. Testirani su adaptivni algoritmi (iltered east ean quare) i (ormalized iltered east ean quare). Algoritmi su poređeni po robusnosti sistema, neophodnom redu adaptivnog filtra i brzini onvergencije. simulaciji su ao test signali korišćeni: sinusoida, klipovana sinusoida i šum realnog ventilatora. zavisnosti od omple snosti test signala menjali su se parametri adaptivnog filtra. ezultati po azuju da je moguće potisnuti akustičku buku do određene granice u zavisnosti od omple snosti signala, ao i da je moguće ta ve algoritme implementirati na otvorenom hardveru.**

***Ključne reči*— A tivna ontrola bu e, adaptivni algoritmi, filtri, hardvers a implementacija, .**

I. UVOD

Jedna od najuspešnijih primena *ANC Acoustic Noise Control* sistema je njihova implementacija u cevi [1]. Razlog tome je što veliki broj uređaja koji prave buku koriste cevi za njihovu primarnu namenu, samim tim jednostavno je implementirati ovakav sistem. Potiskivanje buke prouzrokovane šumom ventilatora, koji se nalaze u mnogim električnim uređajima kao što su transformatori, računari i sistemi za klimatizaciju, je jedna od najčešćih primena ovakvih sistema. Ovakvi akustički zvukovi mogu nepoželjno da utiču na čoveka, da ga psihički zamaraju i ometaju u radu.

U ANC sistemu, digitalni kontroler vrši obradu nad neželjenim signalom i na njegovom izlazu se generiše signal koji je iste amplitude a suprotne faze sa primarnom bukom koju želimo potisnuti. Superpozicijom ova dva zvučna signala na izlazu iz sistema (cevi) se formira zona koja je približna zoni tišine, potiskivanjem početnog šuma [2].

Tradicionalne metode za potiskivanje šuma, poput korišćenja apsorpcionih materijala imaju lošije performanse na niskim frekvencijama. Zbog toga je ANC predložen kao rešenje za taj problem, da bi se u kombinaciji sa zvučnim apsorberima što više smanjio neželjeni akustički šum. Primena ovakvog sistema pronalazi svoje mesto u prostorijama u kojima je neophodno obezbediti što veći nivo tišine, kao što su muzički studio, koncertne sale. Postići će se potiskivanje buke na niskim frekvencijama i doprineti klasičnim načinima potiskivanja buke. Konkretna buka na koju se misli su šumovi ventilatorskih sistema koji se koriste za protok vazduha u samim prostorijama. Samim tim što ove velike cevi kroz koje struji vazduh nije moguće zapušiti sa nekim akustičkim materijalom, neophodno je naći drugi način za postizanje tišine što nam omogućava ovakav način implementacije.

Ideja ovog rada je ispitivanje mogućnosti implementacije ovog sistema za adaptivnu obradu signala na realnom modelu korišćenjem otvorenog hardvera *Bela*, uz ispitivanje krajnjih mogućnosti hardvera i njegovih mogućnosti za primenu u realnim sistemima. Model na kom je sistem implementiran se sastoji od cevi sa zadebljanim zidovima, dva zvučnika i dva mikrofona, koji imaju za cilj da na što bolji način simuliraju realnu cev za ventilaciju kroz koju se prostiru ravanski talasi.

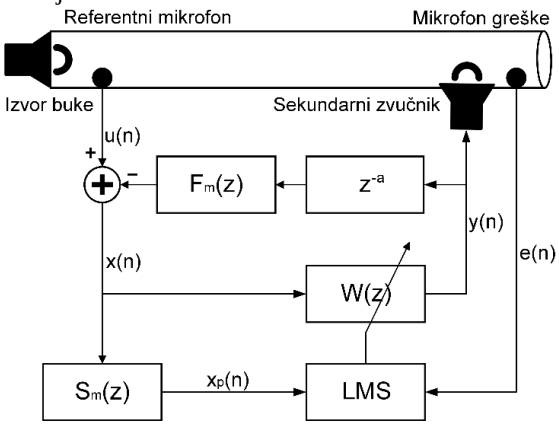
U literaturi [1] je opisana implementacija ovog sistema sa FxLMS (*Filtered east Mean S uare*) algoritmom [3]. Ovaj algoritam pruža stabilnost čitavom sistemu, što je njegova ključna prednosti u odnosu na poznati LMS *east Mean S uare* algoritam [4]. U ovom radu je ispitan FxLMS i zaključeno je da koeficijenti adaptivnog filtra sporo konvergiraju do svojih optimalnih vrednosti. Na osnovu toga je zaključeno da je potrebno upotrebiti drugi adaptivni algoritam [5]. Algoritam koji je približno jednostavan kao i FxLMS je NFxLMS (*Normali ed Filtered east Mean S uare*) [6]. On omogućava bržu konvergenciju koeficijenata, što je jako bitno prilikom implementacije ovog sistema na hardveru.

Krajnji cilj ovog istraživanja je ispitivanje za koji ulazni signal i koju kompleksnost algoritma je moguće realizovati ovakav sistem na hardveru. U radovima iz literature [7] je korišćena frekvencija odabiranja od 8 kHz, što je daleko manje od frekvencije koju je neophodno koristiti u realnom sistemu kako bi čitav sistem funkcionisao. Tokom testiranja sistema testirano je više frekvencija odabiranja, uz ograničenje da sa povećanjem frekvencije odabiranja raste kompleksnost. Posebna pažnja se obraća na maksimalno slabljenje koje će sistem u hardverskoj implementaciji obezbediti, i razlike u odnosu na slabljenje postignuto u simulaciji.

II. METODOLOGIJA

A. ANC

Aktivna kontrola buke je elektroakustički sistem koji potiskuje primarnu buku. Sistem je baziran na principu



Marija Ratković– Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: rm180095d@student.etf.bg.ac.rs).

 ISBN 978-86-7466-930-3

superpozicije. Na slici 1. je prikazan model ANC-a. Sistem zahteva referentni mikrofon neophodan za prikupljanje referentnog signala koji potiče od izvora buke, a koji treba potisnuti. Na kraju cevi se nalazi mikrofon koji prikuplja zbirni signal primarne i sekundarne buke, odnosno skuplja ukupnu grešku. Sekundarna buka proizilazi iz sekundarnog zvučnika koji emituje signal tako da je suprotan primarnoj buci. To ima za cilj da anulira primarnu buku i na taj način stvara zonu tišine u tom okruženju. ANC kontroler podešava svoje parametre na osnovu signala skupljenih na primarnom i sekundarnom mikrofonu, kontroler je baziran na LMS adaptivnom algoritmu. Algoritam je zadužen da podešava koeficijente adaptivnog filtra tako da se greška na sekundarnom mikrofonu minimizira. Na izlazu iz kontrolera se generiše signal koji će biti reprodukovan na sekundarnom zvučniku, koji je jednak po amplitudi i suprotan po fazi sa primarnom bukom. Njihovim kombinovanjem dobija se potiskivanje obe buke.

Sl. 1. Blok šema ANC sistema

B. pis algoritma

U ovom delu je detaljno objašnjen FxLMS algoritam [8], na osnovu blok šeme prikazane na slici 1. Impulsni odzivi modelovanih filtara, S_m i F_m , su određeni pomoću adaptivnog algoritma za identifikaciju nepoznatog sistema. Impulsni odzivi primarne i sekundarne putanje modelovani su funkcijom *fir2*, koja je ugrađena u Matlabu, Primarna buka na ulazu u referentni mikrofon koju treba potisnuti može biti izražena kao:

$$d(n) = P \times u(n) \tag{1}$$

gde P predstavlja impulsni odziv primarnog puta od referentnog mikrofona do mikrofona greške, a $u\ n$ predstavlja odbirke signala na referentnom mikrofonu. M predstavlja red filtra koji je modelovan od impulsnog odziva P. Za dalju obradu unutar LMS algoritma neophodno je obraditi ulazni signal $u\ n$ sa referentnog mikrofona.

U realizaciji ovog sistema se javlja problem akustičke povratne sprege koja potiče od sekundarnog zvučnika ka referentnom mikrofonu. Iz tog razloga neophodno je modelovanje još jednog impulsnog odziva F koji podrazumeva tu putanju i koji utiče na ulazni signal.

$$(n) = u(n) - k(n) \tag{2}$$

gde $k\ n$ predstavlja signal koji je bio izlaz sekundarnog zvučnika zakašnjen za a odbiraka, propušten kroz filtar reda koji je modelovan impulsnim odziv, F_m [9].

$$k(n) = F_m \times y_{a'} \tag{3}$$

Broj odbiraka a za koji treba zakasniti sekundarni signal je izračunat kao odnos dužine dela puta od sekundarnog zvučnika do referentnog mikrofona i brzine prostiranja zvuka. Tako dobijena vrednost u vremenu pomnožena je vrednošću frekvencije odabiranja kako bi se dobio potrebni broj odbiraka. Neophodno je uračunati i vreme kašnjenja samog hardvera, označeno sa t_{Bela}, pri implementaciji algoritma na hardveru.

$$a = (t - t_{Bela}) \times f_s \tag{4}$$

U simulaciji nije neophodno korišćenje ovog dela, jer nema reprodukcije sa sekundarnog signala na sekundarni mikrofon. Samim tim nema ni ometanja u vidi akustičke povratne sprege. Ipak u realnoj implementaciji neophodno je posvetiti pažnju ovom delu. Na osnovu izloženog Zaključuje se da je u simulaciji $k\ n$ =0.

Sekundarna putanja podrazumeva deo cevi od sekundarnog zvučnika do mikrofona greške, uz to ona obuhvata: digitalno analogni (D/A) konvertor, filter za rekonstrukciju, pojačavač, zvučnik i akustičku putanju od zvučnika do mikrofona greške, mikrofon, mikrofonski pretpojačavač i A/D konvertor. Neophodno je da ulazni signal pre ulaska u LMS algoritam bude propušten kroz model impulsnog odziva sekundarne putanje S_m [10], reda N.

$$_p(n) = S_m \times \ _1' \tag{5}$$

gde je $_1$' ulazni signal za LMS algoritam, koji je jedan od parametara koji konfigurišu u relaciji za izračunavanje koeficijenata adaptivnog filtra, reda . Signal y koji se reprodukuje na sekundarnom zvučniku dobija se propuštanjem signala $_p$ kroz adaptivni filtar W. Svaki od odbiraka se računa na sledeći način:

$$y(n) = W \times \ _2' \tag{6}$$

Sekundarna buka na mikrofonu greške $y_p(n)$, koja treba da potisne primarnu buku $d\ n$, dobija se propuštanjem sekundarne buke sa sekundarnog zvučnika kroz filtar koji modeluje sekundarnu putanju S i ima red N:

$$y_p(n) = S \times y' \tag{7}$$

Signal greške $e(n)$ je primljen na mikrofonu greške, i on predstavlja razliku primarne i sekundarne buke:

$$e(n) = d(n) - y_p(n) \tag{8}$$

U $F\ \ MS$ algoritmu koeficijenti adaptivnog filtra W se u svakoj iteraciji optimizuju kako bi greška $e\ n$ bila što manja, računaju se na sledeći način:

$$w(n+1) = w(n) + \mu \times \ _p(n) \times e(n) \tag{9}$$

Parametar je konstantna male vrednosti koja se zadaje tako da konvergencija koeficijenata bude što brža. Ova vrednost ne sme biti prevelika da se optimalna vrednost ne bi preskočila u nekoj od iteracija. Algoritam bi trebalo da se izvrši onoliko puta koliko je potrebno da greška dostigne neku određenu, dovoljno malu vrednost. To će se postići kroz stalno menjanje koeficijenata filtra kako bi se što bolje prilagodila greška traženoj vrednosti.

 ISBN 978-86-7466-930-3

U simulaciji je umesto FxLMS algoritma korišćen NFxLMS, kako bi koeficijenti brže iskonvergirali do optimalnih vrednosti [11]. Za NFxLMS se može koristiti manji red adaptivnog filtra što je ključni razlog za njegovo korišćenje u ovom radu, prilikom implementiranja na hardveru je potrebno smanjiti broj računskih operacija što se na ovaj način postiže. Jedina razlika između ova dva algoritma je što se drugačije računaju koeficijenti $w\,n\;\;1$, tačnije promenljiv je korak adaptacije n. Koeficijenti NFxLMS alagoritma se računaju:

$$w(n+1) = w(n) + \mu(n) \times \;_{p}(n) \times e(n) \tag{10}$$

Parametar n se izračunava kao:

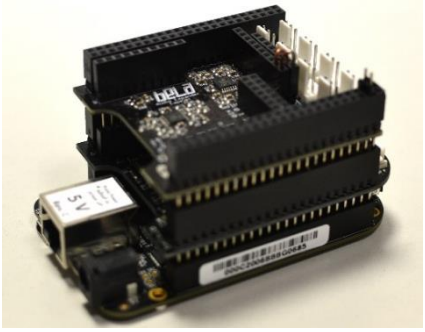
$$\mu(n) = \frac{\mu}{s+\delta} \tag{11}$$

gde δ predstavlja malu proizvoljnu konstantu. Vrednost $s\;n$ je izraženo kao:

$$s(n) = \sum_{i=0}^{-1} \;_{p}(n-1)^2 \tag{12}$$

C. Implementacija algoritma na realnom modelu

Algoritam je testiran na realnom modelu koji se sastoji od cevi dugačke približno jedan metar, dva zvučnika, primarnog i sekundarnog i dva mikrofona, kao što je prikazano na slici 2.



Sl. 2. Izgled korišćene cevi za hardversku implementaciju

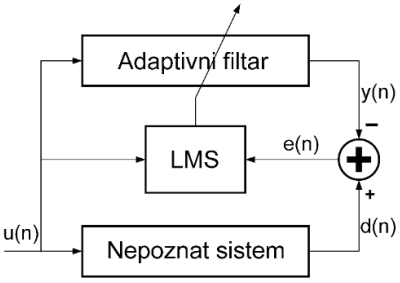
Cev je dugačka 1 m, njen prečnik iznosi 7.5 cm. Korišćeni su širokopojasni zvučnici čija veličine membrane iznosi 3″. Korišćeni su neusmereni elektret mikrofoni. Cev ima rezonantne frekvencije, koje se mogu odrediti preko izraza:

$$f = \frac{c}{4\times} \tag{13}$$

gde je c brzina zvuka u vazduhu koja iznosi približno 340 m/s, a je dužina cevi.

Sl. 3. Bela procesor

Za implementaciju algoritma korišćena je platforma Bela, koja predstavlja računarski sistem namenjen za obradu audio signala, bazira se na *BeagleBone* platformi. Izgled Bela procesora prikazan je na slici 3. Glavna karakteristika ovog procesora je malo kašnjenje kada se obrađuju audio signali i sistemi, kao što je ANC sistem. Korišćeni su dva audio ulaza i jedan audio izlaz koje Bela poseduje, sa frekvencijama odabiranja 22050 Hz. Primarni mikrofon i mikrofon greške su bili povezani na po jedan kanal ulaza, a sekundarni zvučnik je bio povezan na izlaz Bele. Primarni zvuk je generisan pomoću generatora, kojim su generisani signali različitih vremenskih oblika.



Adaptacija algoritma za generisanje sekundarnog zvuka izvršena je pomoću integrisanog razvojnog okruženja koje ovaj sistem poseduje. Razvojno okruženje bazirano je programskom jeziku C.

. Modelo anje impulsnih od i a

U cevi je izvršeno snimanje svih potrebnih impulsnih odziva za softversku realizaciju (impulsni odziv primarne putanje, sekundarne, kao i putanje unazad od sekundarnog zvučnika do referentnog mikrofona). Kao što je ranije navedeno za konkretnu softversku implementaciju ovog sistema nije bio potreban impulsni odziv putanje unazad, *F*, ali će za hardversku implementaciju biti neophodan, zato je i on snimljen. Dobijene impulsne odzive je bilo neophodno modelovati, kako bi bili iskorišćeni u algoritmu.

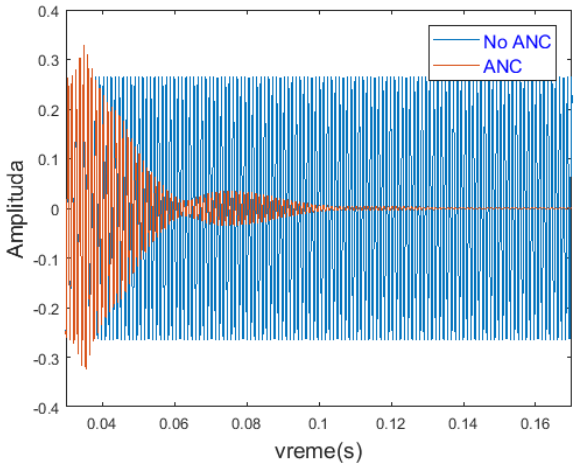
U simulaciji ovi impulsni odzivi su bili modelovani FIR filtrima, korišćenjem ugrađenih funkcija, trudeći se da amplitudska i fazna karakteristika modela budu što sličnije originalnoj. Rezultati simulacija su zavisili od izabranih redova filtara. U zavisnosti od složenosti test signala neophodni redovi filtara su se menjali, od stotog pa sve do dve hiljaditog reda. U realizaciji u realnom vremenu na hardverskoj platformi ti redovi su preveliki i nije moguće koristiti ih. Zbog toga je bilo neophodno na drugi način modelovati tražene impulsne odzive.

Manji red filtara, do stotog reda, je dobijen modelovanjem impulsnih odziva preko paralelne veze IIR filtara drugog reda. Amplitudska karakteristika tako dobijenog modela je približno istog oblika kao i kod originalnog impulsnog odziva. Sa ovakvim modelima algoritam nije konvergirao, iz čega se zaključuje da amplitudska karakteristika nema veliki uticaj i da je mnogo bitnija fazna karakteristika koja se na ovaj način ne uzima u obzir.

Sl. 4. Blok šema za prepoznavanje nepoznatog sistema

Kao optimalno rešenje za modelovanje ovih putanja, tako da red filtra bude dovoljno mali i da se fazna karakteristika na što bolji način modeluje, korišćenje adaptivni algoritam za prepoznavanje nepoznatog sistema. Principska blok šema sistema prikazana je na slici 4. Na ovaj način je očuvana i fazna i amplitudska karakteristika u onoj meri u kojoj je to neophodno kako bi čitav sistem funkcionisao. U simulaciji i u hardverskoj implementaciji su korišćeni isti modelovani filtri stotog reda.

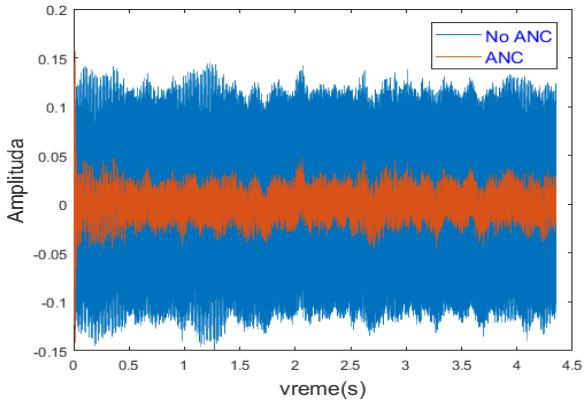
 ISBN 978-86-7466-930-3



U hardverskoj implementaciji nije bilo potrebe modelovati primarnu putanju, jer će signal proći taj put i pretrpeće uticaj impulsnog odziva primarnog puta. Primarni signal koji treba potisnuti će biti pod uticajem zvuka sa sekundarnog zvučnika i to moramo izbeći. Zato je neophodno koristiti impulsni odziv putanje unazad kako bi uspeo da se generiše signal koji se pušta na sekundarnom zvučniku, koji je optimalan za potiskivanje primarnog signala.

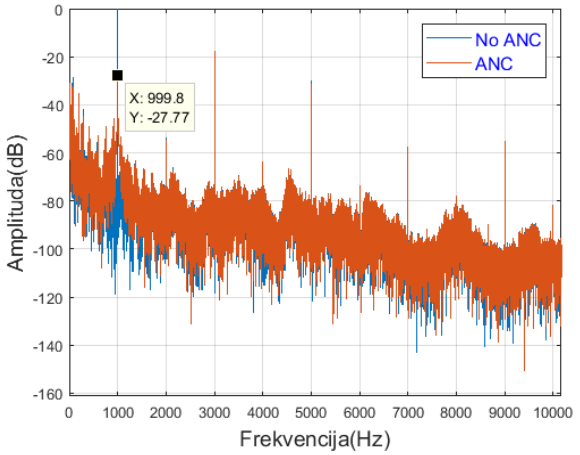
III. REZULTATI

A. e ultati simulacije



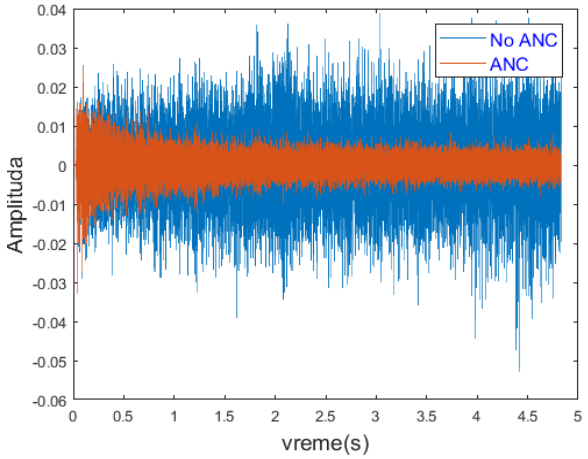
Korišćeno je više različitih primera signala kao izvore buke na referentnom zvučniku, kako bi se ispitale performanse sistema. Za svaki od slučajeva je bilo potrebno koristiti različite redove adaptivnog filtra. Za složenije signale bilo je neophodno povećati red filtra, kako bi dobili što bolje potiskivanje zvuka sa referentnog zvučnika. Takođe, pored menjanja redova filtra neophodno je bilo podešavati i statički korak adaptacije . Pritom se mora obratiti pažnja da vrednost ne bude prevelika jer bi se preskočilo optimalno rešenje i filtar bi prooscilovao.

Prvi najjednostavniji primer na kome je isproban sistem je bila sinusoida koja je potisnuta u potpunosti, što se može videti sa slike 4. Na slici 4 je prikazan vremenski oblik originalnog signala na ulazu u mikrofon greške kada ne bi bilo ANC sistema i signal greške *e*, gde jasno uviđamo da postaje nula. Za ovaj primer bio je dovoljan da vrednost reda adaptivnog filtra bude =50, a korak adaptacije =0.001.



Sl. 4. Vremenski oblik originalnog i signala greške za sinusnu pobudu

Sledeći slučaj na kom je testiran sistem je „klipovana“ sinusoida. Ovaj signal je dobijen direktnom reprodukcijom signala na referentni zvučnik u cevi i njegovim snimanjem na primarnom i sekundarnom mikrofonu. Samim tim nije bilo potrebe propuštati ulazni signal kroz impulsni odziv *P*, jer je korišćen snimljeni primarni signal na mikrofonu greške. Ovaj signal je složeniji i nije se mogao potpuno potisnuti kao u prvom slučaju, ali se vidi na slici 5. da je dosta oslabljen. Koeficijenti teže konvergiraju jer je sam signal složeniji. Korišćen je red filtra =100, a =0,0005.



Sl. 5. Vremenski oblik originalnog i signala greške pobudni signal klipovane sinusoide

Sl. 6. Spektar originalnog signala i signala greške za šum oblika klipovane sinusoide

Kao što se vidi na slici 6. na kojoj su prikazani spektri originalnog i potisnutog signala najviše je potisnut osnovni harmonik i to za 27 dB. Pored potiskivanja prvog harmonika uočava se da na ostale harmonike algoritam nije imao uticaj i ne potiskuje ih. Najvažnije je upravo potiskivanje na osnovnoj frekvenciji što je upravo postignuto.

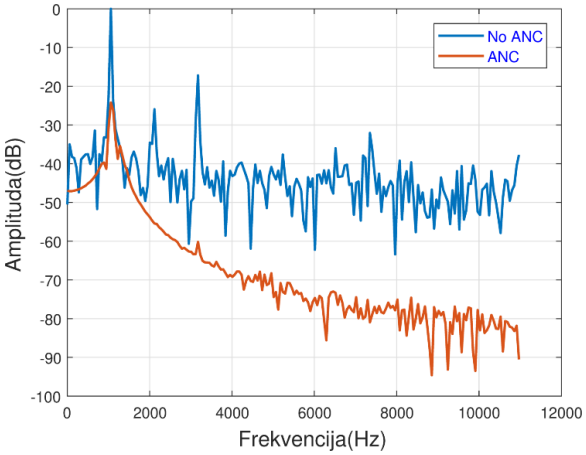
Sl. 7. Vremenski oblik originalnog signala i signala greške za šum ventilatoa

Najsloženiji širokopojasni signal koji je testiran je snimak ventilatora. Zbog same složenosti ovog signala potiskivanje je bilo najlošije, ali ipak postoji što se vidi na slici 6. Kada se

 ISBN 978-86-7466-930-3

poredi signal bez ovog algoritma kada samo prođe kroz cev i signala greške kada se koristi algoritam, jasno se primećuje razlika da je signal oslabljen i to za 13 dB kada se koristi ANC. Zbog same složenosti signala algoritam mora biti kompleksniji kako bi koeficijenti konvergirali.Samim tim bilo je potrebno da red adaptivnog filtera bude veći i iznosi =700, korak adaptacije iznosi 0.002. Takođe, modelovana sekundarna putanja se adaptirala u odnosu na Gausov šum i red adaptivnog filtra za prepoznavanje nepoznatog sistema morao biti 600 da bi se dobro modelovala sekundarna putanja.

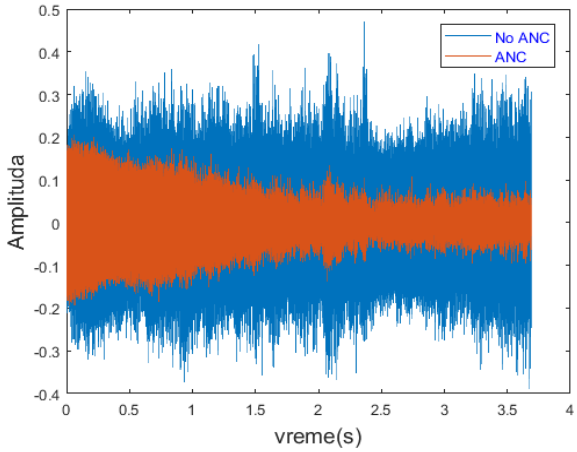
B. ard erska implementacija na Beli platformi



Implementacije na hardveru su dosta zahtevnije od softverskih simulacije jer se mora voditi računa o nizu problema. Jedan od problema je na primer određeno vreme izvršavanja čitave obrade signala na jednom odbirku. Ovaj problem uvodi ograničenja odmah na početku i zahteva da redovi filtara (modelovanih i adaptivnog) budu što manji da bi obrada signala stigla da se izvrši za određeno vreme. Maksimalno dozvoljeno vreme obrade je $1/f_s$, gde je f_s frekvencija odabiranja. To dovodi do nemogućnosti korišćenja složenijih i bržih adaptivnih algoritama od LMS-a, jer će biti povećan broj računskih operacija i samim tim duža obrada. Drugi problemi na koje se mora paziti su modelovanje adekvatnog kašnjenja, tako da izlaz sekundarnog zvučnika reprodukuje odbirak u trenutku kada isti taj odbirak stiže od primarnog zvučnika da bi oba signala superponirala i poništila. Ovo je rešeno tako što je izmereno rastojanje između referentnog mikrofona i sekundarnog zvučnika, koje iznosi =0.87 m. Pa je kašnjenje izračunato i iznosi t=2.55 ms. Nakon toga treba oduzeti kašnjenje koje je potrebno za propagaciju signala sa ulaza na izlaz (kašnjenje hardvera)Ovo vreme iznosi t_{Bela}=0.93 ms. Na kraju kako bi se dobio broj odbiraka, vreme t_{Bela} je pomnoženo sa frekvencijom odabiranja:

$$samples = (t - tBela) \times fs = 35. \quad (15)$$

Sl. 8. Vremenski oblik originalnog signala i signala greške za sinusoidalnu pobudu za implementaciju na hardveru

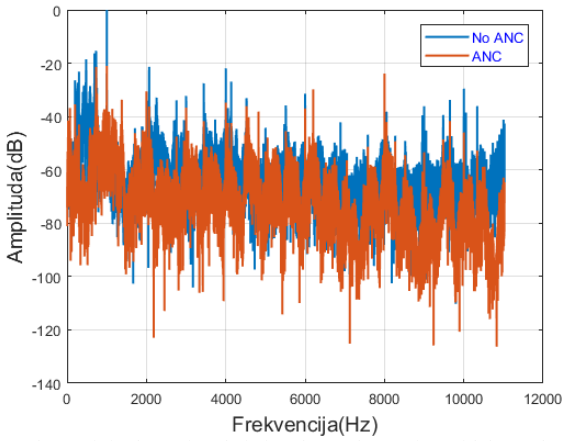


Prvi signal koji je korišćen za testiranje sistema, korišćenjem generatora kao izvora, je sinusoida frekvencije 900 Hz. Na slici 8 prikazan je vremenski oblik sinusoide na ulazu u zvučnik i signala greške koji se prikuplja na mikrofonu greške. Jasno se primećuje da je sinusoida potisnuta u velikoj meri nakon 3.5 s.

Sl. 9. Spektar originalnog signala i signala greške za sinusoidalnu pobudu za implementaciju na hardveru

Ako se poredi signal greške koji se dobija u softverskoj realizaciji (slika 4) i signal dobijen u hardverskoj realizaciji jasno se uviđa da hardversko rešenje ne potiskuje sinusoidalni signal u potpunosti. Na slici 9 prikazani su spektri originalnog signala i signala greške. Zaključuje se da je algoritam uspeo da potisne sinusoidu i oslabi je za 24 dB u odnosu na signal smetnje. Red adaptivnog filtra korišćen za ovaj test primer iznosio je =100, a koeficijent adaptacije =0.00002.

Drugi primer koji je testiran je signal klipovane sinusoide reprodukovan na referentnom zvučniku. Klipovana sinusoida je kompleksniji signal i teže je potisnuti ga. Na slici 10 su prikazani signali skupljeni na referentnom mikrofonu i na mikrofonu greške, gde jasno uviđamo da je uspešno potisnuta primarna buka. Red adaptivnog filtra neophodan da bi algoritam dobro radio je =100, a korak adaptacije =0.00008. Ovaj primer je uspešno potisnut i oslabljen za 20 dB, kao što se može videti na slici 11.



Sl. 10. Vremenski oblik originalnog signala i signala greške za klipovanu sinusoidalnu pobudu za implementaciju na hardveru

Algoritam na hardveru je testiran i za šum ventilatora, što je njegova suštinska primena, ali rezultat nije pozitivan. Šum ventilatora je mnogo složeniji signal od ova dva prethodno

 ISBN 978-86-7466-930-3

opisana, samim tim neophodno je da red filtra bude mnogo veći. Povećavanjem reda filtra povećava se i potrebno vreme za izvršavanje čitavog procesa i prevazići će se maksimalno vreme koje je moguće na hardveru. Cilj narednih istraživanja i obrađivanja ovog sistema će upravo biti optimizovanje algoritma tako da uspešno potiskuje šum ventilatora.

Sl. 11. Spektar originalnog signala i signala greške za sinusoidalnu pobudu za implementaciju na hardveru

IV. ZAKLJUČAK

U ovom radu prikazana je implementacija ANC algoritma kroz softversku simulaciju i hardversku realizaciju. Softversko rešenje je jednostavnije implementirati jer predstavlja simulaciju realnog problema iz kojeg se izostavlja veliki broj spoljašnjih faktora koji otežavaju realizaciju sistema na hardveru. Implementacijom algoritma u softveru se dobijaju približno najbolja moguća rešenja kojima će se težiti u realnim sistemima. Jedna od najvećih razlika između ova dva načina testiranja algoritma je što implementacija na hardveru korišćenjem pravog modela mora biti u realnom vremenu. Postoji ograničeno vreme za koje algoritam mora biti izvršen, samim tim neophodno je smanjivati redove filtara modelovanih impulsnih odziva, kao i red adaptivnog filtra čime se gubi na performansama samog algoritma. Dodatne komplikacije koje se javljaju kad se implementira sistem na pravom modelu je kompenzacija kašnjenja koja potiče od samog procesiranja na platformi Bela, kao i pojava akustičke povratne sprege na koju se mora obrtati posebna pažnja. Takođe Bela hardver ima određena ograničenja, kao što su frekvencija odabiranja, kašnjenje koje se javlja prilikom obrade podataka, kao i maksimalno vreme za koje se mora izvršiti algoritam. Iz svih navedenih razloga zaključuje se da će finalna rešenja na realnom sistemu biti lošija, što se i vidi iz prikazanih rezultata. Kroz softversku implementaciju test signal sinusoide je oslabljen za 36 dB dok na realnom modelu pri reprodukciji signala sinusoide maksimalno slabljenje iznosi 24 dB. Može se videti da postoji razlika ali suštinski u oba slučaja sinusoidalna buka je potisnuta. Takođe za primer u kome je primarni signal klipovana sinusoida se vidi razlika u potiskivanju od 20 dB pri primeni na hardveru.

Buduća nadogradnja ovog rada će se kretati u smeru pronalaženja rešenja za potiskivanje realnog šuma ventilatora na realnom modelu u cevi. Rešenje tog problema predstavljalo bi primenu ANC sistema u svakodnevnom životu. Mogućnosti korišćenja ovakvih sistema bile bi u određenim prostorima gde je od velikog značaja potiskivanje spoljašnje buke na niskim frekvencijama, koja potiče od ventilatora, klima uređaja, ventilacionih sistema itd.

ZAHVALNICA

Autori žele da se zahvale profesorki Jeleni Ćertić na korisnim savetima prilikom implementacije algoritama. Ovaj rad je realizovan u okviru projekta TR36026 koji finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

ANC (Acoustic Noise Control) systems are necessary in the premises where the elimination of unwanted sounds is required. In this paper, we have done simulation of ANC system in the duct and implementationon hardware. FxLMS (Filtered x Least Mean Square) and NFxLMS (Normalized Filtered x Least Mean Square) adaptive algorithms were tested, they were compared by robusntness, necessary order of adaptive filter and convergence rate. In the simulation were used: sinusoid, clipped sinusoid and fan noise. Depending on the complexity of the test signal the parameters of the adaptive filter have changed. The results show that it is possible to supress acoustic noise to a certain limit depending on the complexity of the signal.

Application of Microwave Imaging for Brain Diagnostics

Marija Nikolic Stevanovic, Darko Ninkovic, Tushar Singh, Branislav Ninkovic, Miodrag Tasic, and Branko Kolundzija

***Abstract*— We present the application of the distorted Born iterative method for permittivity estimation of a realistic human phantom, which is an essential step in microwave medical diagnostics. Permittivity reconstruction is a difficult task due to the complexity of the electromagnetic model and the ill-posedness of the inverse scattering problems. Assuming that prior knowledge of the head anatomy is available from other imaging modalities, such as magnetic resonance imaging, we showed that electromagnetic tissue parameters could be accurately estimated even for tissues deeply located in the head. In our implementation of DBIM, we have gradually improved the estimation accuracy by initializing more complex models with results obtained for simpler models.**

***Index Terms*—Microwave imaging, inverse scattering, distorted Born iterative method, human phantoms.**

I. Introduction

In the last decade, the application of microwaves in medical diagnostics has gained much attention. The advantages of medical microwave imaging (MMWI) are non-invasiveness, low cost, utilization of nonionizing radiation, and ease of portability. However, due to the relatively low resolution of MMWI, it is envisioned primarily as a complementary screening tool for medical applications [1]–[3].

The gold standards in medical diagnostics are magnetic resonance imaging (MRI), computed tomography (CT), and positron emission tomography (PET) [4], [5], which produce high-resolution images with well-resolved tissues. However, their application is usually limited to large medical centers due to their high cost, and they are not appropriate for bedside monitoring. Additionally, CT and PET scans utilize harmful ionizing radiation.

The essential elements of any MMWI system are an antenna array, a reconstruction algorithm based on inverse scattering, and a reliable efficient 3D electromagnetic solver. Additionally, realistic human models (phantoms) are necessary for designing and testing MMWI systems.

Microwave imaging algorithms are generally classified into two categories: qualitative and quantitative. The goal of qualitative algorithms in medical imaging is to detect possible lesions or other tissues changes between measurements. They cannot infer the electromagnetic properties of the changes; instead, they estimate their location and shape. Examples of qualitative imaging algorithms are truncated singular value decomposition (TSVD) [6] and the linear sampling method (LSM) [7]. In contrast, quantitative algorithms reconstruct the complex permittivity in the whole domain of interest. Since different tissues have different electromagnetic properties, permittivity maps are also images of particular body parts.

Solving quantitative algorithms is difficult due to the complex scattering phenomenon. They are non-linear and ill-posed, making them prone to false solutions and more computationally intensive than qualitative algorithms. Examples are the inexact Newton methods [8] and the distorted Born iterative method (DBIM) [9], [10].

In this paper, we study the application of the DBIM to the permittivity reconstruction of a realistic head phantom. Although the utilized method is well-established, there are only a few examples of its application to realistic 3D human models. The main reasons for this are the non-uniqueness of the solution, the lack of detailed anatomical models adapted for electromagnetic analysis, and the extremely long computational time. The goal of this work is to test the algorithm's ability to estimate tissues' permittivities. Thus, we assume that the tissue boundaries are available, e.g., from a prior MRI screening. To initialize the algorithm, we first compute the average permittivity of the head.

The paper is organized as follows. After the introduction, we explain the DBIM in Section II. Section III describes the numerical examples and presents the obtained results. Finally, in the concluding section, we summarize the obtained results and give guidelines for future work.

II. Distorted Born Iterative Method

The goal of quantitative microwave imaging is to estimate the complex permittivity of the unknown object or the whole domain of interest. Fig. 1 illustrates a three-dimensional (3D) microwave imaging scenario consisting of an unknown non-magnetic inhomogeneous object, which occupies a volume v' and has the permittivity ε. The object is located in a known non-magnetic background medium whose permittivity is ε_b.

 ISBN 978-86-7466-930-3

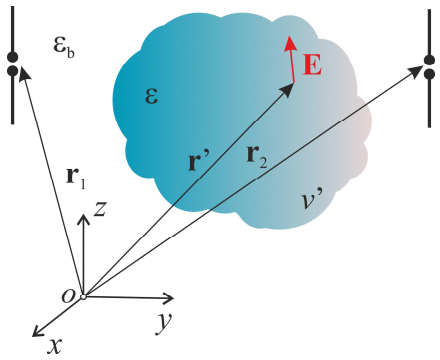

Fig. 1. Measurement scenario.

The measurements are taken by an array consisting of M antennas, out of which only two are shown in Fig. 1. The differential transmission coefficient between the i-th and the j-th antenna due to the presence of the object is given by [11]:

$$\Delta s_{ji} = -\frac{\mathrm{j}\omega}{2a_i a_j}\int_{v'} \Delta\varepsilon(\mathbf{r}')\,\mathbf{E}^j(\mathbf{r}';\varepsilon_\mathrm{b})\cdot\mathbf{E}^i(\mathbf{r}';\varepsilon)\mathrm{d}v', \tag{1a}$$

$$\Delta s_{ji} = s_{ji}(\varepsilon) - s_{ji}(\varepsilon_\mathrm{b}),\ i,j=1,\ldots,M, \tag{1b}$$

$$\Delta\varepsilon(\mathbf{r}') = \varepsilon(\mathbf{r}') - \varepsilon_\mathrm{b}(\mathbf{r}') \tag{1c}$$

where ω is the angular frequency, $s_{ji}(\varepsilon)$ is the transmission coefficients computed (or measured) in the presence of the scatterer, $s_{ji}(\varepsilon_\mathrm{b})$ is the transmission coefficient computed when the object is removed and substituted by the background medium, $\mathbf{r}'$ is the position vector of a point inside the object, $\mathbf{E}^j(\mathbf{r}';\varepsilon_\mathrm{b})$ is the electric field vector produced by the j-th antenna at $\mathbf{r}'$ in the background medium (the incident field), $\mathbf{E}^i(\mathbf{r}';\varepsilon)$ is the electric field vector produced by the i-th antenna at $\mathbf{r}'$ when the object is present (the total field), a_i and a_j are the complex amplitudes of the incident power waves at the i-th and j-th port, respectively.

If the estimate of the target permittivity ($\hat{\varepsilon}$) is utilized instead of the background permittivity (ε_b), (1) becomes

$$\Delta s_{ji} = -\frac{\mathrm{j}\omega}{2a_i a_j}\int_{v'} \Delta\varepsilon(\mathbf{r}')\,\mathbf{E}^j(\mathbf{r}';\hat{\varepsilon})\cdot\mathbf{E}^i(\mathbf{r}';\varepsilon)\mathrm{d}v', \tag{2a}$$

$$\Delta s_{ji} = s_{ji}(\varepsilon) - s_{ji}(\hat{\varepsilon}),\ i,j=1,\ldots,M, \tag{2b}$$

$$\Delta\varepsilon(\mathbf{r}') = \varepsilon(\mathbf{r}') - \hat{\varepsilon}(\mathbf{r}'). \tag{2c}$$

Since the object permittivity is unknown, the Born approximation is utilized, $\mathbf{E}^i(\mathbf{r}';\varepsilon)\approx\mathbf{E}^i(\mathbf{r}';\hat{\varepsilon})$. Thus, (2a) becomes

$$\Delta s_{ji} \approx -\frac{\mathrm{j}\omega}{2a_i a_j}\int_{v'} \Delta\varepsilon(\mathbf{r}')\,\mathbf{E}^j(\mathbf{r}';\hat{\varepsilon})\cdot\mathbf{E}^i(\mathbf{r}';\hat{\varepsilon})\mathrm{d}v'. \tag{3}$$

In the limit when $\hat{\varepsilon}\approx\varepsilon$, the left-hand side of (3) approaches zero. The equation (3) is fundamental for DBIM.

In order to apply DBIM, it is necessary to divide the domain of interest into smaller domains (voxels), v_k, $k=1,\ldots,L$. We assume that all voxels have the same volume ΔV, which has to be sufficiently small so that the permittivity is approximately constant in each voxel. We use ε_k and $\hat{\varepsilon}_k$ to denote the true and estimated complex permittivity of the k-th voxel.

DBIM is an iterative algorithm that needs to be initialized. If there is no prior knowledge about the permittivity of the inspected object, typically, the background permittivity is utilized, i.e., $\varepsilon_k^{(1)} = \varepsilon_{\mathrm{b},k}$, where $\varepsilon_{\mathrm{b},k}$ is the permittivity of the background medium in the k-th voxel and the superscript (1) denotes the iteration number. In the i-th iteration, the linear system of equations is

$$\Delta\mathbf{s}^{(i)} = \mathbf{L}^{(i)}\Delta\boldsymbol{\varepsilon}^{(i)}, \tag{4}$$

where $\Delta\mathbf{s}^{(i)}$ is a known vector whose elements are differences of the scattering parameters,

$$\Delta\mathbf{s}^{(i)} = \left[\Delta s_{1,1}^{(i)} \quad \Delta s_{1,2}^{(i)} \quad \cdots \quad \Delta s_{M,M}^{(i)}\right]^\mathrm{T}, \tag{5a}$$

$$\Delta s_{ij}^{(i)} = s_{ij}(\boldsymbol{\varepsilon}) - s_{ij}(\hat{\boldsymbol{\varepsilon}}^{(i)}),\ i,j=1,\ldots,M, \tag{5b}$$

$\hat{\boldsymbol{\varepsilon}}^{(i)}$ is the current permittivity estimate

$$\hat{\boldsymbol{\varepsilon}}^{(i)} = \left[\hat{\varepsilon}_1^{(i)} \quad \hat{\varepsilon}_2^{(i)} \quad \cdots \quad \hat{\varepsilon}_L^{(i)}\right]^\mathrm{T}, \tag{6}$$

$\mathbf{L}^{(i)}$ is the system matrix

$$\mathbf{L}^{(i)} = -\frac{\mathrm{j}\omega\Delta V}{2}\cdot \begin{bmatrix} \dfrac{\mathbf{E}^1(\mathbf{q}_1;\hat{\boldsymbol{\varepsilon}}^{(i)})\cdot\mathbf{E}^1(\mathbf{q}_1;\hat{\boldsymbol{\varepsilon}}^{(i)})}{a_1 a_1} & \cdots & \dfrac{\mathbf{E}^1(\mathbf{q}_L;\hat{\boldsymbol{\varepsilon}}^{(i)})\cdot\mathbf{E}^1(\mathbf{q}_L;\hat{\boldsymbol{\varepsilon}}^{(i)})}{a_1 a_1} \\ \dfrac{\mathbf{E}^1(\mathbf{q}_1;\hat{\boldsymbol{\varepsilon}}^{(i)})\cdot\mathbf{E}^2(\mathbf{q}_1;\hat{\boldsymbol{\varepsilon}}^{(i)})}{a_1 a_2} & \cdots & \dfrac{\mathbf{E}^1(\mathbf{q}_L;\hat{\boldsymbol{\varepsilon}}^{(i)})\cdot\mathbf{E}^2(\mathbf{q}_L;\hat{\boldsymbol{\varepsilon}}^{(i)})}{a_1 a_2} \\ \vdots & \cdots & \vdots \\ \dfrac{\mathbf{E}^M(\mathbf{q}_1;\hat{\boldsymbol{\varepsilon}}^{(i)})\cdot\mathbf{E}^M(\mathbf{q}_1;\hat{\boldsymbol{\varepsilon}}^{(i)})}{a_M a_M} & \cdots & \dfrac{\mathbf{E}^M(\mathbf{q}_l;\hat{\boldsymbol{\varepsilon}}^{(i)})\cdot\mathbf{E}^M(\mathbf{q}_L;\hat{\boldsymbol{\varepsilon}}^{(i)})}{a_M a_M} \end{bmatrix}, \tag{7}$$

and $\Delta\boldsymbol{\varepsilon}^{(i)}$ is an unknown vector

$$\Delta\boldsymbol{\varepsilon}^{(i)} = \left[\Delta\varepsilon_1^{(i)} \quad \Delta\varepsilon_2^{(i)} \quad \cdots \quad \Delta\varepsilon_L^{(i)}\right]^\mathrm{T}, \tag{8}$$

whose elements are the permittivity updates. The system (4) is solved by means of truncated singular value decomposition. The regularized solution is

$$\Delta\boldsymbol{\varepsilon}^{(i)} = \sum_{n=1}^{n_\mathrm{max}} \frac{1}{\sigma_i}\left(\mathbf{u}_n^\mathrm{H}\cdot\Delta\mathbf{s}^{(i)}\right)\mathbf{v}_n, \tag{9}$$

where $\mathbf{u}_n$, $\mathbf{v}_n$ are the singular vectors of matrix $\mathbf{L}^{(i)}$, σ_i are the corresponding singular values, and n_max is the truncation index, obtained from the condition $10\log_{10}(\sigma_{n_\mathrm{max}}/\sigma_1) < -20$ dB. The permittivity estimate in the next iteration is obtained as

 ISBN 978-86-7466-930-3

$$\hat{\boldsymbol{\varepsilon}}^{(i+1)} = \hat{\boldsymbol{\varepsilon}}^{(i)} + \Delta\hat{\boldsymbol{\varepsilon}}^{(i)}, \tag{9}$$

The iterative algorithm terminates when the magnitude of each member of the vector $\Delta\boldsymbol{\varepsilon}^{(i)}$ is smaller than some predefined value.

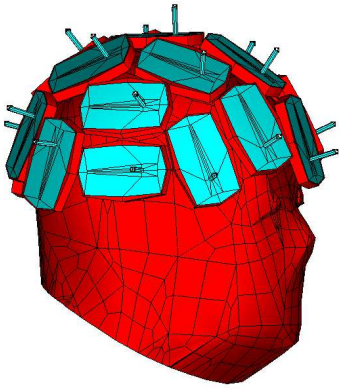
In some cases, prior knowledge about the tissue is available, i.e., from MRI scans. In these situations, we estimate the tissue permittivity, assuming that their surface boundaries are known. Thus, we can reduce the number of unknowns to the number of tissues. The measurement model becomes

$$\Delta\mathbf{s}^{(i)} = \mathbf{L}^{(i)}\mathbf{H}\,\Delta\boldsymbol{\varepsilon}^{(i)}, \tag{10}$$

where $\mathbf{H}$ is the transformational matrix of size $L\times N$, and N is the number of tissues. The (k,j) element of $\mathbf{H}$ is one if v_k belongs to j-th domain and zero otherwise. The unknown vector is now

$$\Delta\boldsymbol{\varepsilon}^{(i)} = \left[\Delta\varepsilon_1^{(i)} \quad \Delta\varepsilon_2^{(i)} \quad \cdots \quad \Delta\varepsilon_N^{(i)}\right]^{\mathrm{T}}, \tag{11}$$

where $\Delta\varepsilon_j^{(i)}$ refers to the j-th domain.



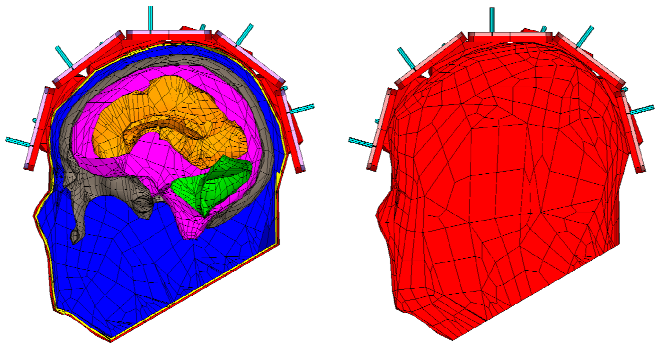


Fig. 2. Head model and the antenna array.

III. Numerical Results

In order to test the DBIM algorithm, we considered a realistic head model derived from the NEVA woman model [12]–[14]. The antenna array consisted of 21 identical microstrip trapezoidal patch antennas described in [12]. The antennas were fed by coaxial cables as illustrated in Fig. 2. The operating frequency of the array was 1 GHz, as this frequency is found to be the optimal in terms of both penetration depth and resolution.

The forward simulations were computed using the full-wave electromagnetic solver WIPL-D Pro [15]. All results presented in this paper are generated using a desktop computer: Intel Core i7-9700 CPU @3 GHz, NVIDIA GeForce GTX 750 Ti GPU, with 32 GB of RAM under the Windows 10 operating system.

In the first example, the goal was to find the equivalent homogeneous head phantom, which is equivalent (in terms of scattering parameters) to the realistic head phantom comprising seven tissues (skin, fat, mucous membrane, skull, gray matter, white matter and cerebellum).

(a) (b)

Fig. 3. (a) Reference head model with seven tissues. (b) Equivalent homogeneous head model filled with the average tissue.

The head interior was divided into $L = 8676$ voxels. As there was only one domain (averaged tissue), the transformation matrix $\mathbf{H}$ was a column vector of size $L\times 1$ with all elements being equal to one. As the initial permittivity estimate, we used the value calculated by the standard averaging procedure $\varepsilon_r^{(1)} = 41.47 - \mathrm{j}14.15$ [12]. After six iterations, the permittivity value converged to $\varepsilon_r^{(6)} = 34.64 - \mathrm{j}12.68$. As a comparison, the gradient optimization [12] yielded for the average tissue permittivity $\varepsilon_r = 34.68 - \mathrm{j}12.68$, which is almost the same result. The number of unknowns in the WIPL-D model (current coefficients) for this example was 24109, and an iteration lasted about 6 minutes.

In the second scenario, the goal was to reconstruct the permittivities of five tissues (skin, fat, mucous membrane, skull, and gray matter) from the head model shown in Fig. 4, assuming that the tissue boundaries are known. As the initial permittivity, we used the value obtained in the first experiment, $\varepsilon_r^{(1)} = 34.64 - \mathrm{j}12.68$, for all tissues.

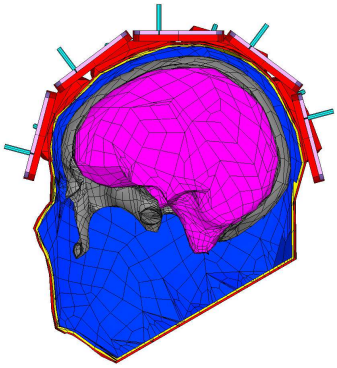

Fig. 4. Model with five tissues.

The WIPL-D model with five tissues has 48354 unknowns and each iteration lasted about 55 minutes. The results obtained after 20 iterations of the algorithm are shown in Table I. The true permittivities of tissues are given in the second column, and the estimated permittivities are shown in the third column. The last column indicates the number of voxels per each tissue.

 ISBN 978-86-7466-930-3

TABLE I. ESTIMATION RESULTS FOR THE HEAD WITH FIVE TISSUES

Tissue Name	ε_r	$\varepsilon_r^{(20)}$	Number of voxels
Skin	45.71 – j15.84	45.79 – j15.82	3445
Fat	11.29 – j2.09	11.27 – j2.17	5086
Mucous Membrane	45.66 – j15.95	45.64 – j15.94	35340
Grey Matter	52.28 – j17.71	52.28 – j17.71	18267
Skull Bone	20.58 – j6.54	20.59 – j6.55	7179

In the last example, the goal was to reconstruct the permittivities of the head phantom with seven tissues (Fig. 3a), assuming that the tissue boundaries are known. Again, all elements of the vector $\boldsymbol{\varepsilon}^{(1)}$ were initialized with the averaged tissue value $\varepsilon_r = 34.64 - j12.68$. Firstly, we ran the algorithm with a smaller number of voxels for 20 iterations, and each of them lasted about 60 minutes. We used the obtained results as the initial guess for the permittivities for the next 10 iterations with an increased number of voxels. The execution time of each of those iterations was about 105 minutes. The number of unknowns in the WIPL-D model for this scenario was 60778. Table II shows the results obtained after all 30 iterations.

TABLE II. ESTIMATION RESULTS FOR THE HEAD WITH SEVEN TISSUES

Tissue Name	ε_r	$\varepsilon_r^{(30)}$	Number of voxels
Skin	45.71 – j15.84	45.69 – j15.85	463/3445
Fat	11.29 – j2.09	11.33 – j2.03	655/5086
Mucous Membrane	45.66 – j15.95	45.73 – j15.92	4480/35340
Grey Matter	52.28 – j17.71	52.42 – j17.91	1690/13285
Skull Bone	20.58 – j6.54	20.67 – j6.70	903/7179
White Matter	38.58 – j11.18	38.33 – j11.27	492/3864
Cerebellum	48.86 – j23.51	34.66 – j12.65	140/1118

The biggest error was obtained for the cerebellum permittivity, which is the smallest domain located deep inside the head. The estimated permittivity values are shown in Fig. 5 (dots at the end represent the true values). Moreover, it can be observed that the cerebellum permittivity has changed insignificantly. Thus, we ran additional 10 iterations of DBIM for estimating the permittivity of the cerebellum, while the permittivities of other six tissues were fixed to the values obtained after 30 iterations. Finally, the permittivity of the cerebellum converged closely to the true value ($\varepsilon_r^{(40)} = 48.80 - j23.51$).

IV. CONCLUSION

We studied the capability of the DBIM to estimate the permittivities of tissues in realistic human head phantoms. We considered phantoms of different complexity and utilized the simplest model to initialize more elaborate ones. The permittivity was accurately estimated under the assumption that tissue boundaries are known. We will consider the case in which no prior knowledge is available in future work. However, voxel-based meshing has to be utilized in that case, which yields a significantly larger number of unknowns in the forward electromagnetic model and, consequently, increases the computational time enormously.

Current distribution in a hollow cylindrical conductor influenced by a parallel filament

Dragan Filipović, Tatijana Dlabač

***Abstract*—This paper presents a rigorous solution for the current distribution in a hollow cylindrical conductor in the presence of a current filament placed outside the conductor. The currents are assumed low-frequency, time-harmonic, flowing in opposite directions. As a starting point, we chose a redholm-type integral equation for the current density whose solution is sought in the form of an infinite sum of the proper harmonics – the modified essel functions of the second ind and trigonometric functions. The un nown coefficients in the sum are determined by equating the coefficients standing with the corresponding functions on both sides of the integral equation. The method presented in the paper allows treatment of the cases when the filament is inside the conductor and or the currents have the same direction.**

***Index Terms*—current distribution; hollow conductor; filament; integral equation**

I. INTRODUCTION

Determination of current distribution in a system of parallel cylindrical conductors with time-varying currents is a very complex problem since this distribution in each of the conductors is not only affected by its own electromagnetic field (skin effect), but also by the fields of all other conductors (proximity effect). There are very few cases where this problem can be solved in a closed form, so generally an implementation of various numerical methods is required. Among the most commonly used approaches to the combined skin and proximity effects we mention here: usage of Maxwell's equations in terms of the magnetic vector potential [1–4], method of integral equations [5–11], boundary integral equation formulation [12,13], method of model functions [14], etc.

In this paper we use an integral equation to solve in a closed form the problem of low-frequency current distribution in a cylindrical hollow conductor in the presence of an outer current filament, the currents being assumed sinusoidal and to flow in opposite directions. The solution is sought in the form of an infinite sum of proper harmonics with some unknown coefficients. These coefficients are found in a closed form by equating coefficients with the corresponding functions on both sides of the integral equation.

Tatijana Dlabač is with the Maritime Faculty Kotor, University of Montenegro, 85330 Kotor, Montenegro (e-mail: tanjav@ucg.ac.me), (https://orcid.org/0000-0001-9473-5558)

II. INTEGRAL EQUATION FOR THE CURRENT DENSITY IN A HOLLOW CYLINDRICAL CONDUCTOR IN THE PRESENCE OF A FILAMENT

Geometry of the problem is shown in Fig. 1. A current filament is parallel to a massive hollow cylindrical conductor of radii *a* and *b*.

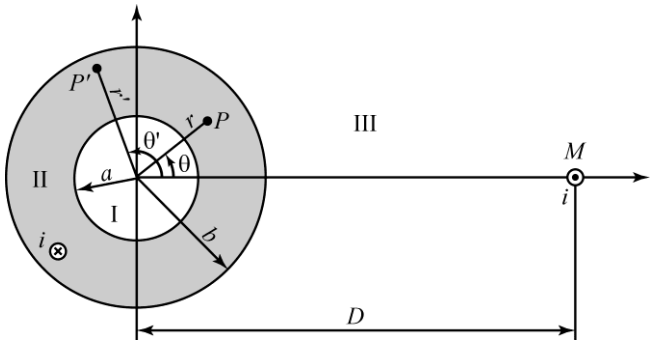

Fig. 1. Massive hollow cylindrical conductor and filament

The distance between the filament and the conductor axis is , and the parameters of the conductor are σ and μ_0. Currents of equal r.m.s. *I* and of frequency *f* flow through the conductor and the filament in opposite directions. The objective is to find the current distribution in the massive conductor.

Following [5]-[6], [9], [11], we can write an integral equation for current density in the conductor:

$$(r,\theta)=\frac{k^2}{4\pi}\left[\int_S r' \quad (r',\theta')\ln\frac{r^2+r'^2-2rr'\cos(\theta-\theta')}{2}dr'd\theta' - I\ln\frac{r^2+\quad^2-2r\quad\cos\theta}{2}\right]+\quad , \tag{1}$$

where $k^2=j\omega\mu_0\sigma$, is an unknown constant, and *S* is the annulus $a\le r\le b$, $0\le\theta\le 2\pi$.

Current density (r,θ) in (1) is subject to the condition:

$$\int_S (r,\theta) r\,dr\,d\theta = I. \tag{2}$$

III. SOLUTION OF THE INTEGRAL EQUATION

Separation of variables in the wave equation for current density leads to the following particular solutions (harmonics): $I_n(kr)$, $_n(kr)$, $\cos n\theta$, $\sin n\theta$, where I_n and $_n$ are

 ISBN 978-86-7466-930-3

modified Bessel functions. Symmetry requires that (r,θ) be an even function in θ, which eliminates sin$n\theta$. Hence, an appropriate form of the solution of (1) is

$$(r,\theta)=\sum_{n=0}^{\infty}\left[A_n I_n(kr)+B_n \quad _n(kr)\right]\cos n\theta \tag{3}$$

with some unknown coefficients A_n and B_n. When (3) is substituted into (1), we obtain

$$\begin{aligned}&\sum_{n=0}^{\infty}\left[A_n I_n(kr)+B_n \quad _n(kr)\right]\cos n\theta=\\&=\frac{k^2}{4\pi}\sum_{n=0}^{\infty}A_n F_n(r,\theta)+\frac{k^2}{4\pi}\sum_{n=0}^{\infty}B_n G_n(r,\theta)+\\&+\frac{k^2 I}{2\pi}\sum_{n=1}^{\infty}\left(\frac{r}{}\right)^n\frac{\cos n\theta}{n}+\end{aligned} \tag{4}$$

where

$$F_n(r,\theta)=\begin{cases}\dfrac{4\pi}{k}\left[b\ln\dfrac{b}{}I_1(kb)-a\ln\dfrac{r}{}I_1(ka)\right]-\dfrac{4\pi}{k^2}\left[I_0(kb)-I_0(kr)\right], n=0\\ \left\{-\dfrac{2\pi}{nk}\left[b\left(\dfrac{r}{b}\right)^n I_{n-1}(kb)-a\left(\dfrac{a}{r}\right)^n I_{n+1}(ka)\right]+\dfrac{4\pi}{k^2}I_n(kr)\right\}\cos n\theta,\ n>0\end{cases} \tag{8}$$

$$G_n(r,\theta)=\begin{cases}\dfrac{4\pi}{k}\left[a\ln\dfrac{r}{} \quad _1(ka)-b\ln\dfrac{b}{} \quad _1(kb)\right]-\dfrac{4\pi}{k^2}\left[\ _0(kb)-\ _0(kr)\right], n=0\\ \left\{-\dfrac{2\pi}{nk}\left[a\left(\dfrac{a}{r}\right)^n \quad _{n-1}(ka)-b\left(\dfrac{r}{b}\right)^n \quad _{n-1}(kb)\right]+\dfrac{4\pi}{k^2} \quad _n(kr)\right\}\cos n\theta,\ n>0\end{cases} \tag{9}$$

With F_n and G_n given by (8) – (9), we can equate the constant terms and the coefficients with ln (r/ , r^n cos$n\theta$ and r^{-n} cos$n\theta$ on both sides of (4), to get respectively

$$\begin{aligned}0=&A_0\left(kb\ln\frac{b}{}I_1(kb)-I_0(kb)\right)+\\&+B_0\left(-kb\ln\frac{b}{} \quad _1(kb)-\ _0(kb)\right)+\end{aligned} \tag{10}$$

$$0=-A_0 I_1(ka)+B_0 \quad _1(ka) \tag{11}$$

$$0=-A_n I_{n-1}(kb)+B_n \quad _{n-1}(kb)+\frac{kI}{\pi b}\left(\frac{b}{}\right)^n \tag{12}$$

$$0=A_n I_{n+1}(ka)-B_n \quad _{n+1}(ka). \tag{13}$$

To determine the five unknown constants (A_0, B_0, A_n, B_n and) we need one more equation beside the four equations given by (10) - (13). This additional equation is obtained from (2) if we replace (r, θ) by (3). Then, we have

$$F_n(r,\theta)=\int_S r' I_n(kr')\ln\frac{r^2+r'^2-2rr'\cos(\theta-\theta')}{2}dr'd\theta' \tag{5}$$

$$G_n(r,\theta)=\int_S r' \quad _n(kr')\ln\frac{r^2+r'^2-2rr'\cos(\theta-\theta')}{2}dr'd\theta' \tag{6}$$

and we made use of [15]

$$\ln\left(1+\frac{r^2}{2}-\frac{2r}{}\cos\theta\right)=-2\sum_{n=1}^{\infty}\left(\frac{r}{}\right)^n\frac{\cos n\theta}{n},\ \frac{r}{}<1. \tag{7}$$

The double integrals F_n and G_n, given by (5) - (6), seemingly very complex, can be evaluated in a closed form. This is done in the Appendix for F_n; G_n is found in the same way. Here we state the result.

$$\begin{aligned}I=&\int_0^{2\pi}d\theta\int_a^b r \ (r,\theta)dr=\\&=\sum_{n=0}^{\infty}\int_0^{2\pi}\cos n\theta\int_a^b r\left(A_n I_n(kr)+B_n \quad _n(kr)\right)dr=\\&=A_0 2\pi\int_a^b rI_0(kr)dr+B_0 2\pi\int_a^b r \quad _0(kr)dr.\end{aligned} \tag{14}$$

The integrals in (14) are readily evaluated by making the change of variables kr = and using the identities [16]

$$I_0(\ )=(\ I_1(\ ))'$$

$$_0(\ )=-(\quad _1(\ ))'.$$

Hence (14) becomes

$$I=\frac{2\pi}{k}\left\{A_0\left[bI_1(kb)-aI_1(ka)\right]+B_0\left[a \quad _1(ka)-b \quad _1(kb)\right]\right\}. \tag{15}$$

Now, (11) and (15) can be solved for A_0 and B_0

 ISBN 978-86-7466-930-3

$$A_0 = \frac{kI}{2\pi b}\frac{{}_1(ka)}{I_1(kb)\ {}_1(ka) - I_1(ka)\ {}_1(kb)} \tag{16}$$

$$B_0 = \frac{kI}{2\pi b}\frac{I_1(ka)}{I_1(kb)\ {}_1(ka) - I_1(ka)\ {}_1(kb)} \tag{17}$$

and A_n, B_n are found from (12) - (13)

$$A_n = \frac{kI}{\pi b}\left(\frac{b}{}\right)^n \frac{{}_{n+1}(ka)}{{}_{n+1}(ka)I_{n-1}(kb) - {}_{n-1}(kb)I_{n+1}(ka)} \tag{18}$$

$$B_n = \frac{kI}{\pi b}\left(\frac{b}{}\right)^n \frac{I_{n+1}(ka)}{{}_{n+1}(ka)I_{n-1}(kb) - {}_{n-1}(kb)I_{n+1}(ka)}. \tag{19}$$

The remaining unknown can be determined from (10), (16) – (17), but it is of no importance.

Finally, (3) and (16) - (19) determine current density in the massive conductor

$$\begin{aligned}(r,\theta) &= \frac{kI}{2\pi b}\frac{{}_1(ka)I_0(kr) + I_1(ka)\ {}_0(kr)}{I_1(kb)\ {}_1(ka) - I_1(ka)\ {}_1(kb)} + \\ &+ \frac{kI}{\pi b}\sum_{n=1}^{\infty}\left(\frac{b}{}\right)^n \frac{{}_{n+1}(ka)I_n(kr) + I_{n+1}(ka)\ {}_n(kr)}{I_{n-1}(kb)\ {}_{n+1}(ka) - I_{n+1}(ka)\ {}_{n-1}(kb)}\cos n\theta.\end{aligned} \tag{20}$$

Physically, the first term on the right-hand side of (20) is due to the skin effect, and the infinite sum accounts for the influence of the filament (proximity effect).

The same method applies if the filament is inside the conductor. In this case $b/$ in the infinite sum in (20) should be replaced by $/b$.

Expression (20) may also be derived by using Maxwell's equations [4]. In this approach the magnetic vector potential is determined in media I, II and III (Fig. 1), which includes usage of appropriate boundary conditions on the interfaces $r=a$ and $r=b$. The approach in the present paper is much simpler –solving integral equation (1) does not involve any boundary conditions.

It may be shown that the particular cases $a = 0$ (massive conductor [6], [11]), and $b - a = d << a$ (thin tubular conductor [5], [9]), follow from (20). Derivation for the former case is straightforward; for the latter case, it requires usage of a few formulas that involve Bessel functions.

IV. Conclusion

In this paper, we derived a closed-form solution for the current distribution in a hollow cylindrical conductor in the presence of a current filament placed outside the conductor. A solution of an integral equation for the current density is found in the form of an infinite sum of proper harmonics - the modified Bessel functions of the second kind and the trigonometric functions. A remarkable feature of the method used is that it does not involve any boundary conditions.

Appendix

In this Appendix we prove (8), relation (9) is justified by the same procedure.

Let $n = 0$. Then

$$\begin{aligned}F_0(r,\theta) &= \int_0^{2\pi} a\theta' \int_a^b r' I_0(kr') \ln\frac{r^2 + r'^2 - 2rr'\cos(\theta-\theta')}{2}\,dr' = \\ &= \int_0^{2\pi} a\theta' \left[\int_a^r r' I_0(kr') \ln r^2 \frac{r^2 + r'^2 - 2rr'\cos(\theta-\theta')}{r^2\ \ 2}\,dr' + \int_r^b r' I_0(kr') \ln r'^2 \frac{r^2 + r'^2 - 2rr'\cos(\theta-\theta')}{r'^2\ \ 2}\,dr'\right] = \\ &= \int_0^{2\pi} a\theta' \left\{\int_a^r r' I_0(kr')\left[\ln\frac{r^2}{2} + \ln\left(1 + \frac{r'^2}{r^2} - 2\frac{r'}{r}\cos(\theta-\theta')\right)dr'\right] + \int_r^b r' I_0(kr')\left[\ln\frac{r'^2}{2} + \ln\left(1 + \frac{r^2}{r'^2} - 2\frac{r'}{r}\cos(\theta-\theta')\right)dr'\right]\right\} \\ &= \int_0^{2\pi} a\theta' \left[\ln\frac{r^2}{2}\int_a^r r' I_0(kr')dr - 2\int_a^r r' I_0(kr')\sum_{m=1}^{\infty}\left(\frac{r'}{r}\right)^m \frac{\cos m(\theta-\theta')}{m}\,dr' + \int_r^b r' \ln\frac{r'^2}{2} I_0(kr')dr' - 2\int_r^b r' I_0(kr')\sum_{m=1}^{\infty}\left(\frac{r}{r'}\right)^m \frac{\cos m(\theta-\theta')}{m}\,dr'\right]\end{aligned} \tag{A1}$$

where we used (7). We do not need to evaluate the integrals that include infinite sum, since $\cos m(\theta-\theta') = \cos m\theta\cos m\theta' + \sin m\theta\sin m\theta'$, and the subsequent integration in θ' gives zero, since $\int_0^{2\pi}\cos m\theta' d\theta' = \int_0^{2\pi}\sin m\theta' d\theta' = 0,\ m \geq 1$. The two remaining integrals are evaluated as follows

$$\int_a^r r' I_0(kr')dr' = \frac{1}{k^2}\int_{ka}^{kr} u I_0(u)du = \frac{1}{k}\left(rI_1(kr) - aI_1(ka)\right), \tag{A2}$$

where the change of variables $kr'=u$ and the identity

$$uI_0(u) = \left(uI_1(u)\right)',$$

were used. Similarly, by using integration by parts

 ISBN 978-86-7466-930-3

$$\begin{aligned}
&\int_r^b r'\ln\frac{r'^2}{2}I_0(kr')dr' = \frac{2}{k^2}\int_{kr}^{kb} u\ln\frac{u}{k}I_0(u)du = \\
&= \frac{2}{k^2}\left[uI_1(u)\ln\frac{u}{k}\Big|_{kr}^{kb} - \int_{kr}^{kb} uI_1(u)\frac{du}{u}\right] = \\
&= \frac{2}{k^2}\left(kb\ln\frac{b}{}I_1(kb) - kr\ln\frac{r}{}I_1(kr) - \int_{kr}^{kb} I_1(u)du\right) = \\
&= \frac{2}{k^2}\left[kb\ln\frac{b}{}I_1(kb) - kr\ln\frac{r}{}I_1(kr) - \left(I_0(kb) - I_0(kr)\right)\right]
\end{aligned} \tag{A3}$$

since [16]

$$I_1(u) = I_0'(u).$$

Now, relation (8) for $n = 0$ follows from (A1) - (A3).

For $n \geq 1$

$$\begin{aligned}
F_n(r,\theta) = &\int_0^{2\pi}\cos n\theta' d\theta'\left[\ln\frac{r^2}{2}\int_a^r r'I_n(kr')dr' - \right. \\
&-2\int_a^r r'I_n(kr')\sum_{m=1}^{\infty}\left(\frac{r'}{r}\right)^m\frac{\cos m(\theta-\theta')}{m}dr' + \\
&\left.+\int_r^b r'ln\frac{r'^2}{2}I_n(kr')dr' - 2\int_r^b r'I_n(kr')\sum_{m=1}^{\infty}\left(\frac{r}{r'}\right)^m\frac{\cos m(\theta-\theta')}{m}dr'\right]d\theta'
\end{aligned} \tag{A4}$$

In this case, the integrals $\int_a^r r'I_n(kr')dr'$ and $\int_r^b r'\ln\frac{r'^2}{2}I_n(kr')dr'$ are irrelevant, since the subsequent integration in θ' gives zero $\left(\int_0^{2\pi}\cos n\theta' d\theta' = 0,\ n \geq 1\right)$, hence (A4) becomes

$$\begin{aligned}
F_n(r,\theta) = &-2\sum_{m=1}^{\infty}\frac{1}{mr^m}\int_0^{2\pi}\cos n\theta'\cos m(\theta-\theta')d\theta'\int_a^r r'^{m+1}I_m(kr')dr' - \\
&-2\sum_{m=1}^{\infty}\frac{r^m}{m}\int_0^{2\pi}\cos n\theta'\cos m(\theta-\theta')d\theta'\int_r^b r'^{-m+1}I_m(kr')dr'.
\end{aligned} \tag{A5}$$

Only the term with $m = n$ should be kept in the infinite sums, since for $m \neq n$

$$\begin{aligned}
&\int_0^{2\pi}\cos n\theta'\cos m(\theta-\theta')d\theta' = \\
&= \cos n\theta\int_0^{2\pi}\cos n\theta'\cos m\theta' d\theta' + \sin m\theta\int_0^{2\pi}\cos n\theta'\sin m\theta' d\theta' = 0,
\end{aligned}$$

due to orthogonality of the sine and cosine functions. As a consequence, (A5) simplifies to

$$\begin{aligned}
F_n(r,\theta) = &\left(-\frac{2\pi}{nr^n}\int_a^r r'^{n+1}I_n(kr')dr' - \right. \\
&\left.-\frac{2\pi r^n}{n}\int_r^b r'^{-n+1}I_n(kr')dr'\right)\cos n\theta
\end{aligned} \tag{A6}$$

where we have taken into account that

$$\begin{aligned}
&\int_0^{2\pi}\cos n\theta'\cos n(\theta-\theta')d\theta' = \\
&= \cos n\theta\int_0^{2\pi}\cos^2 n\theta' d\theta' + \sin n\theta\int_0^{2\pi}\cos n\theta'\sin n\theta' d\theta' = \pi\cos n\theta.
\end{aligned}$$

The change of variables $kr'=u$ and the relations [16]

$$u^{n+1}I_n(u) = \left(u^{n+1}I_{n+1}(u)\right)'$$
$$u^{-n+1}I_n(u) = \left(u^{-n+1}I_{n-1}(u)\right)'$$

enable to evaluate the two integrals in (A6)

$$\int_a^r r'^{n+1}I_n(kr')dr' = \frac{1}{k}\left(r^{n+1}I_{n+1}(kr) - a^{n+1}I_{n+1}(ka)\right) \tag{A7}$$

$$\int_r^b r'^{-n+1}I_n(kr')dr' = \frac{1}{k}\left(b^{-n+1}I_{n-1}(kb) - r^{-n+1}I_{n-1}(kr)\right). \tag{A8}$$

Finally, from (A6) - (A8)

$$\begin{aligned}
F_n(r,\theta) = &-\frac{2\pi}{nk}\left\{r\left[I_{n+1}(kr) - I_{n-1}(kr)\right] + b\left(\frac{r}{b}\right)^n I_{n+1}(kb) - \right. \\
&\left.-a\left(\frac{a}{r}\right)^n I_{n+1}(ka)\right\}\cos n\theta = \\
&= \left\{-\frac{2\pi}{nk}\left[b\left(\frac{r}{b}\right)^n I_{n-1}(kb) - a\left(\frac{a}{r}\right)^n I_{n+1}(ka)\right] + \frac{4\pi}{k^2}I_n(kr)\right\}\cos n\theta
\end{aligned}$$

since [16]

$$I_{n+1}(kr) - I_{n-1}(kr) = -\frac{2n}{kr}I_n(kr).$$

Therefore, the proof of (8) is completed.

Jamming a Drone - EM Simulation of Simple EW and EW Countermeasures Scenarios

Tomislav Milošević

***Abstract*—The paper discusses electromagnetic simulations ( ) of an electronic warfare (W) scenario where a drone is jammed using a continuous wave (CW) jammer. W countermeasures have been proposed based on calculated currents induced on specific parts of the drone critical for jamming effectiveness, such is antenna or wire in printed circuit board. All the simulations relate to widely used 2.4 G z frequency band.**

***Index Terms*—jamming, drone, anti-drone.**

I. Introduction

VARIOUS types of drones exist on a consumer market spanning from pieces dedicated to sport or entertainment to high class devices capable to carry out complex tasks. Besides utilization of drones along with positive legislation, even drones with basic functionality can potentially be used for malicious activities in scenarios which are not socially tolerable or could even be harmful. For example, a very basic drone can be used by paparazzi in invading celebrities' privacy or by criminals and terrorists in compromising security of a potential target. Therefore, in parallel with development of the drones, various anti-drone systems have been developed as well.

This paper presents a scenario where a radio-controlled drone is flying within an active zone of an anti-drone system. Anti-drone system itself is simply a helix antenna with a reflector.

Communication systems in general may exhibit restricted or completely inhibited functionality when subjected to interference, jamming or outer EW measures [1], [2]. Described model of jamming system represents the class of anti-drone systems which uses a CW signal to jam the drone flight-control receiver. In order to reduce the effect of the jammer, simple passive countermeasures can be used. In general, passive countermeasures do not involve the emission of any signals or noise [1]. It will be shown that using the results of EM reconnaissance, a simple, partial shielding of the jamming sensitive parts of the drone can significantly reduce the effectiveness of the jamming. It is assumed that anti-drone system and the drone receiver both operate at 2.4 GHz, the frequency widely used for Wireless LAN [3].

The basic principle of an anti-drone system operation is to induce current – a strong jamming signal on the drone side and saturate the receiver. Also, it is possible that the anti-drone system induces current in the printed circuit board (PCB) which is a part of the drone electronic system causing the malfunctioning of onboard electronics. Addressing the practical side of anti-drone system as described, one can say that receiving of control signals through the drone receiver will be blocked and that additionally a spurious signal would be induced in the electronic circuits.

The effects of the jamming will be simulated using WIPL-D Pro, a full wave 3D electromagnetic Method-of-Moments (MoM) based software which applies Higher Order Basis Functions over bilinear surfaces combined with Surface Integral Equations [4]. The software considers the bilinear surfaces as nonplanar quadrilaterals defined uniquely by four vertices [5]. Thanks to the inherent property of MoM, the size of EM model and accordingly the complexity of the simulation does not increase with increased jammer-to-drone distance [4].

II. Model of the Drone

The model of the drone is shown in the Fig. 1. It contains a camera mounted below the drone, which represents a payload of the drone. The drone with its payload is modeled as a dielectric object with the following dielectric properties: ε_{rReal}=2.2 and ε_{rImag}=-0.066. Beside the dielectric, the drone contains some metallic parts which are also shown in the Fig. 1. The "upper" metallic parts represent the monopole antenna with the ground plane. The monopole antenna is intended to be used for receiving flight control signals. The "lower" metallic parts represent a simplified PCB with a rectangular half-loop on it.

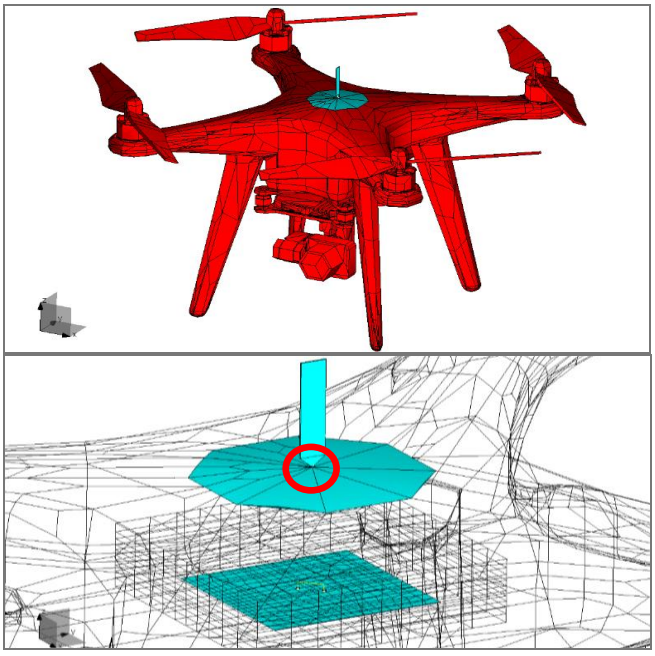

Figure 1. The model of the drone with the payload and the metallic parts of the drone.

Tomislav Milošević is with WIPL-D d.o.o., Gandijeva 7, 11073 Belgrade, Serbia (e-mail: tomislav.milosevic@wipl-d.com).

 ISBN 978-86-7466-930-3

Inducing the jamming current on the receiver will be monitored on the wire used to feed the monopole antenna. The wire is located at the very end of the antenna and it is encircled in red in Fig. 1.

The current induced in drone PCB is monitored on the grounded half-loop. Actually, as presented with markings outlined in the Fig. 2, the induced current is calculated over the "horizontal" wire. The dimensions of the metallic surface representing demonstration model of the PCB and the half-loop are also displayed in the Fig. 2.

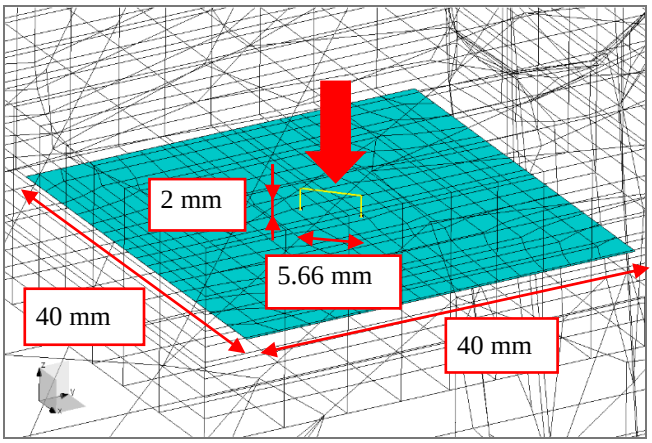

Figure 2. Demonstration model of the circuit board located within the drone.

It can be seen in the Fig. 3 that interior of the drone accommodates the described model of a PCB where onboard electronics is located. In other words, the metallic surface and the half-loop are immersed in the air box inside the drone dielectric.

The S-parameters and 3D radiation pattern[1] of the monopole antenna from Fig. 1 when the drone hovers above the PEC plane are shown in the Fig. 4.

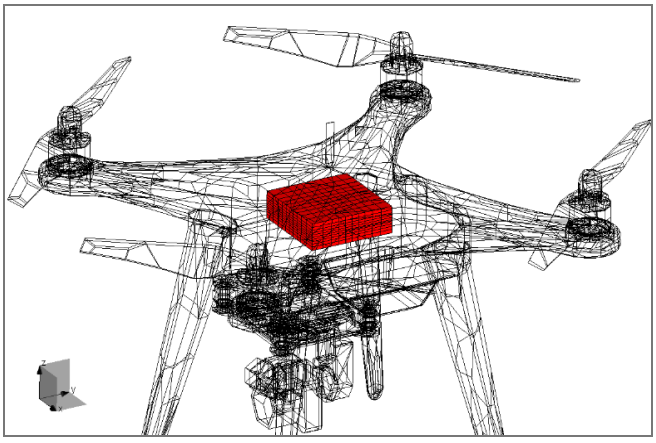

Figure 3. The air box in which the PCB with the half-loop is located.

III. The Model of the Jammer

The simplified model of the jammer in the form of the EM gun only contains a helix antenna and an octagon reflector both located over the PEC ground plane. The details related to geometry of the EM gun structure are presented in the Fig. 5. The center of the antenna reflector is located at the height of 0.1 meter and the axis of the helix is oriented at elevation angle of 35°. The radiation pattern of the jammer antenna above PEC plane is also shown in the Fig. 5. It can be seen that the 3D radiation pattern is influenced by PEC presence and that the position of the antenna has been adjusted to boost the radiation at a sector of interest to a gain higher than 10 dB. The sector of interest covers elevation angles from approximately 9° to approximately 57°.

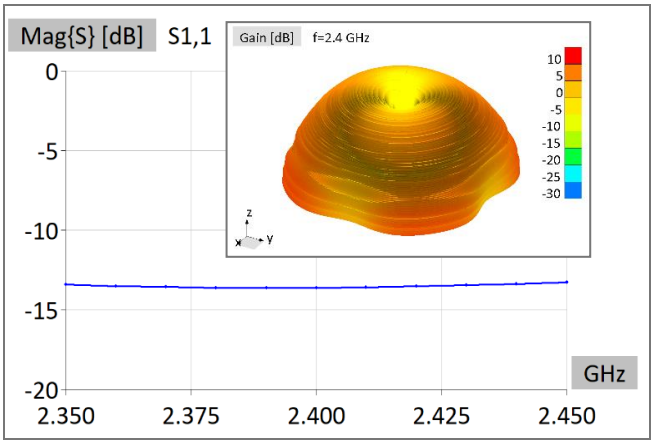

Figure 4. S-parameters and radiation pattern of the monopole mounted on the drone hovering above PEC plane.

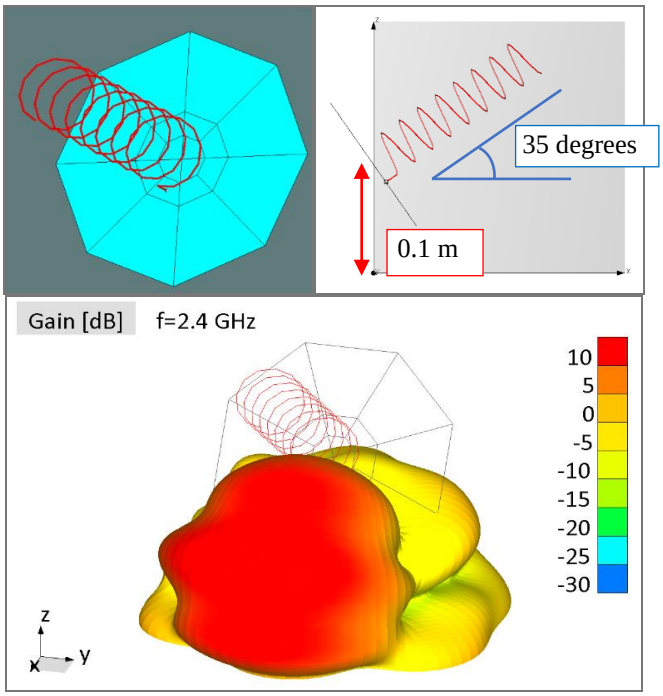

Figure 5. The model and the position of the jammer/EM gun over the PEC plane with 3D radiation pattern at 2.4 GHz.

IV. Jamming Scenario

The particular jamming scenario is illustrated in the Fig. 6 in 3D view, bird's view, and side view, from top to bottom. Both, drone and anti-drone system are located above the ground modeled as a Perfect Electric Conductor (PEC) plane. It is assumed that the drone flies through the zone protected with the jammer along a straight line, which is a realistic assumption.

[1] In this paper, all *Gain* values are in dBi.

 ISBN 978-86-7466-930-3

The top part of the Fig. 6 shows the direction of the antenna rotation starting from the lowest phi angle (phi = 0°) and the drone flight direction. The middle part of the figure explains the details related to the distance between the antenna and the drone, the angles of antenna rotation, and the drone flight direction. Finally, the lower part of the figure shows the side view of the jamming scenario.

The initial location of the drone is (x, y, z) = (15 m, 0 m, 5 m). The final location of the drone is (x, y, z) = (15 m, 25.98 m, 5 m). The jammer antenna is located in (x, y, z) = (0 m, 0 m, 0.1 m) as shown in Fig. 6 and it is being rotated from phi=0° to phi=60° (Fig. 6) keeping the elevation angle of 35°. This means that the monopole antenna mounted on the drone is constantly illuminated with the jammer signal during the described flight along the straight line. The helix antenna which is part of the jammer operates in axial mode at 2.4 GHz (see also Fig. 4 and S_{11} of the monopole antenna mounted on the drone).

Induced current in the middle of the wire located in the root of the monopole antenna mounted on the drone is shown in the Fig. 7. The current induced in the middle of the wire which is part of the half-loop on the PCB is shown in the Fig. 8.

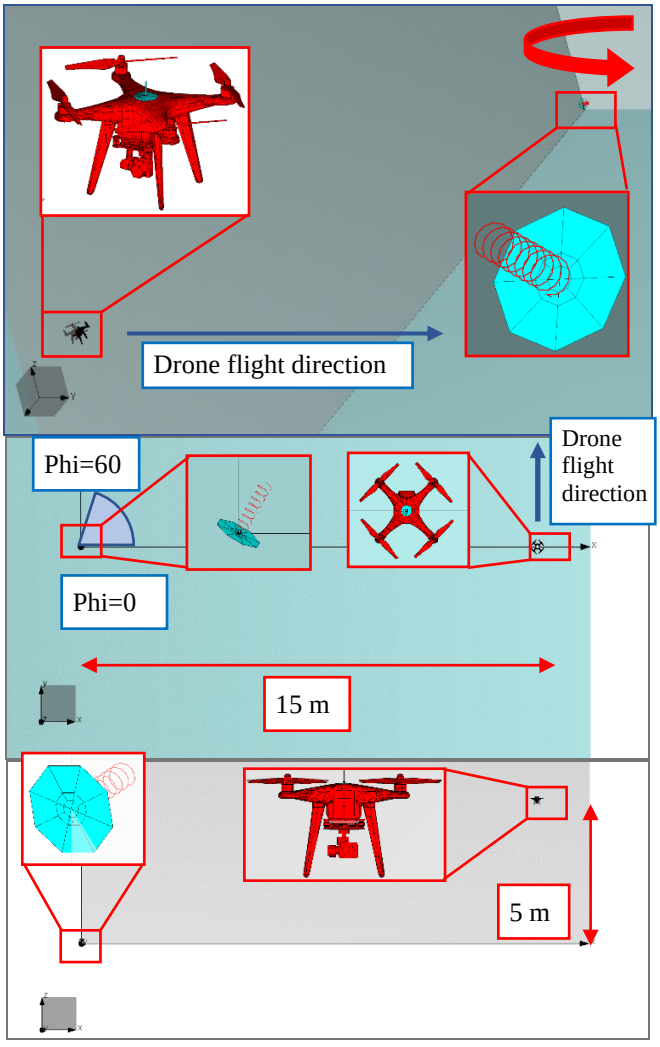

Figure 6. Investigated scenario in 3D, birds view, and side view, from top to bottom, respectively.

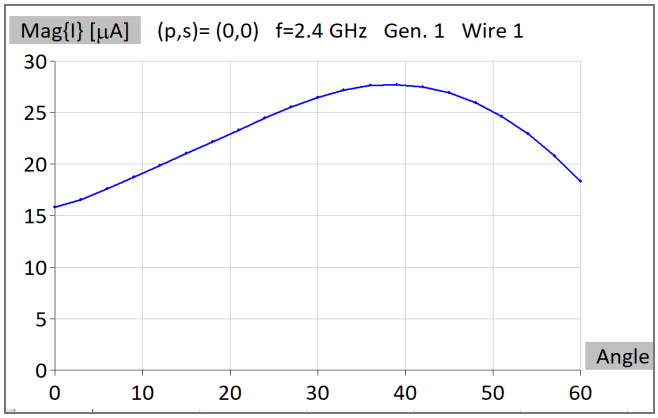

Figure 7. The current induced in the middle of the wire in the root of the monopole antenna.

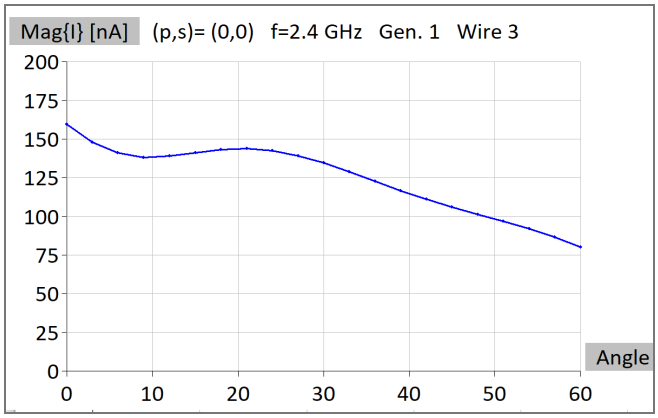

Figure 8. The current induced in the middle of the upper wire in the half-loop on PCB.

V. Decreasing Jamming Effectiveness

The presumption of the successful jammer countermeasures is the reliable information of the exact position of the jammer which can be revealed by visual surveillance or EM reconnaissance.

In order to decrease jamming effectiveness, the drone can be modified using a simple, commonly available objects. The PBC area can be easily protected from the outer influence by enclosing it in full (could be a piece of food-wrapping aluminum foil), which is a straight-forward action. However, the antenna used for receiving control signals cannot be fully enclosed for obvious reasons, but, when the position of the jammer is known, it can be partially enclosed so that the covered part coincides with the direction where the jammer is located. The very simple enclosure will be considered here, the one comprising a smooth cylinder or conical object (could be a disposable paper cup). with a metalized part located towards the jammer as described (again, the metallization could simply be a piece of an aluminum foil).

The model of the modified drone is shown in the Fig. 9. The drone dielectric is being displayed in yellow in the upper part of this figure. The cup, with assumed relative dielectric constant of $\varepsilon_{rCupReal}$=3 is colored in blue. The metallic sheet representing the aluminum foil is in cyan and clearly visible in both parts of the Fig. 9. Mechanical connections which should be added to real-life drone

 ISBN 978-86-7466-930-3

structure are excluded from this EM model, without losing the quality of approximation. Enclosing the PCB using thin metal sheet following a box shape displayed in Fig. 3 can be noticed in the lower part of the Fig. 9. More precise explanation of the scenario with metallic sheet is presented in Fig. 10 where the arrow points to the cup which is mounted on the top of the drone. In other words, the metallic sheet is positioned on the left side of the cup.

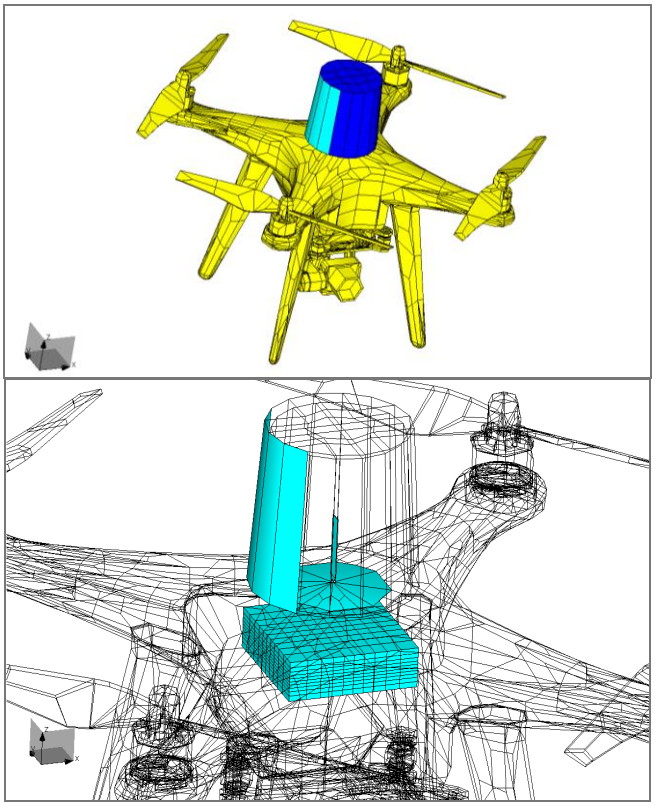

Figure 9. The drone with modifications and the metallic parts with enclosing of PCB.

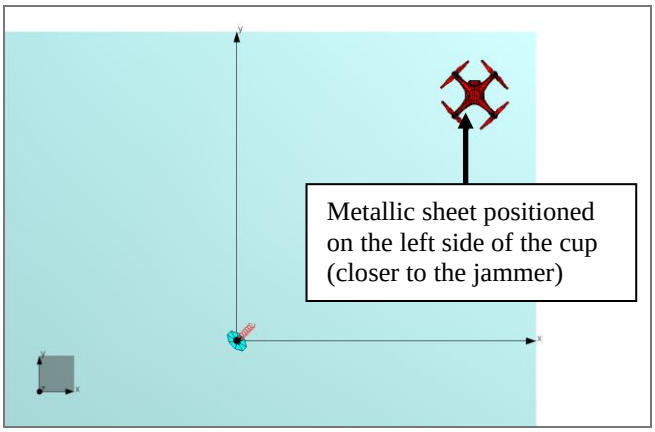

Figure 10. The position of the drone and the jammer with explained position of the metallic sheet. Not to be scaled.

The output results are displayed and compared in Figs 11-12. Fig. 11 displays comparison of the induced currents on the wire in the root of the antenna without the cup, with the cup and metallic sheet, and with the metallic sheet, only. It can be seen that without the metallic sheet attached to the cup, the level of induced current is the highest. Adding metallic sheet wrapped around the cup lower levels of induced currents are obtained. Similar result appears with the metallic sheet added and without the cup. This proves that metallic sheet mainly influences the jamming signal.

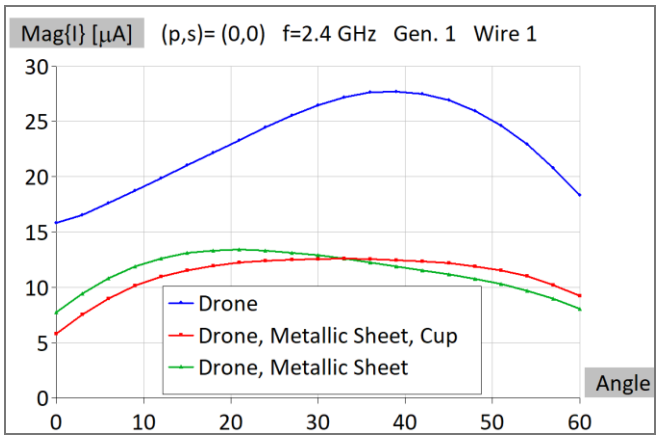

Figure 11. The comparison of currents induced in the middle of the wire in the root of the monopole antenna.

Fig. 12 displays comparison of currents on the PCB wire in three previously explained cases. The drop in level of the induced signal for shielded PCB is clearly noticeable.

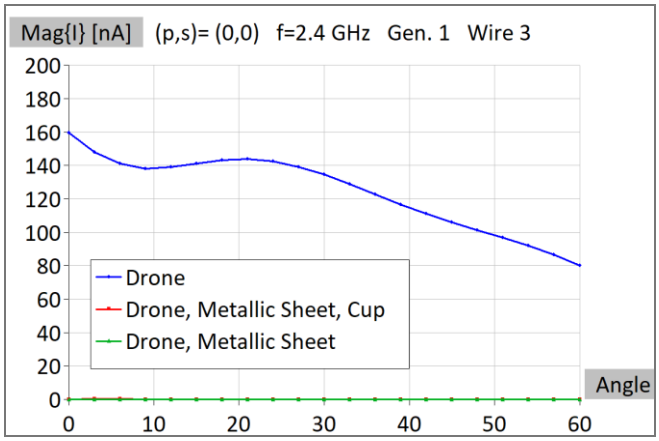

Figure 12. The comparison of currents induced in the middle of the upper wire in the half-loop on PCB

VI. Computer Platform and Simulation Time

All scenarios were simulated using a MoM based software and dedicated sweeping tool rotating the jammer from angle phi=0° to phi=60° in 21 equidistant points and moving the drone in the appropriate direction. The most demanding simulation of the jammed drone with the metallic sheet and the cup required 16,761 elements and 36,060 unknowns. The simulation time per a single angle of rotation for the same model is about than 8 minutes. The computer used for carrying out the simulation is Intel® Xeon® Gold 5118 CPU @ 2.30GHz (2 processors) with 192 GB RAM and a GPU card NVIDIA GeForce GTX 1080 Ti. GPU card is used for both matrix fill-in and matrix inversion.

 ISBN 978-86-7466-930-3

VII. Conclusion

A scenario encompassing the drone and an anti-drone system in the form of an EM gun over the PEC ground plane has been investigated. The effectiveness of jamming is demonstrated by calculating the induced currents at 2.4 GHz. Also, basic countermeasures were presented based on simple modifications of the drone.

The main effect of the jamming comes from the saturation of the receiver. Such a result can be explained easily as the antenna is directly exposed to the jamming signal. It was shown that mounting metallic sheet between the jammer and the receiving monopole, using an auxiliary cylindrical object like a paper cup, can significantly reduce the effectiveness of the jammer signal.

The current induced in the PCB elements might cause malfunction of drone electronics but being significantly lower than the level of the current on the antenna connection, is of secondary importance to the jamming scenario. Furthermore, the countermeasures can be performed easier by enclosing critical area around the PCB.

As it has been confirmed that simple countermeasures can make the drone resilient to jamming from a single source, the counter-countermeasures should include the distribution of several jammers in different locations around the target as it makes the method of partial shielding impractical.

Utilization of a Method-of-Moments (MoM) based software, for calculation of the induced currents has been also demonstrated. The numerical results have been obtained with high efficiency on an affordable desktop machine.

Further investigation could include propagation effects, or adding some objects such as metallic fences or lampposts and their influence on jammer-to-drone link.

Simulation Study of Voxel-Based Head Phantom for Medical Microwave Imaging

Mladjen Stevanetic, Branko Kolundzija, Tushar Singh, Marija Nikolic Stevanovic

***Abstract*—The paper describes the crucial role of phantoms in icrowave Imaging (WI) for medical devices. Accurate modelling of numerical scenarios is crucial in designing, testing, and developing WI devices. Phantoms with appropriate tissue electrical properties are inevitable components of imaging scenarios. Therefore, high computing resources are required to develop such phantom, and simulation of such scenarios requires a more prolonged time. A defined blueprint is required to reduce the comple ity of such scenarios to use them effectively for WI purposes. In the given paper, a brief study of the three-dimension vo el model of the head is presented, where a unit cell is a cube with tissue-mimic ing properties. The phantom is developed on the WIP -D Pro simulation platform. urther, the vo els are grouped in the form of , where is the number of vo els on each a is. omogenization techniques are implemented on the grouped vo els and result in one big cube, the main building element of the electromagnetic model. The C simulation is performed with plane wave e citation for different values of , and the results are analyzed for convergence to the reference model. Also, the relative mean absolute deviation (*A*) of the whole phantom as a result of the homogenization process is presented and its convergence is compared with the convergence of the mean deviation of simulated results.**

I. Introduction

BRAIN stroke has been one of the leading causes of death in humans over the last decade. Early-stage screening of stroke is a crucial step for diagnosis and treatment purposes [1]. Conventional technologies such as MRI, CT and X-ray are the gold standard for stroke detection due to accurate scanned results with high spatial resolution for clinical diagnosis. Although, these methods have several disadvantages, such as expensive procedures, low portability and ionizing radiation [2] – [3]. On the other hand, Microwave Imaging (MWI) is envisioned as a complementary tool to the imaging technologies for brain stroke detection. It is a low health risk, non-invasive, and cost-effective procedure [4] – [5].

Developing medical devices based on microwave imaging requires accurate electromagnetic modelling of imaging scenarios. The vital components of imaging scenarios are powerful EM simulation environment, anthropomorphic phantoms, tissue electrical properties and a measurement system. The simulation tool provides ease in modelling and accurate numerical analysis. The measurement system reduces to the antenna system around the organ of interest. Tissue mimicking properties help to understand the wave propagation through the human organ. Realistic human-like phantoms are crucial to understanding the complex structure of the organ with defined electrical properties. Modelling complex phantoms is the decisive factor for the accuracy and validation of the imaging scenario. Voxel and STL formats are widely available for designing phantoms [6]. The source format of the phantom is highly complex and requires efficient strategies to reduce the complexity of the structure while retaining accuracy.

The proposed study is focused on the study and accurate design of voxel based anatomically realistic head phantom for MWI purposes. The phantom data is usually derived from MRI images. The model is obtained from an online repository [7] in binary format. The 3D EM simulation platform WIPL-D Pro helps to transform the medical data into the 3D electromagnetic head model [8]. The unit structure of the actual phantom is a voxel or small cube with a side length of approximately 1 mm. The source file contains around 4 million such voxels. Each voxel has its own defined tissue properties. Simulation of such a model is very challenging. Therefore, with efficient procedures, the complexity is reduced. The voxels are grouped to form a big cube and then homogenization techniques are implemented on these big cubes. As mentioned, each voxel defined with one cube leads to a huge requirement of resources, therefore at the initial stage voxels are grouped using the parameter N, where N denotes the total number of voxels along each axis. The reference model is created with N=3. The homogenization is implemented using various mixing formulas [9]. A group of voxels with the given value of N is treated as one big cube, and its electrical property is derived from the averaging techniques. Implementing these methods significantly reduces the computational requirement and speeds up the simulation for EM analysis within the measurement system. In order to study the agreement between homogenization techniques and reduction in complexity, EM simulation is performed for various values of N ranging from 3 to 12 voxels in each axis. The excitation is a plane wave for the bistatic RCS estimation. The deviation between the reference model and the model with higher values of N gives the information on the accuracy of the simplification process in terms of % error. At the same time, the Relative Mean Absolute (*MA*) differences between the reference model and other models (with N>3) give insight in the averaging process and its convergence.

The paper is divided into three main sections. Section II is about the voxel model and homogenization techniques,

Mladjen Stevanetic is with WIPL-D d.o.o. Belgrade, Serbia (e-mail: mladjen.stevanetic@wipl-d.com)

Branko Kolundzija is with WIPL-D d.o.o. Belgrade, Serbia and School of Electrical Engineering, University of Belgrade, Serbia (e-mail: branko.kolundzija@wipl-d.com).

Tushar Singh is with WIPL-D d.o.o. Belgrade, Serbia and School of Electrical Engineering, University of Belgrade, Serbia (e-mail: tushar.singh@wipl-d.com).

Marija Nikolic Stevanovic is with School of Electrical Engineering, University of Belgrade, Serbia (e-mail: mnikolic@etf.bg.ac.rs).

 ISBN 978-86-7466-930-3

Section III is focused on numerical results, and Section IV concludes the paper.

II. Voxel Phantom and Homogenization

A. o el phantom

The voxel phantom represents dispersive dielectric properties data of a part of the human body (organ(s)), as a result of the MRI (Magnetic Resonance Imaging) or CT (computed tomography x-ray) scans of respective human body part [7].

That scan outputs the grid of points, named voxels, distributed in three-dimensional volume that covers the scanned organ with a specific resolution. Each voxel brings different dielectric properties of tissue. Although some phantom use Cole-Cole and Debye parameters to present dielectric properties of the tissue [10] - [11], this type of phantom comes with the binary input that holds identifications of tissue types for each voxel. The number of voxels varies depending on organ size and scanning resolution from 2 to 20 million or more. The resolution or distance between voxels is considered around 0.5 mm or 1 mm. Some of the voxels contain information on the surrounding media, in our case it is air.

However, it is very challenging and still under research to simulate the entire model with millions of unknowns, defined with thousands of domains i.e., closed regions with the same dielectric properties. Today's most robust full MoM solver, WIPL-D, reinforced with the HOBFs and fully parallelized, still requires large simulation time for millions of unknowns. Therefore, we designed a simple procedure, built-in WIPL-D, for transforming the medical data to the electromagnetic model being simulated in a reasonable amount of time and providing valuable information for overall phantom analysis.

B. omogeni ation

All the voxels are treated as small cubic volumes in space with specific dielectric constant values. Generally, these values are different for different voxels but are similar for the voxels of the same tissue type. In order to decrease the complexity of such a significant problem, we perform the averaging techniques on voxels. We create bigger cubic volumes that contain several voxels, taking the same number of voxels per each of the coordinate axes of a new, larger volume. If we treat one voxel as a small cube with a size equal to the resolution of the phantom, we create a big cube with N voxels per axis. Fig. 1 shows a preview of the Zubal head phantom [7] in two resolutions *N*=3 and *N*=8 on the WIPL-D Pro platform.

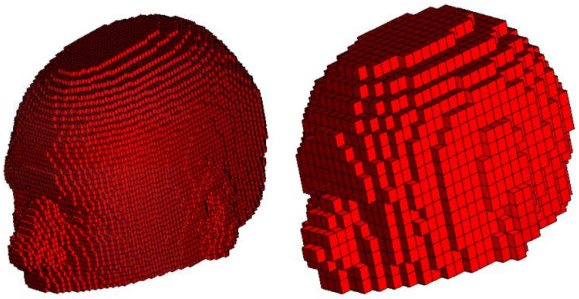

Fig. 1. Zubal anthropomorphic head phantom. Left, resolution *N*=3 and right, resolution *N*=8.

By increasing *N*, the resolution and therefore the complexity is gradually decreased, but the error due to averaging procedure is increased.

The new, big cube, represents a building element of the electromagnetic model. Its effective permittivity is obtained using mixing or averaging formulas applied to all the dielectric constant values of the voxels inside the same cube. These formulas were initially implemented for physical mixtures.

Standard averaging formula implements standard arithmetic mean:

$$\varepsilon_{eff} = \frac{\sum_{i=1}^{N^3} v_i * \varepsilon_i}{\sum_{i=1}^{N^3} v_i}, \quad (1)$$

where ε_i is voxel dielectric constant and v_i is voxel volume.

Lichtenecker formula is a logarithmic formulation of physical components of the mixture as shown below:

$$\ln(\varepsilon_{eff}) = \frac{\sum_{i=1}^{N^3} v_i * \ln(\varepsilon_i)}{\sum_{i=1}^{N^3} v_i}. \quad (2)$$

The formula has been established for biological materials such as human blood [12].

Looyenga equation is considered to be the most reliable formulation to predict the effective permittivity of the mixture [13] - [14]:

$$\varepsilon_{eff}^{(\frac{1}{M})} = \frac{\sum_{i=1}^{N^3} v_i * \varepsilon_i^{(\frac{1}{M})}}{\sum_{i=1}^{N^3} v_i}, \quad (3)$$

where $M = 2, 3$. Looyenga equation is considered up to third degree. All the formulas were implemented and the results of conversion of the phantom to the electromagnetic model as well as simulated results, and its comparison, were provided for each of the formulas. That is given in the next section.

Once the effective dielectric constant that represents averaged value of all the voxels permittivity inside a big cube is obtained, the second level of homogenization is applied. It implies all the big cubes being considered to define a finite number of the domains. Hence the number of big cubes is still significant, for example, more than 100000 in some cases, each cube cannot represent a separate domain. Therefore, all the cubes are divided into several groups, where, inside each group, a relative deviation of the effective dielectric constant is kept below some small threshold. In other words, the cubes in the group possess similar values of effective dielectric constant. One group defines one domain. The domain dielectric constant is a mean value of all effective dielectric constants within the group. The domain dielectric constant is assigned to all the cubes in the group as their new averaged value (new effective dielectric constant) because it is used in the electromagnetic simulation of the phantom. We called it "the assigned dielectric constant".

The number of the domains approximately goes from 100 to 300 for all the resolutions and all four mixing formulas considered in the paper. The higher the resolution (lower *N*)

 ISBN 978-86-7466-930-3

the number of domains generally decreasing and approaches to the number of different tissue types in the model. Each domain represents a closed region, and all the mesh elements, or big cubes' sides, inside the domain were removed to reduce complexity and thus the number of unknowns in the final model. Only domains' surface mesh elements took part in the MoM simulation.

The last part of big cubes' creation is the calculation of the deviation. For each cube, the deviation is calculated per the above-mentioned formulas. The formula used for averaging is also used for calculating deviation. The only difference is that part ε_i in the above equations is changed with the $|\varepsilon_i - \varepsilon'_{eff}|$ which is the deviation of one small voxel. Therefore, the Lichtenecker method is given as

$$\ln(\delta) = \frac{\sum_{i=1}^{N^3} v_i * \ln |\varepsilon_i - \varepsilon'_{eff}|}{\sum_{i=1}^{N^3} v_i}, \quad (4)$$

standard and Looyenga method is

$$\delta^{(\frac{1}{M})} = \frac{\sum_{i=1}^{N^3} v_i * |\varepsilon_i - \varepsilon'_{eff}|^{(\frac{1}{M})}}{\sum_{i=1}^{N^3} v_i}, \quad (5)$$

where $M = 1, 2, 3$, v_i is voxel volume and ε'_{eff} is the assigned dielectric constant value.

Therefore, a mean deviation for each big cube is calculated as the mean absolute distance of each voxel in the cube from the assigned dielectric constant value, rather than the distance from the averaged value ε_{eff}.

C. *Estimation of Error*

In the end, the deviation for the whole phantom is obtained from the particular deviations of big cubes. This value actually represents the error raised from the averaging procedure.

The error value is also calculated using a specific formula which is similar to the averaging process, so, either with standard, Lichtenecker or Looyenga procedure. Lichtenecker method

$$\ln(\Delta) = \frac{\sum_{j=1}^{K} V_j * \ln(\delta_j)}{\sum_{j=1}^{K} V_j}, \quad (6)$$

standard and Looyenga method

$$\Delta^{(\frac{1}{M})} = \frac{\sum_{j=1}^{K} V_j * \delta_j^{(\frac{1}{M})}}{\sum_{j=1}^{K} V_j}, \quad (7)$$

where K is number of big cubes, $M = 1, 2, 3$, δ_j is the big cube deviation and V_j is big cube volume. We can calculate the average value A of the whole phantom using the Lichtenecker method

$$\ln(A) = \frac{\sum_{j=1}^{K} \sum_{i=1}^{N^3} v_{ji} * \ln|\varepsilon_{ji}|}{\sum_{j=1}^{K} \sum_{i=1}^{N^3} v_{ji}}, \quad (8)$$

standard and Looyenga method

$$A^{(\frac{1}{M})} = \frac{\sum_{j=1}^{K} \sum_{i=1}^{N^3} v_{ji} * |\varepsilon_{ji}|^{(\frac{1}{M})}}{\sum_{j=1}^{K} \sum_{i=1}^{N^3} v_{ji}}, \quad (9)$$

where K is number of big cubes, $M = 1, 2, 3$, v_{ji} is voxel volume of i-th voxel in the j-th big cube and ε_{ji} is voxel dielectric constant of i-th voxel in the j-th big cube. The air voxels are omitted from the overall phantom.

Now, we can calculate the relative mean absolute error of the whole phantom as

$$RMA[\%] = \frac{\Delta}{A} * 100\,. \quad (10)$$

This value is provided at the end of the conversion process of the phantom to the electromagnetic model, ready for simulation.

The relative mean absolute deviation of simulated results is given by

$$RMA_{sim}[\%] = \frac{\frac{1}{n} * \sum_{i=1}^{n} |E_i^N - E_i^{Ref}|}{\frac{1}{n} * \sum_{i=1}^{n} |E_i^{Ref}|} * 100, \quad (11)$$

where n is the number of directions for bistatic RCS far-field, here 73x37 for azimuth and elevation, E_i^N is far-field for phantom with resolution N and E_i^{Ref} is far-field for the reference fantom.

III. Results

We used the Zubal head phantom for analysis. The full MoM electromagnetic simulations were performed in WIPL-D software.

Simulations in WIPL-D provide results for bistatic RCS in a number of space angles, with plane wave excitation. The results were provided for different resolutions N=3, 4… 12 and for all mixing formulas, Lichtenecker and Looyenga where M=1, 2, 3. We also provide the MA values for all the conversions.

The phantom with the highest resolution, N=3, is taken as the reference result. At the operating frequency of 1 GHz, this phantom has 500000 unknowns with around 100 domains and the resolution is about 3.5 mm. Simulation time on the machine Intel(R) Xeon(R) CPU E5-2650 v4 @ 2.20GHz (2 processors), with 48 logical processors, 256 GB of RAM and 4 GPU cards NVIDIA GeForce GTX 1080Ti, is about 7.3 hours.

All other phantoms were compared to this reference phantom, mean deviation of the RCS far-field is calculated for each of them relative to the reference phantom i.e., MA_{sim}. In the same manner, the differences were provided for the MA values too, relative to the reference phantom.

The next four figures present a comparison of MA_{sim} and MA relative to the reference phantom.

 ISBN 978-86-7466-930-3

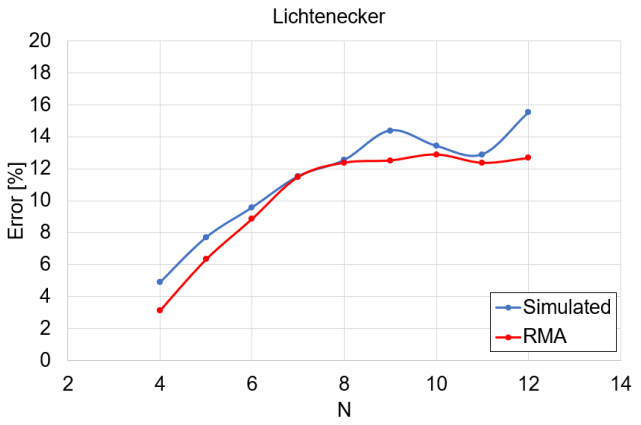

Fig. 2. Lichtenecker method. The Error for the blue trace represents the mean deviation of the RCS far-field relative to the reference phantom N=3 i.e., MA_{sim}. The Error for the red trace represents differences in MA also relative to the reference phantom N=3. N is resolution.

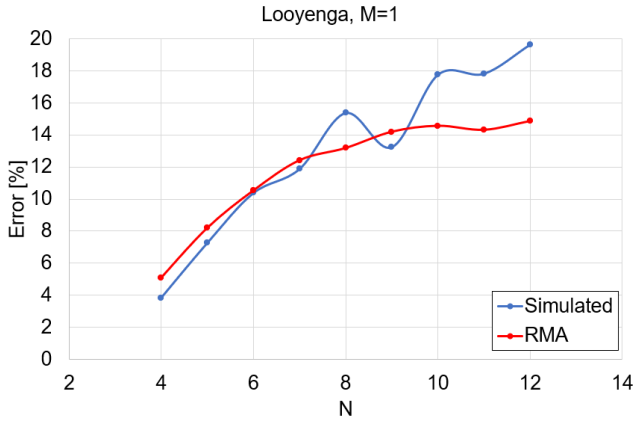

Fig. 3 Looyenga method, with M=1 degree. The Error for the blue trace represents the mean deviation of the RCS far-field relative to the reference phantom N=3 i.e., MA_{sim}. The Error for the red trace represents differences in MA also relative to the reference phantom N=3. N is resolution.

IV. Conclusion

We present a novel technique for the conversion of large voxel phantoms by averaging and homogenization of the voxel data to the electromagnetic simulation ready model. The obtained model is suitable for analysis of the imaging scenario, with reasonable simulation time.

We've also shown the estimated error, or relative mean absolute value MA, as a result of the simplification process. A comparison in error behavior between MA and simulated RCS results is provided. It can be seen that the MA expresses very similar behavior with the mean deviation in simulated results, for different resolutions, relative to some phantom of a very high resolution taken as the reference. The estimated convergence of the MA can serve as a guide of anticipating the characteristics of the phantom before performing electromagnetic simulation itself.

Radome Shape Impact on Automotive Radar Sensor Operating at 79 GHz

Nebojša Pupavac and Miodrag Tasić, *Member, IEEE*

***Abstract*—At high frequencies radome (adar Dome) degrades the automotive radar performance significantly. To gain better understanding of this phenomenon the radome shape and its impact on radiation pattern of the radar antenna array is analyzed in this paper. To analyze the impact of the radome shapes, an array of printed antennas is simulated with two different radome shapes and compared against the radiation pattern simulated without any radome. A simple single patch antenna for G z is designed using WIP -D software platform, which was used for simulation of the antenna array with and without radome.**

***Index Terms*— adome; radar sensor; antenna array; patch antenna.**

I. Introduction

A radome (radar dome) is a protective shield that encloses mmWave radar sensors and the antenna. It protects the antennas and electronics from external environment effects. The radome should be designed to minimally attenuate the electromagnetic signals transmitted and received by the antennas and as such should effectively be transparent to radio waves.

Since short range automotive radars work in 77-81 GHz frequency range [1], wavelengths of radar signals are rather small (3.75 mm at 80 GHz). This can cause significant interactions between radar signals and the plastic parts of the vehicle (painted bumper) and/or used radome, resulting in unpredictable error in the angle of arrival estimation [2]. Sometimes a calibration of the system can include the radar itself [3], but in the most cases radome is designed separately, with a goal to minimize reflections [4].

Although there are some general guidelines for automotive radar design [5], an electromagnetic simulation is necessary step in this process. In this paper we present results of the electromagnetic simulations for two radomes scenarios: spherical radome and rectangular radome, covering microstrip patch array. We will compare radiation patterns of these two systems with the radiation pattern of the microstrip patch array without the radome. The results can be used as a starting point in finding the optimal radome shape for a particular automotive radar design.

Miodrag Tasić is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: tasic@etf.bg.ac.rs), (https://orcid.org/0000-0002-8356-1190)

II. Guidelines for Radome Design

Since the most radomes are designed out of perfect dielectric material (with the relative permeability equal to 1, and the conductivity which is close to 0), main parameters for selecting appropriate material are relative permittivity and the loss tangent. The lower loss tangent provides the smaller attenuation by the radome, and overall smaller effect of the radome on the antenna performance. In finding optimal relative permittivity and a shape of the radome, the electromagnetic theory of time-harmonic electromagnetic fields for the plane-wave assumption can be used.

Electromagnetic wave reflections occur at the boundaries of the plane of mismatch. The plane of mismatch is the boundary of two domains with different dielectric permittivity. The interaction of the electromagnetic wave at the boundaries leads to the reflection and transmission of waves, quantized in terms of reflection coefficient ,

$$= \frac{\sqrt{\varepsilon_{r1}} - \sqrt{\varepsilon_{r2}}}{\sqrt{\varepsilon_{r1}} + \sqrt{\varepsilon_{r2}}}, \tag{1}$$

and transmission coefficient *T*,

$$T = \frac{2\sqrt{\varepsilon_{r1}}}{\sqrt{\varepsilon_{r1}} + \sqrt{\varepsilon_{r2}}}. \tag{2}$$

Expressions (1) and (2) hold for an incident plane wave normal to the infinite flat boundary between the domains with relative permittivities ε_{r1} and ε_{r2} [6]. These expressions indicate that lower relative permittivity of radome dielectric material causes lower degradation of radar performance (since the other domain is air, with relative permittivity close to 1). However, optimal radome material needs to provide adequate mechanical characteristics, and the boundary in the general case is not a flat surface. Therefore, the selection of the dielectric material is always a tradeoff.

The radome thickness is particularly important for optimal performance of the automotive radar sensors. To avoid reflection at the radome wall, its thickness should be equal to an integer multiple, *n*, of the half of the wavelength in the radome [6]:

$$t_{opt} = n\frac{c_0}{2f_r\sqrt{\varepsilon_r}}, \tag{3}$$

 ISBN 978-86-7466-930-3

where c_0 is speed of light in vacuum, ε_r is relative permittivity of radome material, and f_r is central frequency.

Typical parameters for the radome materials are shown in Table I. For radome shape analyses PTFE is selected as optimal solution which could be fabricated and tested to confirm simulation results presented in this paper. For $\varepsilon_{rPTFE} = 2$ and $f_r = 79\,\text{GHz}$, the optimal thickness of radome material from (3) is obtained for $n = 2$, $t_{opt} = 2.68\,\text{mm}$ (since the radome has to be at least 2 mm thick). Note that (3) is valid for electromagnetic plane waves at infinite flat boundary.

TABLE I
TYPICAL RADOME MATERIALS

aterial	elative Permittivity (ε_r)	oss tangent tg(δ)
Polycarbonate	2.9	0.012
ABS	2.0-3.5	0.0050-0.019
PEEK	3.2	0.0048
PTFE	2	<0.0002
Plexiglass	2.6	0.009
PE	2.3	0.0003
PBT	2.9-4.0	0.002

The optimal distance between the antenna and the internal surface of the radome helps to minimize the effects of reflections caused by the radome. These effects become minimal if the waves returned to the antenna are in phase with the transmitted waves. So, the optimal distance between antenna and radome is [5]:

$$d_{opt} = m\frac{c_0}{2f_r}. \tag{4}$$

For $m = 7$ we have $d_{opt} = 13.29\,\text{mm}$. A spherical radome in that case would have inner diameter of $26.58\,\text{mm}$, which is sufficient to cover the whole automotive radar sensor, including all necessary components.

III. ANTENNA DESIGN

We will model typical automotive radar sensors at 79 GHz, with four microstrip patch antennas. The layout of the single patch antenna is shown in Fig. 1. A substrate thickness is $t = 127\,\mu\text{m}$, with relative permittivity $\varepsilon_r = 3$, and loss tangent $\tan\delta = 0.0017$.

The patch width (W) and length ( ) are calculated using the standard approximation [7],

$$W = \frac{c_0}{2f_r\sqrt{\frac{\varepsilon_r+1}{2}}}, \tag{5}$$

$$= \frac{c_0}{2f_r\sqrt{\varepsilon_{eff}}}, \tag{6}$$

where ε_{eff} is given by

$$\varepsilon_{eff} = \frac{\varepsilon_r+1}{2} + \frac{\varepsilon_r-1}{2}\left(1+12\frac{t}{W}\right)^{-\frac{1}{2}}. \tag{5}$$

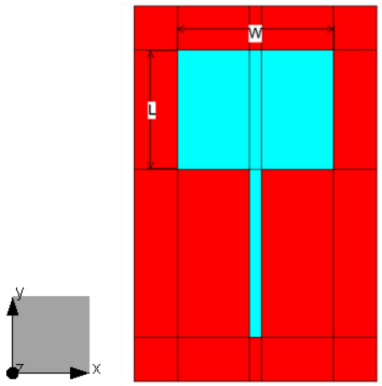

Fig. 1. Single rectangular patch antenna.

Antenna matching is achieved by adjusting the length of 0.1 mm wide feeding line using software package for electromagnetic modeling WIPL-D Pro [8]. Parameter s_{11} over desired frequency bandwidth is shown in Fig. 2, whereas radiation pattern in H-plane and E-plane is shown in Fig. 3.

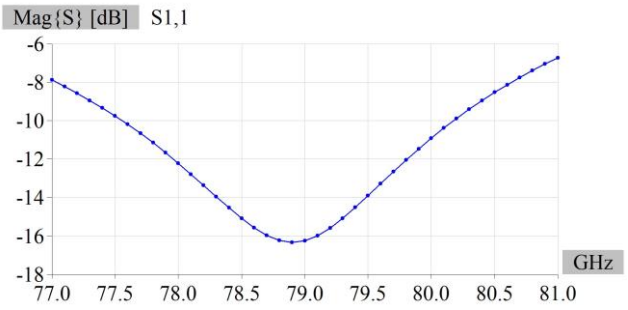

Fig. 2. Parameter s_{11} for a single microstrip patch antenna.

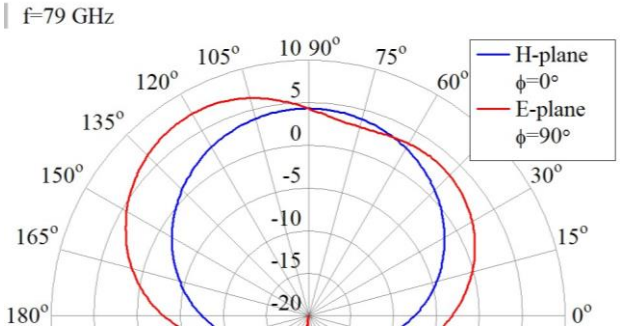

Fig. 3. Radiation pattern (Gain in dB) for a single microstrip patch antenna.

 ISBN 978-86-7466-930-3

Typical automotive radar sensors at 79 GHz are using 3 Tx and 4 Rx antennas. In this simulation only Rx antenna is simulated. It is made of four single microstrip patch antennas shown in Fig. 1, with λ/2 spacing, as shown in Fig. 4.

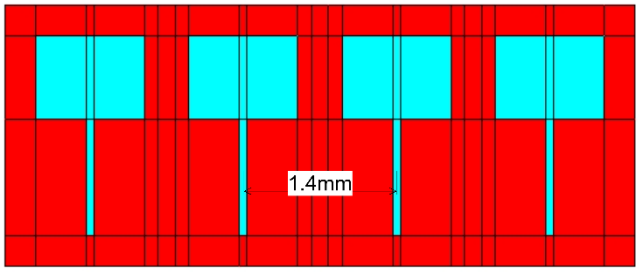

Fig. 4. Antenna Array with λ/2 spacing.

Since the array is symmetrical, only first two antennas (from left to right) are connected to generators, G1 and G2. The third and fourth antennas are symmetrical, so it is assumed that inner antennas have identical, but mirrored radiation pattern, as well as the outer antennas.

Fig. 5 shows that H-plane radiation patterns of both inner and outer antenna are deformed compared to the radiation pattern of a single antenna from Fig. 3 (where H-plane radiation pattern was symmetrical). Inner antenna deformation is less significant because it is surrounded by identical antennas from both left and right side.

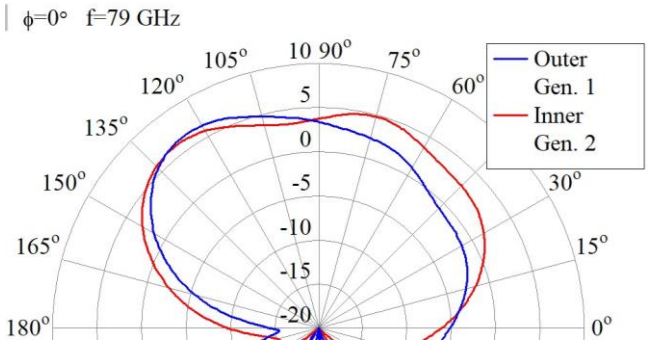

Fig. 5. Inner and Outer Antenna Radiation Patterns in H-plane.

IV. Antenna Array With Radome

Antenna array with a spherical radome of radius $d_{\text{opt}} + t = 13.42$ mm, with the center in the center of the array, is shown in Fig. 6.

Antenna array with a rectangular radome, with the same distance from the antenna array, having square cross section with the same width as the sphere radome diameter is shown in Fig. 7.

Both radomes are made from the material with relative permittivity 2 and thickness $t_{\text{opt}} = 2.68$ mm.

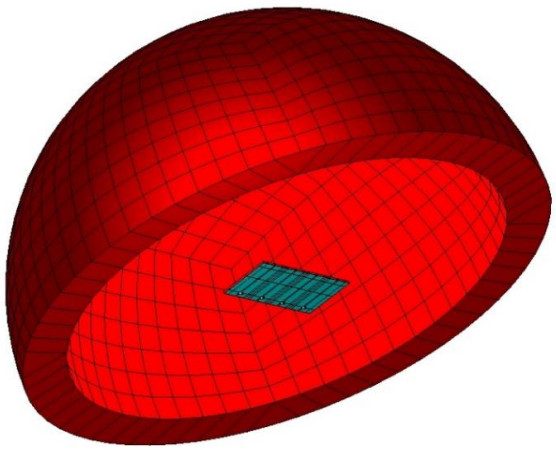

Fig. 6. Antenna array with the spherical radome.

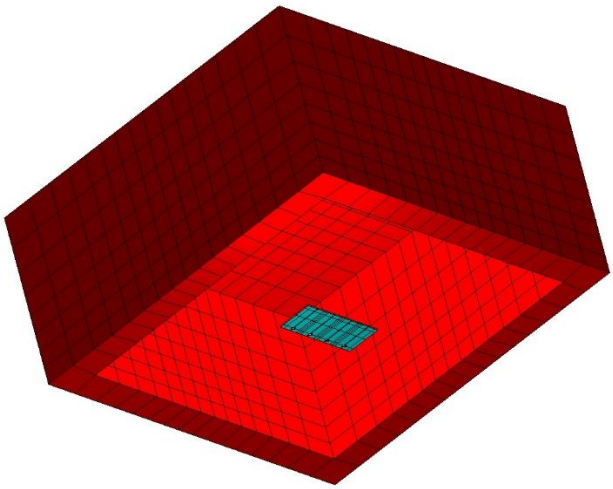

Fig. 7. Antenna array with the rectangular radome.

The electrical distance through the radome in boresight is equivalent to the thickness of the radome wall. The radome wall thickness t_{opt} is designed to cancel reflections from the radome, but in the case of normal incidence of the electromagnetic plane wave on infinite flat boundary Therefore, at boresight of the radome, the reflections at the inner wall will mainly cancel, resulting in low net reflections.

In the case of a rectangular (flat) radome, when moving away from the boresight to higher grazing angles of arrival, the distance traveled by the mmWave signal is greater than "optimal thickness", as illustrated in Fig. 8. This causes multiple reflections at the radome interface boundary resulting in ripples in the antenna radiation patterns and leading to nulls. These ripples and nulls can cause inconsistency in the detection of the objects at higher grazing angles resulting in angle estimation errors.

In the case of the spherical radome, the radome performance at different grazing angles will be more similar to the performance at boresight.

 ISBN 978-86-7466-930-3

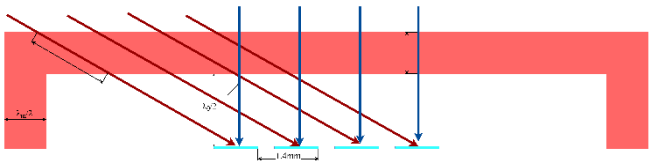

Fig. 8. Cross sectional view of the rectangular radome and the antenna array.

Radiation patterns of the outer antenna in E-plane, without a radome, and with spherical and rectangular radomes are shown in Fig. 9, whereas the similar graph for the inner antenna is shown in Fig. 10.

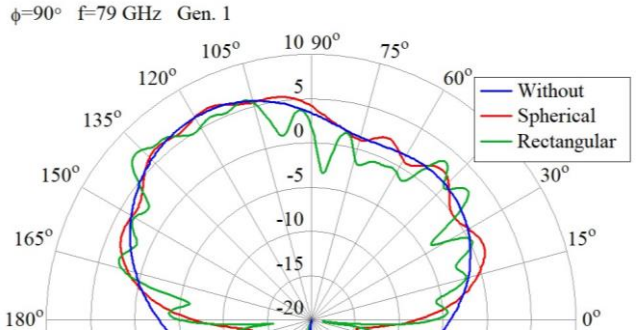

Fig. 9. Outer antenna radiation pattern in E-plane.

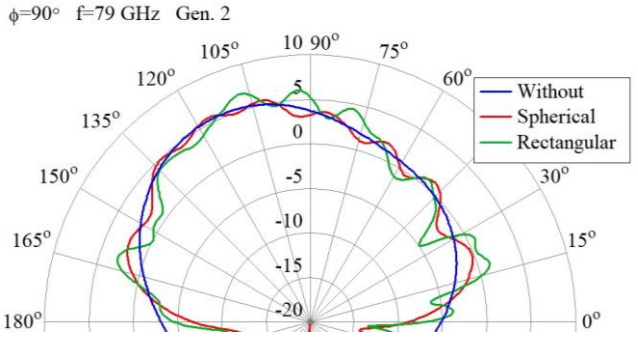

Fig. 10. Inner antenna radiation pattern in E-plane.

Radiation patterns of the outer antenna in H-plane, without a radome, and with spherical and rectangular radomes are shown in Fig. 11, whereas the similar graph for the inner antenna is shown in Fig. 12.

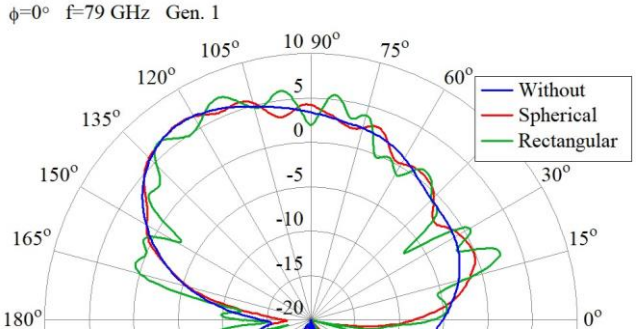

Fig. 11. Outer antenna radiation pattern in H-plane.

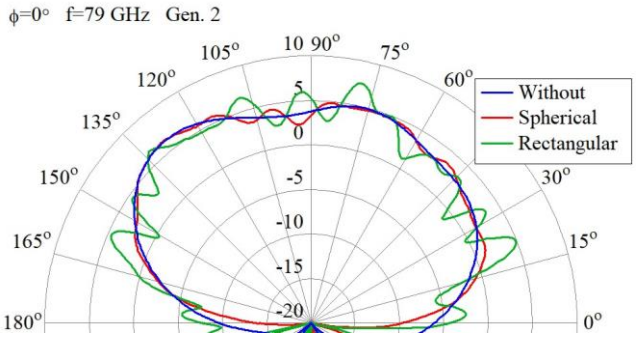

Fig. 12. Inner antenna radiation pattern in H-plane.

The radiation pattern from 180° to 360° is not interesting for the radar performance, also the simulation result is not relevant as the model doesn't include the complete PCB which is in realty much larger and has many components which are not modeled and neglected for the antenna simulation.

For the most applications azimuth angle of arrival estimation is more important. Therefore, the radiation patterns for H-plane (azimuth plane) are also shown in Cartesian system, in Figs. 13 and 14, to emphasize the ripples caused by radomes and to show the difference between the two radome shapes. Expected field of view of the automotive sensor is around ±60°, so antenna patterns from 15° to 165° are shown.

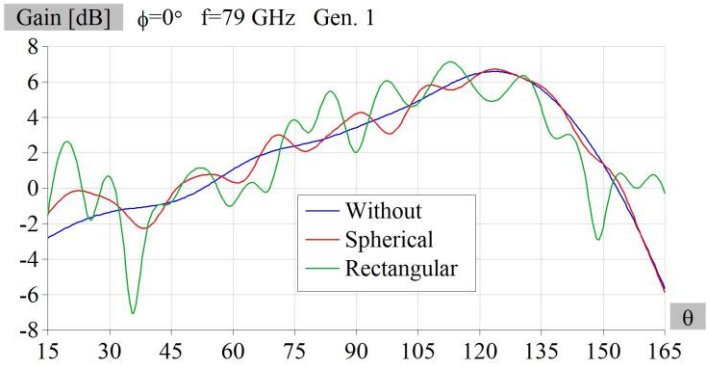

Fig. 13. Outer antenna radiation pattern in H-plane (Cartesian).

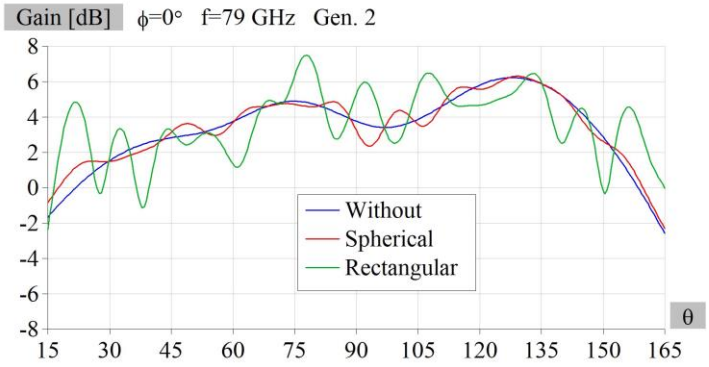

Fig. 14. Inner antenna radiation pattern in H-plane (Cartesian).

 ISBN 978-86-7466-930-3

V. CONCLUSION

The aim of these simulations was to show weather the radome shape could improve automotive radar sensor performance and if it makes sense to invest in designing more complicated radome shapes compared to the most common rectangular design. The simplified model comprising of only 4 Rx antennas (typically mmWave sensors are using 4 Rx and 3 Tx antennas) is showing that spherical radome has significantly reduced ripples compared to the flat radome.

Also, the spherical radome cannot fulfill half wavelength conditions for each antenna, so some of the ripples still appear comparing to the scenario without a radome.

Main influence of the above-mentioned ripples is the degradation of the radar performance by means of angle of arrival estimation and the maximal detection range. To confirm the simulation results, a realistic antenna array with both Rx and Tx antennas should be measured using Vector Network analyzer (VNA) and referent (horn) antenna using different radomes. Also, the complete mmWave sensor with the identical antenna array and targets at different angle of arrival could be tested to indicate the angle estimation accuracy degradation introduced by different radomes and compared with the radar simulation results.

Implementing Gradient Model for Surface Roughness in WIPL-D

Milan P. Radović, Aleksandar Z. Golubović *Student Member, IEEE* and Miloš M. Jovičić

***Abstract*—The implementation of gradient method for surface roughness correction in WIPL-D software package is presented. Surface roughness model is tested on modified ring resonator model. Finally, simulation results from WIPL-D and CST Studio Suite are compared.**

***Index Terms*—surface roughness, gradient model, effective conductivity, WIPL-D, ring resonator, surface impedance**

I. Introduction

MODERN automotive radar systems are often developed in mm-Wave technology [1],[2] and require precise design and manufacturing. Hence, accurate full-wave electromagnetic modeling of such systems has an immense importance in development. To that aim, many electromagnetic effects, that are negligible at lower frequencies, should be taken into consideration at higher frequencies. One of such effects is surface roughness of conductors.

In this case study, gradient method [3] for surface roughness approximation is implemented in WIPL-D software package [4]. The implementation is tested on a model of modified ring resonator [5]. The results are then compared to the results acquired by CST Studio Suite [6].

Skin effect is a tendency of alternating currents to concentrate on the surfaces of conductors, and exponentially drop with conductor depth. It is a result of opposing Eddy currents induced by the changing magnetic fields. If a cylindrical wire-like conductor is observed, the countering Eddy currents will be strongest along the center of the cylinder and drop towards the surface. This will create a characteristic current density profile in the conductor, as shown in Fig. 1. With higher frequencies, currents are more concentrated at the surface of the conductor. We define skin depth, δ, as the depth at which the current density drops to $\frac{1}{e}$ of it's value (around 36.7%)

Skin depth is given by [7]

$$\delta = \sqrt{\frac{2\rho}{\omega\mu}}\sqrt{\sqrt{1+(\rho\omega\varepsilon)^2}+\rho\omega\varepsilon}, \tag{1}$$

Milan P. Radović is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia and with NOVELIC d.o.o., Veljka Dugosevica 54/B5, 11000 Belgrade, Serbia (e-mail: milan.radovic@novelic.com).

Aleksandar Z. Golubović is with the School of Electrical Engineering, University of Belgrade and with NOVELIC d.o.o. (e-mail: aleksandar.golubovic@novelic.com).

Miloš M. Jovičić is with NOVELIC d.o.o. (e-mail: milos.jovicic@novelic.com)

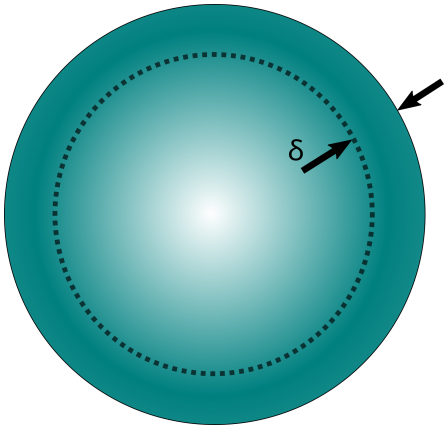

Fig. 1: Illustration of current density and the skin depth.

where ρ is the specific electrical resistance, ω is the angular frequency of current , μ is the permeability of the conductor and ε permittivity. At frequencies of interest, (1) can be approximated by

$$\delta = \sqrt{\frac{2}{\sigma\omega\mu}}. \tag{2}$$

At low frequencies, the skin depth is larger than the imperfections of the conductor surface. Therefore, when modeling conductors for electromagnetic analysis it is common to approximate the surface of the conductor as ideally flat. However, at high frequencies the skin depth is small enough that it is of comparable size to the roughness of the surface (0.23 μm at 80 GHz). The rough surface of the conductor and the comparable skin depth qualitatively make the current paths longer. At microscopic levels, the roughness structures are electrically larger causing resonant frequencies to shift lower. Additionally, longer current paths will induce larger resistive losses.

We define R_q as the root mean square average of the profile height deviations from the mean line of ideal surface. Different copper deposition methods will yield different surface profiles with different R_q. Some of the most widely used copper profiles are [8] STD (Standard foil, $R_q = 5-10$ μm), HPF (High Performance Foil, $R_q = 10-15$ μm), RTF (Reverse Treated Foil, $R_q = 3-6$ μm), VLP (Very Low Profile, $R_q = 3-6$ μm), HVLP (Hyper Very Low Profile, $R_q = 1-3$ μm) and ULP (Ultra Low Profile, $R_q = 0.5-1$ μm), which are shown in Fig. 2. At 1 GHz, the skin depth is 2 μm and is considerably smaller than most copper profile R_q. Since

 ISBN 978-86-7466-930-3

most of the high frequency current will be conducted trough irregular boundary surface, it is important to realistically model and correct for the effects which the rough surface will induce.

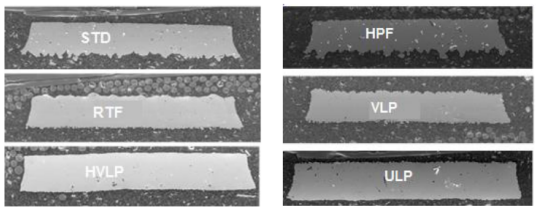

Fig. 2: Microscopic images of common copper deposition profiles.

II. Gradient Method

The gradient method relies on the fact that the surface profile can be described as a conductivity gradient, from conducting copper to non-conductive dielectric.

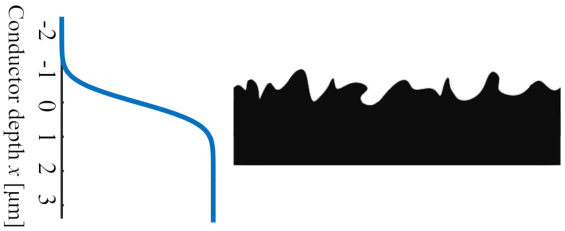

Fig. 3: An example of conductor surface profile and its cumulative distribution function.

It is evident from [3] that the conductivity, $\sigma(x)$, is a cumulative distribution function of x

$$\sigma(x) \propto CDF(x). \tag{3}$$

Cumulative distribution function is given as the integral of probability distribution function over the entire x domain

$$CDF(x) = \int_{-\infty}^{x} PDF(u)\mathrm{d}u. \tag{4}$$

We approximate the probability distribution function with a normal Gauss distribution

$$PDF(x) = \frac{1}{R_q\sqrt{2\pi}} \mathrm{e}^{\frac{-x^2}{2R_q^2}}. \tag{5}$$

Finally, the conductivity function can be written as

$$\sigma = \sigma_0 CDF(x) = \sigma_0 \int_{-\infty}^{x} \frac{1}{R_q\sqrt{2\pi}} \mathrm{e}^{\frac{-u^2}{2R_q^2}} \mathrm{d}u. \tag{6}$$

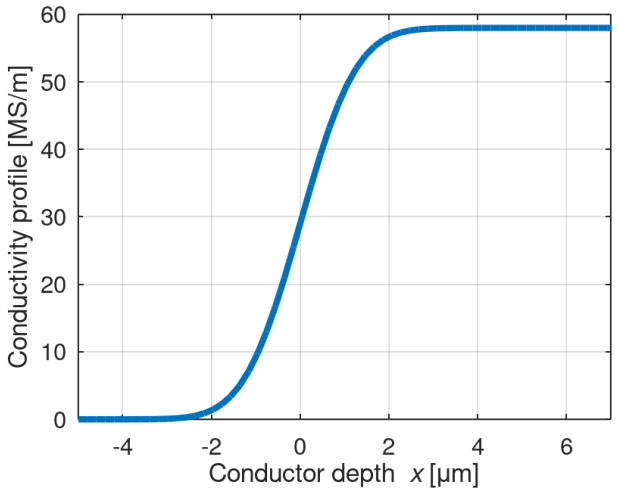

Fig. 4: Conductivity profile of copper surface for $R_q = 1$ µm.

Next, wave equations are derived with additional term that corresponds to variable conductivity due to surface roughness [3]

$$\frac{\partial^2 B_y}{\partial x^2} - \mathrm{j}\omega\mu_0\sigma B_y - \frac{\partial}{\partial x}\ln(\sigma(x))\frac{\partial B_y}{\partial x} = 0, \tag{7}$$

where B is magnetic flux density vector. It should be noted that when the conductivity profile is constant, (7) simplifies down to classical Helmholtz equation which is analytically solvable. However, (7) needs to be numerically solved.

Finite differences method is used to solve (7) for B_y. The results are presented in Fig. 5.

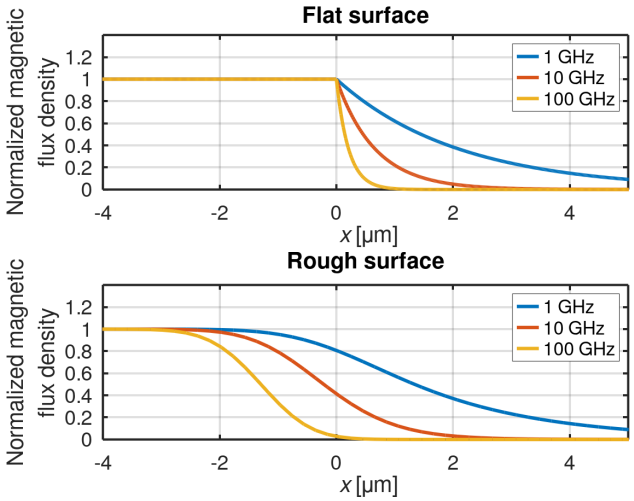

Fig. 5: Comparison of magnetic flux density y component for flat and rough surface ($R_q = 1$ µm).

.

 ISBN 978-86-7466-930-3

The change in magnetic flux density is gradual and not sharp as in the flat approximation, which is more in accordance to the real scenario. Knowing the magnetic flux density it is possible to find the current density distribution given by Fig. 6

$$J_z = \frac{1}{\mu_0}\frac{\partial B_y}{\partial x}. \tag{8}$$

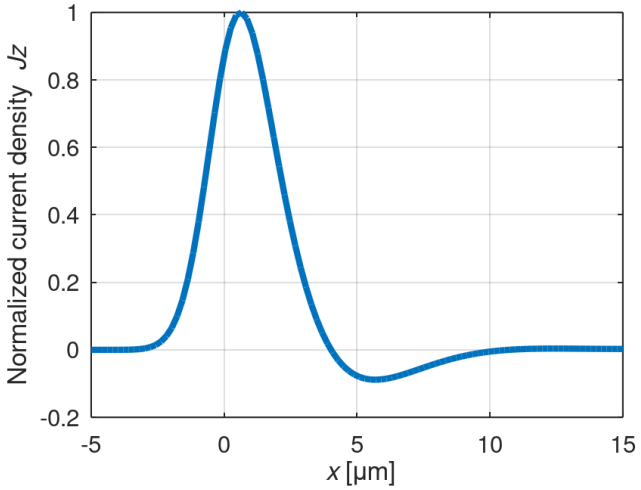

Fig. 6: Normalized current density distribution.

III. Effective Conductivity

The power density of the conductor surface is given by [3]

$$P_{\mathrm{d}} = \int_{\sigma>0} \frac{|J|^2}{2\sigma(x)}\mathrm{d}x. \tag{9}$$

Consider another conductor with a flat surface that has the same power density as observed rough surface conductor. Its conductivity profile will be a step function

$$\sigma(x) = \begin{cases} \sigma_{\mathrm{eff}}, x < 0 \\ 0, x > 0 \end{cases}. \tag{10}$$

By equalizing the two power distributions, we can calculate the effective conductivity that a flat conductor will need to have, in order to the reproduce the same power distribution as a rough surfaced one

$$\int_{\sigma>0} \frac{|J_{\mathrm{rough}}|^2}{2\sigma(x)}\mathrm{d}x = \int_{\sigma>0} \frac{|J_{\mathrm{flat}}|^2}{2\sigma_{\mathrm{eff}}}\mathrm{d}x. \tag{11}$$

Finally, effective conductivity for different R_q values is numerically computed (7).

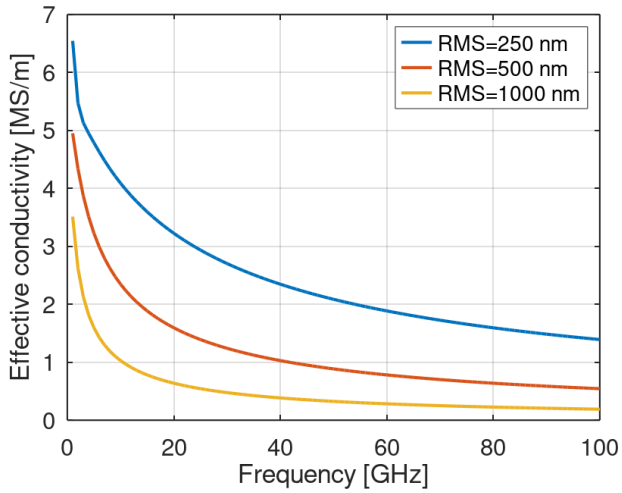

Fig. 7: Comparison of effective conductivity in function of frequency for different values of R_q.

IV. Effective Permeability

Previous method models the resistive losses that will be induced from the surface roughness, however, due to different surface profile the conductor will have different reactive losses.

Similarly to previous modeling of effective conductivity, we will model an effective permeability to account for reactive losses. We observe another conductor with identical magnetic field energy distribution, however, with effective permeability. Equalizing the two energy distributions we can calculate the effective permeability as

$$\int_{\sigma>0} \frac{|B_{y,\mathrm{rough}}|^2}{2\mu_0\mu_{\mathrm{r}}}\mathrm{d}x = \int_{\sigma>0} \frac{|B_{y,\mathrm{flat}}|^2}{2\mu_0\mu_{\mathrm{r,eff}}}\mathrm{d}x. \tag{12}$$

By numerically solving, we yield (Fig. 8):

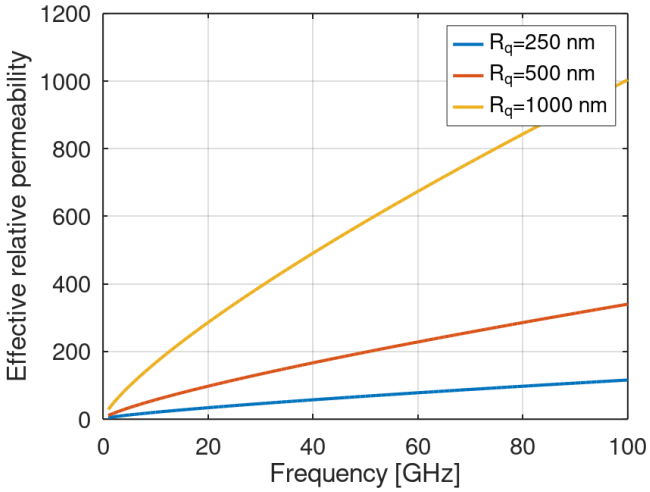

Fig. 8: Comparison of effective permeability in function of frequency for different values of R_q.

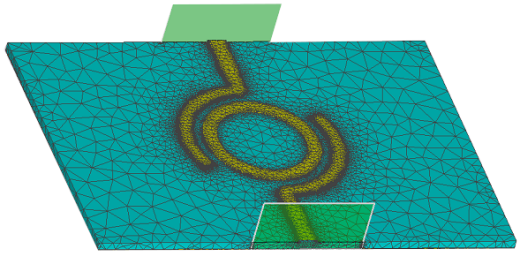
 ISBN 978-86-7466-930-3

V. Implementation and Results



By obtaining both conductivity and permeability, we can model both resistive and reactive losses. The software package WIPL-D can model distributed loadings with surface impedance, hence we need to translate our parameters into surface impedance as,

$$Z_s = R_s + jX_s = \frac{1}{\sigma_{eff}\delta(\sigma_{eff})} + \frac{1}{\sigma_0\delta(\mu_{r,eff})}. \quad (13)$$

We model a modified ring resonator in both WIPL-D and CST Studio Suite for the purposes of result comparison (Figure 9). In CST we use the surface roughness method provided with the software, while in WIPL-D we use the frequency table function to implement the surface impedance into the model.

(a)

(b)

Fig. 9: a) Ring resonator model in WIPL-D and b) ring resonator model in CST

Since CST uses gradient method that accurately model surface roughness, matching of results obtained by CST and WIPL-D will prove a successful implementation of gradient method in WIPL-D.

The comparison of simulated reflection coefficient for both flat and rough surface of modified ring resonator is shown in 10. From these figures we can observe that there is an excellent matching between the results, thus the gradient method is successfully implemented in WIPL-D.

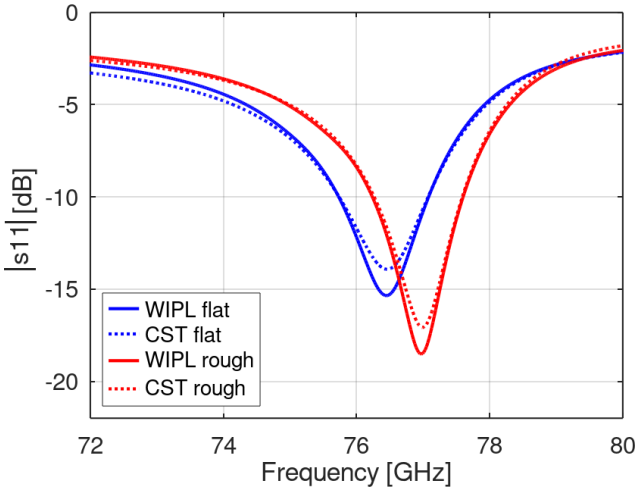


Fig. 10: Comparison of s_{11} for CST and WIPL-D.

VI. Conclusion

Gradient method for surface roughness estimation is implemented in WIPL-D and tested on modified ring resonator model. Results match the ones obtained using CST Studio Suite, thus gradient model implementation is corroborated. This method can be utilized in WIPL-D, for mm-Wave designs, where surface roughness is crucial.

The Ability to Minimize a New Type of Moderate-Bandwidth Microwave Filter

Dušan Nešić, *Member, IEEE*, Tomislav Milošević

***Abstract*—An example of minimizing the width of a microwave filter structure by bending the stubs and reducing the number of required via holes is presented in this paper. It is shown that the filter area can be reduced near 2 times after bending the stubs. EM model of minimized structure is presented and compared with common filter design.**

***Index Terms*—Microwave filter, Minimization, Microstrip.**

I. Introduction

WIDE bandpass filters (WBPFs) are important components found in microwave circuits [1-8]. Their purpose is to suppress DC components of the signal as well as low frequency signal components. This suppression is achieved by combing coupling and short-circuiting stubs [1-4] or by only short-circuiting stubs [5-8]. Also, the defective ground structure (DGS) or multilayers can be also used with the same purpose [1,4].

Fig. 1 shows an infinite periodical series of identical T-cells with a short-circuited stub and uniform lines implemented in microstrip technology. Here, Z and Z_s represent characteristic impedances of the base line θ and stub θ_s. θ is electrical length given as the phase for a given frequency or wavelength ($\theta=2\pi L/\lambda$). Central passband frequency f_c corresponds to $\theta_s = \pi/2$ i.e., $L = \lambda_c/4$. λ_c is wavelength for the frequency f_c.

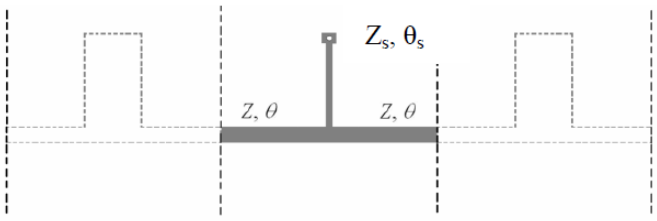

Fig. 1. Scheme of one cell within a filter in microstrip technology.

In [9, 10] relation $\theta_s = 2\theta$ was chosen to eliminate ripples in the stopband. For that relation optimized S_{11}-parameters are for $Z = 50\ \Omega$ for all values of Z_s. Calculated design curve of Z_s on the relative bandwidth (*RBW*) is presented in Fig. 2.

The film for fabrication (etching) for 4-cells filter with the dimensions is outlined in Fig. 3 [10]. Central frequency is 3 GHz while used substrate is FR-4 with $\varepsilon_r = 4.3$. *RBW* is 100% (1.00) for $Z_s = 60.5$ Ohms. The dimensions of the metallization (black surfaces in the Fig. 3) are 15 μm (0.015 mm) wider on both sides (2 x 15 μm) in order to compensate the lateral etching.

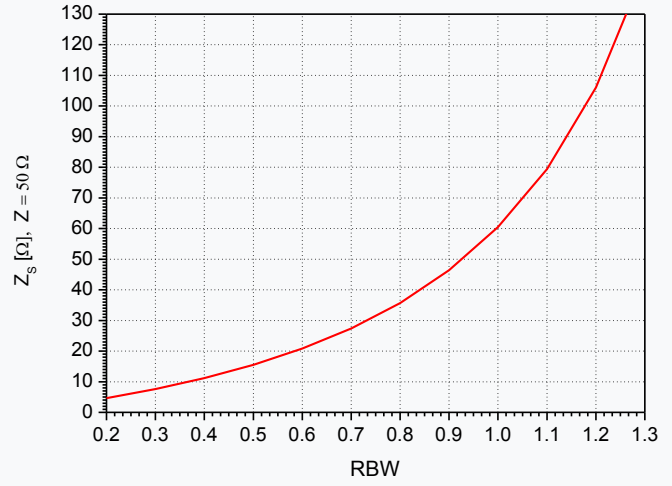

Fig. 2. Design curve of Z_s depending on *RBW* for Z = 50 Ω [9, 10].

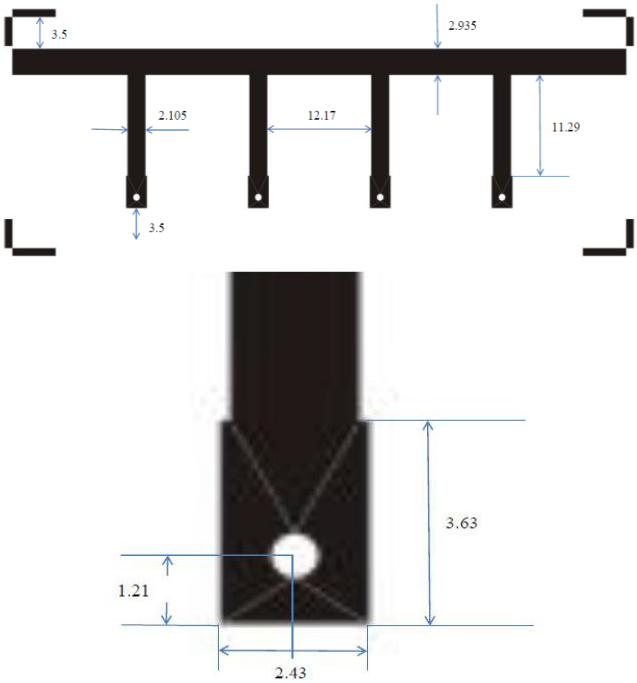

Fig. 3. Dimensions of the film used for etching in mm. Hole radius is equal to 0.385 mm (0.4 mm – 0.015 mm) [10].

 ISBN 978-86-7466-930-3

One of the problems with all structures, including filters, is minimization. Here, one cell has an area of about $\lambda_c^2/16$ (λ_c is wavelength for the central passband frequency f_c). The area can be reduced by bending the stubs and connecting the pair of stubs to one via [8].

II. Minimization

Bending the stubs and connecting a pair of stubs to one via is possible according to the relation $\theta_s = 2\theta$. Actually, the length of one stub is approximately the same as the length of a line between the stubs, see Fig. 3. The EM model of the commonly used filter (the model without bending stubs) and the model of the filter with bent stubs are all presented in the Fig. 4 in Program Package WIPL-D [11]. After bending, the area of the filter is reduced near 2 times. The comparison of calculated S-parameters is given in the Fig. 5. A good agreement between the results can be noted.

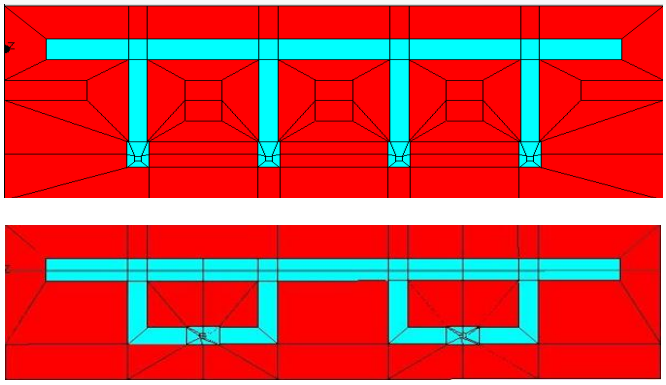

Fig. 4. Commonly used model and the model with bending of the stubs.

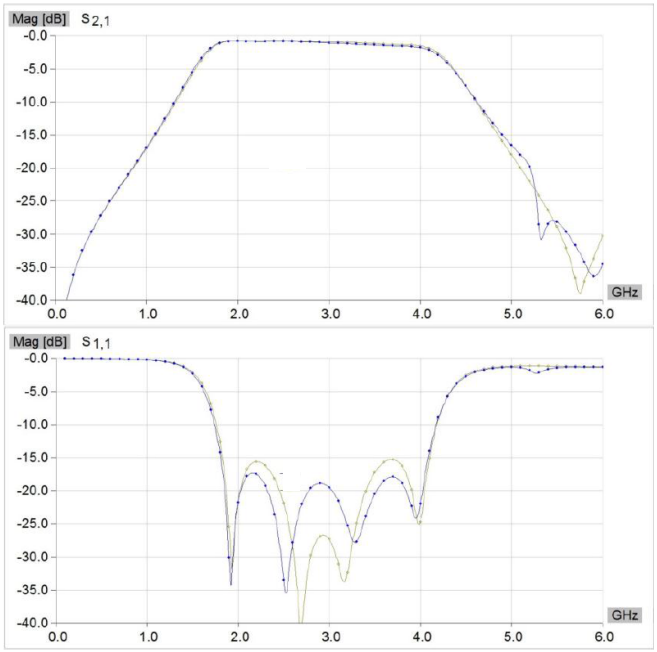

Fig. 5. The comparison between the S-parameters of the commonly used model and the model with bent stubs which are displayed in Fig. 4. No bending (yellow); Bending (blue).

The solution with low Zs values, i.e. implementation with wide microstrip stubs, can be realized as a parallel connection of branches with two times higher Zs. The EM model for 2 times lower Zs than the model presented in Fig. 4 ($Zs = 60.5\ \Omega / 2 = 30.25\ \Omega$) is outlined in Fig. 6 in Program Package WIPL-D [11]. That way the filter achieves relative bandwidth of about 75% (0.75) according to Fig. 2. It is accompanied by the model with bending stubs.

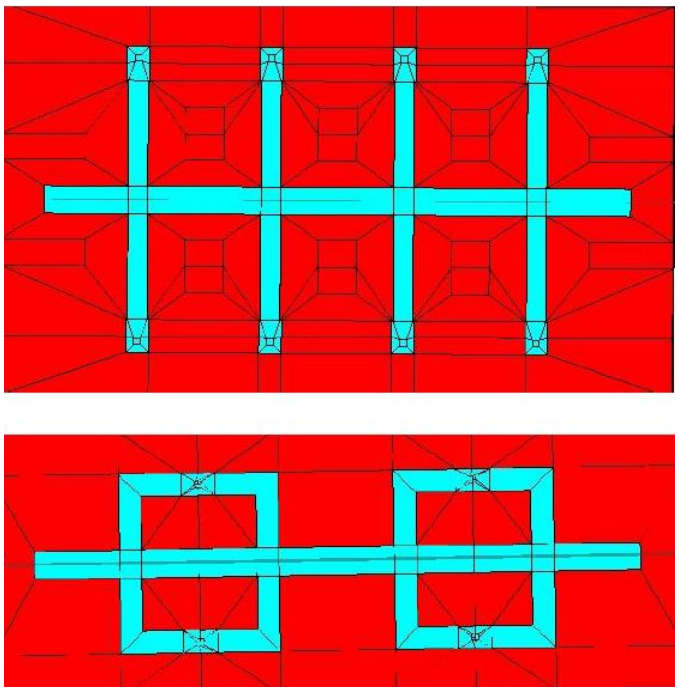

Fig. 6. EM model of the filter with parallel connection of stubs with twice higher Zs and the model with bent stubs.

The comparison between the S-parameters of the model without and the model with bending is shown in Fig. 7. It can be seen that, if the parameter S_{21} is observed, the model with stub bending gives a bit "worse", but still acceptable result in the higher frequency stop-band. The filter area is also reduced near 2 times.

III. Conclusion

An example of minimizing the width of the filter structure by bending the branches as well as reducing the number of required holes for vias was presented. A solution applying low impedances, i.e., wide microstrip lines of branches, was also given, as a parallel connection of branches with twice as large Z_s. It is accompanied with a model with bending of branches and minimization.

It can be seen that minimization of the filters was performed successfully and that responses of the filters after bending the stubs are almost the same as the response of the commonly designed filters.

Uopštenje izraza za transfer funkcije između antena u problemima inverznog rasejanja

Anja Kovačević, Marija Nikolić Stevanović, *Member, IEEE*, i Antonije Đorđević

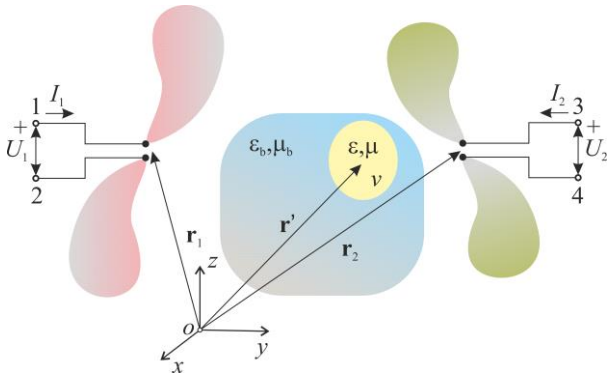
***Apstrakt*—U radu su izvedeni izrazi za priraštaje koeficijenata rasejanja proizvoljnog para antena usled prisustva rasejača koji se nalazi u linearnoj nehomogenoj sredini. Glavni doprinos rada je uopštenje izraza za slučaj kada sredina u kojoj se nalazi rasejač poseduje magnetska svojstva. Takođe je pokazano da dobijeni izraz važi i u slučaju kada su nominalne impedanse pristupa različite i kompleksne.**

***Ključne reči*—Mikrotalasno formiranje slike; antenska merenja; transfer funkcija.**

I. Uvod

Mikrotalasi imaju brojne primene u određivanju lokacije ili oblika nedostupnih objekata, poput detekcije zakopanih objekata pomoću radara za podzemna ispitivanja [1], pozicioniranja objekata iza zidova [2], medicinske dijagnostike [3] i nedestruktivnog ispitivanja materijala [4]. Svim navedenim aplikacijama zajedničko je korišćenje antena koje emituju elektromagnetsko zračenje, a potom mere perturbaciju elektromagnetskog polja usled prisustva ispitivanog objekta (rasejano polje). Većina algoritama za dobijanje slike polazi od jednačine inverznog rasejanja koja povezuje rasejano električno polje i izvore polja, odnosno indukovane struje u objektu [5]. Međutim, izlazi mernih sistema nisu vektorske veličine poput rasejanog električnog polja. Umesto toga, rezultati merenja [6] su najčešće skalarne veličine poput *s*-parametara [7]. Zbog toga je neophodno transformisati jednačinu rasejanja tako da u njoj figurišu veličine koje se zaista dobijaju kao rezultat eksperimenta. Izraz za bistatički prenos između realnih antena prvi put je izveden u [8], za slučaj kada se antene nalaze u vakuumu. Izvođenje je generalizovano u [9] tako da važi za proizvoljnu linearnu nemagnetsku sredinu. U [10] je prikazano alternativno izvođenje izraza za bistatički prenos na osnovu teoreme reciprociteta za elektromagnetska polja [11], [12]. U ovom radu se produbljuju izvođenja iz [10] tako što i rasejač, i okolna sredina mogu biti proizvoljni linearni dielektrici (tj. mogu posedovati magnetska svojstva). Takođe, uopštava se merni sistem tako što se dopušta da pristupi antena imaju različite nominalne impedanse, koje mogu biti kompleksne veličine.

Rad je organizovan na sledeći način. Nakon opštih razmatranja u Uvodu, u drugom poglavlju je izveden izraz za napon praznog hoda na pristupu prijemne antene usled prisustva rasejača, odakle se dobijaju izrazi za priraštaje impedansnih parametara. Zatim je izveden izraz za priraštaj napona na prilagođenom prijemniku, odakle su, zajedno sa Penfield-Kurokawa relacijama [7], određeni priraštaji parametara rasejanja između antena usled prisustva rasejača.



A. Kovačević, M. Nikolić Stevanović, i A. Đorđević – Univerzitet u Beogradu – Elektrotehnički fakultet, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: ka180112d@student.etf.bg.ac.rs, mnikolic@etf.rs, edjordja@etf.bg.ac.rs).

II. Elektromagnetski model

A. Priraštaji impedansnih parametara

Posmatramo mikrotalasni merni sistem, namenjen za dobijanje slike nedostupnih objekata u kome, radi jednostavnosti, postoje samo dve antene (slika 1). Nedostupni objekat je na slici označen žutom bojom i nalazi se u linearnoj nehomogenoj sredini, koju nazivamo okolni medijum. U opštem slučaju okolni medijum obuhvata dielektrik (obojen plavom bojom) koji sakriva objekat, medijum u kome se nalaze antene, kao i metalne i dielektrične delove antena.

Sva izvođenja koja slede, važe i za merni sistem koga čini proizvoljan broj antena.

Slika 1. Merna postavka sa definisanim referentnim smerovima struja i napona na pristupima antena.

Merni sistem možemo da posmatramo kao dvoportnu mrežu opisanu impedansnim (*z*) parametrima ili parametrima rasejanja (*s*) [7]. Pretpostavićemo da leva (prva) antena radi kao predajna, a desna (druga) kao prijemna. Predajna antena napaja se idealnim strujnim generatorom struje I_1, a priključci prijemne antene su otvoreni ($I_2 = 0$). Na slici 1 su prikazani usvojeni referentni smerovi za struje i napone na priključcima antena. Međusobna impedansa, z_{21}, definiše se kao

$$z_{21} = \left.\frac{U_2}{I_1}\right|_{I_2=0}, \tag{1}$$

gde je U_2 napon praznog hoda prijemne antene. U problemima inverznog rasejanja koristi se i priraštaj međusobne impedanse, koji se definiše kao

$$\Delta z_{21} = \frac{\Delta U_{2,\text{o.c.}}}{I_1} = \frac{U_{2,\text{o.c.}} - U^0_{2,\text{o.c.}}}{I_1}, \tag{2}$$

 ISBN 978-86-7466-930-3

gde su $U_{2,oc}$ i $U^0_{2,o.c.}$ naponi praznog hoda indukovani na pristupima antene u prisustvu i odsustvu rasejača, a $\Delta U_{2,o.c.}$ njihova razlika. Usvajajući oznake sa slike 1, imamo da je

$$\Delta U_{2,o.c.} = \int_3^4 \left(\mathbf{E}^1_{tot} - \mathbf{E}^1_{inc}\right)\cdot \mathrm{d}\mathbf{l} = \int_3^4 \mathbf{E}^1_{s}\cdot \mathrm{d}\mathbf{l}\,, \tag{3}$$

gde je $\mathbf{E}^1_{tot}$ vektor ukupnog električnog polja (polje u prisustvu rasejača), $\mathbf{E}^1_{inc}$ vektor incidentnog električnog polja (polje u odsustvu rasejača), a $\mathbf{E}^1_{s}$ vektor rasejanog električnog polja, pri čemu gornji indeks označava predajnu antenu.

Prema zapreminskoj teoremi ekvivalencije, izvori rasejanog polja su ekvivalentne električne i magnetske struje koje se nalaze u okolnom medijumu [5], [6]. (Ti izvori zamenjuju rasejač.) Ekvivalentne struje postoje samo unutar zapremine rasejača, a njihove zapreminske gustine određene su vektorima

$$\mathbf{J}^1_{eq}(\mathbf{r}') = \mathrm{j}\omega(\varepsilon - \varepsilon_b)\mathbf{E}^1_{tot}(\mathbf{r}'), \tag{4}$$

$$\mathbf{M}^1_{eq}(\mathbf{r}') = \mathrm{j}\omega(\mu - \mu_b)\mathbf{H}^1_{tot}(\mathbf{r}'), \tag{5}$$

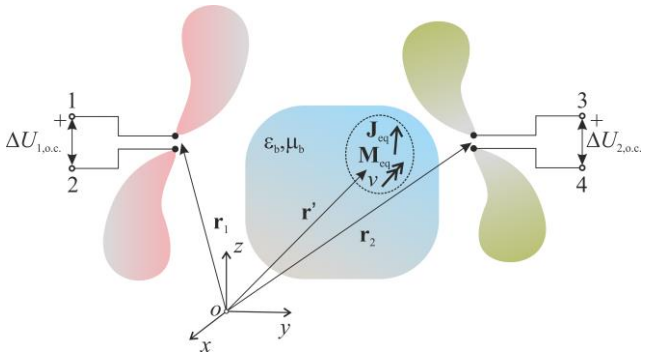
gde je $\mathbf{r}'$ vektor položaja proizvoljne tačke u rasejaču, ε i μ su permitivnost i permeabilnost rasejača, ε_b i μ_b su permitivnost i permeabilnost okolnog medijuma, a $\mathbf{H}^1_{tot}(\mathbf{r}')$ je vektor ukupnog magnetskog polja u tački $\mathbf{r}'$ (polje u prisustvu rasejača). Primena zapreminske teoreme ekvivalencije i odgovarajući naponi prikazani su na slici 2.

Da bismo odredili $\Delta U_{2,o.c.}$ primenićemo teoremu reciprociteta [11], [12] na scenario sa slike 2, u kome pobudu predstavljaju ekvivalentne struje ($\mathbf{J}^1_{eq}, \mathbf{M}^1_{eq}$), a odziv je rasejano polje na mestu prijemne antene ($\mathbf{E}^1_{s}$). Na slici 3 prikazan je obrnut scenario, u kome je prethodna pobuda ($\mathbf{J}^1_{eq}, \mathbf{M}^1_{eq}$) ukinuta, a na mestu tih struja je okolni medijum. Druga antena radi kao predajna i napaja se idealnim strujnim generatorom struje I_2. S obzirom na to da je druga antena jedini izvor zračenja, kao i da nema rasejača, druga antena proizvodi incidentno električno i magnetsko polje ($\mathbf{E}^2_{inc}, \mathbf{H}^2_{inc}$). Gornji indeks sada označava predajnu antenu. Na osnovu teoreme reciprociteta važi

$$\int_v \left(\mathbf{E}^2_{inc}\cdot\mathbf{J}^1_{eq} - \mathbf{H}^2_{inc}\cdot\mathbf{M}^1_{eq}\right)\mathrm{d}v = \int_4^3 \mathbf{E}^1_{s}\cdot I_2\,\mathrm{d}\mathbf{l} = -I_2\Delta U_{2,o.c}\,. \tag{6}$$

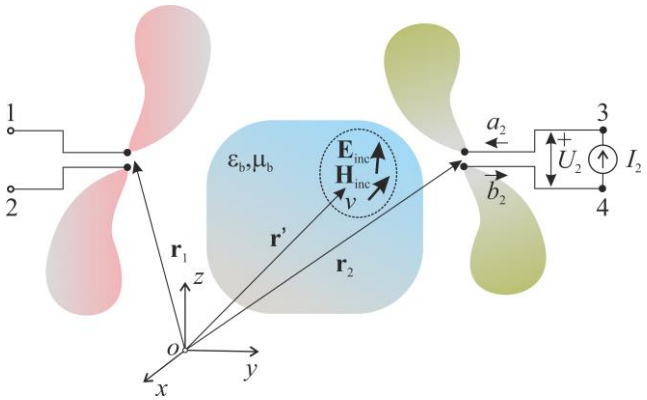
Iz (6) sledi

$$\Delta U_{2,o.c} = -\frac{\int_v \left(\mathbf{E}^2_{inc}\cdot\mathbf{J}^1_{eq} - \mathbf{H}^2_{inc}\cdot\mathbf{M}^1_{eq}\right)\mathrm{d}v}{I_2}, \tag{7}$$



a iz (2) i (7) dobijamo

$$\Delta z_{21} = \frac{\Delta U_{2,o.c}}{I_1} = -\frac{\int_v \left(\mathbf{E}^2_{inc}\cdot\mathbf{J}^1_{eq} - \mathbf{H}^2_{inc}\cdot\mathbf{M}^1_{eq}\right)\mathrm{d}v}{I_1 I_2}\,. \tag{8}$$



Isti postupak se može primeniti i kada niz čini M antena. U tom slučaju važi

$$\Delta z_{ji} = \frac{\Delta U_{j,o.c}}{I_i} = -\frac{\int_v \left(\mathbf{E}^j_{inc}\cdot\mathbf{J}^i_{eq} - \mathbf{H}^j_{inc}\cdot\mathbf{M}^i_{eq}\right)\mathrm{d}v}{I_j I_i}\,,$$

$$i, j = 1,\ldots,M\,. \tag{9}$$

Slika 2. Ekvivalentne struje u okolnom medijumu kao izvori rasejanog polja i indukovanih napona na pristupima antena.

Slika. 3. Primena teoreme reciprociteta za scenario ilustrovan na slici 2.

B. Priraštaji parametara rasejanja

Slika 4 ilustruje pojednostavljenu mernu postavku koja je namenjena za određivanje *s*-parametara. Posmatramo opšti slučaj u kome su nominalne impedanse portova predajne i prijemne antene kompleksne veličine i iznose Z_{c1} i Z_{c2}, respektivno. Prva antena pobuđena je realnim naponskim generatorom unutrašnje impedanse Z_{c1}, a pristup druge antene zatvoren je impedansom Z_{c2}. Koeficijent transmisije definiše se kao

$$s_{21} = \left.\frac{b_2}{a_1}\right|_{a_2=0}\,, \tag{10}$$

gde je a_1 kompleksni intenzitet incidentnog talasa na pristupu prve antene, a b_2 kompleksni intenzitet reflektovanog talasa na pristupu druge antene. Penfield-Kurokawa izrazi za kompleksne intenzitete incidentnih i reflektovanih talasa („talasa snage“) [7] glase:

$$a_i = \frac{U_i + I_i Z_{ci}}{2\sqrt{R_{ci}}}\,, \tag{11}$$

$$b_i = \frac{U_i - I_i Z^*_{ci}}{2\sqrt{R_{ci}}}\,, \tag{12}$$

 ISBN 978-86-7466-930-3

respektivno, gde i označava indeks pristupa ($i=1,2$), a R_{ci} je realni deo impedanse Z_{ci}. Priraštaj koeficijenta transmisije definisan je sa [7]

$$\Delta s_{21}=\frac{\Delta b_2}{a_1}=\frac{b_2-b_2^0}{a_1}, \tag{13}$$

gde su b_2 i b_2^0 kompleksni intenziteti reflektovanih talasa u prisustvu i odsustvu rasejača, redom, a Δb_2 njihova razlika. Odgovarajući scenario prikazan je na slici 5.

Na osnovu (12), priraštaj kompleksnog intenziteta reflektovanog talasa na pristupu druge antene je

$$\Delta b_2=\frac{\Delta U_2-\Delta I_2 Z_{c2}^*}{2\sqrt{R_{c2}}}, \tag{14}$$

pri čemu je

$$\Delta U_2=-\Delta I_2 Z_{c2}. \tag{15}$$

Kada se (15) zameni u (14), dobija se

$$\Delta b_2=\frac{-\Delta I_2 Z_{c2}-\Delta I_2 Z_{c2}^*}{2\sqrt{R_{c2}}}=\frac{\Delta U_2\sqrt{R_{c2}}}{Z_{c2}}, \tag{16}$$

gde je

$$\Delta U_2=\int_3^4 \mathbf{E}_s^1\cdot\mathrm{d}\mathbf{l}. \tag{17}$$

Da bismo odredili ΔU_2, primenjujemo teoremu reciprociteta. U tu svrhu, zamenjujemo realni naponski generator ekvivalentnim strujnim generatorom koji je prikazan u donjem levom uglu slike 4. Ekvivalentan sistem prikazan je na slici 5. U obrnutom scenariju koji je prikazan na slici 6, druga antena radi kao predajna, pri čemu je pobuđena strujnim generatorom struje E/Z_{c2}. Na sličan način kao u (7), dobija se

$$\Delta U_2=-\frac{\int_v\left(\mathbf{E}_{\mathrm{inc}}^2\cdot\mathbf{J}_{\mathrm{eq}}^1-\mathbf{H}_{\mathrm{inc}}^2\cdot\mathbf{M}_{\mathrm{eq}}^1\right)\mathrm{d}v}{E/Z_{c2}}, \tag{18}$$

pri čemu se ($\mathbf{J}_{\mathrm{eq}}{}^1,\mathbf{M}_{\mathrm{eq}}^1$) i ($\mathbf{E}_{\mathrm{inc}}^2$, $\mathbf{H}_{\mathrm{inc}}^2$) određuju iz scenarija prikazanih na slikama 5 i 6, redom. Kada se (16) i (18) uvrste u (13), sledi

$$\Delta s_{21}=-\frac{\int_v\left(\mathbf{E}_{\mathrm{inc}}^2\cdot\mathbf{J}_{\mathrm{eq}}^1-\mathbf{H}_{\mathrm{inc}}^2\cdot\mathbf{M}_{\mathrm{eq}}^1\right)\mathrm{d}v}{a_1\dfrac{E}{\sqrt{R_{c2}}}}. \tag{19}$$

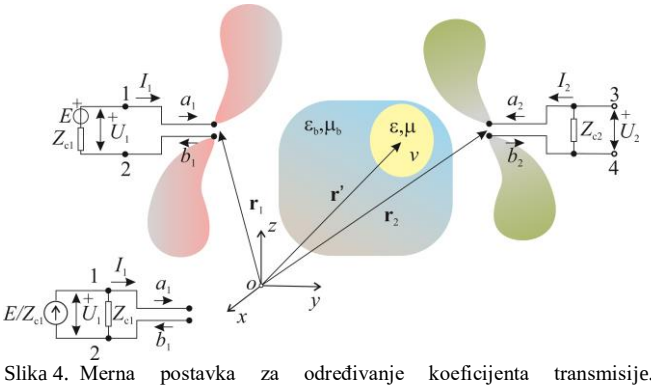
Na osnovu (11), imamo da je

$$a_2=\frac{U_2+I_2Z_{c2}}{2\sqrt{R_{c2}}}=\frac{E}{2\sqrt{R_{c2}}} \tag{20}$$

jer je

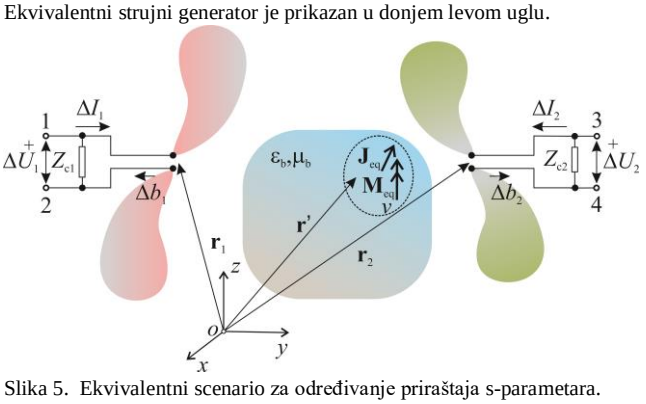
$$I_2=\frac{E}{Z_{c2}}-\frac{U_2}{Z_{c2}}. \tag{21}$$

Konačno, kada se (20) zameni u (19), dobija se izraz za priraštaj koeficijenta transmisije:



$$\Delta s_{21}=-\frac{\int_v\left(\mathbf{E}_{\mathrm{inc}}^2\cdot\mathbf{J}_{\mathrm{eq}}^1-\mathbf{H}_{\mathrm{inc}}^2\cdot\mathbf{M}_{\mathrm{eq}}^1\right)\mathrm{d}v}{2a_1a_2}. \tag{22}$$

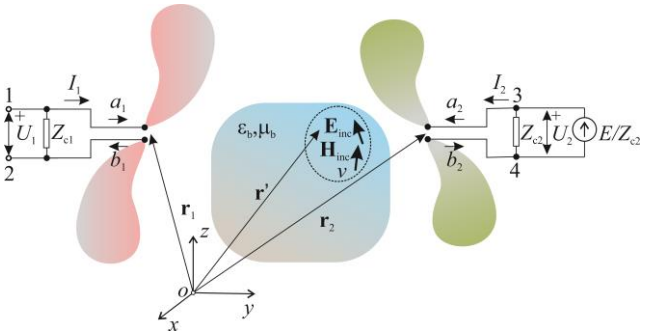
Na sličan način mogu se odrediti i priraštaji koeficijenata refleksije. Rezultati za priraštaje svih parametara rasejanja mogu se generalizovati za bilo koji par antena u mernom sistemu od M antena:



$$\Delta s_{ji}=-\frac{\int_v\left(\mathbf{E}_{\mathrm{inc}}^j\cdot\mathbf{J}_{\mathrm{eq}}^i-\mathbf{H}_{\mathrm{inc}}^j\cdot\mathbf{M}_{\mathrm{eq}}^i\right)\mathrm{d}v}{2a_ia_j},\ i,j=1,\ldots,M. \tag{23}$$

III. Zaključak

U ovom radu predstavljeno je izvođenje priraštaja bistatičke transfer funkcije (koeficijenta transmisije) između antena usled prisustva rasejača u proizvoljnoj linearnoj nehomogenoj sredini. Ova jednačina je fundamentalna za teoriju inverznog rasejanja i sastavni je deo većine algoritama za dobijanje slike pomoću mikrotalasa. Dobijeni izraz je opštiji od izraza u [9] i [10] jer se ne ograničava na nemagnetske sredine. Takođe, pokazano je da važi i u slučaju kada su nominalne impedanse pristupa kompleksne i različite.



Slika 4. Merna postavka za određivanje koeficijenta transmisije. Ekvivalentni strujni generator je prikazan u donjem levom uglu.

Slika 5. Ekvivalentni scenario za određivanje priraštaja s-parametara.

 ISBN 978-86-7466-930-3

Slika 6. Teorema reciprociteta primenjena na scenario sa slike 5.

ZAHVALNICA

Sredstva za realizaciju ovog rada delimično su obezbeđena od strane Ministarstva za obrazovanje, nauku i tehnološki razvoj Republike Srbije, Sporazumom o realizaciji i finansiranju naučnog rada Elektrotehničkog fakulteta u Beogradu (broj ugovora 1817/3), i od strane Srpske akademije nauka i umetnosti (projekat F133).

ABSTRACT

We derive the expressions for the increments of the scattering coefficients of an arbitrary antenna pair due the presence of the scatterer in a linear inhomogeneous medium. The main contribution of this work is the generalization of the expressions in the case when the medium in which the scatterer is located has magnetic properties. It was also shown that the same expressions are valid in the case when the nominal impedances of the ports are different and complex.

Generalization of transfer functions among antennas in inverse-scattering problems

The Improved GM PHD algorithm for Multi-Target Radar Tracking

Zvonko Radosavljević, Dejan Ivković and Branko Kovačević

***Abstract*—Gaussian mixture probability hypothesis density (GM PHD) is a modern nonlinear algorithm for tracking multiple targets in a clutter environment. It is accompanied by known problems that are primarily related to the impossibility of associating the measurement of existing targets and determining the quality of the tracks. For this purpose the automatics track initialization by known 'two point initialization' was introduced. Difference of successive measurements from two radar antenna revolutions is compared with the threshold, which depends on the velocity of the target. The paper proposes to improve the algorithm by introducing the probability of the existence of a target and to reject false tracks. The results of intensive simulations of tracking multiple radar targets have shown the justification for the application of the proposed algorithms.**

***Index Terms*—Target tracking, probability hypothesis density, track while scan (TWS) radars.**

I. INTRODUCTION

Multi-target tracking in clutter, assuming linear target trajectory propagation and linear target measurement equation, naturally leads to a Gaussian mixture (GM) target tracking solution. As the origin of measurements is uncertain, both true tracks (which follow targets) and false tracks (which do not) exist [1].

The random finite sets (RFS) are representations of multi-target states and multi-target measurements. The modeling of multi-target dynamics using random sets leads to algorithms which incorporate track initiation and termination, a procedure that has mostly been performed separately in tracking algorithms. The first systematic treatment of multi-sensor multi-target filtering, as part of a unified framework for data fusion using random set theory was finite set statistics (FISST). The alternative to optimal multi-target filtering is the Probability Hypothesis Density (PHD) filter [2], [3], [4]. It is a recursion propagating the 1st moment, called the intensity function or PHD, associated with the multi-target posterior.

A Gaussian mixture, consisting of a weighted sum of Gaussian PDF, each with different means and covariance's, is the natural form of the PDF of target state. Using such a structure, a mixture component is created for every possible association, using every possible pairing of targets and measurements with the mean and covariance calculated assuming that the particular hypothesis is true, and the weight calculated to represent the probability that the particular hypothesis is true. The serious problem in multi-target tracking is the unknown association of measurements with appropriate targets [5], [6]. Moreover, the data association problem makes up the growth of the computational load in multi target tracking algorithms. Recently, multi-target tracking formulations involve explicit associations between measurements and targets

The Gaussian Mixture Probability Hypothesis Density Filter (GM-PHD Filter) provided a closed form solution to the PHD filter recursion for multiple target tracking [7]. The posterior intensity function is estimated by a sum of weighted Gaussian components whose means, weights and covariances can be propagated analytically in time. In particular, the means and covariances are propagated by the Kalman filter.

The original Gaussian Mixture PHD filter algorithm provided a means of estimating the number of targets and their states at each point in time. The method for determining the targets simply used the weights of the Gaussian components and did not take into account tempo al continuity. We show that if a target is not detected for each iteration, the Gaussian components can still track the targets in the presence of some missed detections. The trajectory of the target in the past, before it has been detected, can also be determined by keeping the trajectories of each of the Gaussian components. The original formulation of the GM PHD filter allowed targets to be spawned from existing targets [8].

The paper proposes and tests the improved GMPHD algorithm with automatic track initialization (ATI) via 'two point methodology'. Each incoming measurement (from the previous scan) is paired with each incoming measurement from the current scan in order to examine the possibility of initializing a new trace based on the knowledge of the maximum speed of movement of the targets [9].

Rest of papers is organized as follows. Second chapter is dedicated basic problem statements, which precedes Third chapter, which brief decrypted GM PHD algorithm. Results of experiments are given by Fourth chapter. Final conclusions are given by the Fifth chapter.

II. PROBLEM STATEMENTS

Consider the target tracking scenario with two dimensions. Also, consider the tracking algorithm with two parameters:

Zvonko Radosavljević and Dejan Ivković is with the Millitary Technical Institute, Belgrade, Ratka Resanovica bb, 11030 Belgrade, Serbia (e-mail: zvonko.radosavljevic@gmail.com and divkovic555(@)gmail.com).

Branko Kovačević is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: kovacevic_b@etf.rs).

 ISBN 978-86-7466-930-3

probability of detection (P_D) and clutter density. The clutter density is depending on target dynamics and characteristic of sensor. Generally, clutter is defined by number of selection measurement from size of selection gate. At begin, consider the target state $x_k \in R^{n_z}$ at time interval *k*. The dynamic target trajectory state models at the time *k* are given by the:

$$x_k = Fx_{k-1} + \nu_k \tag{1}$$

where F is the propagation matrix, ν_k is a zero mean and white Gaussian sequence with covariance *R*. At each scan the sensor returns a random number of random target and clutter measurements. At time *k*, one sensor delivers a set of measurements $z_k = \{z_{k,j}\}_{j=1}^{M_k}$ track out of which a set of measurements are selected for track update. Converted target measurement *y* is given by [10] :

$$y_k = Hx_k + w_k \tag{2}$$

where *H* is measurements matrix and the measurements noise w_k is zero mean and white Gaussian sequence. A measurements of target is present in each scan with a probability of detection P_D . Clutter measurements follow the Poisson distribution characterized at location by clutter measurements density $\rho_k(y)$ [11].

At time k a set of $m(k)$ measurements $Y(k) = \{y_i(k)\}_{i=1}^{m(k)}$ are detected, where each measurement either originate from one of *n* known linear measurement models or is a false detection. The sequences $\nu(k)$ are mutually independent and uncorrelated with the process noise.

A. Finite Sets statistics

Finite set statistics is the concept of belief-mass functions, which are non adaptive generalizations of probability mass functions and are equivalent to probability mass function on certain abstract topological spaces. The multi-target state and multi-target measurement at time k are represented as finite subsets X_k and Z_k, respectively.

The models of motion of the multi-target system using a randomly varying RFS is given by the [12]:

$$\Gamma_k = \Phi_k[X_{k-1}, V_{k-1}] \cup B_k[X_{k-1}] \tag{3}$$

where $\Phi_k[X_{k-1}]$ represents the dynamics of the existing targets, X_{k-1} is the random set of the state vectors of the random number of targets, and V_{k-1} denotes the system process noise, while $B_k[X_{k-1}]$ represents the process of target birth.

III. The Gaussian Mixture PHD Filter Algorithm

In this section, we describe the linear-Gaussian multiple target model and the recently developed Gaussian Mixture PHD filter. The multiple target models for the PHD recursion is described here. Each target follows a linear Gaussian dynamical model [13],

$$f_{k|k-1}(x|\xi) = N[x; F_{k-1}(\xi), Q_{k-1}] \tag{4}$$

$$g_k(y|x) = N[y; H_k(x), R_k] \tag{5}$$

where $N(.;m,P)$ denotes a Gaussian density with mean *m* and covariance *P*, F_{k-1} is the state transition matrix, Q_{k-1} is the process noise covariance, H_k is the observation matrix and R_k is the observation noise covariance. The survival $p_{Sk}(x) = p_{S,k}$ and detection $p_{Dk}(x) = p_{D,k}$ probabilities are state independent. The intensities of the spontaneous birth and spawned targets are Gaussian mixtures,

$$\gamma_k(x) = \sum_{i=1}^{J_\gamma(k)} w_{\gamma k}^i N[x; m_{\gamma k}^i, P_{\gamma k}^i] \tag{6}$$

$$\beta_{k|k-1}(x|\varsigma) = \sum_{j=1}^{J_\beta(k)} w_{\beta k}^j N[x; F_{\beta k-1}^j(\varsigma) + d_{\beta k-1}^j Q_{\beta k-1}^j] \tag{7}$$

where $J_{\gamma k}, w_{\gamma k}^i, m_{\gamma k}^i, P_{\gamma k}^i,\ i = 1,..., J_\gamma(k)$ are given model parameters that determine the shape of the birth intensity, similarly, $J_{\beta k}, w_{\beta k}^j, F_{\beta k-1}^j, d_{\beta k-1}^j$ and $Q_{\beta k-1}^j$ $j = 1,..., J_\beta(k)$ determine the shape of the spawning intensity of a target with previous state.

A. Algorithm steps

1 Prediction step

Under the assumptions that each target follows a linear Gaussian dynamical model, the survival and detection probabilities are constant, the intensities of the birth and spawned targets are Gaussian mixtures, and that the posterior intensity at time *k-1* is a Gaussian mixture of the form [14]

$$D_{k-1|k-1}(x) = \sum_{i=1}^{J(k-1)} w^i{}_{k-1} N[x; m^i{}_{k-1}, P^i{}_{k-1}] \tag{11}$$

Then the predicted intensity to time *k* is also a Gaussian mixture, and is given by

$$D_{k|k-1}(x) = D_{S\,k|k-1}(x) + D_{\beta\,k|k-1}(x) + \gamma_k(x) \tag{12}$$

where $D_{S\,k|k-1}(x)$ is the PHD of existing targets, $D_{\beta\,k|k-1}(x)$ is the PHD for spawned targets, and $\gamma_k(x)$ is the PHD of spontaneous birth targets.

The density for existing targets, $D_{S\,k|k-1}(x)$, is determined from the linear Gaussian model using the Kalman prediction equations,

 ISBN 978-86-7466-930-3

$$D_{S\,k|k-1}(x) = p_{S\,k} \sum_{j=1}^{J(k-1)} w^{j}{}_{k-1} N[x; m^{j}_{S\,k|k-1}, P^{j}_{S\,k|k-1}] \quad (13)$$

where

$$m^{j}_{Sk|k-1} = F_{k-1} m^{j}{}_{k-1} \quad (14)$$

$$P^{j}_{S\,k|k-1} = Q_{k-1} + F_{k-1} P^{j}{}_{k-1} F^{T}{}_{k-1} \quad (15)$$

and similarly for the spawned target density,

$$D_{\beta\,k|k-1}(x) = \sum_{j=1}^{J(k-1)} \sum_{l=1}^{J_{\beta}(k)} w^{j}{}_{k-1} w^{l}_{\beta} N[x; m^{j,l}_{\beta\ k|k-1}, P^{j,l}_{\beta\ k|k-1}] \quad (16)$$

where

$$m^{j,l}_{\beta\ k|k-1} = F^{l}_{\beta\,k-1} m^{j}{}_{k-1} + d^{l}_{\beta\,k-1} \quad (17)$$

$$P^{j,l}_{\beta\ k|k-1} = Q^{l}_{\beta\,k-1} + F^{l}_{\beta\,k-1} P^{j}{}_{k-1} (F^{l}_{\beta\,k-1})^{T} \quad (18)$$

2 Update step

Under the above assumptions, and that the predicted intensity to time *t* is a Gaussian mixture of the form [15]

$$D_{k|k-1}(x) = \sum_{i=1}^{J(k|k-1)} w^{i}{}_{k|k-1} N[x; m^{i}{}_{k|k-1}, P^{i}{}_{k|k-1}] \quad (19)$$

Then the posterior intensity at time *k* is also a Gaussian mixture, and is given by

$$D_{k|k}(x) = [1 - p_{D\,k}] D_{k|k-1,}(x) + \sum_{y \in Y^{k}} \sum_{j=1}^{J(k|k-1)} w^{j}{}_{k}(y) \quad N[x; m^{j}{}_{k|k}(y), P^{j}{}_{k|k}] \quad (20)$$

where the weights are calculated according to the closed form PHD update equation,

$$w^{j}{}_{k}(y) = \frac{p_{D\,k} w^{i}{}_{k|k-1} N[y; H_{k} m^{j}{}_{k|k-1}, R_{k} + H_{k} P^{j}{}_{k|k-1} H^{T}{}_{k}]}{K_{k}(y) + p_{D\,k}) \sum_{l=1}^{J(k|k-1)} w^{l}{}_{k|k-1} N[y; H_{k} m^{l}{}_{k|k-1}, R_{k} + H_{k} P^{l}{}_{k|k-1} H^{T}{}_{k}]} \quad (21)$$

and the mean and covariance are updated with the Kalman filter update equations,

$$m^{j}{}_{k|k}(y) = m^{j}{}_{k|k-1}(y) + K^{j}{}_{k}[y - H_{k} m^{j}{}_{k|k-1}(y)] \quad (22)$$

$$P^{j}{}_{k|k} = [I - K^{j}{}_{k} H_{k}] P^{j}{}_{k|k-1} \quad (23)$$

$$K^{j}{}_{k} = P^{j}{}_{k|k-1} H^{T}{}_{k} [H_{k} P^{j}{}_{k|k-1} H^{T}{}_{k} + R_{k}]^{-1} \quad (24)$$

B. GMPHD practical implementation of algorithm

At begin, we given weights, mean and covariance of the each track:

$$\{w^{(i)}{}_{k-1}, m^{(i)}{}_{k-1}, P^{(i)}{}_{k-1}\}_{i=1}^{J(k-1)}$$

At each scan we given measurement set $Z(k)$, from the radar sensor .

Step 1: **Prediction for birth targets**

$i = 0.$

for j=1,…, $J_{\gamma}(k)$

i=i+1.

$$w^{(i)}{}_{k|k-1} = w^{(j)}_{\gamma\ k},$$

$$m^{(i)}{}_{k|k-1} = m^{(j)}_{\gamma\ k}$$

$$P^{(i)}{}_{k|k-1} = P^{(j)}_{\gamma\ k}$$

End

for j=1,…, $J_{\beta}(k)$

for l=1,…, $J(k-1)$

i=i+1.

$$w^{(i)}{}_{k|k-1} = w^{(l)}{}_{k-1} w^{(j)}_{\beta\ k}$$

$$m^{(i)}{}_{k|k-1} = d^{(j)}_{\beta\ k-1} + F^{(j)}_{\beta\ k-1} m^{(l)}{}_{k-1}$$

$$P^{(i)}{}_{k|k-1} = Q^{(j)}_{\beta\ k-1} + F^{(j)}_{\beta\ k-1} P^{(l)}{}_{k-1} (F^{(j)}_{\beta\ k-1})^{T}$$

end

end

Step 2: **Prediction for existing targets**

for j=1,…, $J(k-1)$

i=i+1.

$$w^{(i)}{}_{k|k-1} = p_{S\,k} w^{(j)}_{\gamma\ k-1},$$

 ISBN 978-86-7466-930-3

$$m^{(i)}_{k|k-1} = F_{k-1} m^{(j)}_{\gamma\ k-1}$$

$$P^{(i)}_{k|k-1} = Q_{k-1} + F_{k-1} P^{(j)}_{k-1} (F_{k-1})^T$$

end

$$J(k|k-1) = i$$

Step 3: **Construction of PHD update components**

for j=1,…, $J(k|k-1)$

$$\eta^{(j)}_{k|k-1} = H_k m^{(j)}_{k|k-1}$$

$$S^{(j)}_k = R_k + H_k P^{(j)}_{k|k-1} H^T_k$$

$$K_k = P^{(j)}_{k|k-1} H^T_k [S^{(j)}_k]^{-1}$$

$$P^{(j)}_{k|k} = [I - K^{(j)}_k H_k] P^{(j)}_{k|k-1}$$

end

Step 3: **(Update)**

for j=1,…, $J(k|k-1)$

$$w^{(j)}_k = (1 - p_{D,k}) w^{(j)}_{k|k-1},$$

$$m^{(j)}_k = m^{(j)}_{k|k-1},$$

$$P^{(j)}_k = P^{(j)}_{k|k-1}$$

end

l=0.

for each $y \in Y^k$

l=l+1,

for j=1,…, $J(k|k-1)$

$$w^{(lJ(k|k-1)+j)}_k =$$

$$p_{Dk} w^{(j)}_{k|k-1} N(y; \eta^{(j)}_{k|k-1}, S^{(j)}_k)$$

$$m^{[lJ(k|k-1)+j]}_k =$$

$$= m^{(j)}_{k|k-1} + K^{(j)}_k [y - \eta^{(j)}_{k|k-1}]$$

$$P^{[lJ(k|k-1)]}_k = P^{(j)}_{k|k}$$

End

$$w^{[lJ(k|k-1)+j]}_k = \frac{w^{[lJ(k|k-1)+j]}_k}{\mathrm{K}^{(y)}_k + \sum_{i=1}^{J(k|k-1)} w^{[lJ(k|k-1)+i]}_k}, \; j = 1,\ldots, J(k|k-1)$$

end

$$J(k) = lJ(k|k-1) + J(k|k-1)$$

Output $\{w^{(i)}_k, m^{(i)}_k, P^{(i)}_k\}_{i=1}^{J(k)}$

C. *Output Calculation*

Finally, we can calculate the output state estimate and covariance (for output purpose only):

$$\hat{x}_{k|k} = \sum_{l=1}^{Np} w^l_k x^l_k \tag{25}$$

$$P_k = \left(\sum_{l=1}^{Np} w^l_k \cdot x^l_k \cdot x^{l\,T}_k \right) - \hat{x}_k \cdot \hat{x}^{\,T}_k \tag{26}$$

IV. Results of Experiment

For the purpose of simulations, we propose a two-dimensional scenario (Fig. 1) with an unknown crossing and time varying number of targets in clutter over the region [−500; 500] × [−500; 500]. The state $\boldsymbol{x}_k = [\, x_k\ v_{xk}\ y_k\ v_{yk}\,]^T$, of each target consists of position (x_k; y_k) and velocity (v_{xk}; v_{yk}), while the measurement is a noisy version of the position [16]. Each target has survival probability $p_{S;k}$ = 0,9, detection probability $p_{D;k}$=0,99 and follows the linear Gaussian dynamics. Each simulation experiment consists of a number of simulation runs. In each simulation run, targets will repeat their trajectories. The measurements are generated independently. Each algorithm uses the same set of measurements. False tracks may be initiated using target measurements, either in a conjunction with a clutter measurement, or by using measurements from different targets in different scans. The sampling period of radar sensor is *T=1s*. Duration of the scenario is 70 scans. The implemented GM-PHD is evaluated by Monte Carlo (MC) simulations over representative 2-dimensional test scenario. A target motion scenario (Fig.2) includes non-maneuvering flights modes. Dimension of terrain surveillance is x=500m and y=500m.

Transition matrix and process noise matrix are given by:

$$F = \begin{bmatrix} 1 & T & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & T \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad Q_k = q \begin{bmatrix} T^3/3 & T^2/2 & 0 & 0 \\ T^2/2 & T & 0 & 0 \\ 0 & 0 & T^3/3 & T^2/2 \\ 0 & 0 & T^2/2 & T \end{bmatrix} \tag{27}$$

respectively. Measurements matrix and measurements noise matrix is given by:

 ISBN 978-86-7466-930-3

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \quad R_k = \begin{bmatrix} \sigma_x^2 & 0 \\ 0 & \sigma_y^2 \end{bmatrix} \tag{28}$$

respectively.

For the purpose of performance testing tracking targets, we propose Wasserstein distance diagram.

A. *Wasserstein distance:*

The Wasserstein distance from theoretical statistics was adopted as a means of defining a performance metric for multi target distances which penalizes when the estimate of the number of targets is incorrect. When the number of targets is estimated correctly, the Wasserstein distance is the same as the Hausdor distance but the Hausdor does not penalise for incorrectly estimating the number of targets. This metric has been used for assessing the performance of the PHD filter.

Let X_t and Y_t be the finite sets of target states and estimated target states at time interval *k*.. The L^P Wasserstein distance between the two sets is defined as:

$$d_P^W(X_t, Y_t) = \inf_C \Big(\sum_{x_t \in X_t} \sum_{\hat{x}_j \in \hat{X}_t} C_{ij} d(x_i, \hat{x}_j)^P \Big)^{1/P} \tag{29}$$

where C is an $|X_t| \times |\hat{X}_t|$ matrix $\{C_{ij}\}$ such that $\forall i = 1...|X_t|, j = 1...|\hat{X}_t|$:

$$\sum_{i=1}^{|X_t|} C_{ij} = \frac{1}{|\hat{X}_t|}, \sum C_{ij} = \frac{1}{|X_t|}, C_{ij} \geq 0 \tag{30}$$

The L^{∞} Wasserstein distance is defined as:

$$d_{\infty}^W(X_t, \hat{X}_t) = \inf_C \max_{xi \in X_t, \hat{x}_j \in \hat{X}_t} C_{ij} d(x_i, \hat{x}_j) \tag{31}$$

Where $\tilde{C}_{ij} = 1$ if $C_{ij} > 0$ and $\tilde{C}_{ij} = 0$ if $C_{ij} = 0$

B. *Two point differencing initializations*

Initialization with the difference of successive observations (Two point differentiation initializing) uses measurements located in the 'window' of the trace from two successive scans to initialize the trace. This procedure is repeated for all measurements from the scan k-1 . Consider such a measurement $z_{k-1,j}$. The new trace is initialized by measurement $z_{k-1,j}$ and each selected measurement $z_{k,i}$, forming a Gaussian probability density function with the mean value given as:

$$\hat{x}_k^{(2)} = \begin{bmatrix} z_{k,i} \\ \dfrac{z_{k,i} - z_{k-1,j}}{\Delta T_k} \end{bmatrix} \tag{32}$$

where ΔT_k one is the period of rotation of the radar antenna. Since there is no a priori knowledge of the target speed, it can be modeled through a uniform distribution of a priori pdf measurements. At the moment k, the Np particles of the mean value $\hat{x}_k^{(2)}$ are initialized, as well as the symmetric and semi-finite covariance matrices $P_{(2|2)}$ which correspond to the normal distribution of several variables (Figure 1):

$$x_k^p = N[\hat{x}_k^{(2)}; P_{(2|2)}] \tag{33}$$

where the initial covariance error of the condition is calculated under the assumption that there is no process noise [24]:

$$P_{(2|2)} = \begin{bmatrix} R_k & R_k / T \\ R_k / T & 2R_k / T^2 \end{bmatrix} \tag{34}$$

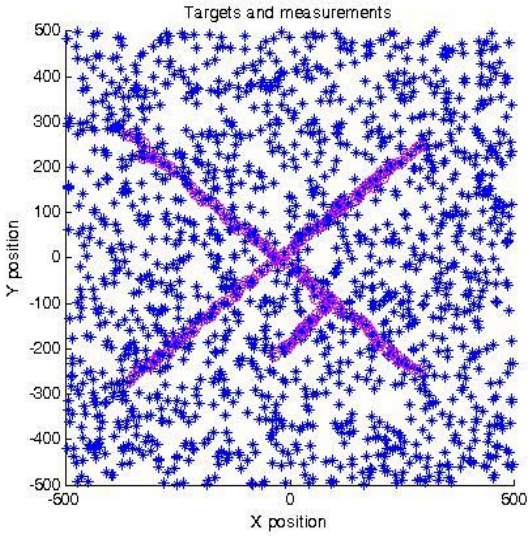

Fig. 1. Simulation scenario: targets and measurements .

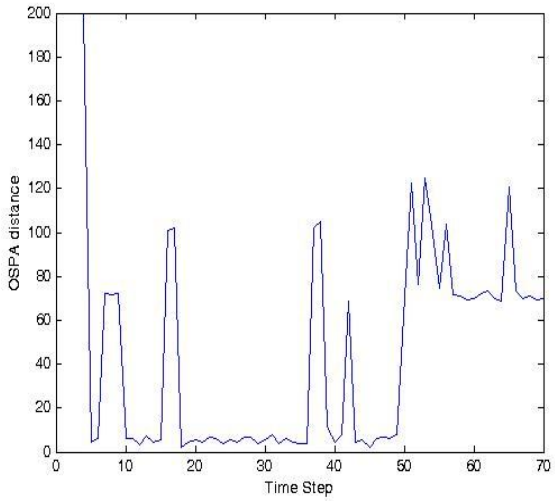

Fig. 2. Wasserstein distance metric (OSPA diagram)

 ISBN 978-86-7466-930-3

Simulation results (OSPA diagram- Fig. 2) show good performance for tracking two crossing targets with one spawned targets, from scan 50 (Fig. 1). Blue dots (measurements) and magenta circle (targets) show good initializing and tracking targets in heavy clutter environments.

V. CONCLUSION

An improved GM PHD algorithm for radar sensor approaches has been presented for tracking multiple targets in high clutter density which has the ability to estimate the number of targets, track the trajectories of the targets over time, operate with missed detections and give the trajectories of the targets in the past once a target has been identified. It has been shown to outperform the ability to operate in clutter with fewer false tracks and can initiate and eliminate targets more accurately.

Future research should better determine the association of radar received measurements with existing targets as well as automatic initialization of targets. The theoretical constraints of the proposed tracking algorithm have been discussed in the case of crossing targets. It is anticipated that the problem of retaining the correct target identity in this scenario can be resolved by considering the previous trajectories of targets.

Especially, the proposed algorithm will be tested in practice on the example of video tracking [17, 18].

***Abstract*—this paper derives four -stage recursive least squares parameter estimation algorithm for Controlled Autoregressive Autoregressive Moving Average (CARARMA) systems. By applying the decomposition technique, (CARARMA) system decompose into four subsystems, which contain one parameter vector each. Compared with the recursive generalized least squares algorithm, the proposed algorithm improves the accuracy of estimated parameters and decrease the computational burden. The simulation example is given to indicate the efficiency of the proposed algorithm**.

Keywords— parameter estimation, decomposition technique,* computational burden, *(Q-Q) plot, estimation error.

I. INTRODUCTION

The modeling of manufacturing systems plays a critical function in system analysis and control. System identification is fundamental for structuring the systems mathematical models and parameter estimation is the basis of system identification [1]. In the past decades, researchers have done a lot of research work on parameter estimation methods such as the iterative algorithms, the maximum likelihood methods, the filtering technique, multiple-stage algorithms and so on. Multi-stage least squares identification algorithm is recently employed for parameter estimation of various system models. The main contribution in this technique is to reduce the computational load. The computational load is a significant feature of the recursive algorithms. Low computational load can help the recursive algorithms realize best performances in the systems. The computational efficiency in least squares [2]. The main idea is based on the decomposition technique that can split the main identification system into few small-size subsystems, so as to enhance the computational efficiency and easy to solve. Four-Stage Recursive Least Squares Algorithm is proposed for CARARMA Systems. The decomposition technique is using in this algorithm to reduce the Computational burden. The layout of the rest of this article is arranged as follows.Section 2 derives four-stage recursive identification algorithm. Section 3 presents recursive generalized extended least squares algorithm. Section 4, a illustrative example is given to demonstrate the performance of this algorithm. Finally, the conclusions are offered in section 5.

II. FOUR-STAGE RECURSIVE IDENTIFICATION ALGORITHM

Consider linear, time-invariant, discrete-time system [3] as shown in fig. 1, described by (CARARMA), which can be expressed as:

$$A(z)y(k) = B(z)u(k) + \frac{D(z)}{C(z)}v(k) \tag{1}$$

where

$\{u(\mathrm{k})\}$ and $\{\mathrm{y(k)}\}$ are the input and output, $\{v(\mathrm{k})\}$ is the white noise sequence with zero mean and unit variance σ^2 [9] and $\mathrm{A(z)}, \mathrm{B(z)}, \mathrm{C(z)}$and $\mathrm{D(z)}$ are polynomials in the unit backward shift operator z [4].

$$A(z) = 1 + \sum_{i=1}^{n_a} a_i z^{-i}$$

$$B(z) = \sum_{i=1}^{n_b} b_i z^{-i}$$

$$C(z) = 1 + \sum_{i=1}^{n_c} c_i z^{-i}$$

$$D(z) = 1 + \sum_{i=1}^{n_c} d_i z^{-i}$$

The equation (1) can be rewritten as:

$$y(k) = [1 - A(z)]y(k) + B(z)u(k) + w(k) \tag{2}$$

$w(k)$ is defined as

$$w(k) = [1 - C(z)]w(k) + D(z)v(k) \tag{3}$$

 ISBN 978-86-7466-930-3

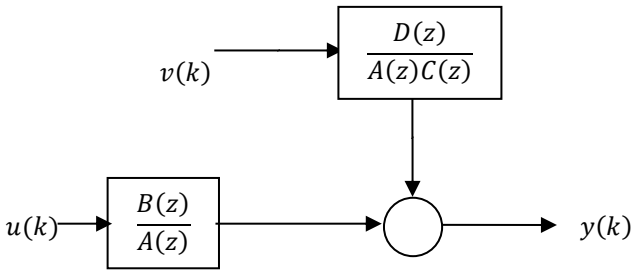

Fig. 1. CARARMA Model.

The parameter vector $\{\theta_1, \theta_2, \theta_3, \theta_4\}$ and the information vectors $\{\varphi_1(k), \varphi_2(k), \varphi_3(k), \varphi_4(k)\}$ are defined as:

$$\theta_1 := [a_1, a_2, \dots, a_{n_a}]^T$$

$$\theta_2 := [b_1, b_2, \dots, b_{n_b}]^T$$

$$\theta_3 = [c_1, c_2, \dots, c_{n_c}]^T$$

$$\theta_4 := [d_1, d, \dots, d_{n_d}]^T$$

$$\varphi_1(k) = [-y(k-1), -y(k-2), \dots, -y(k-n_a)]^T$$

$$\varphi_2(k) = [u(k-1), u(k-2), \dots, u(k-n_b)]^T$$

$$\varphi_3(k) = [-w(k-1), -w(k-2), \dots, -w(k-n_c)]^T$$

$$\varphi_4(k) = [v(k-1), v(k-2), \dots, v(k-n_d)]^T$$

Then,

$$y(\mathrm{k}) = \varphi_1{}^T(k)\theta_1 + \varphi_2{}^T(k)\theta_2 + w(k) \quad (4)$$

$$w(k) = \varphi_3{}^T(k)\theta_3 + \varphi_4{}^T(k)\theta_4 + v(k) \quad (5)$$

Using equation (5), equation (4) can be written as [5].

$$y(k) = \varphi_1{}^T(k)\theta_1 + \varphi_2{}^T(k)\theta_2 + \varphi_3{}^T(k)\theta_3 + \varphi_4{}^T(k)\theta_4 + v(k)$$

$$y(k) = \varphi^T(k)\theta + v(k) \quad (6)$$

$$\varphi^T(k) = [\varphi_1{}^T(k)\ \varphi_2{}^T(k)\ \varphi_3{}^T(k)\ \varphi_4{}^T(k)]$$

$$\theta = [\theta_1; \theta_2; \theta_3; \theta_4]$$

The basic principle in this work is to decomposed the identification system in equation (6) into four subsystems, and the parameters of each subsystem are estimated separately [6].

Define four intermediate output variables:

$$y_1(k) = y(k) - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\theta_4, \quad (7)$$

$$y_2(k) = y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\theta_4, \quad (8)$$

$$y_3(k) = y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_4{}^T(k)\theta_4, \quad (9)$$

$$y_4(k) = y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3, \quad (10)$$

This system can be decomposed into the following four subsystems:

$$y_i(k) = \varphi_i^T(k)\theta_i + v(k), \quad i = 1,2,3,4. \quad (11)$$

Define the cost functions:

$$J_i(\theta_i) := \sum_{j=1}^{k} [y_i(j) - \varphi_i{}^T(j)\theta_i]^2, \quad i = 1,2,3,4.$$

Let $\hat{\theta}(k) = [\hat{\theta}_1(k); \hat{\theta}_2(k); \hat{\theta}_3(k); \hat{\theta}_4(k)]$ be the estimate of $\theta = [\theta_1; \theta_2; \theta_3; \theta_4]$ .Also, let the partial derivatives of $J_i(\theta_i), i = 1,2,3,4$ with respect to θ_i be zero

$$\frac{\partial J_i(\theta_i)}{\partial \theta_i} = -2\varphi_i(j) \sum_{j=1}^{k} [y_i(j) - \varphi_i{}^T(j)\hat{\theta}_i(k)] = 0 \quad (12)$$

Then, the following RLS algorithm can be obtained:

$$\hat{\theta}_i(k) = \hat{\theta}_i(k-1) + L_i(k)\big[[y_i(k) - \varphi_i{}^T(k)\hat{\theta}_i(k-1)\big] \quad (13)$$

$$L_i(k) = P_i(k-1)\varphi_i(k)[1 + \varphi_i{}^T(k)P_i(k-1)\varphi_i(k)]^{-1},$$

$$P_i(k) = [I - L_i(k)\varphi_i{}^T(k)]P_i(k-1),$$

$$P_i(0) = p_0 I, \ \ i = 1,2,3,4$$

Substituting equations (9, 10, 11and12) into equation (13) [7].

$$\hat{\theta}_1(k) = \hat{\theta}_1(k-1) + L_1(k)\big[y(k) - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\theta_4 - \varphi_1{}^T(k)\hat{\theta}_1(t-1)\big] \quad (14)$$

$$\hat{\theta}_2(k) = \hat{\theta}_2(k-1) + L_2(k)\big[y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\theta_4 - \varphi_2{}^T(k)\hat{\theta}_2(k-1)\big] \quad (15)$$

$$\hat{\theta}_3(k) = \hat{\theta}_3(k-1) + L_3(k)\big[y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_4{}^T(k)\theta_4 - \varphi_3{}^T(k)\hat{\theta}_3(k-1)\big] \quad (16)$$

$$\hat{\theta}_4(k) = \hat{\theta}_4(k-1) + L_4(k)\big[y(k) - \varphi_1{}^T(k)\theta_1 - \varphi_2{}^T(k)\theta_2 - \varphi_3{}^T(k)\theta_3 - \varphi_4{}^T(k)\hat{\theta}_4(k-1)\big] \quad (17)$$

Although the all RLS sub-algorithms are derived for calculating $\hat{\theta}_1(k), \hat{\theta}_2(k), \hat{\theta}_3(k)\ and\ \hat{\theta}_4(k)$. They are unattainable to be completed, because the right-hand sides all RLS sub-algorithms include the unknown parameters$\theta_1, \theta_2, \theta_3\ and\ \theta_4$. In order to handles this issue; the parameters $\theta_i\ i = 1,2,3,4$ are replaced with $\hat{\theta}_i(k-1)$ [8].
Then, $\hat{\theta}_1(k), \hat{\theta}_2(k), \hat{\theta}_3(k)\ and\ \hat{\theta}_4(k)$ can be calculated by

$$\hat{\theta}_1(k) = \hat{\theta}_1(k-1) + L_1(k)\big[y(k) - \varphi_2{}^T(k)\hat{\theta}_2(k-1) - \varphi_3{}^T(k)\hat{\theta}_3(k-1) - \varphi_4{}^T(k)\hat{\theta}_4(k-1) - \varphi_1{}^T(k)\hat{\theta}_1(k-1)\big]$$

$$= \hat{\theta}_1(k-1) + L_1(k)\big[y(k) - \varphi^T(k)\hat{\theta}(k-1)\big] \quad (18)$$

$$\hat{\theta}_2(k) = \hat{\theta}_2(k-1) + L_2(k)\big[y(k) - \varphi_1{}^T(k)\hat{\theta}_1(k-1) - \varphi_3{}^T(k)\hat{\theta}_3(k-1) - \varphi_4{}^T(k)\hat{\theta}_4(k-1) - \varphi_2{}^T(k)\hat{\theta}_2(k-1)\big]$$

 ISBN 978-86-7466-930-3

$$= \hat{\theta}_2(k-1) + L_2(k)\left[y(k) - \varphi^T(k)\hat{\theta}(k-1)\right] \quad (19)$$

$$\hat{\theta}_3(k) = \hat{\theta}_3(k-1) + L_3(k)\left[y(k) - {\varphi_1}^T(k)\hat{\theta}_1(k-1) - {\varphi_2}^T(k)\hat{\theta}_2(k-1) - {\varphi_4}^T(k)\hat{\theta}_4(k-1) - {\varphi_3}^T(k)\hat{\theta}_3(k-1)\right],$$

$$= \hat{\theta}_3(k-1) + L_3(k)\left[y(k) - \varphi^T(k)\hat{\theta}(k-1)\right] \quad (20)$$

$$\hat{\theta}_4(k) = \hat{\theta}_4(k-1) + L_4(k)\left[y(k) - {\varphi_1}^T(k)\hat{\theta}_1(k-1) - {\varphi_2}^T(k)\hat{\theta}_2(k-1) - {\varphi_3}^T(k)\hat{\theta}_3(k-1) - {\varphi_4}^T(k)\hat{\theta}_4(k-1)\right]$$

$$= \hat{\theta}_4(k-1) + L_4(k)\left[y(k) - \varphi^T(k)\hat{\theta}(k-1)\right] \quad (21)$$

Notice that the right-hand sides of equations (18)–(21) include the unknown information vectors $\varphi_3(k)$ which contains the unknown inner variables $w(k-i)$ and $\varphi_4(k)$ which contains unknown inner variables $v(k-i)$, so that, this algorithm cannot be performed [9]. Replacing $w(k-i)$ and$v(k-i)$ with their estimates $\hat{w}(k-i)$ and $\hat{v}(\mathrm{k-i})$, and $\hat{\varphi}_3(k), \hat{\varphi}_4(k)$ are written as

$$\hat{\varphi}_3(k) = [-\hat{w}(k-1), -\hat{w}(k-2), \dots, -\hat{w}(k-n_c)]^T \quad (22)$$

$$\hat{\varphi}_4(k) = [\hat{v}(k-1), \hat{v}(\mathrm{k-2}), \dots, \hat{v}(\mathrm{k-n_d})]^T \quad (23)$$

$$\hat{\varphi}(k) = [\varphi_1, \varphi_2, \hat{\varphi}_3, \hat{\varphi}_4]^T$$

Where,

$$\hat{w}(k) = y(k) - {\varphi_1}^T(k)\hat{\theta}_1 - {\varphi_2}^T(k)\hat{\theta}_2 \quad (24)$$

$$\hat{v}(k) = \hat{w}(k) - {\hat{\varphi}_3}^T(k)\hat{\theta}_3 - {\hat{\varphi}_4}^T(k)\hat{\theta}_4 \quad (25)$$

Thus, Four-Stage Recursive Least Squares Algorithm for CARARMA Systems is summarize as:

$$\hat{\theta}_1(k) = \hat{\theta}_1(k-1) + L_1(k)\left[y(k) - \hat{\varphi}^T(k)\hat{\theta}(k1)\right] \quad (26)$$

$$L_1(k) = P_1(k-1)\varphi_1(k)[1 + {\varphi_1}^T(k)P_1(k-1)\varphi_1(k)]^{-1} \quad (27)$$

$$P_1(k) = [I - L_1(k){\varphi_1}^T(k)]P_1(k-1) \quad (28)$$

$$\varphi_1(k) = [-y(k-1), -y(k-2), \dots, -y(k-n_a)]^T \quad (29)$$

$$\hat{\theta}_2(k) = \hat{\theta}_2(k-1) + L_2(k)\left[y(k) - \hat{\varphi}^T(k)\hat{\theta}(k-1)\right] \quad (30)$$

$$L_2(k) = P_2(k-1)\varphi_2(k)[1 + {\varphi_2}^T(k)P_2(k-1)\varphi_2(k)]^{-1} \quad (31)$$

$$P_2(k) = [I - L_2(k){\varphi_2}^T(k)]P_2(k-1) \quad (32)$$

$$\varphi_2(k) = [u_1(k-1), u_1(k-2), \dots, u_1(k-n_1)]^T \quad (33)$$

$$\hat{\theta}_3(k) = \hat{\theta}_3(k-1) + L_3(k)\left[y(k) - \hat{\varphi}^{\mathrm{T}}(k)\hat{\theta}(k-1)\right] \quad (34)$$

$$L_3(k) = P_3(k-1)\hat{\varphi}_3(k)\left[1 + {\hat{\varphi}_3}^T(k)P_3(k-1)\hat{\varphi}_3(k)\right]^{-1} \quad (35)$$

$$P_3(k) = \left[I - L_3(k){\hat{\varphi}_3}^T(k)\right]P_3(k-1) \quad (36)$$

$$\hat{\varphi}_3(k) = [-\hat{w}(k-1), -\hat{w}(k-2), \dots, -\hat{w}(k-n_c)]^T \quad (37)$$

$$\hat{\theta}_4(k) = \hat{\theta}_4(k-1) + L_4(k)\left[y(k) - \hat{\varphi}^T(k)\hat{\theta}(k-1)\right] \quad (38)$$

$$L_4(k) = P_4(k-1)\hat{\varphi}_4(k)\left[1 + {\hat{\varphi}_4}^T(k)P_4(k-1)\hat{\varphi}_4(k)\right]^{-1} \quad (39)$$

$$P_4(k) = \left[I - L_4(k){\hat{\varphi}_4}^T(k)\right]P_4(k-1) \quad (40)$$

$$\hat{\varphi}_4(k) = [\,\hat{v}(k-1), \hat{v}(\mathrm{k-2}), \dots, \hat{v}(\mathrm{k-n_d})]^T \quad (41)$$

III. The Recursive Generalized Least Squares Algorithm

In order to demonstrate the features of the Four-Stage -RLS algorithm, the following discuss recursive generalized extended least squares (RGELS) algorithm [10]. As we all know, (RGELS) algorithm can identify CARARMA Systems. The main issue is to replace $w(k-i)$ and $v(k-i)$ with their estimates in the information vector. Finally, (RGLS) algorithm can obtained and the estimated parameter vectors of CARARMA model can be calculated as [11].

$$\hat{\theta}(k) = \hat{\theta}\,(k-1) - L(k)\,[y(k) - \hat{\varphi}\,(k)^T\,\hat{\theta}(k-1)] \quad (42)$$

$$L(k) = \frac{P(k-1)\hat{\varphi}\,(t)}{1 + \hat{\varphi}^T(k)P(k-1)\hat{\varphi}\,(k)} \quad (43)$$

$$P(k) = [I - L(k)\hat{\varphi}^T(k)]\,P(k-1). \quad (44)$$

$$\hat{\varphi}(k) = [\varphi_s(k)\ \ \varphi_n(k)]^T,\ \hat{\theta}(k) = [\hat{\theta}_s(k)\,;\hat{\theta}_n(k)] \quad (45)$$

$${\varphi_s}^T(k) = [-y(k-1), -y(k-2), \dots, -y(k-\ na), u(k\ -1), u(k-2), \dots, u(k-n_b)] \quad (46)$$

$${\varphi_n}^T(k) = [-w(k-1), -w(k-2), \dots, -w(k-\ n_c), v(k\ -1), v(k-2), \dots, v(k-n_d)] \quad (47)$$

$$\hat{w}(k) = y(k) - {\varphi_s}^T(k).\hat{\theta}_s(k) \quad (48)$$

$$\hat{v}\,(k) = y(k) - \hat{\varphi}^T(k)\hat{\theta}(k) \quad (49)$$

$$\hat{\theta}_s(k) = \left[\hat{a}_1(k), \hat{a}_2(k), \dots, \hat{a}_{n_a}(k), \hat{b}_1(k), \hat{b}_1(k), \dots, \hat{b}_{nb}(k)\right] \quad (50)$$

$$\hat{\theta}_n(k) = \left[\hat{c}_1(k), \hat{c}_2(k), \dots, \hat{c}_{n_c}(k), \hat{d}_1(k), \hat{d}_1(k), \dots, \hat{d}_{nd}(k)\right] \quad (51)$$

IV. simulation results

The effectiveness of Four-Stage -RLS algorithm has been checked on samples generated by the following (CARARMA) model:

$$\mathrm{A}(z)y(k) = B(z)u(k) + \frac{D(z)}{C(z)}v(k)$$

$$A(z) = 1 + 0.72z^{-1} + 0.81z^{-2}$$

$$B(z) = 0.22z^{-1} + 0.33z^{-2}$$

$$C(z) = 1 + 0.65z^{-1}$$

$$D(z) = 1 + 0.55z^{-1}$$

 ISBN 978-86-7466-930-3

$$\theta = [a_1, a_2, b_1, b_2, c_1, d_1]^T,$$

$$= [0.72, 0.81, 0.22, 0.33, 0.65, 0.55]^T,$$

The input $u(k)$ adopts a persistent excitation sequence with $m = 0$ and $\sigma = 1$, while $v(k)$ is a white noise sequence with $m = 0$ and $\sigma = 0.3^2$.

Quantile-quantile (Q-Q) plot and estimation error have been used in order to evaluate the performance of the proposed algorithm.

A. Quantile-quantile (Q-Q) plot

Quantile-quantile (Q-Q) plot is a diagnostic tool, which is widely used to assess the distributional similarities and differences between two independent univariate samples. It is also used to determine how well a specified probability distribution fits a given sample [12].

The following steps create a Quantile-Quantile-plot (Q-Q-plot)

1. Rank your data in ascending order: $x_1, \ldots\ldots, x_n$

2. For each data point x_i compute the empirical percentiles ρ_i of data points smaller than or equal to x_i ,i.e

$$\rho_i = \frac{i}{n}$$

3. Define a theoretical matching normal distribution as the normal distribution with the same mean and variance as the sample.

4. For each percentile ρ_i find the corresponding quantile y_i in the theoretical normal distribution.

5. Plot y_i against x_i

6. If $x_i = y_i$ for all i we get a straight line indicating that x_i's are normally distributed [13].

B. The estimation error

The estimation error is determined as [14].

where

$$\delta = \sqrt{\frac{\|\hat{\theta}_1 - \theta_1\|^2 + \|\hat{\theta}_2 - \theta_2\|^2 + \|\hat{\theta}_3 - \theta_3\|^2 + \|\hat{\theta}_4 - \theta_4\|^2}{\|\theta_1\|^2 + \|\theta_2\|^2 + \|\theta_3\|^2 + \|\theta_4\|^2}} \qquad (40)$$

As it's known, when the parameter estimation errors become smaller with the sequences increasing, the accuracy of the estimated parameters is increased.

Four-Stage -RLS algorithm and (RGELS) algorithm have been applied to estimate the parameters of the system and the estimation errors for these algorithms versus sequences (k) are shown in Fig. 2.

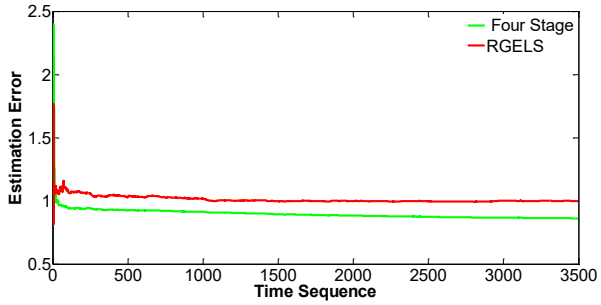

Fig. 2. Four-Stage -RLS and (RGELS) estimation errors versus *k*

The figure demonstrates that Four-Stage -RLS algorithm can achieved more accurate estimates than the (RGELS) algorithm.

Fig. 3 shows Q-Q plots for a residuals generation of Four-Stage -RLS algorithm (blue color) and (RGELS) algorithm (red color) which are tested in comparison with the standard normal distribution (black color) to determine the extent of the quantiles match.

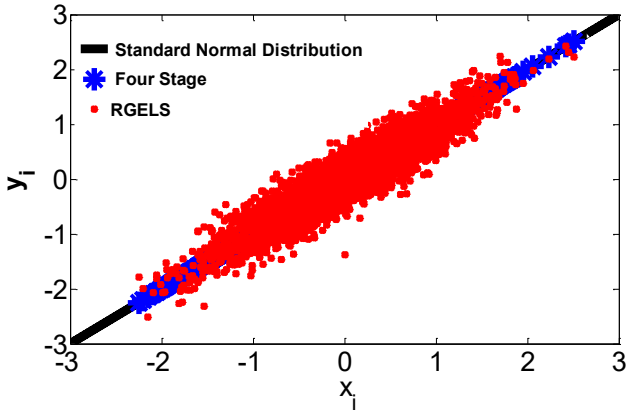

Fig. 3 Q-Q plots for a residuals generation of Four-Stage -RLS algorithm " blue color" and (RGELS) algorithm" red color".

The figure offers that, the result of the Four-Stage -RLS algorithm matches more closely along standard normal distribution than the result of the (RGELS) algorithm. This result indicates that the proposed algorithm is more effective than (RGELS) algorithm.

The estimated output and the true output of Four-Stage -RLS algorithm are plotted in Fig. 4.

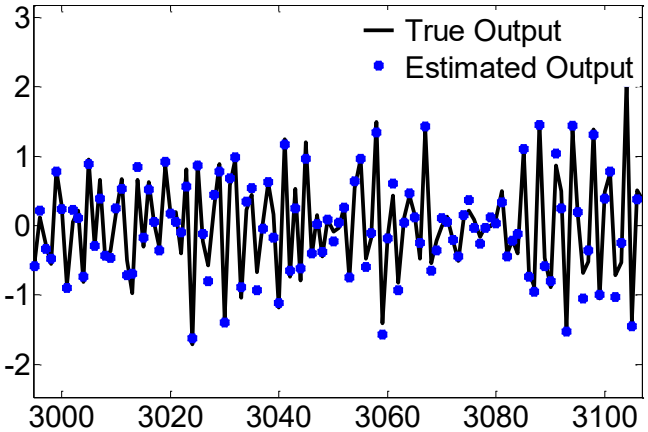

Fig. 4 The estimated output and the true output of Four-Stage -RLS algorithm

 ISBN 978-86-7466-930-3

The figure illustrate that estimated output is close to the true output, which means the estimated model can fit the validation data well [10].

V. CONCLUSIONS

In this paper, Four-Stage recursive identification algorithm is derived. Through a simulation results, it is shown that the proposed algorithm has some advantages, in comparison with (RGLES) algorithm. Four-Stage -RLS improves the accuracy for estimated parameters, and has higher computational efficiency than (RGLES) algorithm. The proposed technique in this article can be extended to study the parameter estimation algorithm of (MISO) and (MIMO) systems with colored noise.

Consensus on the Auxiliary Variables in Distributed Gradient-Based Temporal Difference Algorithms

Miloš S. Stanković, Marko Beko, Nemanja Ilić and Srdjan S. Stanković

***Abstract*—In this paper we discuss important properties of two novel distributed algorithms for iterative multi-agent off-policy learning of linear value function approximation in Markov Decision Processes (MDP). The algorithms are derived using the off-policy Gradient Reinforcement Learning (GRL) methodology, together with linear dynamic consensus iterations over an underlying inter-agent communication network represented by directed graphs. The proposed algorithms are entirely decentralized, offering new possibilities for choosing different behavior policies while evaluating one single target policy. The presented algorithms formally differ only in the way of applying consensus iterations to the so-called auxiliary variables. The presented proof of weak convergence of both algorithms represents a firm basis for deriving relevant conclusions concerning the role of the consensus iterations. It is shown that the algorithm utilizing consensus on the auxiliary variables shows slightly inferior asymptotic properties, but can provide a higher convergence rate. The figure of merit of each of the algorithms is presented and discussed using the theoretical results obtained under generally nonrestrictive assumptions.**

I. Introduction

Decentralized multi-agent decision making algorithms have recently gained much popularity due to their high effectiveness in dealing with uncertain and dynamic environments typical for the emerging areas of Cyber-Physical Systems (CPS) and Internet of Things (IoT). Numerous distributed estimation, optimization and adaptation methods have been successfully developed using recursive collaborations aimed at achieving a consensus on variables of interest (e.g. [1]–[15] and references therein).

Reinforcement learning (RL) is a general methodology for decision making in uncertain environments based on models in the form of Markov Decision Process (MDP) based on utilization of approximate dynamic programming [16], [17]. A very important issue in this domain is the problem of approximation of the value function under very large state space and the presence of a discrepancy between the behavior policy of an agent and a policy that is currently targeted for evaluation (off-policy learning, e.g. [18]). Recently, in [19]–[22] several fast gradient-based algorithms for temporal-difference (TD) learning have been proposed. Distributed and multi-agent RL methods have become very popular very recently (see, e.g. [1], [23]–[25] and references therein). Different setups have been adopted in a number of recent works [26]–[32].

In this paper we shall present and discuss two distributed algorithms for *iterative multi-agent off-policy learning* of linear approximation of the value function in MDPs [1]. The algorithms represent generalizations of the recently proposed single agent off-policy gradient algorithm GTD2(λ) [1], [19]–[21], incorporating a distributed consensus scheme operating over a network of typically sparsely connected agents. Another important property of the algorithms is that the local recursions of each agent can be based on eligibility traces [20], [21], where each agent may choose different λ parameters. We provide a firm theoretical background in the form of a proof that the parameter estimates *weakly converge* to consensus points [1], [19], [28], [29], [31], [33], under nonrestrictive connectivity assumption on the topology of the underlying digraph and on the state-visiting distributions of the agents (their behavior policies). The main focus of this paper is placed on the dilemma whether or not to apply consensus to the *auxiliary variables* in the DGTD2(λ)-type algorithms with one-time-scale (see [19], [28], [31]). Notice that the paper [33] deals with the basically two-time-scale algorithms of DGTDC(λ)-type. The given analysis will be exclusively concerned with the limit points of the mean asymptotic ODEs: in this sense the behavior of the estimates for large, but finite t, including the derivation of the corresponding ODEs, can be found in [1], [33]. The limit sets are analyzed by formulating appropriate Lyapunov functions, following the line of thought of [21]. A discussion on role of convexification of the auxiliary variables is provided apart, showing that the two algorithms converge to the same limit points only in special cases. Application of consensus to the auxiliary variables causes, in principle, inferior asymptotic performance, having in mind that the implicitly imposed constraint increases the achievable estimation error. On the other hand, introduction of consensus can contribute to the overall convergence rate at the global level; however, the global convergence rate depends largely on the network connectivity.

The paper is organized as follows. In Section II we formulate the problem and define the algorithms. In Section III a rigorous weak convergence analysis is presented focused on the limit points, while Section IV is devoted to a general discussion on the application of consensus to the auxiliary variables in the DGTD2(λ) algorithms.

II. Distributed Gradient Temporal Difference Algorithms

A. Problem Formulation. Definition of the Algorithm

Consider *N autonomous agents* learning linear approximation to the *state value function* for a given policy in an MDP (denoted as $\mathrm{MDP}^{(0)}$), using observations of sample transitions in additional N *independent* MDPs, denoted as $\mathrm{MDP}^{(i)}$, $i = 1, \ldots, N$. Assume a finite state space $\mathcal{S} = \{1, \ldots, M\}$, and that $\mathrm{MDP}^{(0)}$ has the transition matrix P, and $\mathrm{MDP}^{(i)}$ the transition matrices $P^{(i)}$, $i = 1, \ldots, N$; these chains are induced by π and $\pi^{(i)}$, and referred to as the *target policy* and *behavior policies*, respectively. We are, therefore, dealing with a *cooperative off-policy learning* problem [1], [16], [18], [31].

We introduce the one-stage *reward function* $r_\pi : \mathcal{S} \to \mathcal{R}$, specifying the expected reward at each state $s \in \mathcal{S}$, where $\mathcal{R}$ is the set of real numbers [16], [21]. The associated discounted *total reward criterion* (*value function*), with the state dependent discount factors $\gamma(s) \in [0, 1]$, $s \in \mathcal{S}$, is given by

$$v_\pi(s) = E_s^\pi\{r_\pi(S_0) + \sum_{n=1}^{\infty} \gamma(S_1)\gamma(S_2)\cdots\gamma(S_n) \cdot r_\pi(S_n)\}, \tag{1}$$

where $E_s^\pi\{\cdot\}$ indicates the expectation w.r.t. to the Markov chain $\{S_n\}_{n>0}$ induced by π, with the initial state $S_0 = s$. Denote by Γ the $M \times M$ diagonal matrix with $\gamma(s)$ as diagonal entries and $v_\pi = [v_\pi(s_1) \cdots v_\pi(s_M)]^T$.

We assume the following [21]:

(A1) a) P is such that $I - P\Gamma$ is nonsingular; b) $P^{(i)}$ is irreducible and for all $s, s' \in \mathcal{S}$ $P_{ss'}^{(i)} = 0 \Rightarrow P_{ss'} = 0$, $i = 1, \ldots, N$.

By the MDP theory [1], [16], [21], [34], v_π uniquely satisfies the *Bellman equation* $v_\pi = r_\pi + P\Gamma v_\pi$ (see e.g. [21], [34]). Within the framework of the *temporal-difference* (TD) algorithms, it is usual to consider the Bellman equation depending on the so-called *λ-parameters*, procedurally introduced by the so-called *eligibility traces*. In this sense, $v_\pi = T^{(\lambda)}v_\pi$ is considered as a *generalized Bellman equation*, where $T^{(\lambda)}v = r_\pi^\lambda + P^{(\lambda)}v$, $\forall v \in R^{|S|}$, is the *generalized Bellman operator* for a vector $r_\pi^{(\lambda)}$ and a substochastic matrix $P^{(\lambda)}$ [16], [21].

Let $\phi : S \to R^p$ be a function that maps each state to a p-dimensional feature vector $\phi = [\phi_1 \cdots \phi_p]^T$; let the subspace spanned by feature vectors ϕ be $\mathcal{L}_\phi$. In general, TD algorithms look for some function $v \in \mathcal{L}_\phi$ that satisfies $v \approx T^{(\lambda)}v$. We assume that the approximation functions are parameterized as $v(s) = \phi(s)^T\theta$, $s \in \mathcal{S}$ using parameters $\theta \in \mathcal{R}^p$, so that the algorithms learn the vector θ. If we define the $M \times p$ matrix Φ as a matrix composed of p-vectors $\phi(s)$ as row vectors, we have $v_\theta = \Phi\theta$.

In order to construct a distributed algorithm for finding an approximation function $v_\theta \in \mathcal{L}_\phi$ by using observations from $\mathrm{MDP}^{(i)}$, $i = 1, \ldots, N$, we define the following *global objective function*

$$J(\theta) = \sum_{i=1}^{N} q_i J_i(\theta) = \frac{1}{2}\sum_{i=1}^{N} q_i \|\Pi_{\xi_i}(T^{(\lambda_i)}v_\theta - v_\theta)\|_{\xi_i}^2, \tag{2}$$

where $J_i(\theta)$ are the *local objective functions*, $q_i > 0$ the *a priori* defined weighting coefficients, λ_i is the local λ-parameter and Π_{ξ_i} denotes the projection onto the subspace $\mathcal{L}_\phi$ w.r.t. the weighted Euclidean norm $\|v\|_{\xi_i}^2 = \sum_{s\in\mathcal{S}} \xi_{i;s} v(s)^2$ for a positive M-dimensional vector ξ_i with components $\xi_{i;s}$ (see [21], [31]). In accordance with [21], [34], we take ξ_i to be the invariant probability distribution for the local Markov chain $\mathrm{MDP}^{(i)}$, with the transition matrix $P^{(i)}$ induced by $\pi^{(i)}$ ($\xi_i^T P^{(i)} = \xi_i^T$). It follows that

$$\nabla J(\theta) = \sum_{i=1}^{N} q_i(\Phi^T\Xi_i(P^{(\lambda_i)} - I)\Phi)^T w_i(\theta), \tag{3}$$

where Ξ_i is an $M \times M$ diagonal matrix with the components of ξ_i on the diagonal, and $w_i(\theta)$ the unique solution (in w_i) of the equation

$$\Phi w_i = \Pi_{\xi_i}(T^{(\lambda_i)}v_\theta - v_\theta), \tag{4}$$

assuming that $w_i \in \mathrm{span}\{\phi(S)\}$.

In the off-policy scenario, we introduce the local *importance sampling ratios* $\rho_i(s, s') = P_{ss'}^i / P_{ss'}$ for $s, s' \in \mathcal{S}$, $i = 1, \ldots, N$; denote $\rho_i(n) = \rho_i(S_n, S_{n+1})$, as well as $\gamma(n) = \gamma(S_n)$ [21], [34]. The local *temporal-difference term* is defined by

$$\delta_i(v_\theta; n) = \rho_i(n)(R(n+1) + \gamma(n+1)v_\theta(S_{n+1}) - v_\theta(S_n)). \tag{5}$$

The local *eligibility trace vectors* $\{e_i(n)\}$ are generated by

$$e_i(n) = \lambda_i(n)\gamma(n)\rho_i(n-1)e_i(n-1) + \phi(S_n), \tag{6}$$

where $\lambda_i(n) \in [0, 1]$ are the local *λ-parameters*, $i = 1, \ldots, N$ [21], [34].

The distributed algorithms for learning linear approximation to the state value function for a given policy π we are going to analyze consist of two main parts: 1) *local parameter updates* based on the *gradient descent* methodology using local state transition observations from $\mathrm{MDP}^{(i)}$, and 2) interchange of the current parameter estimates aimed at achieving *consensus* between the agents. The local parameter updates are defined by

$$\begin{aligned}\theta_i'(n) =& \theta_i(n) + \alpha_i(n)q_i\rho_i(n)(\phi(S_n) \\ &- \gamma(n+1)\phi(S_{n+1}))e_i(n)^T w_i(n)\end{aligned} \tag{7}$$

$$\begin{aligned}w_i'(n) =& w_i(n) + \beta_i(n)(e_i(n)\delta_i(v_{\theta_i(n)}; n) \\ &- \phi(S_n)\phi(S_n)^T w_i(n))\end{aligned} \tag{8}$$

where $v_{\theta_i(n)} = \Phi\theta_i(n)$; $\theta_i(0)$ is chosen arbitrarily, while for $w_i(0)$ and $e_i(0)$ we have $w_i(0)$, $e_i(0) \in \mathrm{span}\{\phi(S)\}$ [21]. Notice that the algorithm incorporates the *auxiliary variables* $w_i(n)$ and $w_i'(n)$; their role is essential for this paper [19], [21].

The second, communication part of the algorithm performs the following convexification w.r.t. the approximation parameter θ, leaving local auxiliary parameters unchanged, *i.e.*,

$$\theta_i(n+1) = \sum_{j=1}^{N} a_{ij}(n)\theta_j'(n), \qquad w_i(n+1) = w_i'(n), \tag{9}$$

where $a_{ij}(n)$ are random variables, elements of a random matrix $A(n) = [a_{ij}(n)]$ [11], [31], [35]. If one adopts that the

 ISBN 978-86-7466-930-3

available N MDP's are connected by communication links in accordance with a directed graph $\mathcal{G} = (\mathcal{N}, \mathcal{E})$, where $\mathcal{N}$ is the set of nodes and $\mathcal{E}$ the set of arcs, then matrix $A(n)$ has zeros at the same places as the graph adjacency matrix A_G and is *row-stochastic, i.e.*, $\sum_{j=1}^{N} a_{ij}(n) = 1$, $i = 1, \ldots, N$, $\forall n \geq 0$. The algorithm (7), (8) incorporating consensus only w.r.t. θ according to (9) will be denoted as AlgA.

We also consider a modification of AlgA, denoted as AlgB, obtained by applying convexification to both θ_i and w_i, $i = 1, \ldots, N$, in such a way that the second relation in (9) becomes

$$w_i(n+1) = \sum_{j=1}^{N} a_{ij}(n) w'_j(n). \tag{10}$$

A comparative analysis of AlgA and AlgB is in the main focus of this paper.

III. Convergence Analysis

A. Prerequisites

1) Choice of λ-parameters: The results given below are applicable to both *state-dependent* and *history-dependent* λ_i. In the first case, we have simply $\lambda_i(n) = \lambda_i(S_n)$ for a given function $\lambda_i : \mathcal{S} \to [0, 1]$, while in the second case $\lambda_i(n) = \lambda(y_i(n), e_i(n-1))$, $y_i(n) = f(y_i(n-1), S_n)$, where $y(n)$, $n \geq 0$, is a memory state summarizing the history of the past states up to time n (see [21], [34]).

Different choices of λ_i lead to different generalized Bellman operators. For example, in the case of state-dependent λ_i, we have:

$$T^{(\lambda_i)} v = (I - P\Gamma\Lambda_i)^{-1} r_\pi + (I - P\Gamma\Lambda_i)^{-1} P\Gamma(I - \Lambda_i)v, \tag{11}$$

where Λ_i is an $M \times M$ diagonal matrix with entries $\lambda_i(s)$; therefore, we have $P^{(\lambda_i)} = (I - P\Gamma\Lambda_i)^{-1} P\Gamma(I - \Lambda_i)$. For the history-dependent λ_i-parameters, the formulation is more complex [21], [34] (the details are out of the scope of this paper).

2) Properties of the State-Trace Processes: Under the behavior policies $\pi^{(i)}$, the *state-trace processes* are defined as $\{S_n, e_i(n)\}$. These state-trace processes are Markov chains with the weak Feller property [21], [34]. Let $Z_i(n) = (S_n, e_i(n), S_{n+1})$. We have the following important result [21], [34]: a) the state-trace weak Feller-Markov chain process $Z_i(n)$ has a unique invariant probability measure ζ_i; for each initial condition the *occupation probability measure* converges weakly to ζ_i [21, Theorem 2.1(i)]; b) if E_{ζ_i} denotes the expectation of the stationary state-trace process with initial distribution ζ_i, then $E_{\zeta_i}\{\|f(Z_0)\|\} < \infty$ and $\frac{1}{n}\sum_{j=0}^{n-1} f(Z_i(j))$ converges to $E_{\zeta_i}\{f(Z_i(0))\}$ in mean and a.s., where $f(z)$ is a Lipschitz continuous function in the trace variable e [21, Theorem 2.1(ii)].

The results a) and b) are used to prove the following:
1) $E_{\zeta_i}\{\phi(S_0)\phi(S_0)^T\} = \Phi^T \Xi_i \Phi$;
2) $E_{\zeta_i}\{e_i(0)\ \delta_i(v; 0)\} = \Phi^T \Xi_i (T^{(\lambda_i)} v - v)$, $\forall v \in \mathcal{R}^M$
3) $E_{\zeta_i}\{e_i(0)\rho_i(0)(\phi^j(S_0) - \gamma(1)\phi^j(S_1))\} = \Phi^T \Xi_i (I - P^{(\lambda_i)})\Phi_j$, $1 \leq j \leq p$;
4) $E_{\zeta_i}\{e_i(0)\rho_i(0)(1 - \lambda_i(1))\gamma(1)\phi^j(S_1)\} = \Phi^T \Xi_i P^{(\lambda_i)} \Phi_j$, $1 \leq j \leq p$;

where $\phi^j(\cdot)$ is the j-th component of $\phi(\cdot)$ and Φ_j the j-th column vector of Φ [21, Proposition 2.1].

Under (A1), the results from [21, Proposition 2.2] also show that the sequences of traces $\{e_i(n)\}$ satisfy the condition $E\{\|e_i(n) - \hat{e}_i(n)\|\} \leq c(n)$, where $c(n) \to 0$ when $n \to \infty$, while $\{e_i(n)\}$ and $\{\hat{e}_i(n)\}$ are obtained using the same trajectory of states, but with different initial conditions $e_i(0)$ and $\hat{e}_i(0)$. Also, $\{e_i(n)\}$ is uniformly integrable, and, consequently, the random variables $\{Z_i(n)\}$, $n \geq 0$, are tight [36].

Let

$$g_i(\theta_i, w_i, Z_i) = \rho_i(s, s')(\phi(s) - \gamma(s')\phi(s'))e_i^T w_i \tag{12}$$

and

$$k_i(\theta_i, w_i, Z_i) = e_i \bar{\delta}_i(s, s', v_{\theta_i}) - \phi(s)\phi(s)^T w_i, \tag{13}$$

where $\bar{\delta}_i(s, s', v_{\theta_i}) = \rho_i(s, s')(r(s, s') + \gamma(s')v_{\theta_i}(s') - v_{\theta_i}(s))$. We also have:

$$\begin{aligned} \bar{g}_i(\theta_i, w_i) &= E_{\zeta_i}\{g_i(\theta_i, w_i, Z_i(0))\} \\ &= (\Phi^T \Xi_i (I - P^{(\lambda_i)})\Phi)^T w_i, \end{aligned} \tag{14}$$

$$\begin{aligned} \bar{k}_i(\theta_i, w_i) &= E_{\zeta_i}\{k_i(\theta_i, w_i, Z_i(0))\} \\ &= \Phi^T \Xi_i (T^{(\lambda_i)} v_{\theta_i} - v_{\theta_i}) - \Phi^T \Xi_i \Phi w_i, \end{aligned} \tag{15}$$

and

$$\bar{g}_i(\theta_i, w_i(\theta_i)) = (\Phi^T \Xi_i (I - P^{(\lambda_i)})\Phi)^T w_i(\theta_i). \tag{16}$$

Comparison with (3) shows that $\bar{g}_i(\theta_i, w_i(\theta_i) = -\nabla J_i(\theta_i)$.

Based on the above definitions and the results from [21], we have the following important ergodic properties:

Lemma 1 ([21]): Under (A1), the following holds for each θ_i and w_i and each compact set $D_i \subset \mathcal{Z}_i$:
a) $\lim_{m,n\to\infty} \frac{1}{m}\sum_{s=n}^{n+m-1} E_n\{k_i(\theta_i, w_i, Z_i(s+1)) - \bar{k}_i(\theta_i, w_i)\} I(Z_i(n) \in D_i) = 0$ in mean,
b) $\lim_{m,n\to\infty} \frac{1}{m}\sum_{s=n}^{n+m-1} E_n\{g_i(\theta_i, w_i, Z_i(s+1)) - \bar{g}_i(\theta_i, w_i)\} I(Z_i(n) \in D_i) = 0$ in mean,
c) $\lim_{m,n\to\infty} \frac{1}{m}\sum_{s=n}^{n+m-1} E_n\{g_i(\theta_i, w_i(\theta_i), Z_i(s+1)) - \bar{g}_i(\theta_i, w_i(\theta_i))\} I(Z_i(n) \in D_i) = 0$ in mean,
where $E_n\{\cdot\}$ denotes the conditional expectation given the history $(Z_i(0), \cdots, Z_i(n))$ and $I(\cdot)$ denotes the indicator function.

B. Global Model

Let $X(n) = [\Theta(n)^T \vdots W(n)^T]^T$, $\Theta(n) = [\theta_1(n)^T \cdots \theta_N(n)^T]^T$, $W(n) = [w_1(n)^T \cdots w_N(n)^T]^T$; similarly, $X'(n) = [\Theta'(n)^T \vdots W'(n)^T]^T$, together with the corresponding vector components. Then, we have for AlgA the following global model at the network level

$$\begin{aligned} X'(n) &= X(n) + \Gamma(n)F(X(n), n), \\ X(n+1) &= \mathrm{diag}\{(A(n) \otimes I_p), I_{Np}\} X'(n), \end{aligned} \tag{17}$$

where $\otimes$ denotes the Kronecker's product, while $\Gamma(n) = \mathrm{diag}\{\alpha_1(n), \ldots, \alpha_N(n), \beta_1(n), \ldots, \beta_N(n)\} \otimes I_p$,

$$F(X(n), n) = [F^\theta(X(n), n)^T \vdots F^w(X(n), n)^T]^T,$$

$$\begin{aligned} F^\theta(X(n), n) = [&q_1 g_1(\theta_1(n), w_1(n), Z_1(n))^T \cdots \\ &q_N g_N(\theta_N(n), w_N(n), Z_N(n))^T]^T, \end{aligned}$$

 ISBN 978-86-7466-930-3

$$F^w(X(n),n) = [k_1(\theta_1(n), w_1(n), Z_1(n))^T + e_1(n)^T\omega_1(n+1)\cdots k_N(\theta_N(n), w_N(n), Z_N(n)) + e_N(n)^T\omega_N(n+1)]^T$$

with $g_i(\cdot)$ defined by (12).

Introduce dummy variables $X = [\Theta^T \vdots W^T]^T$, together with $\bar{F}(X) = [\bar{F}^\theta(\Theta, W)^T \vdots \bar{F}^w(\Theta, W)^T]^T$, $F^\theta(\Theta,\ W) = [q_1\bar{g}_1(\theta_1, w_1)^T \cdots q_N\bar{g}_N(\theta_N, w_N)^T]^T$, with $\bar{g}_i(\cdot,\cdot)$ defined by (14), $F^w(\Theta, W) = [\bar{k}_1(\theta_1, w_1)^T \cdots \bar{k}_N(\theta_N, w_N)^T]^T$, with $\bar{k}_i(\cdot,\cdot)$ defined by (15).

In the case of AlgB, we have a slightly modified model (17): instead of $\mathrm{diag}\{(A(n)\otimes I_p), I_{Np}\}$ in the second relation in (17), we have $\mathrm{diag}\{(A(n) \otimes I_p), (A(n) \otimes I_p)\}$, as a consequence of consensus w.r.t. w_i.

C. Communication Part of the Algorithm

The result of this subsection is a slight generalization of the results in [5], based on [11].

Define $\Psi(n|k) = A(n)\cdots A(k)$ for $n \geq k$, $\Psi(n|n+1) = I_N$. Let $\mathcal{F}_n$ be an increasing sequence of σ-algebras such that $\mathcal{F}_n$ measures $\{X(k), k \leq n, A(k), k < n\}$.

(A2) There is a scalar $\alpha_0 > 0$ such that $a_{ii}(n) \geq \alpha_0$, and, for $i \neq j$, either $a_{ij}(n) = 0$ or $a_{ij}(n) \geq \alpha_0$.

(A3) There are a scalar $p_0 > 0$ and an integer n_0 such that $P_{\mathcal{F}_n}\{$agent j communicates to agent i on the interval $[n, n+n_0]\} \geq p_0$, for all n and $i = 1,\ldots N$, $j \in \mathcal{N}_i$.

(A4) The digraph $\mathcal{G}$ is strongly connected.

According to [5], [11], it is possible to show that (A2)-(A4) imply that $\Psi(k) = \lim_n \Psi(n|k)$ exists w.p.1; moreover, its rows are equal and $E\{|\Psi(n|k) - \Psi(k)|\}$, $E_{\mathcal{F}_n}\{|\Psi(n|k) - \Psi(k)|\} \to 0$ geometrically as $n - k \to \infty$, uniformly in k and ω (w.p.1). In addition, $E_{\mathcal{F}_n}\{\Psi(n|k)\}$ converges to $\Psi(k)$ geometrically, uniformly in ω and k, as $n \to \infty$.

D. Convergence Proofs

(A5) Sequence $\{A(n)\}$ is independent of the processes in MDP^i, $i = 1,\ldots, N$.

(A6) There is a $N \times N$ matrix $\bar{\Psi}$ such that $E\{|E_k\{\Psi(n)\} - \bar{\Psi}|\} \to 0$ as $n - k \to \infty$, which, under the conditions of Lemma 1, has the form

$$\bar{\Psi} = \begin{bmatrix} \bar{\psi_1} & \cdots & \bar{\psi_N} \\ & \cdots & \\ \bar{\psi_1} & \cdots & \bar{\psi_N} \end{bmatrix} = \begin{bmatrix} \hat{\Psi} \\ \vdots \\ \hat{\Psi} \end{bmatrix},$$

where $\sum_i \bar{\psi}_i = 1$ ($|\cdot|$ denotes the infinity norm).

(A7) Sequence $\{X(n)\}$ is tight.

1) AlgA):

Theorem 1: Let (A1)–(A7) hold. Let $X^\alpha(n)$ be generated by AlgA, (7), (8), (9), with $\beta_i(n) = \alpha_i(n) = \alpha$ and define for $t \geq 0$, $t \in \mathcal{R}$, $X^\alpha(t) = X(n)$ for $t \in [(n - n_\alpha)\alpha, (n - n_\alpha + 1)\alpha)$. Let $w_i^\alpha(0) = w_{i,0}^\alpha$, $e_i(0) = e_{i,0} \in \mathrm{span}\{\phi(S)\}$. Then, for any integers n'_α such that $\alpha n'_\alpha \to \infty$ as $\alpha \to 0$, there exist positive numbers $\{T_\alpha\}$ with $T_\alpha \to \infty$ as $\alpha \to 0$ such that for any $\epsilon > 0$

$$\limsup_{\alpha\to 0} P\{(X^\alpha(n'_\alpha + k)) \notin N_\epsilon(\bar{\Sigma}) \text{ for some } k \in [0, T_\alpha/\alpha]\} = 0, \quad (18)$$

$i = 1,\ldots, N$, where $N_\epsilon(\cdot)$ denotes the ϵ-neighborhood, while $\bar{\Sigma} = \bar{\Sigma}_\theta \times \cdots \bar{\Sigma}_\theta \times \bar{\Sigma}_{w_1} \times \cdots \bar{\Sigma}_{w_N}$ is the set of points $\bar{\theta}, \ldots, \bar{\theta}, \bar{w}_1, \ldots, \bar{w}_N$ satisfying

$$\begin{aligned} \sum_{i=1}^N \bar{\psi}_i q_i G_i^T \bar{w}_i &= 0, \quad (19)\\ G_1\bar{\theta} + b_1 - H_1\bar{w}_1 &= 0,\\ &\vdots\\ G_N\bar{\theta} + b_N - H_N\bar{w}_N &= 0, \end{aligned}$$

where $G_i = \Phi^T\Xi_i(P^{(\lambda_i)} - I)\Phi$, $b_i = \Phi^T\Xi_i r_\pi^{(\lambda_i)}$, $r_\pi^{(\lambda_i)}$ is a constant M-vector in the affine function $T^{(\lambda_i)}(\cdot)$, while $H_i = \Phi^T\Xi_i\Phi$, $i = 1,\ldots, N$.

Proof: The proof is based on [1], [33] and the general results from [5], [11], [36]. In order to apply the proof of Theorem 3.1 in [5], it is essential to verify whether the basic assumptions from [5] concerning $F(X(n), n)$ hold in our case. We can easily conclude that Lemma 1 implies that the assumptions (C3.2) and C(3.3') from Section 3 in [5] hold. Following further [5], it follows that the Skorokhod embedding implies that we have the limit process $X^\alpha(\cdot) \to X(\cdot)$, where $\dot{X} = \mathrm{diag}\{\bar{\Psi} \otimes I_p, I_{Np}\}\bar{F}(X)$ [5]. By Lemma 1 and (A6), all the rows of $\bar{\Psi}$ are equal. Consequently, $\Theta(\cdot) = [\theta(\cdot)^T \cdots \theta(\cdot)^T]$, $\forall\theta(\cdot) \in \mathcal{R}^p$, implying that $\dot{\theta} = \bar{\psi}_1 q_1 \bar{g}_1(\theta, w_1) + \cdots + \bar{\psi}_N q_N \bar{g}_N(\theta, w_N)$; we also have $\dot{w}_1 = \bar{k}_1(\theta, w_1), \ldots \dot{w}_N = \bar{k}_N(\theta, w_N)$, having in mind that consensus is not applied to the auxiliary variables.

In order to prove (18), we study the limit set

$$E = \cap_{\tau\geq 0}\mathrm{cl}\{\theta(t), w_1(t), \ldots, w_N(t) | \theta(0), w_1(0), \ldots, w_N(0) \in \mathcal{R}^{(N+1)p}, t \geq \tau\}. \quad (20)$$

where $\mathrm{cl}\{\cdot\}$ denotes the closure of a given set. Following [21] (Proposition 4.1), we introduce the Lyapunov function

$$V(\theta, w_1, \ldots w_N) = \frac{1}{2}\|\theta - \bar{\theta}\|^2 + \frac{1}{2}\sum_{i=1}^N q_i\bar{\psi}_i\|w_i - \bar{w}_i\|^2, \quad (21)$$

where $\bar{\theta}$ and $\bar{w}_i$ are given by (19). We have directly

$$\begin{aligned} \dot{V}(\theta, w_1, \ldots w_N) =& \langle\theta - \bar{\theta}, -\sum_{i=1}^N q_i\bar{\psi}_i G_i^T w_i\rangle \\ &+ \sum_{i=1}^N q_i\bar{\psi}_i\langle w_i - \bar{w}_i, G_i\theta + \bar{g}_i - \bar{H}_i w_i\rangle \\ =& -\sum_{i=1}^N q_i\bar{\psi}_i\langle w_i - \bar{w}_i, H_i(w_i - \bar{w}_i)\rangle. \end{aligned} \quad (22)$$

Therefore, $\dot{V}(\theta, w_1, \ldots w_N) < 0$ for $w_i \in \mathrm{span}\{\phi(S)\}$ and $w_i \neq \bar{w}_i$, implying that $\hat{w}_i = \bar{w}_i$ if $[\hat{\theta}^T\hat{w}_1^T \ldots \hat{w}_N^T]^T \in$

 ISBN 978-86-7466-930-3

E and $\hat{w}_i \in \text{span}\{\phi(S)\}$, $i = 1, \dots, N$. Similarly, if $[\hat{\theta}^T \bar{w}_1^T \dots \bar{w}_N^T]^T \in E$, then $\hat{\theta} = \bar{\theta}$. In such a way we conclude that for initial conditions $w_i(0) \in \text{span}\{\phi(S)\}$ the limit set E is indeed the set $\bar{\Sigma}$ of points satisfying (19).

The steps remaining to prove (18) are standard for the stochastic approximation theory (see [1], [21], [36]). ■

2) AlgB):

Theorem 2: Let (A1)–(A7) hold. Let $X^\alpha(n)$ be generated by AlgB (7), (8), (9) and (10), with $\beta_i(n) = \alpha_i(n) = \alpha$, and let both $w_i^\alpha(0) = w_{i,0}^\alpha$ and $e_i(0) = e_{i,0} \in \text{span}\{\phi(S)\}$. Then, for any integers n'_α such that $\alpha n'_\alpha \to \infty$ as $\alpha \to 0$, there exist positive numbers $\{T_\alpha\}$ with $T_\alpha \to \infty$ as $\alpha \to 0$ such that for any $\epsilon > 0$

$$\limsup_{\alpha \to 0} P\{ \begin{bmatrix} \theta_i^\alpha(n'_\alpha + k) \\ w_i^\alpha(n'_\alpha + k) \end{bmatrix} \notin N_\epsilon(\bar{\Sigma}) \quad \text{for some } \ k \in [0, T_\alpha/\alpha]\} = 0, \tag{23}$$

$i = 1, \dots, N$, where $N_\epsilon(\cdot)$ denotes the ϵ-neighborhood, while $\bar{\Sigma} = \bar{\Sigma}_\theta \times \bar{\Sigma}_w$ is the set of points $\bar{x} = [\bar{\theta}^T \bar{w}^T]^T \in \mathcal{R}^{2p}$ satisfying

$$\bar{G}\bar{\theta} + \bar{g} - \bar{H}\bar{w} = 0, \qquad \bar{G}^T \bar{w} = 0, \tag{24}$$

where $\bar{G} = \sum_{i=1}^N \bar{\psi}_i q_i \Phi^T \Xi_i (P^{(\lambda_i)} - I)\Phi$, $\bar{b} = \Phi^T \sum_{i=1}^N \bar{\psi}_i q_i \Xi_i r_\pi^{(\lambda_i)}$, $r_\pi^{(\lambda_i)}$ is a constant M-vector in the affine function $T^{(\lambda_i)}(\cdot)$, while $\bar{H} = \sum_{i=1}^N \bar{\psi}_i q_i \Phi^T \Xi_i \Phi$.

Proof: AlgA differs from AlgB only in the communication part of the algorithm. Formally, the procedure of the proof remains the same as in Theorem 1, after replacing $\text{diag}\{(A(n) \otimes I_p), I_{Np}\}$ by $\text{diag}\{(A(n) \otimes I_p), (A(n) \otimes I_p)\}$. This implies that, asymptotically, instead of $\text{diag}\{(\hat{\Psi} \otimes I_p), I_{Np}\}$ we have now $\text{diag}\{(\hat{\Psi} \otimes I_p), (\hat{\Psi} \otimes I_p)\}$. In this sense, we obtain $X(\cdot) = [\theta(\cdot)^T \cdots \theta(\cdot)^T w(\cdot)^T \cdots w(\cdot)^T]^T$, where $\theta(\cdot)$ and $w(\cdot)$ satisfy the following ODE:

$$\begin{bmatrix} \dot{\theta} \\ \dot{w} \end{bmatrix} = \bar{\psi}_1 q_1 \begin{bmatrix} \bar{g}_1(\theta, w) \\ \bar{k}_1(\theta, w) \end{bmatrix} + \cdots + \bar{\psi}_N q_N \begin{bmatrix} \bar{g}_N(\theta, w) \\ \bar{k}_N(\theta, w) \end{bmatrix} \tag{25}$$

The limit points (24) follow from (25), according to Theorem 1. Namely, we define the Lyapunov function

$$V(\theta, w_1, \dots w_N) = \frac{1}{2}\|\theta - \bar{\theta}\|^2 + \frac{1}{2}\|w - \bar{w}\|^2, \tag{26}$$

where $\bar{\theta}$ and $\bar{w}$ are given by (24) and obtain for the derivative that

$$\begin{aligned} \dot{V}(\theta, w) &= \langle \theta - \bar{\theta}, \bar{G}^T w \rangle + \langle w - \bar{w}, \bar{G}\theta + \bar{b} - \bar{H}w \rangle \\ &= -\langle w - \bar{w}, \bar{H}(w_- \bar{w}) \rangle. \end{aligned} \tag{27}$$

Therefore, $\dot{V}(\theta, w) < 0$ for $w_i \in \text{span}\{\phi(S)\}$ and $w \neq \bar{w}$, implying that $\hat{w} = \bar{w}$ if $[\hat{\theta}^T \hat{w}^T]^T \in E$ and $\hat{w} \in \text{span}\{\phi(S)\}$. In the same way, if $[\hat{\theta}^T \bar{w}^T]^T \in E$, then $\hat{\theta} = \bar{\theta}$. Consequently, for the initial conditions $w_i(0) \in \text{span}\{\phi(S)\}$, the limit set of ODE (25) is the set $\bar{\Sigma}$ satisfying (24). ■

IV. Discussion

The preceding section has been devoted to the weak convergence of the proposed distributed temporal difference learning algorithms. The role of convexification of w_i remains to be clarified. It is clear, from the definition of the criterion function (2) and the algorithm construction, that AlgA follows from the basic local relations (4), providing for all i unique solutions $w_i(\theta)$ for all θ. However, AlgB is based on the introduction of an additional constraint that $w_1(\theta) = \cdots = w_N(\theta) = w(\theta)$, where $w(\theta)$ is the unique solution of

$$\Phi^T (\sum_{i=1}^N \bar{\psi}_i q_i \Xi_i) \Phi w(\theta) = \sum_{i=1}^N \bar{\psi}_i q_i \Pi_{\xi_i} (T^{(\lambda_i)} v_\theta - v_\theta). \tag{28}$$

It is straightforward to observe from (28) that we have for any given θ

$$\Phi^T (\sum_{i=1}^N \bar{\psi}_i q_i \Xi_i) \Phi w(\theta) = \sum_{i=1}^N \bar{\psi}_i q_i \Phi \Xi_i \Phi w_i(\theta). \tag{29}$$

This property is verified by the above theorems.

Consequently, convergence points of θ are different for these two cases. In order to get a clearer insight, assume that $\det H_i \neq 0$. Then, for AlgA we have

$$\sum_{i=1}^N \bar{\psi}_i q_i G_i^T w_i(\theta) = \sum_{i=1}^N \bar{\psi}_i q_i G_i^T [H_i^{-1}(G_i\theta + b_i)] = 0, \tag{30}$$

resulting in

$$\sum_{i=1}^N \bar{\psi}_i q_i G_i^T H_i^{-1} G_i \theta = \sum_{i=1}^N \bar{\psi}_i q_i G_i^T H_i^{-1} b_i = 0, \tag{31}$$

while for AlgB we obtain

$$\bar{G^T} \bar{H}^{-1} \bar{G}\theta = \bar{G^T} \bar{H}^{-1} \bar{b}. \tag{32}$$

Notice that in the case of equal λ-parameters and equal behavior policies for all the agents, both algorithms provide the same solution.

It is difficult to make any general conclusion about the relative advantage of one of the two presented algorithms. It is to be noticed that this issue has not been directly treated in the literature; all the examples of distributed TD algorithms subsume that the consensus operator is applied to both θ and w, without mentioning any alternative (*e.g.*, [28] with the references therein). As far as the limit points of the corresponding ODEs are concerned, it should be noticed that a better approximation could be, in general, expected when consensus is not applied to w. Our experience confirms this statement; however it does not show any significant difference from this point of view. In some cases it could be expected that the application of consensus to w may improve the convergence rate of the algorithm. It is hard to draw any definite conclusion, in general, having in mind that connectedness of the underlying network can play an essential role from this point of view. A comprehensive Monte Carlo analysis could practically resolve the remaining dilemmas. It would be also interesting to analyze the discussed problem in the two-time-scale cases (see [1]).

 ISBN 978-86-7466-930-3

V. Conclusion

In this paper we have presented and discussed two novel algorithms for distributed off-policy gradient-based value function approximation within a collaborative multi-agent reinforcement learning setting. The algorithms are based on an integration of linear dynamic consensus schemes into local gradient-based recursions, involving the so called *auxiliary variables*. We presented rigorous proofs that, under nonrestrictive assumptions, the parameter estimates weakly converge to consensus. Based on these proofs, a discussion is provided of the incorporation of consensus w.r.t. auxiliary variables, defining clearly the figure of merit of the alternative approaches.

Arduino based online laboratory platform for digital control systems analysis and design

Vladimir Mitić, Vladimir Sibinović, Snežana Đorđević, Boban Veselić

***Abstract*— This paper presents a laboratory platform with remote access for e ercising digital control systems analysis and design. The laboratory environment utilizes three types of standard control systems positional servosystem, velocity servosystem and temperature regulation system. It also has online access through a standard Web browser that enables remote e ecution, visualization and data acquisition. tudents can perform different variety of e periments, ranging from bachelor to master level studies. They can wor independently or collaborate within a group with multiuser access to the platform. The laboratory platform is designed a way to be applicable to any regulation system with implemented communication protocols.**

***Index Terms*— aboratory platform, remote access, digital control theory, Arduino.**

I. Introduction

The previous two years, because of the pandemic outbreak, introduced remote learning to all levels of education. While this type of learning is not new, it was never before used at such an extent and for a large number of topics.

Remote laboratories were always popular in engineering education, but their popularity has grown rapidly in recent years. With the development of different technologies, e.g., Internet-of-things, more and more researchers turn to developing remote laboratories for different topics.

The results presented in this paper stemmed from the efforts, started a long time ago, trying to modernize old laboratory teaching platforms that were used to explain control system fundamentals to students. The possibility of remote access to the laboratory setup was a priority from a very beginning. Remote experiments offer more flexibility both for teachers and students, and some experiments were performed at the Faculty of Electronic Engineering in Niš more than 10 years ago [1].

Gaining experience in that field over the years, the authors started developing a new laboratory platform for teaching control system fundamentals. With flexibility and simplicity, as the main guiding principles, a new platform has been designed for teaching digital control systems analysis and design. Remote access to the platform requires from a student to only have a device with internet access. On the other hand, the platform can be built using off the shelf components that are inexpensive.

The paper is organized as follows. Section II presents the hardware system design, while Section III describes the software architecture of the system Section IV shows the educational possibilities and potentials of the realized laboratory platform and demonstrates its ease of use through some examples of laboratory exercises.

II. Hardware architecture

Arduino Due development board has been chosen to be the key component of the laboratory platform. Arduino is an open-source development environment that has become ubiquitous in education, from the primary schools all the way to the universities. Arduino platform provides different inexpensive development boards, that can be used for teaching different topics like programming [2], robotics [3], physics [4], etc. Arduino Due has an Atmel SAM3X8E Arm Cortex-M3 microcontroller, which uses a 32-bit RISC processor operating at the maximum frequency of 84 MHz. This gives the platform adequate processing power and enables further development of the system. It also has plenty of general-purpose input/outputs (GPIOs) for connecting other parts of the system. The main disadvantage is that this system is 3.3V transistor-transistor logic (TTL) and requires logic level converters to work with components having 5V TTL.

In order to be able to create a set of different laboratory exercises, the three standard control systems have been implemented: positional and velocity servosystems using DC motors, and temperature regulation system using heating elements.

A. Positional and elocity ser osystem

The positional and velocity servosystems were realized using Crouzet 82830010 DC motor that has the nominal power output of 33W. A gearbox with the ratio of 12.25 is coupled with the motor for the positional servosystem, for more accurate angular position control. An absolute magnetic encoder with 4096 increments per revolution is chosen for position measuring. These measurements are also used for the angular speed estimation of the motor shaft [5]. This was chosen as the most inexpensive solution with the highest resolution. Since the encoder is absolute, a lot of attention has been dedicated to detecting the zero-crossing condition, especially when operating on high speeds. The motor speed is estimated using simple Euler derivative approximation, which means that for small sampling periods the speed signal can be noisy. According to the predicted motor current requirements, Pololu VNH5019 motor driver has been chosen. A custom printed circuit board (PCB) was designed

Vladimir Mitić is with the Faculty of Electronic Engineering, University of Niš, Aleksandra Medvedeva 14, 18000 Niš, Serbia (e-mail: vladimir.mitic@elfak.ni.ac.rs)

 ISBN 978-86-7466-930-3

and manufactured for easy component interconnection and system replication. All the required mechanical components were designed and 3D printed with the special care for safety and transferability. A photo of the laboratory setup is displayed in Fig. 1.

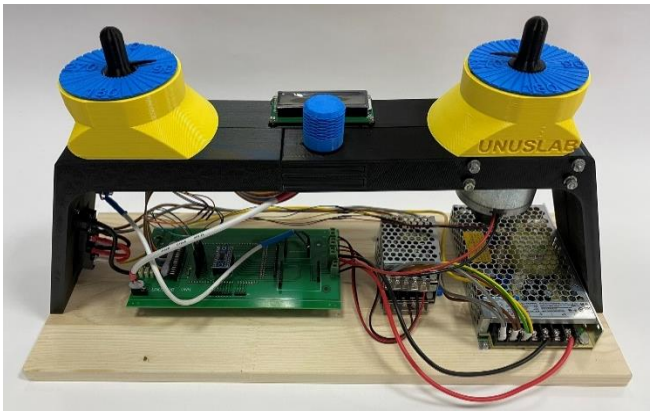

Fig. 1. Velocity servosystem laboratory platform.

A power supply port, an USB port for communication and an USB port for Arduino programming are located in the left-hand side of the platform. The power supplies are integrated into the platform, in the right-hand side, so only a standard PC power cable is needed for powering the system. The laboratory setup was designed to operate both in the stand-alone mode (controlled using the knob and display in the middle) and with usage of a computer. The referent speed/position is selected using the pointer on the left, and the motor rotation is observed using the pointer on the right.

B. Temperature regulation of a thermal process

Temperature regulation system consists of a ceramic resistor with 2.7 Ω resistance and maximum power output of 10 W. It has the role of a control object whose temperature needs to be regulated. A strong MOSFET transistor serves as the actuator of the system, and it allows current switching trough the resistor. The feedback is realized using an analog temperature sensor that is amplified to achieve the highest resolution for the temperature range of 0 ^{0}C – 100 ^{0}C. A photo of the temperature regulation platform is shown in Fig. 2.

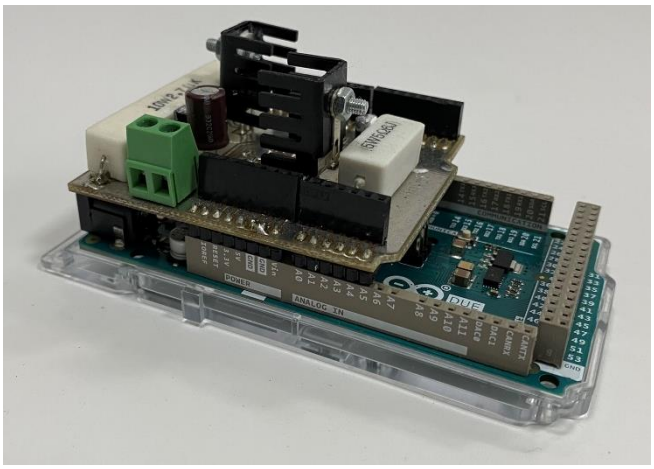

Fig 2. Temperature regulation system

The system also has a secondary ceramic resistor, that has the resistance of 5.6 Ω and maximum power dissipation of 5 W. The resistors represent two different heating elements, that can be utilized either separately or together. This provides flexibility to the platform to be able to emulate different thermal processes.

III. SOFTWARE ARCHITECTURE

The software architecture consists of three parts: (i) real-time control system implemented on the Arduino DUE, (ii) server that generates the user interface (UI) and (iii) a bridge application that connects the previous two. The system block diagram is given in Fig. 3.

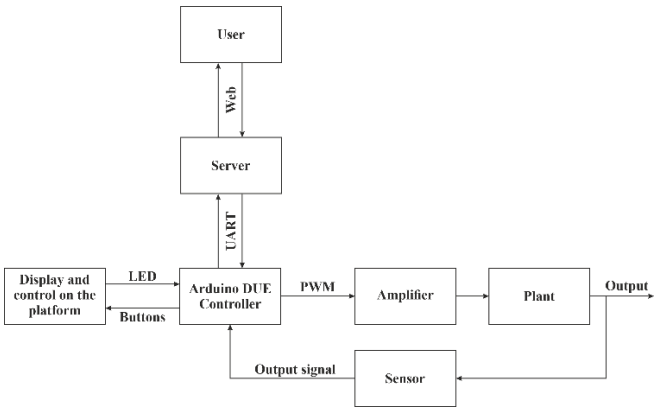

Fig 3. Block diagram of the system.

A. Communication protocols

The real-time control system communicates with the bridge application using universal asynchronous receiver-transmitter (UART) protocol. UART messages are optimized for the minimization of number of bytes, which means that they need to be decoded and passed to the server. This is implemented because of the limited transmission speed of the protocol with really large amount of data (e.g., plot data). The bridge application decodes the UART data and generates Java Script object notation (JSON) messages that are transferred to the server via WebSocket protocol. The communication is organized using a master-slave type of protocol where the server is the master, and the Arduino is the slave. Every message from the server generates a response from the Arduino so any communication error can be easily recognized. If no response is generated retransmission feature has been implemented as well. This provides reliable communication between system components.

B. eal-time control system

The real-time control system consists of three main parts: 1) control loop, 2) communication handler and 3) display handler.

1 Control loop

The control loop must have a real-time component, executed every 4 ms by generating the timer interrupt. It handles the sensor readings for the reference and the output signal, calculate the control signal according to the applied control algorithm, converts that signal from voltage to PWM and forwards it to the selected driver. The control loop can be set to be executed with a longer sampling period, which is the integer product of 4 ms. This enables changing the sampling period of the system. This feature is useful for the experiments that analyze the effects of the sampling period size on a digital control system, as well as for the systems that

 ISBN 978-86-7466-930-3

are considerably slower, such as the temperature regulation system. Several digital control laws can be employed for the control signal calculation. The implemented standard digital controllers are: PD, PID, PID AW, I-P, I-PD and universal controller. PD controller can be used for realization of P controller, by setting the derivative gain to zero. The same goes for PID controller that can be used for the realization of PI controller. PID AW represents the standard PID controller with anti-windup mechanism. I-P and I-PD controllers denote controllers with relocated P and PD actions, respectively. The implemented universal controller can represent any second-order (or less) discrete-time transfer function described by

$$G(z) = \frac{b_2 z^2 + b_1 z + b_0}{a_2 z^2 + a_1 z + a_0} \quad (1)$$

This means that virtually any linear digital controller (up to the second-order) can be tested on the given system.

It is also envisaged that the control signal can be formed using state feedback control approach. In order to implement the state feedback control loop, it is necessary to use the state-space representation of the control plant. The state variables required for the state feedback control can be obtained directly by measuring, or by using state estimation. For this reason, a predictive state observer, a current state observer and a Kalman estimator (filter) were also implemented. The software is realized in a such manner that the real-time simultaneous switching between the controllers can be done. This offers the students the possibility to compare the efficiencies of various controllers.

The desired reference signal can be obtained manually from the user or as the output of the built-in signal generator. The implemented signal generator can generate real-time step, ramp, parabolic, pulse, sine and sawtooth signals. The signal parameters can be arbitrary set and the switching between signals can be done in real-time.

2 Communication handler

The communication handler manages receiving a message, its decoding and generating and sending the corresponding response. The communication handler has various types of error checking, starting from incorrect number of bytes to incorrect data or data types. The number of system parameters that can be changed through the communication handler is 70. This means that every controller gain, every signal generator parameter and every other control loop parameter can be changed by the user through the Web UI. The communication handler is responsible for generating and sending the plot data, which consists of the timestamp, referent signals, output signals, and control signals. The time period of the plot data sending is defined as a user settable parameter, enabling the user to appropriately adjust the plot figure as needed.

3 isplay handler

The display handler controls the information presented on the display and the knob that is used for moving through the menus. The display information is useful when performing experiments in the stand-alone mode (not connected to a computer). Still, for the full functionality of the system the Web UI should be used.

C. Web I

The Web UI is accessible through any Web browser with no special requirements. When granted the access to the platform by the system administrator, the user establishes the connection to the Web UI by typing in the Web address as shown in [6]. Multiple users can access the platform at the same time which enables working in groups, where the members don't need to be in the same location. This has proven to be a useful option, since the pandemic has separated students from each other. The first batch of students that used the laboratory had positive feedback on the look and usability of the Web UI. When accessing the provided Web page, a login screen firstly appears. After entering the correct login information, the control page is shown. The control page is dynamically changing the displayed parameters based on the selected options. Fig. 4. shows the overview of the control page.

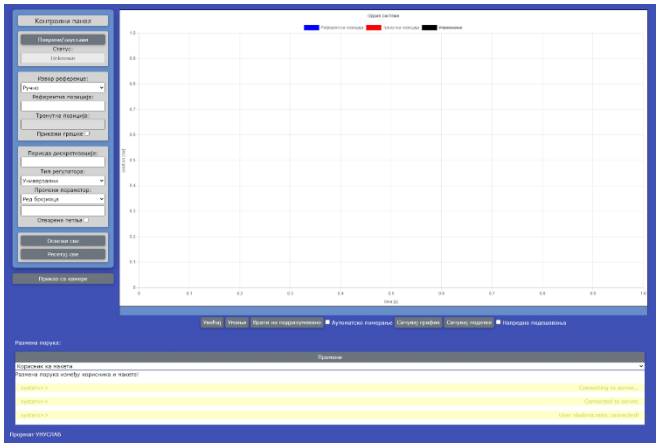

Fig. 4. The control page of the Web UI.

The control page consists of the 1) control panel on the left, 2) control chart on the right and a 3) message panel on the bottom.

1 Control panel

The control panel is used for starting and stopping the system and for system parameter manipulation. It is divided into four sections. The first section consists of the *Start Stop* button and a system status indicator. The possible system statuses are: Unknown, Stopped, Running and Disconnected. The statuses are described in Table 1.

TABLE I
SYSTEM STATUS DESCRIPTION

Status	Description
Unknown	The bridge application is not responding.
Stopped	Control loop is disabled, and plot data sending is stopped.
Running	Control loop is enabled, and new plot data is being displayed.
Disconnected	Connection with the server is terminated, the page should be refreshed

The second section is intended for reference signal control and output signal display. A dropdown list is used for selecting if the reference signal is entered manually or if it is connected to the signal generator. If a signal generator is selected, the corresponding signal parameters are displayed and can be changed. When the state feedback control is enabled, two input fields are displayed. One for each referent

 ISBN 978-86-7466-930-3

state, and two display fields for each measured state variable. A *Show trend* checkbox displays three new fields, showing the current error, the error derivative and the error integral.

The third section is intended for setting the control loop. The first adjustable parameter is the system sampling period. A dropdown list is used for selecting the loop type and controller type. Loop type can be the standard negative feedback or the state feedback. Controller type is used for selecting one of the implemented digital controllers, explained in the previous section. When selecting the desired controller, corresponding parameters of that controller are displayed and can be tuned. Finally, there is a check box for selecting open or closed control loop. This is mostly useful in system identification exercises.

The fourth section consists of two buttons, one for refreshing of all parameters and one for resetting the all parameters to their default values. Below the control panel, there is a button that is used for displaying the webcam image. It opens a new tab that will display a livestream of the laboratory platform that is obtained via a webcam, which is mounted above the platform.

2 Control chart

The control chart is an interactive chart that can be manipulated in various ways by the user. Signal manipulation can be accomplished on the chart itself. Every signal on the chart can be hidden or shown by clicking on the signal name. Every point on the chart can be displayed in detail by hovering the mouse pointer over it. Additional controls for manipulating the chart are located directly below it. They consist of the following buttons: *Zoom in*, *Zoom out*, *eset iew* buttons and *Auto-scroll* checkbox for closer observations of the response, *Sa e graph* and *Sa e data* buttons for storing the response and an *Ad anced settings* checkbox. *Sa e graph* button stores the presented response as an "Graph.png" file while the *Sa e data* button stores the response in a "data.csv" file. Every row in the file represents one timeseries, and every column one signal. This makes the data easily readable, and importable into various software packages (like Matlab) for further detailed analysis. The *Ad anced settings* checkbox displays three new input fields: *Plot ac uisition period*, *Number of seconds to store* and *Number of samples to store*. *Plot ac uisition period* defines the period at which the platform sends the data to the user. This period can be different to the control sampling period if we do not need so much data collected and displayed. *Number of seconds to store* defines the timespan that is shown on the chart and that will be stored with the save button. *Number of samples to store* represents the number of timeseries points that is displayed and stored. Because these two fields affect the same property (timespan of the plot), only one of them should be changed.

With this kind of interactive control chart, it is obvious that it alone is sufficient for any standard system analysis, which is done when executing a laboratory exercise. This enables the students to observe the experiment, notify and immediately correct any unexpected system behavior.

3 Messaging system

The messaging system is a feature that is designed for student groups that are scattered in different places. Using the toggle button on the top of the messaging panel, different types of messaging channels can be selected. Firstly, there is the *ser-de ice* channel that is used for verifying that all the parameters are set correctly. Secondly, there is the *ser-user* channel which is organized in a standard chat form and enables students to collaborate more effectively while performing the given task.

IV. Laboratory Exercises

The realized laboratory platforms have a lot of teaching potential for the students, and they can provide practical engagement for students to better learn and understand control theory. First, students can learn about system identification techniques for different types of control plants. For example, students can record the step response of the system by removing the feedback loop and setting the digital controller to PD with the gains $k_p = 1$, $k_d = 0$. In this way, the value of the referent signal is directly passed to the plant. They can save the response data and use Matlab for system identification. By performing this on the servosystems, they learn about first- and second-order transfer function identification. In case of the thermal plant, they can learn about identifying a system with transport delay.

The second set of experiments are devoted to time-discretization process and signal reconstruction in digital control systems. Students can observe the effects of the sampling period selection on a system performance. They can experimentally determine critical gain and critical frequency when system reaches stability margin, Fig. 5. Also, they can calculate steady state errors to different input signals and experimentally validate them.

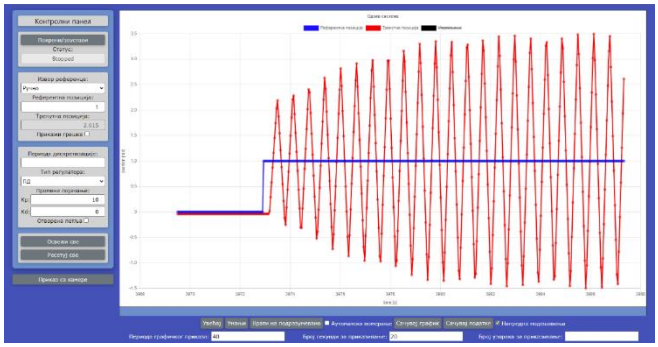

Fig 5. Experimentally determining the critical gain and frequency of a closed loop system.

When it comes to digital control systems design, the implemented digital controllers give the students a lot of possibilities. Starting from standard control loops, they can design P, PI, PD, PID controllers, lead-lag compensators and compare the system responses that they provide. Also, the students can experience some issues related to practical implementation of a control system. One of them is the saturation of the applied control signal, which can greatly affect the performance of a system. Consequently, possibilities are envisaged to implement digital controllers with relocated P and D actions that can reduce control signal peaks, as well as to enhance a control system with an anti-windup structure. The latter is crucial for temperature regulation system because of the large integrator windup produced by the dynamic properties of the system as well as the present transport delay, Fig. 6.

The state feedback control structure implementation widens even more the learning possibilities of the platform.

 ISBN 978-86-7466-930-3

By designing the state feedback controller, students get a better understanding of the state-space representation of a system and its practical usage. The implemented prediction state observer, current state observer and Kalman estimator, as a special type of current state observer, offers possibilities to students to try their design and get insight into state estimation and its possible usages. An example of application of current state observer in state feedback control is given in Fig. 7.

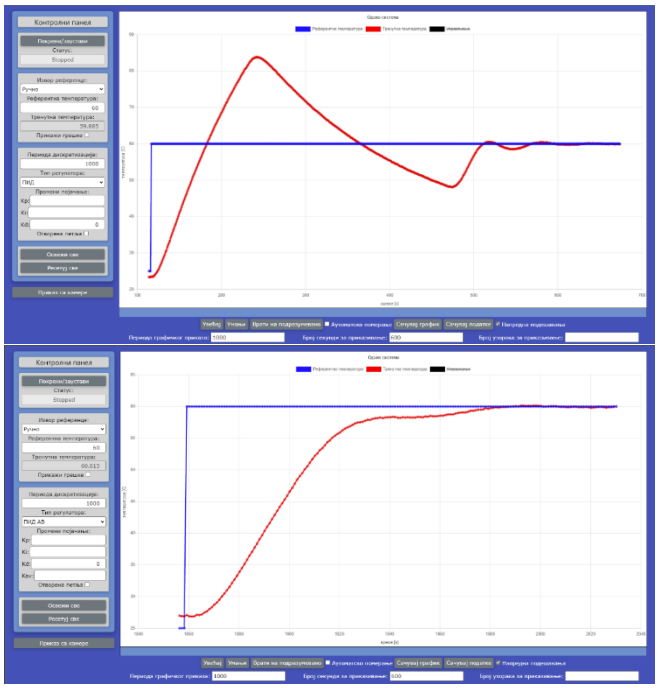

Fig. 6. Temperature regulation system without anti-windup structure (top), and with it (bottom).

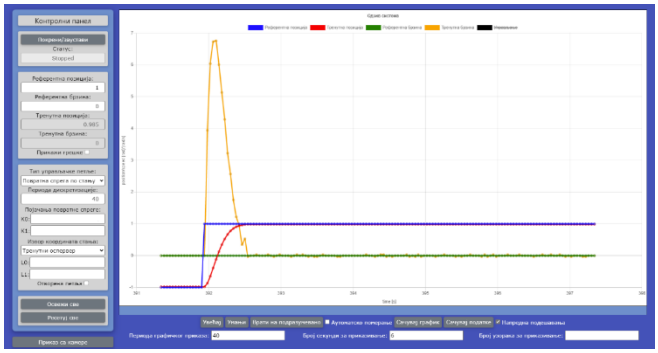

Figure 7. State feedback control implemented with current state observer.

V. Conclusion

The designed laboratory platform represents a universal solution for teaching of different types of digital control systems. User friendly and modern UI makes it very easily understandable for students. Its inexpensiveness makes it a viable option for a lot of educational facilities. The applied motors and drivers can be easily replaced with any motor power and driver combination, without losing any of the functionality of the exercises. The Arduino microcontroller used here enables for realization of even more complex control loops, which can be useful to students at a higher educational level. The scalability of the system makes it work with any digital system with UART protocol and this type of communications handler. The special value of this platform is the possibility of remote access and performing laboratory exercises from a distant location, which was especially useful for students in a pandemic. Future work will be directed to introduction a cooling element to the temperature regulation system, implementing force feedback loops as well as a cascaded control system with the positional outer loop and velocity inner loop for jerk reduction. This will broaden the possible systems for which students can design and test different control structures.

Implementation of the New Curricula in Smart Products and Services Engineering

Marko T. Milojković, Dragan S. Antić, *Senior Member*, Saša S. Nikolić and Nebojša S. Jotović

***Abstract*— Education system proved to have a challenge to cope with today's world of accelerated development of new technologies and ever changing industry. New paradigm dictates not only new teaching contents, but whole new holistic approach to the education of engineers, especially in the field of development of smart products and services. A group of professors from the University of Niš (Faculties of Electronic and Mechanical Engineering) developed a new teaching module named "Smart Products and Services Engineering" and successfully applied for funding from European Education and Culture Executive Agency in the scope of Jean Monnet Erasmus+ project call. Raising the level of knowledge and skills of students in the field of smart products and services should further encourage the development of a modern educational system in one of the most important areas of technology.**

***Index Terms*—Smart products, smart services, engineering education.**

I. Introduction

The advancement of information and communication technologies is emerging at such a pace that they are increasingly penetrating traditional industries, changing products, processes, organizations, business models and entire value chains. Existing products are transformed into smart products [1], [2] which can intelligently communicate with other smart products and react autonomously to changes in their environment. Smart products are expanding into smart services or smart service systems. Designers today must quickly and flexibly integrate new trends and standards into their solutions. Therefore, the application of modern efficient engineering of the new generation of smart products and services, characterized by high interdisciplinarity, networking, complexity and heterogeneity, is more than necessary. Today, it is convenient to consider a holistic approach to engineering, where, in addition to the development of products and services, their complete life cycle is also taken into account. The components of holistic engineering are the models and methods used in the development process, IT tools, information models and organizational structures, united by human resources with appropriate competencies. The key competence of development engineers is creativity, because it enables successful innovations, i.e. the development of creative and market-competitive products. All these modern tendencies dictate a new approach to education of engineers in the field of smart products and services [3], [4], [5].

Marko T. Milojković, Dragan S. Antić, Saša S. Nikolić and Nebojša S. Jotović are with the University of Niš, Faculty of Electronic Engineering, Department of Control Systems, Aleksandra Medvedeva 14, 18000 Niš, Serbia (e-mails: {marko.milojkovic, dragan.antic, sasa.s.nikolic, nebojsa.jotovic}@elfak.ni.ac.rs).

With the goal to enable master students of technical faculties to acquire adequate competencies in the application of methods, models and IT tools in the efficient engineering of smart products and services, group of professors from the University of Niš successfully applied for funding from EACEA (European Education and Culture Executive Agency). Concrete project application was for Erasmus+ programme call Jean Monnet Actions in the field of Higher Education: Modules, with the project named "Smart Products and Services Engineering" (acronym SPaSE) 101047566-JMO-2021-HEI-TCH-RSCH. Project team consists of ten professors from two faculties: six from the Faculty of Electronic Engineering and four from the Faculty of Mechanical Engineering. Project duration is December 2021 - November 2023 (36 months), and during that time, project team is obligated to hold teaching module dedicated to Smart Products and Services Engineering for three generations of students. Students applicable for the module will be the students from technical faculties who already finished basic level of studies (either master students or working persons).

II. Project Objectives

Main objectives of the project "Smart Products and Services Engineering" (SPaSE) are:

- Acquiring the necessary knowledge and skills by the master students of technical faculties in the field of innovation and creative techniques for the development of smart market-competitive products and services.
- Mastering the methods, models and IT tools applicable in efficient engineering of the new generation of smart products and services.
- Transfer of acquired engineering competencies in the field of smart products and services to the business entities in the region.
- More efficient use of available human resources and faster integration of the region in the application of European achievements in this area.

Project aims to contribute to the acquisition of professional competencies and innovative readiness in the field of smart product development both in educational institutions and in economic entities in the region. New student teaching module will be the focal point, where the students will learn the basics of Industry 4.0 (I4.0), application of creativity and innovation in product development, basics of digital product development, application of artificial intelligence, sensor

 ISBN 978-86-7466-930-3

technologies and business models I4.0. Special attention will be paid to the development of relevant competencies [6]: professional, methodological, and social. Students will work in teams on practical projects where they will be able to strengthen creativity and teamwork.

Besides teaching part, project team will have numerous related activities oriented toward teaching and scientific community as well as toward local business entities in the field of smart products and services. A lot of events are planned like: round tables with business, workshops, study visits, writing research papers as well as a handbook on smart products and services. All these activities will help reaching the project specific objectives:

O1: Raising the level of knowledge and skills in the field of smart products and services

O2: Efficient application of methods and IT tools for engineering a new generation of smart products and services

O3: Application of creative and innovative techniques, which provides an opportunity for multidisciplinary application of advanced technologies

O4: Strengthening human and institutional resources in the field of research and development

O5: Encouragement to development of a modern educational system in one of the most important areas of technology

O6: Encouragement to strengthen the competitiveness of the national economy

O7: Increasing the technological readiness of educational institutions and economic entities for Serbia's integration into the EU.

III. Module Composition

Jean Monnet Module "Smart Products and Services Engineering" is composed of 11 courses with 118 school hours of teaching in total. Module is organized in 15 weeks (3 months), two teaching days in a week, with 4 hours teaching blocks.

C1. Introduction to European integration and legislation in the field of smart engineering (6 teaching hours). The main goal is to enhance the existing theoretical understanding of legal, economic, political, and social aspects of European integration. The lectures are based on the interdisciplinary approach regarding the European integration process and its benefits, law, and future aspects with emphasize on the field of smart engineering.

C2. I 4.0: Smart products and services engineering (12 teaching hours). The main goal of the course is to master the knowledge and skills for the efficient application of engineering of the new generation of smart products and services. As part of the course, students will study basic approach in product design and development, modular principle in product development, Industry 4.0 and Reference Architecture Model for Industry 4.0 - RAMI 4.0, holistic approach in product development, smart product and service development models [7], [8].

C3. Creativity and innovation in product development (12 teaching hours). The main aim of this course is for students to master creative skills and competencies and also to present them innovative techniques which will be helpful in developing of future smart products and services [9].

C4. Digital product development (12 teaching hours). The course program will train students to independently use state of the art technologies and methods in the process of development of digital products. The acquired knowledge will enable students to create and holistically administer information, documents and resources in the digital product development process, thus fostering innovation [10].

C5. 3D CAD construction (10 teaching hours). Getting the knowledge about the basic geometrical objects and their relative positions and sections, developing surfaces, as well as the vector analysis and computing graphics. The focus of the course is on parametric design and the proper use of CAD software to produce 3D models, engineering parts, and documentation [11].

C6. Information technology (12 teaching hours). Introduction to the basic IT principles, methods, and techniques. The ultimate goal is the IT education of IT experts, capable of application of information technologies in the industry at all stages during the development of software solutions [12], [13].

C7. Artificial intelligence (12 teaching hours). The aim of course is to introduce the concepts and algorithms at the foundation of modern artificial intelligence, and explore the ideas that give rise to smart products and services. Through real world examples, students will gain knowledge to recognize and apply main tools and algorithms of AI and machine learning with the special emphasize on multilayer artificial neural networks (deep learning) [14], [15].

C8. Big data and data analytics (12 teaching hours). Upon completion of this course the students should become familiar with the principles of Big data and data analytics, gain understanding of the basic tools and techniques for data collection, processing and analysis. The desired outcome is to stimulate the students to adapt EU legislative in this area and apply main tools and algorithms of these concepts in design of simple smart products and services [16], [17].

C9. Internet and sensing technology (12 teaching hours). This course aims to provide an overview of technologies focusing on the Internet of Things and Industrial Internet of Things. Besides fundamentals and operational principles, the emphasize will be on introducing legal EU requirements and frameworks for building secure and reliable systems, opportunities and challenges, successful real-world practices, and efficient internet and sensing applications [18].

C10. Digital twins (10 teaching hours). Digital twin fundamentals, which integrate the internet of things, artificial intelligence, and software programming, will be introduced as a virtual representation of an object or system during its lifecycle, which is updated from real-time data and uses simulation, machine learning, and reasoning to help decision-making [19].

C11. Business models I4.0 (8 teaching hours). This course will be focused on analysing business model characteristics

 ISBN 978-86-7466-930-3

for Industry 4.0, providing an in-depth perspective of companies' processes, structures, and tools for business model innovation. The course will also provide insight in EU good practices and competencies for business model innovation in the course of Industry 4.0 [20].

IV. CONCLUSION

This paper presented main aspects of newly designed student module at the University of Niš, named "Smart Products and Services Engineering". Module implementation is financially supported by European Education and Culture Executive Agency (EACEA) under the umbrella of Jean Monnet Erasmus+ project call. Module is jointly designed by professors from two faculties – Faculty of Mechanical Engineering and Faculty of Electrical Engineering. Module "Smart Products and Services Engineering" is composed of 11 courses with 118 school hours of teaching in total, organized during 15 weeks (3 months), two teaching days in a week, with 4 hours teaching blocks. Topics to be mastered are: Introduction to European integration and legislation in the field of smart engineering, I4.0: Smart products and services engineering, Creativity and innovation in product development, Digital product development, 3D CAD construction, Information technology, Artificial intelligence, Big data and data analytics, Internet and sensing technology, Digital twins, Business models I4.0.

Besides the main goal of the project which is acquiring the necessary knowledge and skills by the master students of technical faculties in the field of innovation and creative techniques for the development of smart market-competitive products and services and mastering the methods, models and IT tools applicable in efficient engineering of the new generation of smart products and services, project has several additional goals. Most important ones are the transfer of acquired engineering competencies in the field of smart products and services to the business entities in the region as well as more efficient use of available human resources and faster integration of the region in the application of European achievements in this area. In order to achieve all these goals, project anticipates besides teaching part, numerous related activities oriented toward teaching and scientific community as well as toward local business entities in the field of smart products and services. A lot of events are planned like: round tables with business, workshops, study visits, writing research papers as well as a handbook on smart products and services.

Denoising the open-loop step response using an encoder-decoder convolutional neural network

Natalija Đorđević, Nenad Džamić, Aleksa Stojić, Goran Kvaščev

***Abstract*—Denoising signals is used as a preprocessing step for all signal processing. ncoder-decoder neural networ s are often proposed as a method of denoising 1D and 2D signals, because of their ability to e tract essential features from the signal and then recreate it without noise. In this paper we propose a simple architecture of a convolutional neural networ for denoising step responses of systems with different open-loop transfer function. The networ is trained on synthetic data with added noise of different distributions, then tested on a portion of synthetic data and real-life step responses.**

***Index Terms*— denoising, encoder-decoder, convolutional neural networ , step response**

I. INTRODUCTION

Signal denoising is an important preprocessing step in every type of signal processing. Even though many observations can be made on generated pure signals, real-life signals always come with a certain amount of noise. For any signals measured on electrical circuits, noise cause can be the imperfect design or layout of the circuit itself, faulty components, close proximity to other electrical equipment, environmental causes etc. However, even if causes are known, the behavior of noise is unpredictable and rarely fits into a specific probability density function. Having a denoising method that would be applicable to different types of signals and noises would be of great importance for signal processing.

In the paper [1], authors used deep recurrent denoising neural networks to denoise ECG signals and improve signal-to-noise ratio of signal from -8.82dB to 7.71dB. They used a synthetic dataset with added noise. Medical signals such as ECG are of great importance, which shows in the number of papers that deal with their denoising. Once again, a convolutional neural network proves efficient with ECG signals in [2]. Seismic data is one of the representatives of noisy real-life data, and effective use of deep convolutional neural networks for denoising of synthetic seismic data can be seen in [3]. Using a convolutional network for denoising images with Gaussian noise is also proposed in [4]. There is not a single specific architecture for denoising convolutional networks that is superior, and a useful comparison of different kinds is given in [5]. However, one structure seems to be mentioned for multiple purposes, and it is the encoder-decoder structure. The authors in [6] suggest the use of an autoencoder for medical image denoising, which served as an initial inspiration to use encoder-decoder networks for 1D signals. Application of the encoder-decoder structure on denoising micro seismic signals is shown in [7].

In this paper we have trained an encoder-decoder neural network to denoise a step response of an open-loop system. This particular structure seemed promising and in various papers was proven to perform well in denoising for different purposes. Its great advantage is that it does not have strict limitations on the results it can produce. There are however many things that have an effect on its performance, such as the architecture, hyperparameters, the dataset etc. In this paper we attempted to make a structure that is not complicated, but performs well, as well as to generate a dataset that is informative enough for our neural network. The reason that the step response signal was chosen is its importance in observing how industrial processes react to a change in reference value. Without diving into the details of which processes each system represents, we will define their behavior only by their open-loop transfer functions.

II. DATASET SYNTHESIS

Collecting data for neural networks can be expensive and time-consuming. In order for our dataset to be as diverse as possible and simultaneously to represent many industrial processes, we used equation (1) as a general form for our open-loop transfer function. [8].

$$G(s) = \frac{e^{-\theta_d s}(1-\alpha s)}{(s+1)^n} \quad (1)$$

Parameter θ_d represents transport delay which is the amount of time that our system needs to react to a change in reference value. The measure $1/\alpha$ represents the position of a zero in the right half-plane. The system in which α is not equal to zero is called the non-minimum phase system and in its step response we can see an initial dip in value before a rise towards the reference value. An example is shown in Fig.1. Finally, the parameter n refers to the order of the system which, in general, dictates the dynamic of the system.

Natalija Đorđević is a teaching associate at the Signals and systems department at the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: natalija.djordjevic@etf..bg.ac.rs)

Goran Kvaščev is a associate professor at the Signals and systems department at the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: kvascev@etf..bg.ac.rs)

 ISBN 978-86-7466-930-3

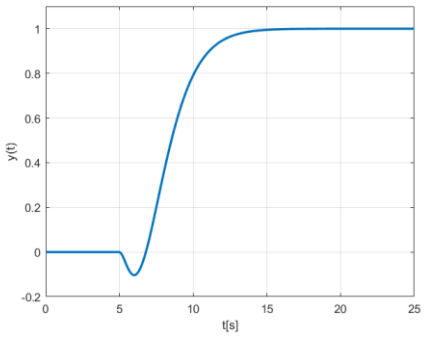

Fig. 1. Step response for a non-minimum phase system with parameters: $\theta_d = 5, n = 3, \alpha = 1$.

Convolutional neural networks are known for needing a large training set to perform well. These parameters can drastically change the output of the system which means that, in order to get a diverse dataset, we should try as many combinations as possible. We generated pure step responses for transfer functions which include parameter values given in Table I. Each signal has a duration of 25s and is sampled with a step size of 0.1s, making it 251 samples long.

TABLE I
TRANSFER FUNCTION PARAMETER VALUES

	Minimum value	Maximum value	Step size
θ_d	0	10	0.2
α	0	2	0.05
n	1	8	1

To every pure signal we generated, we added three types of noise. Given that real-life noise rarely fits into one specific probability density function, feeding different types of noise to our neural network seemed as a good way to have it generalize well after it is trained. The three types of noise added are Gaussian white noise, uniform noise and noise with Rayleigh distribution. All three types of noise have a standard deviation of 0.05. Probability density functions are given in equations (2), (3) and (4), respectively and shown in Fig.2.

$$p(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-0.5\left(\frac{x}{\sigma}\right)^2};\ \sigma = 0.05 \tag{2}$$

$$p(x) = \begin{cases} 10/\sqrt{3}, & x \in \{-0.05\sqrt{3}, 0.05\sqrt{3}\} \\ 0, & x \notin \{-0.05\sqrt{3}, 0.05\sqrt{3}\} \end{cases} \tag{3}$$

$$p(x) = \frac{x}{\sigma^2} e^{-x^2/(2\sigma^2)},\ \sigma = 0.05\sqrt{\frac{2}{4-\pi}} \tag{4}$$

The expected value of the Rayleigh distribution given in equation (4) is a positive non-zero value, so to avoid having an offset in our noise we subtracted the expected value.

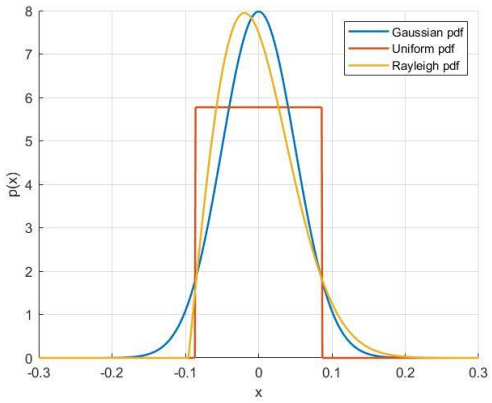

Fig. 2. Comparing three different noise probability density functions.

Final dataset has 50184 samples and 25% percent of it is intended for testing, while the rest is used for training. The test set consists of all step responses for systems of order 4 and 5, while all other orders belong to the training set. This will allow us to test our network on system orders that it has not encountered during training.

III. ARCHITECTURE AND TRAINING OF NEURAL NETWORK

When the term ‘denoising’ is mentioned in the context of neural networks, the autoencoder neural networks are usually suggested as an appropriate architecture. The idea behind them is to have an encoder part of the network, whose role is to extract features from the given input, followed by the decoder part, which tries to recreate the input from the features. Autoencoder networks are a type of unsupervised learning, because the desired output is the same as the input, therefore the input/output pair is not explicitly given during training. These networks served as an inspiration for this paper and creating the encoder-decoder architecture.

Encoder-decoder neural networks fall into the category of convolutional networks and the term ‘convolutional’ refers to the method of feature extraction. Let us consider that the input is a 2D matrix, such as a photograph. The dimensions of the photograph tend to be quite large and if we were to feed it to a regular fully-connected neural network, we would have too many trainable parameters. This would imply a huge amount of time to train and a lot of unnecessary computational resources. Also, each pixel itself might not carry as much information about the photograph as their relations do. So instead of treating individual pixels as separate entities, the idea behind convolutional neural networks is to have filters in the form of kernels (matrices with smaller dimensions) whose parameters are to be learned, which in convolution with the input would produce something more informational. Convolution is simply ‘sliding’ the kernel across the photo and multiplying it with appropriate submatrix of the photo. This way, instead of trying to learn a million neurons, the network has to learn filters which would extract meaningful features. The general advantage of neural networks is that it is not necessary for us to have insight into exactly what these filters are and what features they extract, but only how well the output is decoded using those features.

 ISBN 978-86-7466-930-3

Convolution can also be done with 1D inputs, such as various forms of signals. The principal of convolution stays the same and the kernel is now a vector instead of a matrix. As previously mentioned, the aim of this project is to use a convolutional encoder-decoder network to denoise a step response of an open-loop system.

For this purpose we used *python* and the *tensorflow* library. It allows users to build a sequential neural network model by adding desired layers one-by-one.

For the encoder part of the network, we followed a standard structure of convolutional networks which implies alternatively adding convolutional layers and pooling layers. Convolutional layers learn kernel parameters and produce a convolution of the input with the kernel. It is common practice to have kernels with small dimensions, so in every convolutional layer we used kernels of size 5 (vectors of length 5). Every convolutional layer we added is followed by a *ma -pooling* layer, whose role is to cut down the dimensions. It takes subvectors (of the specified size) of the input and produces an output which is the maximum value of the subvector. If the size is properly defined, we get the effect of having less computation needed, without any crucial loss in information.

The decoder part of the network has the inverse structure of the encoder part. Therefore, all convolutional layers are replaced with transposed convolutional layers. They perform deconvolution, which is an inverse operation to convolution. Opposite of *ma -pooling* layers are *upsampling* layers. They once again make the dimensions larger by repeating the values of their input a specified amount of times. It is easy to notice that the output of the *upsampling* layers will not be exactly the same as the input of *ma -pooling* layers.

The final architecture we chose is the simplest one that performed well. Details of its structure are shown in Table II. and Fig. 3.

TABLE II
ARCHITECTURE OF NEURAL NETWORK

Layer type	Kernel size	Output shape
Convolutional	5	(1, 247, 128)
Max-pooling	2	(1, 124, 128)
Convolutional	5	(1, 120, 64)
Max-pooling	2	(1, 60, 64)
Transposed convolutional	5	(1, 64, 64)
Upsampling	2	(1, 128, 64)
Transposed convolution	5	(1, 132, 128)
Upsampling	2	(1, 264, 128)
Convolutional	5	(1, 264, 1)
Cropping	/	(1, 251, 1)

The activation function for all layers is ReLU, except for the output layer whose activation function always depends on what the network is trying to predict. Since in our case we are doing regression, the adequate activation function is linear. The metric used to access the performance is mean-squared error, also suitable for regression.

When training a neural network it is necessary to make sure not to overfit it to the training data. Overfitting is a term used to describe the behaviour of a network that performs very well on training data, but has problems with data that it has not encountered during training, i.e. it generalizes poorly. One method to prevent overfitting we already implicitly implemented by making a large training dataset. Having a diverse dataset with many samples decreases the chances of overfitting. We also added a kernel constraint with value 3 to every layer, which stops parameters from rising above the given value. Popular method to avoid overfitting is also adding *dropout* layers after convolutional layers. Their role is to remove certain neurons with a specified rate and have them not impact the output. Adding *dropout* layers did not make the network perform better, so they were left out. 20% of samples in the dataset were used for validation. Finally, the network was trained for 7 epochs in mini-batches of size 32.

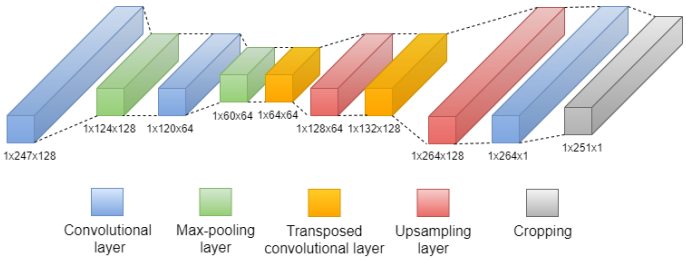

Fig. 3. Neural network architecture

The optimizer used is *Adam* optimizer, which is a type of a stochastic gradient descent algorithm. It is known for keeping track of the first and second momentum to provide quicker and more stable convergence. Its primary hyperparameters are learning rate, β_1 and β_2. We used stochastic grid-search to find optimal hyperparameter values and they are: learning rate = 0.0005, $\beta_1 = 0.9$ and $\beta_2 = 0.99$.

IV. RESULTS

The network was first tested on a generated test set mentioned in chapter II. Average mean-squared error (mse) on the entire test set and on separate noise types are shown in Table III. In Fig. 5 the average values and standard deviations of mse for each of the noises are shown. Gaussian noise has the highest error, however all three have values bellow $9e^{-5}$. One more metric to asses the denoising process is comparing the signal-to-noise ratios (SNR) of signals before and after denoising. The average SNR for all types of noise was 53.5dB in the beginning. Signal-to-noise ratios after denoising are given in Table III.

 ISBN 978-86-7466-930-3

TABLE III
MEAN-SQUARED ERROR FOR DIFFERENT NOISE TYPES

	MSE	SNR (dB)
Gaussian noise	$8.84e^{-5}$	87.8
Uniform noise	$8.14e^{-5}$	88.6
Rayleigh noise	$7.21e^{-5}$	89.9
Entire test set	$8.06e^{-5}$	88.8

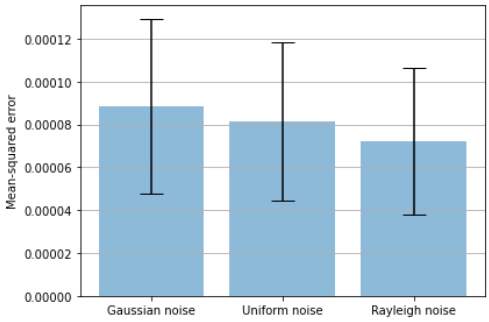

Fig. 4. Means and standard deviations of mean-squared errors for each noise

In Fig 5A. there are three representative step responses: one for each of the three types of noises. Based on observing, the output of the network seems to follow the signal dynamic well. Judging by the mean-squared error and Fig. 5A, Gaussian noise is the most difficult to remove, while Rayleigh noise seems the easiest to remove.

Next step was to test our network in a real-world environment to see how it handles a step response with noise which does not specifically match any distribution. The system we tested on was a handmade dryer that consists of a chamber on a metal surface and it has three platinum temperature sensors and one sensor which measures the airflow. The chamber is 1m long and has a heater of 400W and a ventilator on one side. Since airflow is not steady and turbulence occurs, the signal we captured is very noisy. In Fig 5B. there are three different original signals of airflow, as well as their denoised version. The results are satisfactory considering the amount of noise and the fact that the exact transfer function was not included in the training set.

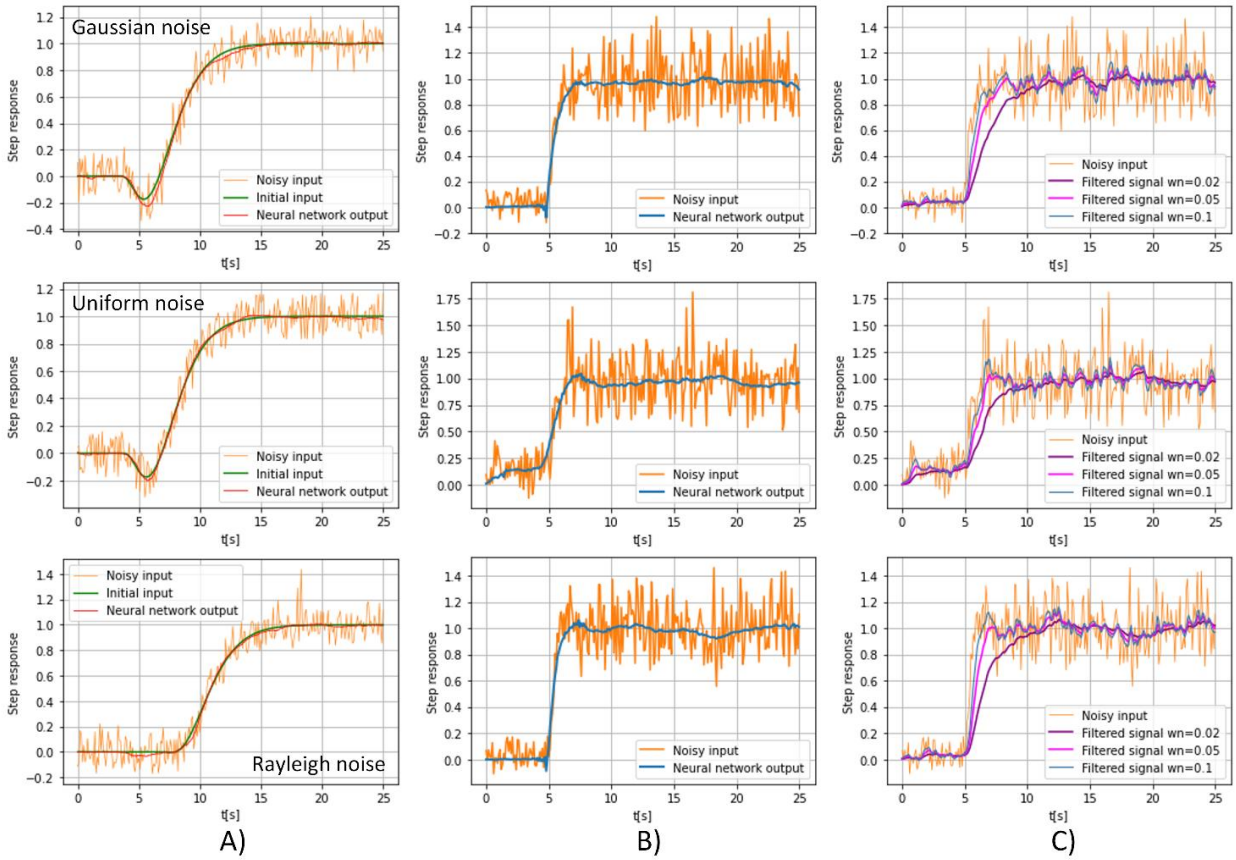

Fig. 5. Step responses before and after denoising. A) synthetic data, B) airflow signal after neural network, C) airflow signal filtered with Butterworth filter

To compare our results with classical filtering methods, we give the same noisy inputs but filtered with a first order Butterworth filter with different normalized frequencies in Fig. 5C. We see that in order to not compromise the dynamic of the signal, we have to settle for less noise removal. The neural network we trained gives better results in terms of removing noise, but still following the dynamic. The comparison we did gives us an insight into why using a neural network for denoising could be a justified option. Conventional filtering methods often have to make sacrifices in terms of degrading

 ISBN 978-86-7466-930-3

some other signal characteristics. Even though the structure of the neural network is not necessarily simple for all purposes, it is very flexible, and if we feed it the right amount of input data to learn from, the results it yields can be satisfactory in many ways.

V. CONCLUSION

The architecture of neural network used in this paper shows great potential for signal denoising. The proposed general form of transfer function in equation (1) also proved to be enough for the network to be able to follow the step response dynamic well. The next step in improving performance and extending it to other signals can move in a couple of directions. Having a training set with more noise distributions would also help the network generalize even better. Next possible extension could be having step responses with added disturbances at different moments in time in our dataset, as well as creating open-loop transfer functions in a more generalized form.

Single Screw Extruder Temperature Control Using PLC and HMI in Cable Production Process

Igor Kocić, Saša S. Nikolić, Aleksandra Milovanović, Darko Mitić, Petar Đekić and Nikola Danković

***Abstract*— In this paper it is developed and described the control software for the temperature regulation of the extruder zones with the mutual influence of zones. Extruder zone temperature control realized using Siemens PID_Temp block FB1132. PID_Temp block does not take into account the interaction of zones. This effect can only be taken into account if all zones are adjusted at the same time. The temperature process of the extruder was identified with an emphasis on the mutual influence of the zones. After that, a simulation was performed in Matlab and Simulink, and the results were experimentally verified using Siemens' LSim_LIB_V3_0_0 library and in a real process.**

***Index Terms*— Extrusion, zone temperature identification, PID Temp controller, PID tuning.**

I. Introduction

Extrusion [1, 8] of plastics and rubber is basically a continuous process. The starting raw material is usually in powder or granules, while in the case of rubber extruders it can also be in the form of a belt. The raw material moves from the basket under the action of gravity towards the feeder, and then enters the cylinder. A screw is placed in the cylinder, which transports the mass in advance under the action of the drive, the mass is further heated, homogenized and finally formed into the desired shape by passing through the tool. The machine in which this process takes place is called an extruder. Single-screw extruders have a huge application in polymer processing, they are simple constructions, have good technical performance, they are cheaper than multi-screw extruders.

Extruder temperature control is a problem that occurs very often in the industry. The main goal of temperature control is to maintain the set temperature. The extruder [1] consists of three basic units:

1. feed zone,
2. melting (compression) zone, and
3. pumping zone

In Section II we analysis the mutual influence of zones in terms of heat transfer from zone to zone on real extruder. Based on the recorded characteristics for zones 1, 2 and 3, a model of the mutual influence of the zones was made. Based on the zone influence model, the synthesis of the temperature controller was performed in Section III using the Siemens PID Temp controller and software was written in SCL for the simultaneous setting of the PID parameters of the zone controller. In chapter four, a check of the controller operation was performed using the Siemens simulation library LSim_LIB_V3_0_0.

II. Extruder Zone Temperature Identification

Figure 1 shows a diagram of a single-screw extruder [1] with nine zones. The basic parts of each extruder are hopper, barrel, screw and head with tool. Each zone of the extruder has its own heating heater, if necessary a cooling fan and a sensor that measures the current temperature value. In addition to measuring the temperature, the melting pressure is also measured at the place where the tool is located. Zones 1 to 5 have heater and cooler, zones 6 to 9 have only heater, cooling is done by the influence of ambient temperature.

It is noticed that zones 2, 3, ..., 8 are inner zones, and zones 1 and 9 are outer zones, and therefore the character of heat dissipation is different.

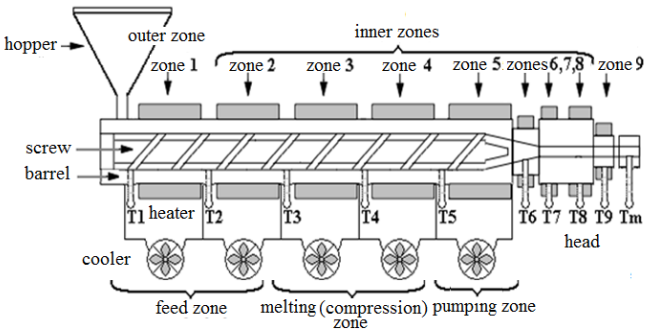

Fig. 1. Diagram of a single-screw PVC extruder

In determining the mutual influence of the zones, we started from the assumption that the control object in this case is the extruder cylinder is homogeneous and isotropic, which is correct because it is made of the same material. The influence of the heater and fan transmission function has not been considered.

In the general case, the temperature field of the extruder cylinder is non-stationary and can be described by the

 ISBN 978-86-7466-930-3

following equation [4, 8]:

$$T = f(x, y, z, t) \tag{1}$$

When heating, the temperature at the measuring points changes over time (2), for isotropic materials, Fourier's law [8] of heat conduction applies (3), where Q is the amount of heat, S is the area, dQ/dS is the specific heat flux, and λ is the heat conduction coefficient:

$$\frac{\partial T}{\partial t} \neq 0 \tag{2}$$

$$dQ = -\lambda \nabla(T) dS dt. \tag{3}$$

If we take into account that the temperature changes over time, which is the case, we get a partial differential equation of parabolic type:

$$\frac{\partial T}{\partial t} = a \frac{\partial^2 T}{\partial x^2} \tag{4}$$

For further simplification, it is assumed that the temperature at the measuring points is equal to the temperature of the entire section, the temperature of the section is considered to be the temperature of the extruder zone. In this way, we consider sections to be isothermal surfaces. For the of further simplification, we will consider that the temperature is transferred only along the x axis ($x>>y$, z in practice the ratio of length and diameter of the cylinder in PVC extruders is large) Fig. 2 and that it is a stationary temperature field. At the time of temperature measurement at the zone boundaries, we can consider it constant.

If we now observe the part of the cylinder between the temperature measurement points of zone 1 (T1) and zone 2 (T2) and consider that these temperatures are constants, and then the following applies to the temperature field Eqs. (4) and (5) reduces to (6) where a is thermal diffusion coefficient:

$$\frac{\partial T}{\partial t} = a\left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2}\right) \tag{5}$$

$$\frac{\partial T}{\partial t} = 0 \ , \frac{\partial T}{\partial y} = 0, \frac{\partial T}{\partial y} = 0 \tag{6}$$

$$a \frac{\partial^2 T}{\partial x^2} = 0 \tag{7}$$

$$\frac{\partial T}{\partial x} = const. \tag{8}$$

By integrating (7) and taking the boundary conditions T(0)=T1, T(L)=T2, where L is the distance from the temperature measurement point T1 to T2, we get that the temperature in x coordinates changes according to (8):

$$T(x) = T_1 - \frac{T_1 - T_2}{L} x \tag{9}$$

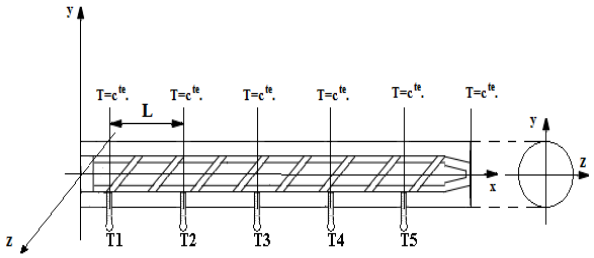

Fig. 2. Extruder cylinder (barrel) in *x*, *y*, *z* coordinate system observed along the x axis

When performing the above equation, we started from the assumption that T1>T2, that only zone 1 is heated, and zone 2 is not. In order to determine the mutual influence of the zones, measured was applied on real Royle 4 1/2" extruder during heating and cooling, heating of zone 1 was done first, where the temperatures in zones 1 and 2 were measured, zone 2 was not heated. The ambient temperature at which the experiment was performed is Ta=17°C. Fig. 3 shows the influence of zone 1 on zone 2 as well as the temperature difference between zones 1 and 2.

The extruder was then cooled to ambient temperature. Only zone 2 was heated and the characteristics of zone 2 were recorded. Then the extruder was cooled, and zones 1, 2 and 3 were heated, and the temperature characteristics of zones 1, 2 and 3 were recorded at the same time so that the mutual influence of zones could be considered. Fig. 5.a shows the characteristics of only zone 2 which is heated by itself and Fig. 5.b shows the characteristics of zones 1, 2 and 3 which are heated at the same time. The extruder is heated to a temperature of 100 ° C, which corresponds to a time of about 25 min. Ambient temperature T_a=17°C.

The Matlab software package was used to draw the temperature characteristics of the characteristic zones.

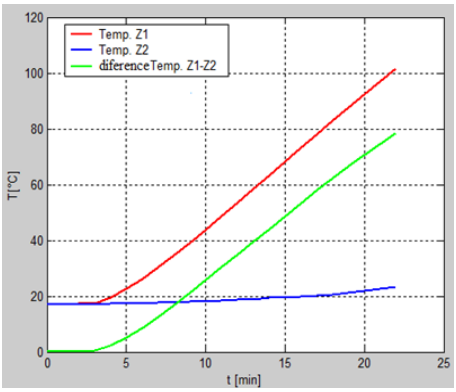

Fig. 3. Influence of Zone 1 to Zone 2

 ISBN 978-86-7466-930-3

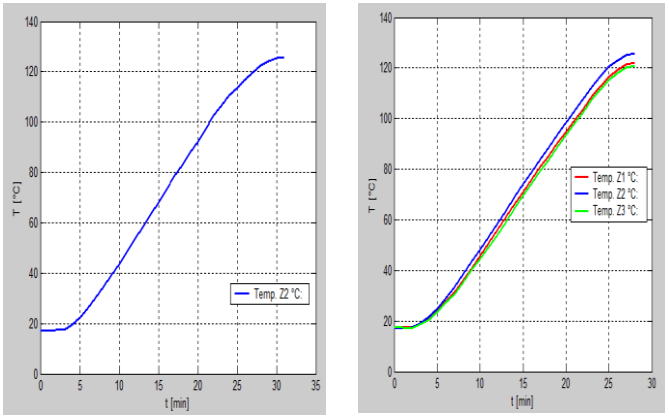

Fig. 4. Characteristics of heated

From Fig. 4 it is clearly seen that the heat transfer from zones 1 and 3 directly affects the temperature of zone 2. In Fig. 5.b we notice that the temperature of zone 1 is slightly higher than the temperature of zone 3, the reason is that zone 1 is the outer zone , and its adjacent zone is the feeder zone whose mass is less than zone 4. Zone 4 is not heated, so part of the heat from zone 3 passed to it.

In identifying and determining the process model, we started from the FOPDT model (9), which approximated the process, starting from the assumption that the transfer function of the object that controls astatism is zero. The parameters of the model are determined on the basis of the bounce response in the open coupling. The moment when the bounce trigger is brought is considered as the zero moment. Based on the recorded characteristics, the dead time T_u, the time constant T_u and the gain K were determined using the Küpfmüller method [10], so the model of the heating process for all three zones is described by the transfer function:

$$G_{ob}(s) = \frac{k_{ob}}{1+sT_{ob}} e^{-sT_u} \qquad (10)$$

To determine the parameters T_u and T_{ob}, a program was written in Matlab. Table gives the values first only for zone 2 when only it is heated, and then for zones 1, 2 and 3 that are heated at the same time.

TABLE I
HEATING ZONE 2 ONLY, AND ZONE 1, 2, 3

	only zone 2 is heated	zone 1, 2, 3 are heated at the same time		
	zone 2	zone 1	zone 2	zone 3
T_u[min]	5.5882	5.05769	4.214	5.117
T_{ob}[min]	21.098	16.654	16.214	17.153
K_{ob}	0.869	0.912	0.945	0.902

Based on the measurements, it is clear that the times T_u and T_{ob} for zone 2 are higher when only zone 2 is heated. It can also be seen that when zones 1, 2, 3 are heated, that zone 2 reaches the temperature the fastest, where the impact of zone 1 and zone 3 on zone 2 is observed.

FOPDT models of zones 1, 2 and 3 were used for the initial analysis of the process. For further analysis, an attempt was made to determine the PT_2 model based on the Streitz approximation through two points [3]. The PT_2 process model is given in (11) where K are the gain of the object, and T_2 are the time constants of the PT_2 model.

$$G_{ob}(s) = \frac{k_{ob}}{(1+sT_1)(1+sT_2)} \qquad (11)$$

If the analysis of the ratio T_{ob}/T_u from table I according to table II (T_{ob}/T_u<9,65) is performed, it is concluded that it is impossible to determine the characteristics of the process described by the PT_2 model according to Streitz's identification method [3]. After that, models were determined for all three zones based on the PT_N model (12), where T is the process time constant, n is the order of the PT_N model, T_{ob} is the object gain taken from the FOPDT model [3]:

$$G_{ob}(s) = \frac{k_{ob}}{(1+sT)^n} \qquad (12)$$

TABLE II
RELATIONSHIP BEETWEN FOPTD AND PTN MODEL

n	1	2	3	4	5	6	7
T_{ob}/T_u		9.65	4.59	3.13	2.44	2.03	1.75
T_{ob}/T	1	2.718	3.695	4.463	5.119	5.699	6.226
T_u/T	0	0.282	0.805	1.425	2.1	2.811	3.549

Based on that, a model of the third order process is made for all three zones. To calculate the time constant of the PT_N model, a program was written in Matlab. The time constants T for the sweater zones are given in Table III.

TABLE III
VALUE OF THE TIME CONSTANT OF THE PTN MODEL

	only zone 2 is heated	zone 1,2,3 are heated at the same time		
	zone 2 (n=3)	zone 1 (n=3)	zone 2 (n=3)	zone 3 (n=3)
T [min]	5.710	4.507	4.3887	4.643

Figure 5a shows the temperature difference $T_{z2}-T_{z1}, T_{z2}-T_{z3}$ and Fig. 5b analyzes the influence of zone 1 on zone 2 according to the equation $(T_{z2}-T_{z1})/T_{z2}$ and the influence of zone 3 on zone 2 according to the equation $(T_{z2}-T_{z3})/T_{z2}$.

The mutual influence of the zones during the simultaneous heating of zones 1, 2 and 3 is the greatest during the transition process when it moves up to 8%, after that it decreases and moves in up to 4% Fig. 5.

 ISBN 978-86-7466-930-3

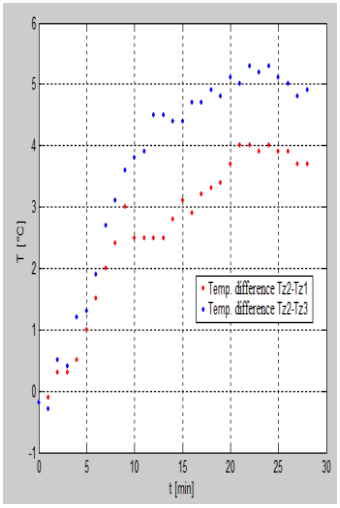

Fig. 5a.

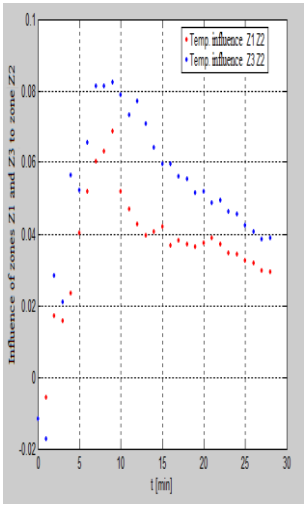

Fig. 5b.

Fig. 5. Influence of zones Z1 and Z3 on zone Z2

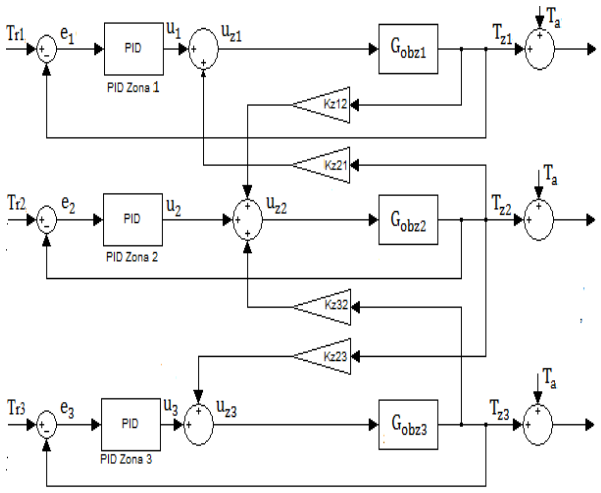

Fig. 6. Model of mutual influence of zones

It is noticed that the temperature difference between zone 2 and zone 3 is greater than between zone 2 and zone 1, the reason is that zone 1 is an external zone, and adjacent to zone 3 is zone 4 which is not heated, so part of the heat is removed from zone 3 to zone 4. Fig. 6 shows a model of the mutual influence of zones.

The equation (13) [9, 10] applies to the simulation model of the impact of zones 1 and 3 on zone 2:

$$T_{z2}(s) = G_{obz2}\left(u_2 + k_{z12}T_{z1} + k_{z32}T_{z3}\right) \qquad (13)$$

In general, applies equation (14), where (i = 1,…,n) is denoted by observed zone:

$$T_{zi}(s) = G_{obzi}\left(u_2 + k_{z(i-1)i}T_{z(i-1)} + k_{z(i+1)i}T_{z(i+1)}\right) \qquad (14)$$

When it is taken into account that zone 2 affects zones 1 and 3, can applies equation (15) [9,10] where the coefficient K_{z2z2} takes into account that part of the energy of zone 2 is spent on heating zones 1 and 3.

$$T_{z2}(s) = G_{obz2}\left(u_2 + k_{z12}T_{z1} + k_{z32}T_{z3} - k_{z2z3}T_2\right) \qquad (15)$$

When simulating the mutual influence of zone heating, all zones are identified separately. This means that it is necessary to heat only the observed zone, make its model, cool it and its neighboring zones. Repeat the procedure for all zones observed. In this way, the coefficient K_{z22} can be determined by comparing the influences when the heated zones are individually and all at once, so model (14) is applied for the simulation.

III. SYNTHESIS TEMPERATURE CONTROLLER

Zone temperature controler is realized using a Siemens PID_Temp block FB1132 [10] with anti windup function and adjustable weight coefficients for proportional and integral action which is a continuous PID controller designed for heating and cooling applications, where y is output of PID controller, K_p proportional gain, b weight coefficient of proportional action, w set value, x measured value, T_i time constant of integral action, T_d time constant of differential action, and time delay differential action, c weighting coefficient of differential action.

$$y = k_p\left[(bw - x) + \frac{1}{T_i s}(w - x) + \frac{T_d s}{aT_d s + 1}(cw - x)\right]. \qquad (16)$$

The PIDT controller (Siemens PID temperature controller block) (16) is integrated within the PID_Temp block [10]. The configuration and algorithm for setting the parameters of the PID_Temp block parameters is performed using the TIA Portal, where one instance is created for each control loop. For zone i, InstPIDTemp(i) is assigned a data block specifically DB(i) within which all settings for that instance are stored. Instances are called from the OB30 block (cyclic interupt) Fig. 7 whose call time is set to 0.1s.

The PID_Temp block has two setup algorithms: pretuning and Fine Tune. For both tuning algorithms from TIA Portal software Siemens does not give a closer explanation of which criterion it uses to obtain parameters. Specifies only the necessary conditions for executing tuning algorithms.

 ISBN 978-86-7466-930-3

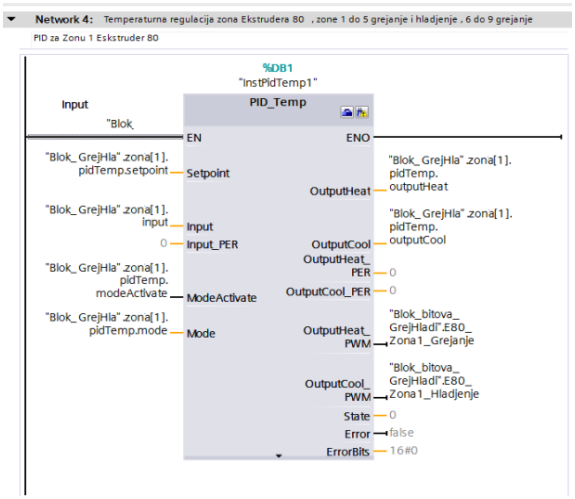

Fig. 7. Calling InstPIDTemp1 from OB30 block for zone 1

The disadvantage of individual adjustment of zones [11, 14] is reflected in the fact that the mutual influence of zones through thermal coupling is not fully taken into account. For this reason, software has been developed to simultaneously enable the setting of all zones from the HMI panel.

Before switching on the pre-tuning, the temperatures of the operating points of all zones are set, which must be higher than the current temperature, it is best to start from the ambient temperature. The inactive PID mode is selected for all zones. When performing pre-tuning, the heating pre-tuning is performed first, the cooling of the zones is temporarily switched off so that one of the zones does not adjust the heating parameters and its adjacent zones have completed the adjustment and switched to cooling mode. This creates a false temperature coupling. When the setting of the heating parameters is completed, the setting of the cooling parameters for all zones is switched on.

IV. Experimental Results

Experimental results were obtained using Royle 4_1/2" extruder for PVC insulation and Siemens library LSim_LIB_V3_0_0 [15], Siemens PLC type S7 1500 3PN/DP, HMI 1500 Comfort series. The simulation of the interaction of zones 1, 2 and 3 was implemented in the software using the model of the interaction of zones by (14), Fig. 8.

The zone transfer functions are simulated by the Siemens function to simulate the third-order process LSIM_PT3. Simulation software was written in SCL. Part of the Zone 2 simulation software is shown in Fig. 8.

The transfer function (12) was realized using the LSim_PT3 block. At the input of the block Block_Zone2 are the control signals from the PID block (InstPidTemp2) of zone 2 and the coefficients of mutual influence of the zones. In the function block Block_Zone2, a program is written that realizes the equation of influence of zone 1, 3 on zone 2 (13). The value thus obtained is fed to the input of the block LSim_PT3_Zone 2, at the output of which the value for the temperature of zone 2 is obtained.

In the theoretical part, only heating is considered, and here the results for heating and cooling are given, Table IV. The simulation program is called from the OB30 object block with a selection period of 0.1 s. In Fig. 9 shows the response ratio of the calculated PID controller according to the PT_3 model and the controller obtained using the PLC simulation library for zone 1. The time to reach the desired temperature of the extruder zones is completely satisfactory. given the mass of the extruder cylinder.

V. CONCLUSION

This paper presents zone temperature controler of extruder zones with special reference to the mutual influence of extruder zones. A model of mutual influence of zones is given, a simulation is done in TIA Portal.

It has been shown that the mutual influence of the zones during the simultaneous heating of the zones is greatest during the transition process when it moves up to 8%, after that it decreases and moves up to 4%.

The paper develops software for simultaneous adjustment of parameters of all extruder zones, as well as for adjustment of individual zones. The big advantage is that the software enables the adjustment of extruder zones from the HMI panel and not only from the TIA Portal software package.

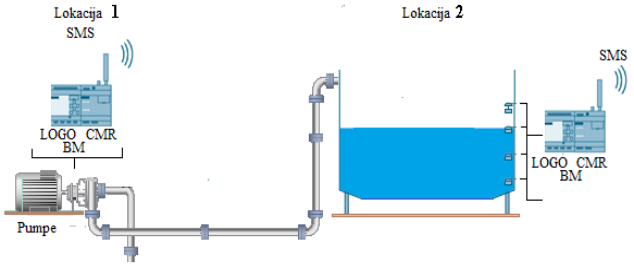
Upravljanje nivoom vode i pumpama upotrebom SMS poruka

Igor Kocić, Zoran Jovanović, *Elektronski fakultet u Nišu*

***Apstrakt*— U radu je opisano daljinsko upravljanje pumpama za dopremanje vode za potrebe proizvodnog procesa upotrebom Siemens Logo PLC kontrolera i odgovarajućih GSM modula. Radi povećanja pouzdanosti rada sistema komunkacija se obavlja dvojako upotrebom SMS poruka i žičane veze. Projektovan je i realizovan softver i hardver za obe vrste komunikacije, kao i softver za HMI panel kojim se vrši upravljanje i nadzor rada celog postrojenja.**

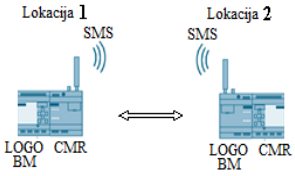
***Ključne reči*— Logo PLC, CMR modul, SMS, sekvencijalno upravljanje**



I. Uvod

U sistemima za upravljanje na daljinu tradicionalno se koristila prosta žičana veza. Osnovni nedostatak takvih sistema javlja se u slučaju prekida kabla u komandnom kolu.
U tom slučaju se u potpunosti gube informacije o sistemu upravljanja na udaljenoj lokaciji. U novije vreme žičana veza se menja radio vezom, čime je pouzdanost takvog sistema značajno povećana. Sa razvojem mobilne telefonije i interneta ostvarena je mogućnost upravljana na daljinu sa velikom pouzdanošću.
Zbog potrebe povećanja pouzdanosti sistema u radu razvijen je upravljački softver i hardver za upravljanje nivoom vode u bazenima upotrebom SMS poruka. Pogodnim algortimom sekvencijalnog upravljanja ostvareno je upravljanje pumpama i nivoom vode u rezervoaru.

U slučaju otkaza mobilne mreže softver omogućava automatski prelaz na žičanu vezu i obrnuto. Postojeću žičanu vezu operater može uključiti ručno u svakom trenutku.



II. Aplikacija-opis hardverskog i softverskog rešenja

Na Sl.1. je dat šematski prikaz lokacije postrojenja, uređaja i opreme. Postrojenje je smešteno na dve udaljene lokacije. Glavni upravljački centar se nalazi u fabrici, a vodozahvat se nalazi na oko 2 km od fabrike. Lokacija bazena je nazvana: "Lokacija 2", a lokacija vodozahvata sa pumpnim postrojenjem nazvana je: "Lokacija 1".
U radu će se nadalje koristiti ovi nazivi. Sistem se sastoji od glavnog upravljačkog centra gde su ujedno nalaze bazeni sa sistemom za merenje nivoa vode i udaljenog pumpnog postrojenja u kome su instalirani frekvencijski regulatori kojima se obavlja pokretanje pumpi i regulacija pritiska u cevovodu i sistem za zaštitu od prevelikog pritiska na cevovodu.

Sl.1. Šematski prikaz procesa daljinskog upravljanja pumpnim postrojenjem

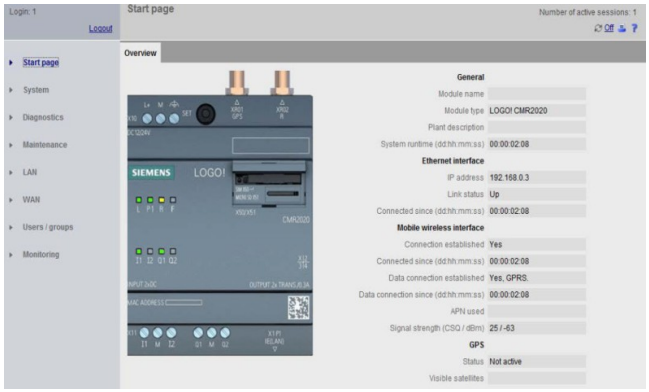
Kašnjenje upravljačkih signala nije od velikog značaja jer su bazeni za vodu velikog kapaciteta. Na obe lokacije se nalaze po jedan PLC kontroler serije LOGO sa komunikacionim modulima tip CMR2020 [2].
Na Sl.2 prikazana je topologija GSM mreže preko koje se obavlja komunikacija SMS porukama.

Sl.2. Topologija mobilne mreže, komunikacija SMS porukama

CMR modul za GSM/GPRS komunikaciju ima široku vrstu primena. Neki od mogućih slučajeva upotrebe su sledeći:

1. Mobilna bežična komunikacija bez LOGO PLC kontrolera,
2. Mobilna bežična komunikacija sa LOGO PLC kontrolerom,
3. Određivanje položaja (GPS).

U svaki CMR modul instalirane su SIM kartice i podešeni potrebni parametri dobijeni od strane mrežnog operatera. Svaki CMR modul povezan je na LOGO PLC [1]. LOGO PLC je sa CMR modulom povezan pomoću lokalne Ethernet mreže. CMR modul koristi omnidirekcionu antenu za mreže tipa GSM (2G), UMTS (3G) i LTE (4G) [2]. Time je omogućeno slanje i primanje SMS poruka povezanih sa događajima koji su programirani u LOGO PLC kontroleru, i pokretanje akcija i slanje informacija o statusu pomoću SMS poruka.
Podešavanje CMR modula obavlja se pomoću internet pretraživača unošenjem default adrese. Nakon inicijalnog podešavanja adrese su promenjene.



Igor Kocić – Elektronski fakultet, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: igkocic@ gmail.com).
Zoran Jovanović – Elektronski fakultet, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: zoran.jovanovic@elfak.ni.ac.rs).

 ISBN 978-86-7466-930-3

Podešavanje CMR modula se sastoji iz sledećih koraka:

1.Podešavanje parametara mobilne i lokalne Ethernet mreže.
2.Podešavanje parametara za SMS poruke.
3.Podešavanje korisnika i grupa korisnika.
4.Podešavanje poruka, akcija, definisanje ulaza, izlaza, događaja, alarmnih i poruka greške.
5.Definisanje poruka i akcija slanja i prijema poruka.

Na Sl.3 prikazan je glavni konfiguracioni ekran CMR modula. Svakom od modula dodeljena su imena i lokalne Ethernet adrese. Podešavanje mobilne mreže obavljeno je unosom PIN koda SIM kartice, broja kartice i aktivacijom interfejsa za komunikaciju preko mobilne mreže. Takođe moguća je komunikacija i sa uređajima koji su u drugoj zemlji uključenjem Roming opcije.

Sl.3. Glavni konfiguracisjki ekran CMR modula

Primer sintakse SMS poruka dat je ispod u formi:

<Password>;LOGO=VM<Address>,<Value>,<Data type>.

Password predstavlja lozinku za komande tipa write "pisanje", čime je ostvarena dodatna zaštita od neovlašćenog slanja poruka.

LOGO=VM<Address> predstavlja lokalnu adresu u memoriji LOGO PLC , <Value> predstavlja vrednost koja se šalje ili prima, Data type je tip podatka koji se šalje ili prima.

SMS poruka komande upisa u LOGO PLC na adresu memorjske lokacije VM0 data je u formi:
SMSupis;LOGO=VM0,50,WORD.
Izvršavanjem ove komande u registar VM0 LOGO PLC kontrolera upisuje se vrednost 50.

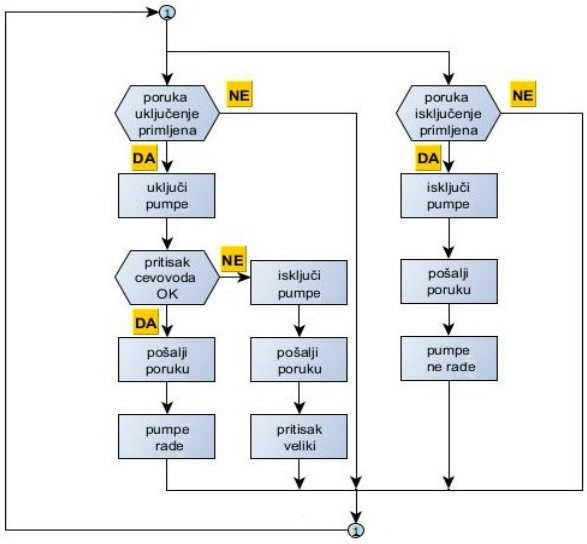
Podešavanje korisnika i grupa korisnika obavljeno je unosom imena korisnika, lozinke, broja telefona korisnika i dozvolom za čitanje i slanje SMS poruka prema CMR modulu. Napravljene su dve grupa korisnika, prva dobija samo poruke o alarmima, a druga grupa pored alarmnih poruka ima dodeljene privilegije isključenja ili uključenja delova postrojenja u normalnom radu ili interventno.

Podešavanje poruka i akcija na događaje urađeno je dodelom ID broja poruke, imenom poruke i akcije kojom se šalje određena poruka.
Ako je nivo u bazenu nizak šalje se poruka čija je sintaksa:

SMSupis;LOGO=VM0,10,WORD.
Za slučaj greške komunikacije korisnicima se šalje poruka:

Text: ! 'Error: Stanica na Lokaciji 1 nedostupna.'.

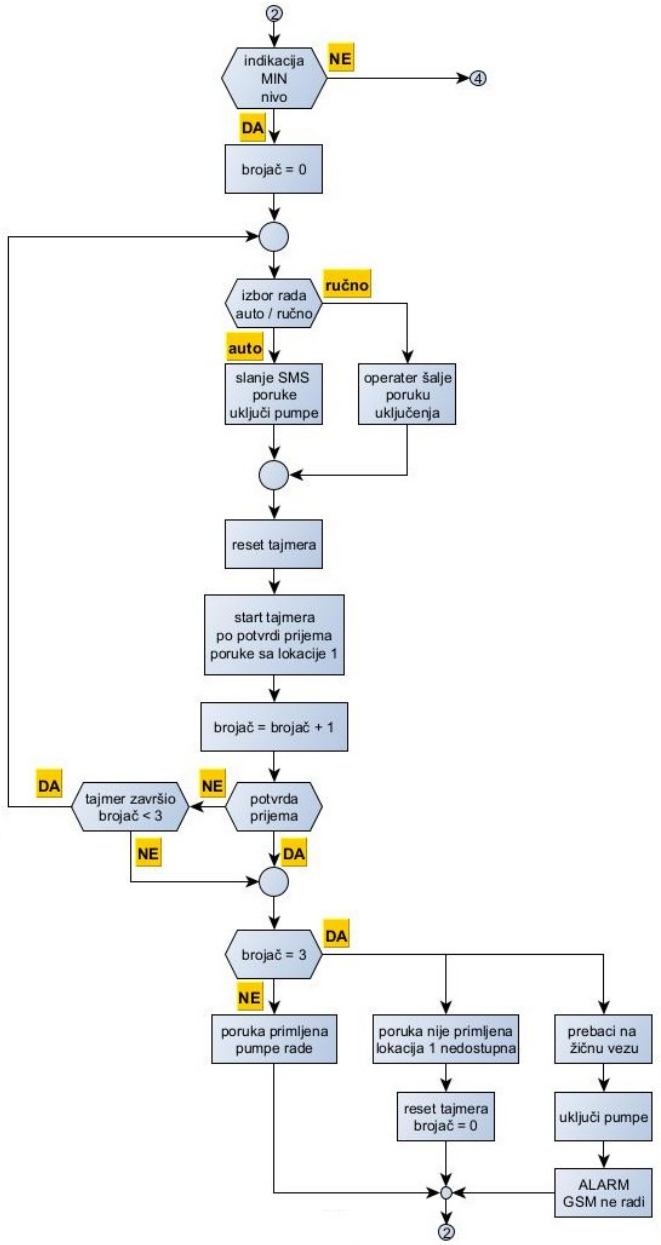
Ako je detektovana greška nivoa šalje se poruka :
Text: ! 'Error: Signal nivoa nije u redu. Senzor ili kabl je neispravan.'



Lokalne Ethernet adrese uređaja su redom:

1. PLC LOGO 8.2 Lokacija 2 bazen 192.168.0.103,
2. CMR modul 192.168.0.21,
3. PLC LOGO 8.2 Lokacija 1 vodozahvat 192.168.0.104,
4. CMR modul 192.168.0.11,
5. Touch HMI Panel KTP400 192.168.0.232

Na ovaj način omogućen je pristup mreži sa bilo koje od dve lokacije upotrebom mrežnih rutera.



Na lokaciji 2 upotrebom senzora za detekciju nivoa vrši se detekcija nivoa u više tačaka. Od interesa je minimalni i maksimalni nivo.
Kada nivo vode u tankovima padne ispod minimalne vrednosti vrši se uključenje pumpi za dopremanje vode. Isključenje pumpi vrši se u dva slučaja:

1. radni uslov isključenja, kad je dostignut željeni nivo vode u tankovima,
2. havarijsko isključenje, koje se obavlja ako se pritisak u cevovodu poveća iznad određene vrednosti.

Sl.5. Deo algoritma rada udaljenog postrojenja upotrebom SMS poruka(lokacija 1)

 ISBN 978-86-7466-930-3

Sl.5. Deo algoritma rada postrojenja upotrebom SMS poruka pri indikaciji minimalnog nivoa (lokacija 2)

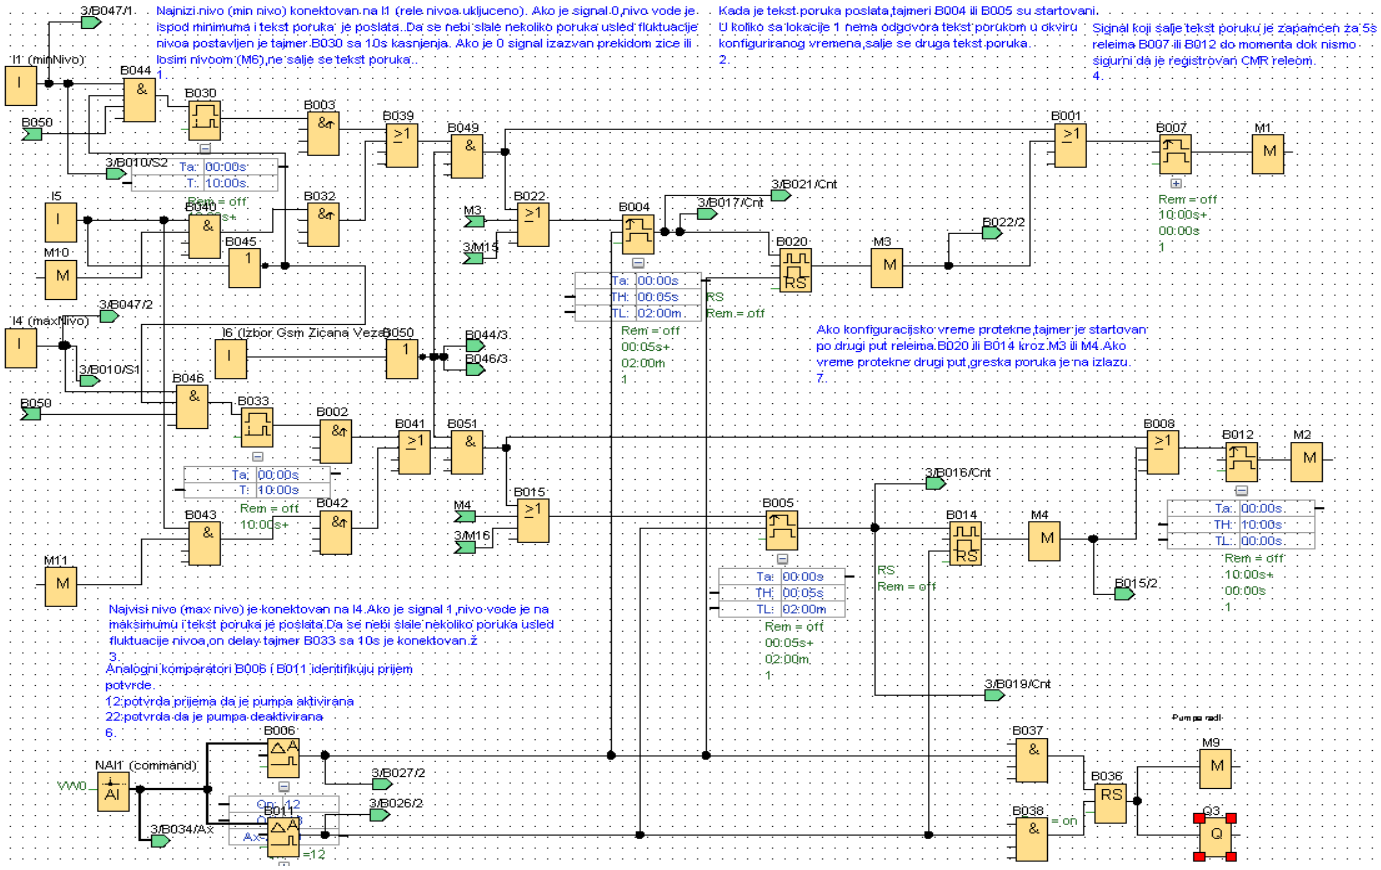
Pored automatskog rada, postrojenje može da radi i u ručnom režimu, kada se uključenje ili isključenje obavlja pomoću HMI panela i relejnom komandom ili SMS porukama koje šalju operateri koji za to imaju definisane privilegije. Postrojenje može da radi i upotrebom "stare" žičane veze, pod uslovom da je SMS komunikacija isključena.

Neki od ulaza, izlaza koji se koriste na LOGO PLC na lokaciji 2 su redom:

1. I1 minimalni nivo,
2. I2 nivo 2,
3. I3 nivo 3,
4. I4 maksimalni nivo,
5. I5 izbor rada ručno ili automatski,
6. I6 izbor SMS ili žičana veza,
7. I7 greška komunikacije,
8. Q1 signal greške komunikacije,
9. Q2 signal indikacije greške usled prevelikog pritiska

Neki od ulaza, izlaza koji se koriste na LOGO PLC na lokaciji 1 su redom:

1. I2 dozvola rada,
2. I4 senzor pritiska (presostat),
3. Q1 uključenje isključenje pumpe.



Na Sl.4. prikazan je deo upravljačkog algoritma za uključenje, isključenje pumpi u udaljenom postrojenju. U slučaju povećanja pritiska u cevovodu senzor pritiska (presostat) isključuje pumpe.

Na Sl.5. prikazan je deo upravljačkog algoritama postrojenja kada je nivo niži od minimalnog. U slučaju da se pojavi greška ili prekid u komunikcionom protokolu koji se trenutno koristi automatski se izvrši prelaz sa trenutnog na žičani tip komunikacije (žičanu vezu). Ako je trenutno aktivna SMS, prebacivanje se obavlja na žičanu vezu.
Softver za komunikaciju SMS porukama napisan je upotrebom Simensovog LOGO!Soft Comfort V8.2 alata za programiranje LOGO PLC kontrolera.

Na Sl.6 dat je deo softvera koji se odnosi na slanje poruka za uključenje i isključenje pumpi u udaljenom pumpnom postrojenju (lokacija 1), kao i dela za prijem i obradu poruka koje šalje udaljeno postrojenje.

Kada nivo vode padne ispod minimalnog nivoa sa lokacije 2 šalje se prva SMS poruka. U slučaju fluktuacije nivoa usled talasanja vode a koja može uticati na sondu za signal minimalnog nivoa, signal aktivacije slanja poruke se filtrira upotrebom tajmera sa kašnjenjem od 10s instrukcije za detekciju rastuće ivice. Obezbeđeno da se svaki zahtev za slanje izvrši jedanput. Nakon slanja poruke aktivira se tajmer kojim je definisano maksimalno vreme potrebno da udaljeno pumpno postrojenje kojom je poslata poruka odgovori (60 s). Ovo vreme eksperimentalno je definisano tako da ne utiče na regulaciju nivoa. Ako vreme za odgovor istekne ista poruka se šalje i drugi put. Ukoliko odgovor sa udaljene lokacije 1 i u tom slučaju ne stigne, automatski se šalje poruka lokacija 1 je neaktivna. Poruka greške se ispisuje na HMI panel i šalje SMS poruka na brojeve koji su konfigurisani u CMR modulu. Komunikacija se automatski prebacuje na žičanu vezu. U režimu ručnog rada operater nadgleda rad postrojenja upotrebom HMI panela i odlučuje kada će da uključi ili isključi pumpe.

 ISBN 978-86-7466-930-3

Sl.6. Deo softvera za slanje i prijem poruka za uključenje, isključenje i indikacju rada pumpi pumpnog postrojenja

Deo softvera koji se koristi za uključenje isključenje pumpi na udaljenoj lokaciji 1 dat je na Sl.7. Poruka koja je primljena se poredi komparatorima B006 i B002. U koliko je primljena poruka koja se nalazi u registru VM0=10 na Logo PLC kontroleru se uključuje izlaz Q1 koji aktivira frekvencijski regulator za kontrolu rada pumpi. Odmah po prijemu vrši se slanje SMS poruke sa vrednosti '11' prema lokaciji 2 koji nosi informaciju da su pumpe startovane.

Ukoliko je primljena poruka VM0=20 izlaz Q1 se isključuje čime se rad frekfentnog regulatora a samim tim i pumpi stopira. Po prijemu te poruke prema lokaciji 2 šalje se poruka sa vrednošću '22' pumpa isključena. Ukoliko se iz nekog razloga pritisak na cevovodu poveća senzor pritiska (presostat) detetektuje nedozvoljenu vrednost pritiska, obavlja se havarijsko isključenje frekvencijskog regulatora pumpi. Prema lokaciji 2 šalje se poruka sa vrednošću '13', uključuje se alarm sa informacijom da je izvršeno havarisjko isključenje pumpi, pritisak povećan pumpe isključene. Takođe se šalje i SMS poruka operateru koji dalje preduzima potrebne mere.

Sl.7. Deo softvera za uključenje isključenje pumpi u udaljenom pumpnom postrojenju

III. REALIZACIJA UPRAVLJAČKE APLIKACIJE ZA UPRAVLJANJE NIVOOM VODE U REZERVOARU

Sekvencijalno upravljanje nivoom vode u bazenu na lokaciji 2 obavljeno je izradom dva upravljačka ormana za prenos poruka upotrebom SMS poruka i ormana sa relejnom logikom, kao i ormanom sa frekfentnim regulatorom koji upravlja radom pumpi.

 ISBN 978-86-7466-930-3

Na Sl.8 prikazan je upravljački orman na lokacijama 1 i 2 .

Sl.8. Upravljački ormani za upravljanje nivoom vode

U svakom od njih je postavljen po jedan LOGO PLC sa komunikacionim CMR modulom i S7 1200 PLC kontrolerom koji upravlja radom postrojenja pomoću zičane veze.
Na Sl.9 prikazan je HMI panel za nadzor postrojenja.

Sl.9. Prikaz HMI panela pri SMS komunikaciji

IV. ZAKLJUČAK

Za realizaciju ovakve vrste upravljačkih zadataka godinama se koristila samo žičana veza i prosta relejna logika. Izrade žičane veze za velike udaljenosti obično se realizuje u momentu izrade cevovoda, kada se paraleleno sa cevima polažu komunikacioni i napojni kablovi do udaljenje lokacije. U slučaju otkaza, oštećenja komuniakcionih veza potrebno je ponovo otkopati deo trase kako bi se otkrio prekid u komunikaciji, što iziskuje značajna sredstva. U novije vreme sve češće se koristi komunikacija SMS porukama upotrebom mreže mobilne telefonije. U radu je pored softvera i hardvera razvijenog za komunikaciju SMS porukama razvijen i deo softvera i hardver za komunikaciju preko žičane veze. Time je mogućnost otkaza sistema smanjena.

ABSTRACT

The paper describes the remote control of water supply pumps for the needs of the production process using Siemens Logo PLC controllers and appropriate GSM modules. In order to increase the reliability of the system, communication is performed in two ways using SMS messages and wired connection. Software and hardware for both types of communication were designed and implemented, as well as software for the HMI panel which manages and supervises the operation of the entire plant.

Water level and pump control using SMS messages

Application of Subtractive Clustering in Data Processing

Boris Barišić, Aleksandra Krstić, Sanja Vujnović, Željko Đurović

***Abstract*—The problem of data clustering is still in development and various approaches to solving it are being proposed, all of which have different success rates. ne of the nonparametric clustering methods is subtractive clustering. The success of this algorithm largely depends on tuning its parameters. In this paper we give a theoretical analysis of different suggestions for choosing their values. ased on probability theory, we e amined the impact of dimensionality and number of samples on the clustering radius. y conducting a controlled e periment with nown sample distributions, the performance of this algorithm with suggested parameters is tested, as well as its robustness.**

***Index Terms*—subtractive clustering, parameters tuning, classification, data processing**

I. Introduction

For a large number of classification problems we do not have adequate a priori knowledge and therefore we are not able to generate an appropriate training set. Starting with Charles Darwin and his systematization of animals and plants into genera, species, families etc. up until the development of systems based on various forms of artificial intelligence, the man has attempted to improve clustering techniques.

Nonparametric clustering methods do not consider optimization criteria or data distributions. They are based on implementing different ways to locate 'valleys' or 'hills' in the probability density function of the data as a natural border between different classes.

In 1992. Yager and Filev suggested *mountain clustering* as one of the techniques [1]. The method is based on dividing the entire data space into a dense grid of small hypercubes whose vertices are potentially cluster centers. The potential i.e., the *mountain* function is then calculated for each vertex as a measure of sample density in its surrounding. Clearly the potential for the vertex to be a cluster center increases with the number of samples surrounding it. The core idea of this method is the following: after finding the first cluster center, potentials of all vertices are reduced inversely proportional to the distance from the vertex to the cluster center. For vertices closer to the center, the potential reduces more. The next cluster center is chosen as the vertex with the highest potential (after reduction). This method of finding cluster centers repeats until the potential in all vertices falls beneath a certain threshold.

Even though it was imagined as a very simple method, its numerical complexity grows exponentially with sample dimensionality due to a large number of hypercubes in the grid. In 1994. Chiu suggested a modification of this algorithm called subtractive clustering [2].

II. Theoretical analysis

A. Algorithm

The idea of *subtracti e* clustering is that every sample in the dataset can be a cluster center. Due to this starting assumption of considering only given samples as cluster centers, the complexity of this algorithm is practically linear.

Samples are assigned a certain density based on which the cluster centers are found during the iterative procedure. Aside from considering a smaller dataset than *mountain* clustering, calculating the density function implies the squared distance between samples, so there is no need for determining the square root.

Based on the description given in [2], the algorithm is comprised of a few steps:

Step 0 For each of N samples we calculate the value of the initial density D_i^1 according to equation (1),

$$D_i^1 = \sum_{j=1}^{N} e^{-\frac{\|X_i - X_j\|^2}{(r_a/2)^2}}, i = \overline{1,N} \tag{1}$$

where r_a is a positive constant called the clustering radius.

Step 1 Based on initial density values we determine the first cluster center X_c^1:

$$X_c^1 = \arg\{\max_{i=1,N} D_i{}^1\} \tag{2}$$

Step 3 Having found the first cluster center, we start the iterative procedure of finding other cluster centers. Since the first center is already found, let the iteration counter start at $k = 1$.

Step 4 We increment the counter to $k = k + 1$ and eliminate the influence of samples near the previously found center by modifying their density function:

$$D_i^k = D_i^{k-1} - D_c^{k-1} e^{-\frac{\|X_i - X_c^{k-1}\|^2}{(r_b/2)^2}}, i = \overline{1,N} \tag{3}$$

 ISBN 978-86-7466-930-3

D_i^k is the new density function value, and D_i^{k-1} is the previous one. D_c^{k-1} is the maximum density from the previous iteration, and X_c^{k-1} is the cluster center found also in the previous iteration. Parameter r_b represents a new clustering radius.

Step 5 Based on the newly modified values of density functions we choose a k[th] cluster center X_c^k:

$$X_c^k = \arg\{\max_{i=\overline{1,N}} {D_i}^k\} \tag{4}$$

Step We check whether D_c^k i.e., the density of samples in radius r_b of k[th] cluster center satisfies:

$$D_c^k \leq \delta D_c^1 \tag{5}$$

If the given condition is not satisfied, we go back to step 4, and if it is, the algorithm ends. Parameter δ is a positive value smaller than 1 and it is called the clustering threshold.

B. Parameter tuning

The success of clustering largely depends on choosing the values for r_a, r_b and δ. Clustering radiuses r_a and r_b should in some way incorporate the information on how samples are scattered around cluster centers.

A great number of scientists and engineers have put their knowledge and experience into determining clear and straight-forward recommendations for choosing the values of parameters involved in clustering. Unfortunately, most of them so far have turned out to be inefficient and inapplicable in most cases. In [3] it is suggested and in [4] analyzed that the parameter r_a should be chosen according to:

$$r_a = \left\{\frac{1}{4}\left[\max\{\|X_i - X_j\|\} + \min\{\|X_k - X_l\|\}\right]\right\}^{\beta} \tag{6}$$

where $i, j, k, l = \overline{1, N}$, and N the total number of samples available. Parameter β should serve as amortization for extreme values of maxima which come from potential outliers [3].

We will perform an analysis on how the theoretical probability density function (pdf) of r_a changes according to N and dimensionality n. First, we consider a one-dimensional case ($n = 1$). Let samples from all clusters have a Gaussian joined probability density function $\mathcal{N}(m, \sigma^2)$. For the sake of simplicity, we will consider the minimum value to be neglectable in respect to the maximum value, as well as the parameter $\beta = 1$. Samples X_i and X_j then become independent identically distributed random variables, and parameter r_a becomes a random variable R_a for which the following holds:

$$R_a = \max\{|X - Y|\} \tag{7}$$

Random variable $Z = X - Y$ will then also have a Gaussian pdf with parameters $\mathcal{N}(0, 2\sigma^2)$, as it is a subtraction of two Gaussian variables. The absolute value of this variable $U = |Z|$ will have a cumulative distribution function (cdf):

$$F_U(u) = P(U \leq u) = P(|Z| \leq u) = P(-u \leq Z \leq u)u_H(u) \tag{8}$$

i.e. the following will hold:

$$F_U(u) = (2F_Z(u) - 1)u_H(u) \tag{9}$$

where $u_H(u)$ represents a Heaviside unit step function.

Now we can easily obtain the probability density function of the random variable U:

$$f_U(u) = 2f_Z(u)u_H(u) \tag{10}$$

If the total number of samples in our dataset is N, then there are $N_U = \binom{N}{2} = \frac{N(N-1)}{2}$ values which can be calculated as $U = |X - Y|$ and let these values be $U_1, \dots, U_{N_U}$. Let us form an array $U_{(1)}, \dots, U_{(N_U)}$, whose elements are variables $U_1, \dots, U_{N_U}$ in a non-declining order. $U_{(1)}$ is the minimum, and $U_{(N_U)}$ the maximum calculated value. If we want to determine the cdf $F_{U_{(k)}}(u)$ for $U_{(k)}$, we will notice that the event of $\{U_{(k)} \leq u\}$ occurs if and only if the k[th] value is not bigger than u, meaning that at least k of N_U random variables $U_1, \dots, U_{N_U}$ have a value less than or equal to u. Imagine we have N_U Bernoullie's experiments, with every experiment testing whether the event $\{U_{(k)} \leq u\}$ (success) occured or not [5]. The probability of success is equal to $P(U_{(k)} \leq u) = F_U(u)$, and the probability of at least k successes occuring in N_U experiments is:

$$F_{U_{(k)}}(u) = P(U_{(k)} \leq u) = \sum_{i=k}^{N_U} \binom{N_U}{i} F_U^i(u)(1 - F_U(u))^{N_U - i} \tag{11}$$

Since the object of our analysis is the maximum value of $|X - Y|$ i.e. $R_a = U_{(N_U)}$, by replacing k with N_U we get:

$$F_{R_a}(r_a) = \left(F_U(r_a)\right)^{\frac{N(N-1)}{2}} \tag{12}$$

The pdf for the parameter R_a is:

$$f_{R_a}(r_a) = \frac{N(N-1)}{2}\left(F_U(r_a)\right)^{\frac{N(N-1)}{2} - 1} f_U(r_a) \tag{13}$$

Let us assume now that our samples are n-dimensional. Let samples $\boldsymbol{X_i}$ and $\boldsymbol{X_j}$ be independent identically distributed vectors whose pdf is $\mathcal{N}(\boldsymbol{M}, \boldsymbol{\Sigma})$. We will additionally assume that their variances along all dimensions are equal and not correlated, i.e. that the covariance matrix has the form $\boldsymbol{\Sigma} = \sigma^2 \boldsymbol{I}$, where $\boldsymbol{I}$ is the identity matrix.

The Euclidian norm $V = \|\boldsymbol{X} - \boldsymbol{Y}\|$ is calculated as

$$V = \sqrt{\sum_{i=1}^{n} (X_i - Y_i)^2} = \sqrt{\sum_{i=1}^{n} Z_i^2} \tag{14}$$

where Z_i is the random variable $Z_i = X_i - Y_i$. We previously showed that the distribution of Z_i will be $\mathcal{N}(0, 2\sigma^2)$, which means that $\frac{Z_i}{\sqrt{2}\sigma}$ will have a Gaussian pdf $\mathcal{N}(0,1)$. We can determine the distribution of random variable

 ISBN 978-86-7466-930-3

$$V = \sqrt{2}\sigma \sqrt{\sum_{i=1}^{n} \left(\frac{Z_i}{\sqrt{2}\sigma}\right)^2} \tag{15}$$

using the results known from probability theory, which state that the square root of the sum of squares of n independent identically distributed variables with distribution $\mathcal{N}(0,1)$ will have a χ distribution with n degrees of freedom [6]. Therefore, the cdf of random variable V will be:

$$F_V(v) = \frac{\gamma\left(\frac{n}{2}, \frac{v^2}{4\sigma^2}\right)}{\Gamma\left(\frac{n}{2}\right)} u_H(v) \tag{16}$$

where Γ is the gamma function, and γ is the lower incomplete gamma function.
The pdf of random variable V is:

$$f_V(v) = \frac{v^{n-1}}{2^{n-1}\sigma^n \Gamma\left(\frac{n}{2}\right)} e^{-\frac{v^2}{4\sigma^2}} \cdot u_H(v) \tag{17}$$

Results given in equations (12) and (13) also hold for the distribution of the maximum value of random variable V with arbitrary dimensionality n.

Fig. 1 shows the probability density function of random variable R_a for different dimensionalities n and different number of samples N. We can see that the clustering radius can be affected by changes in both parameters. Larger dimensionality n results in more additions when calculating the norm, which expectedly also results in larger values of clustering radius. On the other hand, having more samples (larger N) increases the chance of extrema appearing, i.e. the chance of having samples which are far away from each other, which has a bigger clustering radius as a result.

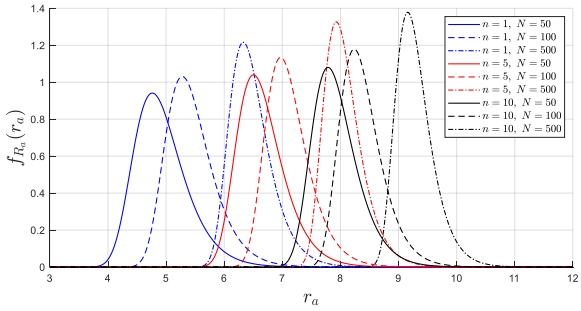

Fig. 1. Probability density function of random variable R_a which represents maximum of Euclidian norm between two samples.

It is also meaningful to analyze how the mathematical expectation m_{R_a} and variance $\sigma^2_{R_a}$ of the pdf of variable R_a change depending on sample number N and dimensionality n. Both statistics have been calculated using numerical integration of pdf in equation (13) and the results are shown in Fig. 2 and Fig. 3. Mathematical expectation and variance increase with the increase of n. On the other hand, larger number of samples increases the mathematical expectation, but decreases variance.

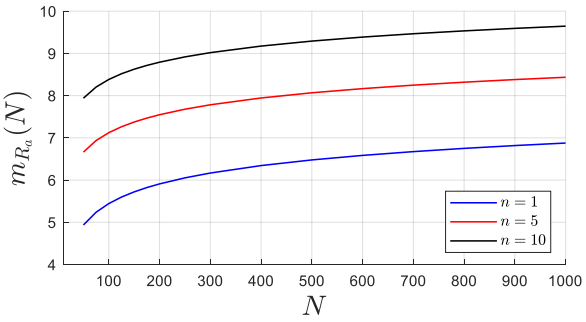

Fig. 2. Mathematical expectation m_{R_a} of random variable R_a depending on dimensionality n and number of samples N.

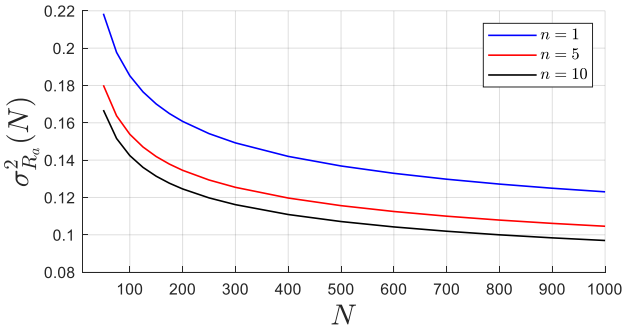

Fig. 3. Variance $\sigma^2_{R_a}$ of random variable R_a depending on dimensionality n and number of samples N.

In the beginning of this analysis, we assumed that parameter $\beta = 1$, which does not have to be the case in general. Let us introduce a random variable $W = R_a^{\beta}$ to show how parameter β affects the clustering radius. We can easily obtain the cdf for random variable W:

$$F_W(w) = P\left(R_a^{\beta} \le w\right) = P\left(R_a \le w^{\frac{1}{\beta}}\right) = F_{R_a}\left(w^{\frac{1}{\beta}}\right) u_H(w) \tag{18}$$

as well as its pdf:

$$f_W(w) = \frac{1}{\beta} w^{\frac{1}{\beta}-1} f_{R_a}\left(w^{\frac{1}{\beta}}\right) u_H(w) \tag{19}$$

For a constant number of samples $N = 100$ and various values of β, the pdf of W is calculated and shown in Fig.4. We can see that by changing the value of β by ± 30 % in respect to the unit value, we make a great impact on the expected value of clustering radius, as well as its variance.

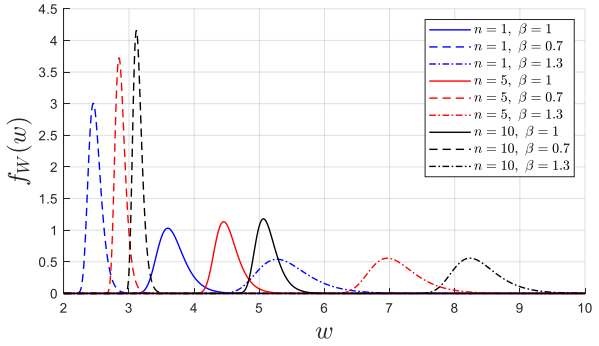

Fig. 4. Probability density function of random variable $W = R_a^{\beta}$ depending on dimensionality of samples n and parameter value β. W represents maximum of Euclidian norm between two samples to the power of β.

 ISBN 978-86-7466-930-3

C. *Classification accuracy*

Performance of clustering algorithm is tested on two-dimensional samples from 5 classes, distributed normally with different covariance matrices.

The main goal of clustering is to find centers of all classes and then test how accurate the classification is. Since the dataset is synthetically generated and all classes and covariance matrices are known, we decided to determine which class a sample belongs to by calculating the statistical distance according to equation (20),

$$d_i^2 = \left(X - X_{c_i}\right)^T \Sigma_{c_i}^{-1} \left(X - X_{c_i}\right) \tag{20}$$

where d_i is the statistical distance of sample X to i^{th} class, whose center is in X_{c_i}, and covariance matrix is Σ_{c_i}. For each sample the statistical distance to all found centers is calculated, and then the sample gets placed in the class for which the distance is minimal. Classification accuracy is finally measured as a percentage of accurately classified samples.

III. Results and Discussion

We generated 300 samples for each of the 5 classes. As previously mentioned, each class is normally distributed. Clustering radius r_a is determined according to (6), and parameter $\beta = 0.5$ [3]. As suggested in [2], the new clustering radius r_b is $r_b = 1.5r_a$. Clustering threshold δ is manually tuned for the algorithm to detect the right number of clusters.

Figure 6. shows all classes and centers which were detected by subtractive clustering.

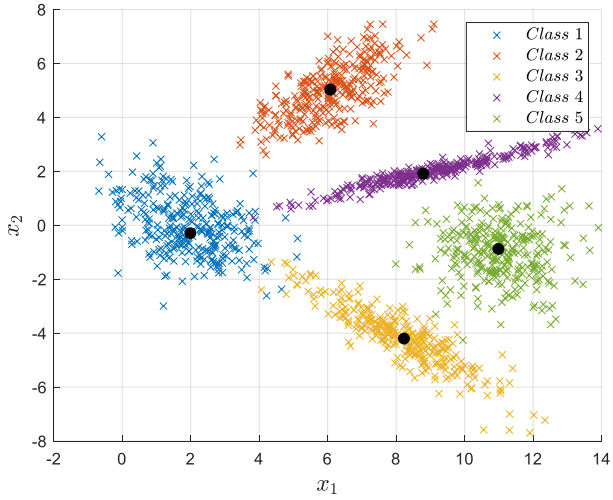

Fig. 5. Sample distribution among classes and corresponding cluster centers found.

To test the sensitivity of the algorithm (with said parameter values) the experiment was repeated 500 times. For each experiment the clustering radius r_a is determined separately. The histogram of the number of detected cluster centers in 500 experiments is given in Fig. 6.

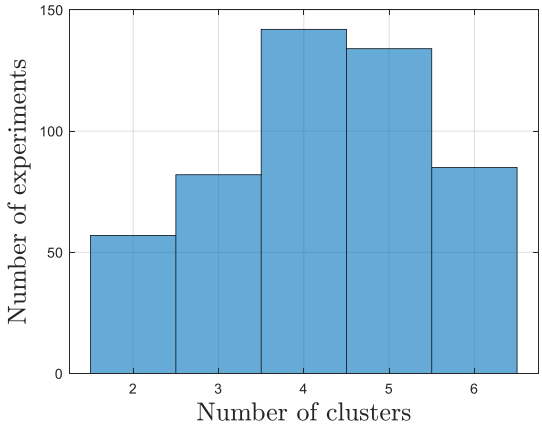

Fig. 6. Histogram of the number of detected cluster centers.

For experiments in which the detected number of centers is correct, i.e. 5, we calculated the classification accuracy as mentioned earlier. Figure 7. shows the histogram of classification accuracy.

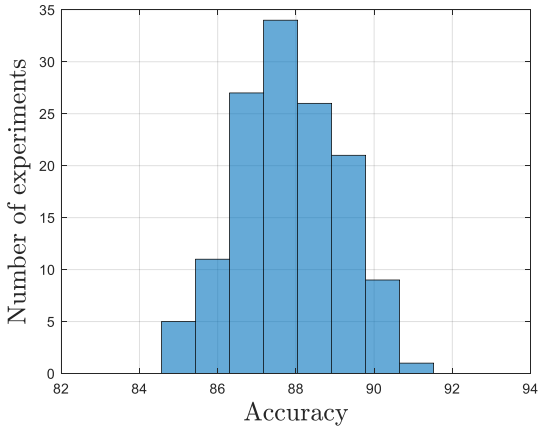

Fig. 7. Histogram of classification accuracy.

In 134 out of 500 experiments the algorithm has managed to detect all cluster centers. The average accuracy in these experiments is 88 %.

Finally, it is also interesting to see how the new cluster radius r_b affects the success of finding cluster centers. We choose o r_b according to:

$$r_b = \varepsilon r_a \tag{21}$$

where ε is a positive constant called the squash factor. Various papers give different suggestions regarding the value of ε, depending on the practical use of the algorithm. Based on [7] and [8] ε should be in an interval of $\varepsilon \in [1, 1.5]$.

We generated the same number of samples with the same distribution as before, and for each of the experiments we tested the success of the algorithm by changing ε from 1 to 1.5 with the step $\Delta\varepsilon = 0.05$. The experiment was repeated one hundered times. Histogram of the number of centers found depending on ε is shown in Fig. 8.

 ISBN 978-86-7466-930-3

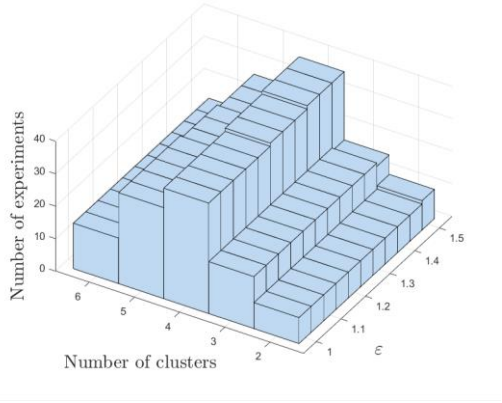

Fig. 8. Histogram of the number of cluster centers found depending on ε.

IV. Conclusion

In this paper we analyzed both theoretically and experimentally the technique of subtractive clustering, as well as suggestions for tuning its parameters. Values of parameters r_a, r_b and δ significantly affect the success of clustering. We observed that even with various suggestions on how to choose the values, the algorithm does not always perform well on different sets with the same distribution.

However, even if we assume that parameters r_a and r_b are tuned correctly, there are no theoretical propositions on choosing the threshold value δ, which has a great impact on the number of clusters found. In case of samples with dimensions $n = 1, 2, 3$ we can visualize the dataset and assess whether the cluster centers have been found correctly. Nevertheless, in most cases the dimensions will be significantly bigger and there would be no unique way to rate the success of the algorithm.

One of the methods to further enhance the algorithm and propose a uniform way for choosing parameter values would be to separately consider the maximum scattering along each of the axis. For example, if we have two-dimensional samples where the variance along one axis is much larger than the other and classes are near to each other, determining the density in the radius as the maximum quadratic norm of two samples, would lead to poor results.

Though the simplicity of subtractive clustering is its big advantage, the results are not ideal. That being said, it can be used as a preprocessing technique for other more sophisticated methods.

AGILIS: Restoring Functional Grasping in Individuals with Tetraplegia using Epineural Electrodes

Christine Azevedo Coste, Charles Fattal, Lucie William, *Member, IEEE*, Lucas Fonseca, *Member, IEEE*, Arthur Hiairrassary, David Andreu, Antoine Geffrier, Jacques Teissier and David Guiraud, *Member, IEEE*

***Abstract*— We propose a novel approach to restore grasping in individuals with complete tetraplegia using epineural stimulation. Two multi-contact cuff electrodes were positioned around radial and median nerves in 2 volunteers during a surgery. The electrodes were maintained for 28 days. A user interface allowed triggering pre-programmed stimulation sequences on demand by executing stereotyped movements or by contracting voluntarily muscle on the contralateral shoulder. The stimulation selectivity obtained with the epineural electrodes was sufficient to obtain functional palmar and key pinch grip.**

***Index Terms*—Functional Electrical Stimulation (FES), Tetraplegia, Neural electrodes.**

I. Introduction

Functional electrical stimulation (FES) is a means of restoring upper limb function in people with complete tetraplegia when functional tendon surgery or nerve transfer is not an option [1].

Intramuscular and epimysial electrodes have been used in the past to restore grip [2,3]. A disadvantage of this approach is the need for one electrode and one cable per muscle to be activated. Miniature, self-contained implant designed to be injected in or near muscles have also been proposed to avoid cables [10].

In the AGILIS approach, we propose to use 1 epi-neural electrode per nerve to activate the different muscles to reduce the number of implanted electrodes [4]. The cuff electrodes were designed to be self-adjusting to nerve diameter.

The objectives of the study we present here were to: 1) evaluate the safety of the procedures of implanting 2 cuff electrodes around the median and radial nerves respectively and maintaining them for 28 days, 2) evaluate the ability of the solution to elicit a functional grip in two participants with complete tetraplegia.

Lucie William with Inria, University of Montpellier, France,

Lucas Fonseca is with with Inria, University of Montpellier, France, (https://orcid.org/0000-0002-7255-5916)

Arthur Hiairrassary is with Neurinnov, Montpellier, France.

David Andreu is with Neurinnov, Montpellier, France.

Antoine Geffrier is with University Hospital Center Pontchaillou, Rennes, France. He was previously with APHP, Paris France.

Jacques Teissier is with Surgical Clinic OrthoSud, Montpellier, France.

David Guiraud is with Inria, University of Montpellier, France and Neurinnov, Montpellier, France.

II. Methods

Two volunteers with complete C4 tetraplegia, AIS A were included. They signed an informed consent. The study was approved by the National Ethics Committee (ClinicalTrials.gov ID NCT04306328).

The electrodes were placed during an initial surgical procedure and explantation surgery took place 28 days later. 2 multi-contact spinal electrodes (CorTec GmbH Freiburg Germany) were wrapped around the nerves above the elbow. Each electrode was connected to a percutaneous cable to connect the multi-source external stimulator (STIMEP, INRIA, Montpellier) [8]. The stimulator was controlled from a computer (Figure 1).

Fig. 1. AGILIS approach principle: 2 multi-contact cuff electrodes are wrapped around radial and median nerves. Percutaneous cables are connected on demand to an external pulse generator. Stimulation configuration patterns are pre-programmed to elicit hand opening/closing. The user controls contralateral shoulder movements or muscle contraction to send commands to the stimulator software: hand opening, palmar or key pinch grip…

Two control interfaces were tested to allow the user to trigger the pre-programmed stimulation patterns: 1) the participant used stereotyped voluntary shoulder movements of the contralateral limb captured by 1 IMU, 2) the participant used voluntary contractions of 2 muscles of the contralateral limb

 ISBN 978-86-7466-930-3

captured by 2 EMGs (trapezius and platysma). A finite state machine (FSM) was defined to associate user commands (EMG threshold detection or predefined movement recognition (IMU)) with actions depending on the current state of the FSM [6].

Various measurements were made wireless sensors (Delsys, Natick, MA) and offline processed using: electromyography (EMG), forces applied to objects (resistive force sensors (FSR)), movements (inertial measurement units (IMU)). The kinematics of the movements were also analysed (Leap Motion, Inc, San Francisco, California). FES-induced evoked muscle contractions (eEMG) were also acquired and post-processed to extract recruitment curves [9].

III. Results

Both participants were able to perform object grasping tasks using two types of grasp (key pinch and digito-palmar). Participant 1 was able to use both control interface modalities (muscle contraction and voluntary movements). Participant 2, due to a significant fatigability of the shoulder muscles, was able to use only voluntary shoulder movements to trigger the stimulation sequences, but in a rather non-robust manner, which led us to propose a third solution based on occipital contactors. Some results have been published in a recent article [7]. Additional results will be detailed during the presentation at the conference.

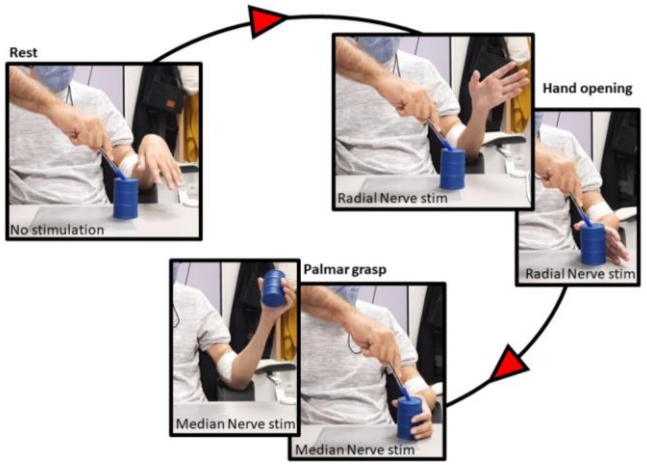

Fig. 2. Example of a sequence of movements for gripping a foam cylinder. The participant triggers the stimulation of the radial nerve which causes the hand to open (extension of fingers and wrist), he positions his hand on the object and then triggers the stimulation of the median nerve which causes the fingers to close around the object which he can then move.

IV. Conclusion

This preliminary study is a further step in the validation of the AGILIS approach which suggests the feasibility of a solution for grip restoration that minimises surgical complexity. Less than 2 hours were required to place the 2 multi-contact epineural electrodes with percutaneous cables around the radial and median nerves. These two electrodes associated with the electrical stimulator allow the injected currents to be controlled to achieve selective activation of the nerve fascicles. Two separate taps could be activated and associated with reproducible configurations (active electrode poles and stimulation parameters). The behaviour of the electrodes remained stable during the implantation period (28 days). Further studies are needed to strengthen the results.

Acknowledgment

The authors would like to thank the two volunteers, as well as Mrs Caralp and Mrs Porra (OT), Mr Panel and Mr Ferrer (PT), and the health care teams responsible for daily care. This study was supported by grants from the EIT Health, the Occitanie Region and the ERC MSCA.

A Device for Monitoring Physiological Parameters and Electrotactile Stimulation

Bojan Jorgovanović, Matija Štrbac, Miloš Kostić, Vojin Ilić, Nikola Jorgovanović

Abstract — **This wor stems from a research and innovation action financed under ecure societies programme of the European Union's Horizon 2020 framewor . pecifically, the aim is to develop an easy-to-use wearable system for enhancing situational awareness of first responders deployed in e treme environments by providing tactile feedbac on the ris factors that can lead to rapid deterioration of their health or operation capabilities. or this purpose, an unobtrusive system was designed to acquire, process, and analyse the data from a battery of novel biosensors and generate actionable information about assessed health ris s, in real-time. Aptly named I T , it leverages electrotactile stimulation to continually convey this information to the first responder wearing it, leveraging the sense of touch. It effectively e pands first responders' sensory bandwidth to include the "feeling" of changes in critical parameters that are not within the reach of human senses, li e the ionic imbalance, the lactate level or physiological strain, much before they manifest through symptoms of e haustion, heatstro e or hypothermia. The developed system further incorporates means for transmitting information to the command centre, where it can be analysed and visualised through a mission specific decision support system, allowing for a more efficient and safer data-driven team management.**

Index Terms— **lectrotactile stimulation; irst responders; Wearable acquisition unit**

I. Introduction

SIXTHSENSE is a multidisciplinary innovation and research action with the overall aim to significantly improve efficacy and safety of first responders' deployment in hazardous environments by optimising on-site team coordination and mission execution.

Nikola Jorgovanović is with the Faculty of Technical Sciences, University of Novi Sad, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia and Global Electronic Solutions doo, Cara Dušana 75, 21000 Novi Sad, Serbia (e-mail: nikolaj@uns.ac.rs).

Between the booming EU economy and the climate change, the number and consequences of disasters occurring in inaccessible rural areas is on a constant rise. First responder deployments in extreme conditions such as fighting wildfires or alpine search and rescue missions have gone from exceptional to regular events in only a couple of decades. As this trend is likely to continue, the risks for wellbeing of the engaged first responders continue to grow. To avoid the loss of life or lasting consequences on the first responders' health, it is important that the key physiological parameters of deployed operatives are monitored in a way that provides timely and actionable information, without hindering their operational capacity [1]. One way to achieve gathering such data and providing feedback is to use a device which could monitor the first responder's physiological parameters and use electrotactile stimulation as a way of conveying a message [2, 3].

At this point, a device that could do both data acquisition and analysis and give feedback to the first responder via stimulation is not available on the market, so it was necessary to develop one. The device presented in this paper is named the Alpha Mobile Device (AMD). The AMD is a system for multimodal data acquisition and control of electrotactile feedback stimulation. The aim of the AMD design was to enable synchronised electrotactile stimulation and acquisition from multiple sensors in a modular and scalable way that enables the inclusion of existing, developed and emerging sensors. The AMD design provides compactness, low power consumption, small overall dimensions and robustness with a main goal to develop a real mobile and wearable system.

II. Architecture of the AMD

The AMD was based on the STM32H743VIT6 microcontroller by ST Microelectronics. This ARM microcontroller has plenty of integrated peripheral modules which can work with very little or no processor core supervision. Furthermore, the STM32H743VIT6 microcontroller includes enhanced power management which provided all necessary power down or sleep operating modes in order to reduce power consumption.

The AMD needed to encompass 3 functionalities - data acquisition, electrotactile stimulation and communication. A block diagram of the AMD is shown in Figure 1.

 ISBN 978-86-7466-930-3

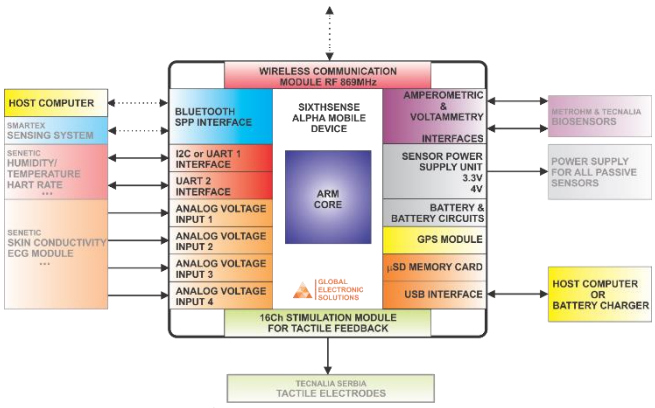

Figure 1. Block diagram of the AMD

A. ata ac uisition

The AMD is equipped with interfaces for acquisition data from following type of sensors:

- Analog sensors with voltage output
- NTC thermistor sensor for temperature measurement
- Electrochemical sensors – Biosensors
- Digital wired sensors with USART interfaces
- Digital wired sensor with I2C interface
- Wireless connected sensor system with Bluetooth SPP interface
- GNSS sensor

The AMD is equipped with four voltage analogue inputs. Analogue voltage input 1 is also equipped with a precise current source which provides a constant current flow of 100µA to pin 13 of the sensor connector. This construction allows temperature measurement using the precise 10kΩ NTC thermistor connected between analogue ground and AIN_0. The other three analogue inputs are standard voltage inputs. By default, all four analogue inputs are connected to the internal 16-bit ADC of the microcontroller with a sampling rate of 1KSPS. If it turns out that the accuracy of the internal ADC is not satisfactory each input can be independently rerouted to a high speed and high accuracy ADC of the AD5941 by SMD jumpers on the PCB.

The AMD is equipped with two inputs for electrochemical sensors (biosensors). This interface is based on the single channel electrochemical front end circuit, AD5941, by Analog Devices. The electrochemical sensor interface can be set to operate in the following modes:

- Amperometric
- Chronoamperometric
- Cyclic Voltammetry

B. Electrotactile stimulation

This functionality is intended for conveying messages to the first responder wearing the device through electrotactile stimulation. The device is designed to be compatible with multi-pad electrodes [4] designed and produced by Tecnalia Serbia doo. The AMD stimulation unit consists of the following blocks:

- DC/DC step-up voltage converter
- Biphasic current source
- Switch area (output demultiplexer)
- Control unit
- Battery and interfaces

The purpose of the DC/DC step-up converter is to provide voltage which is high enough to enable current flow through relatively high electrode-skin interface impedance. The manufactured DC/DC converter for the AMD is capable to boost battery voltage to voltage a level of up to 150V. This converter is based on a modified boost topology with coupled coils, and this design is confirmed in a number of different electrical stimulators previously developed by Global Electronic Solutions. The converter output voltage can be pre-set by the programme of the control unit. This flexibility is very important especially for the Alpha system in order to find the optimal voltage level in real life tests.

Biphasic Current source is based on current controlled H-bridge topology which is capable to create an either monophasic or biphasic current pulse. The amplitude of the current pulse is controlled by a control loop which is integrated into the H-bridge. This approach reduces the number of components and overall module dimensions. The set-point of the pulse amplitude is set by the control unit via a 16-bit D/A converter with standard SPI interface.

The Switch area includes a high-voltage switching circuit that allows multiplexing a signal from the H-bridge and driving it to one or more of the 16 output channels. Only one pole of the current source (cathode) can be distributed to any of the 16 electrode pads while the other pole (anode) is connected to a single predefined electrode pad, known as the unipolar stimulation topology.

The Alpha prototype will be based on ST Electronics' high performance ARM microcontroller (MCU). Only a small part of this microcontroller's resources are intended for the operation of the stimulator subsystem, while a bigger part will be used for the sensor data acquisition module. According to that, the part of the MCU which acts as the Stimulator control unit has the following important functionalities:

- Stimulation pulses waveform timing control
- Stimulation pulses amplitude control
- Stimulation pulse distribution to the pads of the multi-pad electrode
- Execution of the predefined electrotactile stimulation schemes

Beside the subsystems intended exclusively for the stimulator subsystem, there are two other common parts of the Alpha prototype which are necessary for the functioning of the stimulator subsystem and those parts are also integrated in the realized stimulator prototype:

- Battery and a battery electronic circuit
- Communication interfaces

The manufactured prototype is powered by Li-poly rechargeable battery. Battery charging, battery protection and battery monitoring electronic circuits are an integral part of the stimulator prototype. The manufactured device has Bluetooth

 ISBN 978-86-7466-930-3

and isolated USB interfaces. The following functionalities are realized via both communication channels:

- Setting all stimulation parameters (pulse width, pulse rate, pulse amplitude, active output channels)
- Starting/Stopping the stimulation
- Creating stimulation schemes
- Programming via a bootloader application

The device is also equipped with two multicolour LEDs indicating battery status, communication and stimulator activity. A block diagram of the stimulator is shown in Figure 2.

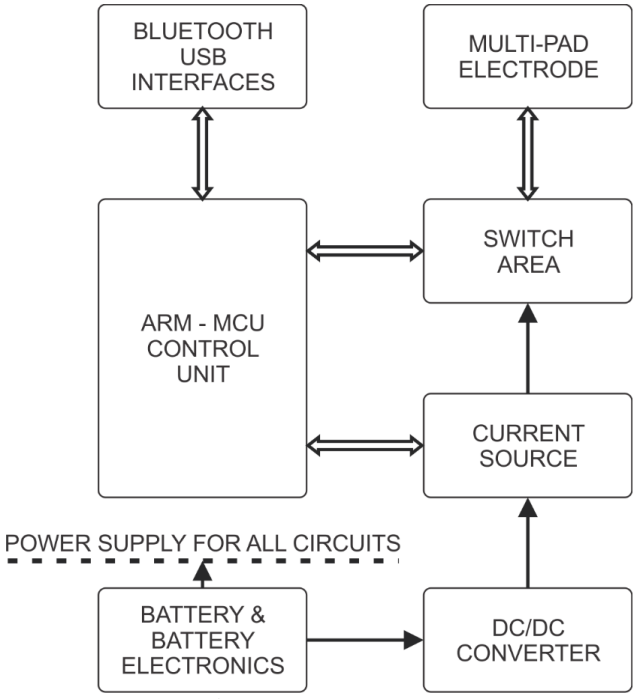

Figure 2. Block diagram of the AMD stimulator

C. Communication

The AMD is equipped with a narrow band RF communication channel for duplex communication between the first responder and the command centre. The communication is based on the GES-RF869 communication module produced by Global Electronic Solutions. The GES-RF869 is a radio module which is in compliance with ETSI EN 300 220-1. This module provides the possibility of exchanging small packets of data, up to 100 Bytes, with low speeds, in a relatively simple way. It works on an operational frequency band ranging from 869,400MHz-869,650MHz which enables it to have radiated power of up to 27dBm (500mW). It provides duty cycle control and obeys the 10% duty cycle restrictions for the 869,400MHz-869,650MHz frequency band. It offers multiple radio communication channels inside the operational frequency band and the possibility of configuring the transmit power. In order to optimize power consumption and communication range the transmit power can be set between 10mW and 500mW. The ISM standalone antenna by Molex is integrated inside of the AMD enclosure.

III. Results

The stimulator was tested on a circuit which resembles the electronic properties of the electrode-tissue interface and the signals were recorded using an oscilloscope. The waveform of the stimulation current is recorded at the serial resistor R_S by voltage input of the oscilloscope. The resistance of R_S is 1kΩ, so 1V at the recorded waveform corresponds to 1mA of measured current. A block diagram of the equipment used for testing the stimulator is shown in Figure 3.

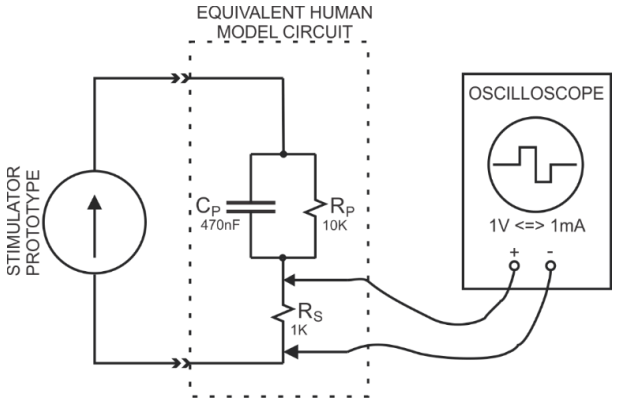

Figure 3. Block diagram of the test equipment

The waveform of a biphasic pulse generated by the AMD stimulator is shown in Figure 4. The pulse width of the generated stimulation pulse is 250µs, and the amplitude is 5mA.

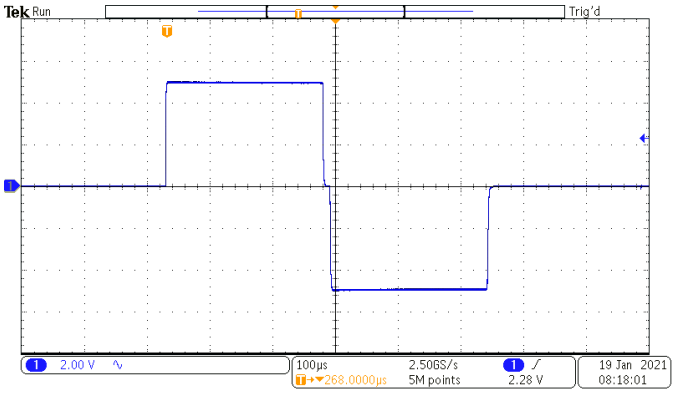

Figure 4. Stimulation pulse biphasic charge compensated test

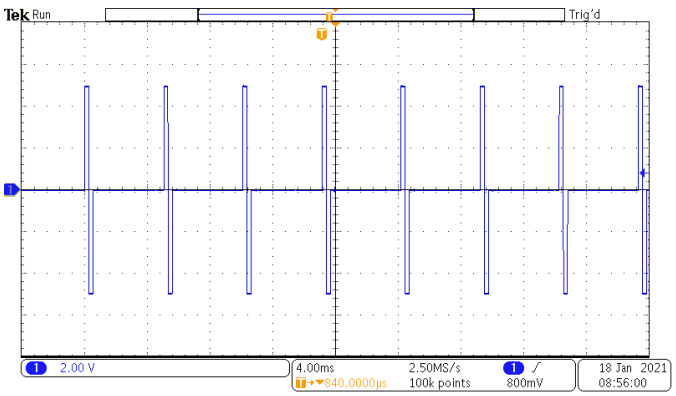

Figure 5. Stimulation pulse train

 ISBN 978-86-7466-930-3

A stimulation pulse train generated by the AMD stimulator is shown in Figure 5. The frequency of the pulse train is 200pps and each pulse has the same stimulation parameters as the pulse shown in Figure 4.

IV. Conclusion

The AMD device was designed and produced for the purposes of the SIXTHSENSE project. It has since been successfully tested in two field trials performed by first responders. The functionality of acquiring data was used for collecting physiological data about the first responders from various sensors. These data were both logged on an integrated µSD card and transmitted to a command centre which was realised through the communication functionality. Through electrotactile stimulation, the first responders were notified if certain parameters were out of regular boundaries. Feasibility tests in the field trials proved that the realized specifications of the voltage converter and the current source provided a sufficient range of stimulation levels for the tactile communication over multi-array electrodes placed on the torso of the user during physical activity, i.e. skiing and walking. The accuracy of the stimulation pulses shown in Figures 4 and 5 is satisfactory for electrotactile stimulation and the pulse amplitude error with respect to the set point value is negligible. Furthermore, initial tests proved that flexibility provided through the creation of stimulation patterns, which consider change of the active electrode pad and stimulation frequency, allow the generation of a large number of feedback messages. Given the number of different interfaces integrated in the device, it can also be used outside the scopes of the SIXTHSENSE project. The mentioned interfaces allow the device to communicate with both analogue and digital sensors of many types which makes it suitable for different kinds of tests and experiments. Furthermore, the powerful STM32H743VIT6 microcontroller used as the core of the device can even be used for certain signal processing applications or for running more complex algorithms than the ones used in this project.

Deep Neural Network Approach for Artifact Detection in Raw ECG

Tanja Boljanić, Jovana Malešević, Goran Kvaščev

***Abstract*— lectrocardiography is a non-invasive technique for monitoring the electrical activity of the heart, and its analysis can detect and then prevent many health problems. Alterations that are not related to cardiac electrical activity represent artifacts in signal and should be minimized in order to correctly interpretate the signal. This is of great importance in wearable systems for electrophysiological monitoring that have numerous applications in healthcare and fitness. This paper presents how to build a classification model to detect artifacts in electrocardiogram (CG) signal using deep neural networ . The ong hort-Term emory (T) networ was proposed for classifying 1 -s single-channel CG segments as *a d* and *Art act* Data set consists of 1 ,2 1 raw CG samples. The results show that the proposed method can classify the data with the accuracy of .1 , i.e., efficiently deal with acceptance of good (.) and rejection of poor (.1) CG quality.**

***Index Terms*— CG; Deep eural etwor ; T , Classification odel**

I. Introduction

ELECTROCARDIOGRAPHIC (ECG) artifacts are alterations that are not related to cardiac electrical activity. The artifacts could be caused by the unexpected motion intensity, loss of electrode-skin contact or movements of different part of the system such as cables. Additionally, some of the common noises that appear in the ECG signal are electromyogram (EMG) noise and baseline drift due to breathing or sudden movement, and such noises can be easily removed using various filtering approaches. The problem occurs if the artifacts last too long, and completely compromise the shape of the signal. Then, the current physical state of the subject could be misinterpreted. That is why it is of great importance to identify these types of artifacts and ignore the parts of the signal in which they appear. This is especially referring to the wearable systems for electrophysiological monitoring that are used for healthcare or fitness where health condition of the subjects is further decided based on the parameters extracted from the ECG signal. Since the subjects perform various physical activity, the quality of the ECG signal even more decreases. As predictions of the physical state are given in the real time, the artifacts detection as well as the other algorithms should be performed automatically.

Lui et al. [1] developed a wearable system for early detection of cardiovascular diseases and used machine learning algorithm for classifying ECG segments as acceptable and unacceptable for further analysis. Using Support Vector Machine (SVM), they could exclude unacceptable segments with an accuracy of 96.4%.

Neural networks are widely used for classification of different types of artifacts or arrhythmias in ECG signal [2-7]. Saadatnejad at al. [2] proposed a method consisting of wavelet transform and multiple recurrent neural networks for classifying arrhythmias in continuous cardiac monitoring on wearable devices. Deep network with wavelet sequences as input was used for classification of five heartbeat signals, resulting in high recognition performance [3]. Six common types of urgent arrhythmias are classified using deep neural network with an overall accuracy of 81% [4]. Deep learning algorithms were also used to classify shockable versus non-shockable rhythms in the presence and absence of cardiopulmonary resuscitation (CPR) artifact for automated external defibrillators [5]. Chauhan and Vig used deep recurrent neural network architecture with Long Short Term Memory (LSTM) units to detect abnormal and normal signals in ECG data [6]. The data included four different types of abnormal beats and the proposed detection system provided 96.5% performance.

The aim of the presented work is to develop a system that can automatically identify artifacts in ECG signals. We propose deep learning method for classification of unwanted artifacts and ECG signal that could be further processed, as we believe that these differences in signal could be reliably detected by a properly trained neural network.

Section II contains the method, including data preparation, and an explanation of used algorithm with the configuration of its parameters. The results are presented and discussed in section III, while the conclusion is attached in the final section.

II. The Method

The proposed algorithm is implemented in the Matlab R2019b software installed in a Windows 10 Pro platform, using the Signal Processing and Deep Learning toolboxes. The computer that was used is equipped with NVIDIA GeForce RTX 3060 graphics processing unit.

A. ataset and Implementation

Dataset that was used in this study was collected by Tecnalia Serbia during the field trials within SIXTHSENSE

Tanja Boljanić and Goran Kvaščev are with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: tanja.boljanic@gmail.com)

 ISBN 978-86-7466-930-3

project [8] in Bormio, Italy. The sensing module based on a multi-electrode array (MEA) for ECG recording was placed below the left major pectoralis. The MEA contains two recording and one referent electrode. The module provides conditioning and A/D conversion of the signal, and it is connected to the sensor for data acquisition via the flat cable. Described prototype was developed for research purposes within the project. This dataset comprises one-lead ECG recordings from 12 mountain rescuers that were performing the rescue task (male/female, 11/1, age (mean ± std), 31.7 ± 6.0 year). The length of the ECG signals ranges from 90 to 200 min with the average of 150 min, and the sampling rate is 1000 Hz. The signal contains motion artifacts due to the unexpected motion intensity and motion state, and the noises due to the change of relative displacement between electrode and skin, as well as the artifacts due to the cable movements. These noises have typical characteristics as transient high amplitude impulse and signal saturation. In order to utilize the automatic identification of the artifacts in signal, the ECG was visually inspected and we manually selected segments that are extremely noisy.

All signals were divided into 10-s segments, with total of 7,517 valid ECG and 2,714 segments labeled as signal with artifacts (7,517 + 2,714 = 10,231). Artifact segments are selected so that more than a half of the segment contain pure noise resulting in visually undetectable QRS complexes. An example of signal's both classes is presented in Fig. 1.

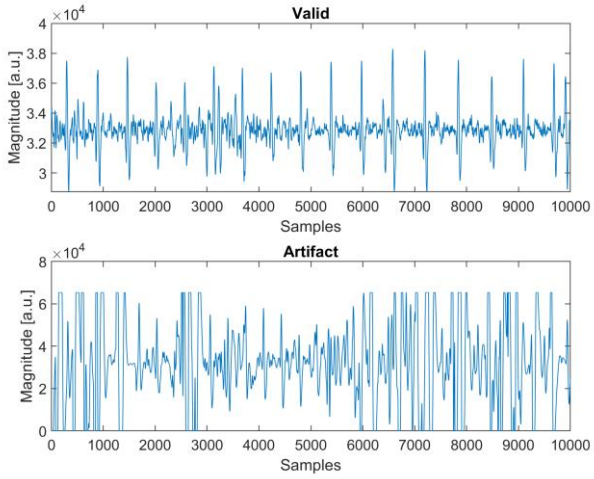

Fig. 1. The example of 10-s ECG segments: a segment without artifacts (*alid*, top) and a segment with artifacts (*Artifact*, bottom)

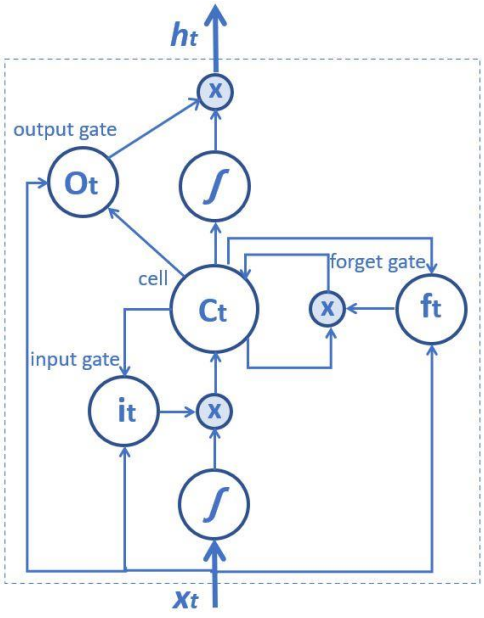
The raw data segments were divided into two sets: 90% and 10% for the training and testing, respectively. Both classes were randomly divided into these two sets. Since 73.5% of the dataset are valid segments, a classifier would learn that it can achieve a high accuracy simply by classifying all signals as *alid.* To avoid this bias, the *Artifact* signal was augmented so that there is the same number of *alid* and *Artifact* signals. This is one form of data augmentation used in deep learning, known as oversampling [9]. *Artifact* signals were augmented after splitting data into two sets, hence the data from the test set are not included in the training set. At the end, the distribution between *alid* and *Artifact* signals was evenly balanced, as showed in Table I.



B. Proposed eep Neural Network

Deep Neural Networks (DNN) are one type of model for machine learning that is subfield of artificial inteligence (AI) [10]. The appropriate deep learning algorythm depends on the task and the available data. Long short-term memory (LSTM) networks are the most commonly used variation of recurrent neural networks (RNN) that are well situated to study sequence and time-series data [11].

TABLE I
THE DIVISION OF THE ENTIRE DATASET INTO TRAINING AND TESTING SETS

Classes	The original number of 10-s segments	Number of 10-s segments after leveling	
		Training	Test
alid	7,517	6,765	752
Artifact	2,714	6,765	271

The LSTM network can effectively learn long-term relationships between time steps of a sequence. It consists of an input gate, forget gate, output gate and cell unit. The cell remembers values over arbitrary time intervals, and the gates regulate the flow of information into and out of the cell. Input gate protects the unit from irrelevant input events, while the forget gate controls when to forget previous memory contents. The output gates controls the output flow. Graphical representation of an LSTM unit is presented in Fig. 2. The LSTM network can look at the time sequence in the forward direction and in both forward and backward directions, which is than called bidirectional LSTM (BiLSTM). This is useful when there is need to learn from the complete time series at each time step.

 ISBN 978-86-7466-930-3

Fig. 2. LSTM block diagram. The variables are: x_t – input vector to the LSTM unit, i_t – input gate's activation vector, f_t – forget gate's activation vector, o_t – output gate's activation vector, c_t – cell state vector, h_t – output vector of the LSTM unit.

C. Network Parameter Configuration

LSTM network was proposed for ECG classification. The network parameters were selected experimentally or following the other studies [9,12,13]. The bidirectional LSTM (BiLSTM) with 200 hidden units was used, as it looks at the sequence in both directions – backwards and forward, which is important when network should learn from full-time series at each time step. Sequence input was set to one dimension, because the input signal is only the amplitude of raw ECG. Two classes were specified by including a fully connected layer of size 2. The last two layers were softmax and classification layer with cross-entropy loss function. The adaptive moment estimation algorithm (ADAM) was used as the optimization method. Architecture of a network is summarized in Table II. The layer information from the table includes the layer type, the size and format of the layer activations, and the size of learnable parameters.

TABLE II
THE DETAILED INFORMATION FOR EACH LAYER OF THE PROPOSED NETWORK MODEL

Name	Type	Activations	Learnables
input	Sequence input	1	-
Bi STM	BiLSTM	400	InputWeights 1600x1 RecurrentWeights 1600x200 Bias 1600x1
fc	Fully Connected	2	Weights 2x400 Bias 2x1
softma	Softmax	2	-
output	Classification Output	-	-

The BiLSTM layer has the following parameters: initial learning rate = 0.01, mini-batch size = 150, epoch = 10, gradient threshold = 1, sequence length = 1000, dropout = 0. Number of epochs in the number of passes through the training data, and increasing this number wasn't resulting in better classification accuracy. Mini-batch size is the number of signals that neural network looks at a time, while the signal is broken into smaller sequences (sequence length) so that the computer does not run out of the memory. Dropout layer was not used as the previous studies showed that it did not increase the network generalization ability [9,12].

III. Results and Discussion

The ECG data were classified using the LSTM network and performance measures of the model were evaluated using a confusion matrix. Confusion matrixes that are obtained after the training and testing process are presented in Fig. 4-5.

A row-normalized row summary represents the percentages of correctly and incorrectly classified observations for each true class, while a column-normalized column summary represents the same thing but for each predicted class. In order to report performance results for binary classification of *alid* and *Artifact* ECG, five statistical metrics are extracted from the confusion matrix and presented in Table III: accuracy, sensitivity, specificity, precision and F1-score.

Fig. 4. Confusion matrix for the training set of the LSTM with a raw ECG. The axes labels represent the class labels, *alid* - "v" and *Artifact* - "a".

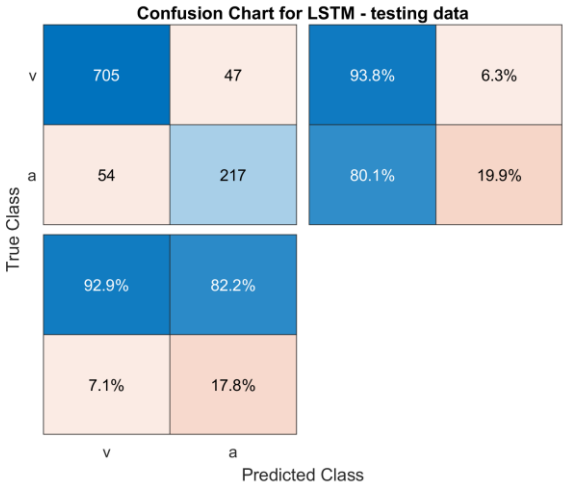


Fig. 5. Confusion matrix for the test set of the LSTM with a raw ECG. The axes labels represent the class labels, *alid* - "v" and *Artifact* - "a".

The LSTM accuracy for the training set was 88.2%, while for the testing set it was 90.1%. The accuracy is the proportion of correctly classified ECG segments of all ECG segments. Sensitivity calculates the number of correctly classified valid ECG segments out of the total samples in the class, while the specificity calculates the number of correctly classified artifact ECG segments out of the total samples in the mentioned class. The precision calculates the number of true positives out of the positive classified classes. Finally, F1-score is the harmonic mean of both the precision and sensitivity measures and it is used as an overall score on how well the model is performing.

 ISBN 978-86-7466-930-3

TABLE III
EVALUATION METRICS FOR A CLASSIFICATION TEST

Accuracy	90.1%
Sensitivity	93.8%
Specificity	80.1%
Precision	92.9%
F1-score	93.3%

The time consumption for training was 53 min, which is acceptable, considering the large database that included more than 10,000 ECG segments (a 10-s duration for each segment). Segments of 10 seconds was used, because most of the ECG monitors display and analyze such signal duration, and Hajeb-M et al. [5] reported that 8 s segments is the best choice for classification accuracy. As mentioned in the method section, we selected the segments of ECG signal that are extremely noisy as *Artifact* signals. In practical applications, it would be of interest to observe not only the signals that are incredibly noisy, but rather signals with various degrees of noise, and it will be considered in the future work. Network parameters that are used are the optimal one for this type of dataset. Other options did not help the network to improve the classification accuracy. Some of the changes that were performed are decreasing the learning rate and the mini-batch size, and increasing the number of epochs.

The overall accuracy of 90.1% indicates that the proposed model could provide accurate prediction on a raw ECG data. By observing the sensitivity and specificity values, it can be seen that performed model recognizes valid ECG segments better than artifacts.

Similar study [9] that was also using LSTM network on raw ECG data showed the accuracy of 70.8%. Chen et al. [4] developed a classification model for six types of urgent arrhythmias combining CNN (Convolutional Neural Network) and LSTM with accuracy of 81.0%, sensitivity of 82.0% and specificity of 97.0%. Combination of CNN and LSTM was also used by Liang et al. [14], who verified the classification accuracy on three different datasets of raw ECG signals and obtained F1-scores of 85.0%, 80% and 82.6%. For detection of shockable rhythms in the presence and absence of cardiopulmonary resuscitation (CPR) artifact, Hajeb-M et al. applied deep-learning algorithm using convolutional layers, residual networks and BiLSTM [5]. The sensitivity, specificity, accuracy and F1-score were 95.2%, 86.0%, 88.1% and 83.5%, respectively.

IV. CONCLUSION

Automatic detection of artifacts in ECG signal is important goal in wearable monitoring systems in order to accurate determine subject's physical state. This work proposes to use deep learning technique for classifying ECG signal. LSTM network was used on a raw ECG signal that was divided into 10-s segments. The classification accuracy of 90.1% indicate that the proposed model shows promising results. The future work will include more data to improve the training of the neural network. Also, ECG signals with various degrees of noise will be considered. One of the possible applications of this research could be within the SIXTHSENSE project, to improve the existing algorithm for determining the heart rate signal from the ECG of the first responders (mountain rescuers and firefighters).

Inhibition Potency of Terpyridine Metal Complexes toward Penicillin-Binding Protein 1A

Svetlana Jeremić, Enisa Selimović, Milan Dekić, and Tanja Soldatović

***Abstract*—The potency of copper(II) and zinc(II) terpyridine complexes to inhibit penicillin-binding protein 1A (PBP1a) was investigated by *in silico* methods. The geometries of ligands are optimized using DFT calculations. In order to estimate the binding sites, inhibition constants and binding energies between ligands and PBP1a protein, molecular docking analysis is performed. The inhibition potency of examined terpyridine metal complexes is compared with the inhibition potency of lactivicin, an antibiotic already used in the treatment of Gram-negative and Gram-positive bacteria. Performed docking analysis indicated that investigated terpyridine metal complexes show higher inhibition potency toward PBP1a protein than lactivicin. The results identified these complexes as potential antimicrobial agents for further *in vitro* experiments.**

***Key words* — copper(II) terpyridine; zinc(II) terpyridine; penicillin-binding protein 1A; lactivicin; molecular docking analysis.**

I. Introduction

Antibiotics have transformed medicine by changing the outcome of bacterial infections. Since the discovery of penicillin by Sir Alexander Fleming in 1928, antibiotics extend expected life spans for almost 25 years in the USA and have had similar beneficial effects worldwide. Nevertheless, the emergence of resistant microorganisms endangering the efficacy of antibiotics - bacterial infections have again become a threat due to the resistance that has been seen to nearly all antibiotics that have been developed. This has been attributed to the overuse and misuse of antibiotics, as well as a lack of new drug development, urging to renew efforts in the research of new antimicrobials and investigation of their mechanism of action [1].

Epidemic antibiotic resistance has been described in numerous pathogens, including common respiratory pathogens such as *Streptococcus pneumoniae*. This pathogen causes pneumonia, otitis media, and sepsis, and has been responsible for over one million yearly deaths worldwide [2]. Presently, 25% of all invasive strains are resistant to penicillin, amoxicillin, and cephalosporins [3, 4].

In the last few decades we have seen a dramatic increase in the number of β-lactam antibiotics and understanding of their mechanism in inhibition of peptidoglycan biosynthesis. Peptidoglycan component of bacterial cell wall consists of polymerized chains of repeating disaccharide subunits (N-acetylglucosamine and N-acetylmuramic acid cross-linked by stem pentapeptides), whose function is to provide cellular shape and maintain osmotic pressure [5]. Both the polymerization of disaccharide subunits and peptide cross-linking reactions are catalyzed by penicillin-binding proteins (PBPs), membrane-associated enzymes essential for cell division and daughter cell formation. PBPs possess the ability to covalently bind β-lactam antibiotics [6]. All enterobacteria appear to possess a similar spectrum of PBPs differing in molecular weight and affinity for β-lactams [7]. The high molecular-weight (HMW) PBPs (PBP1a/1b, PBP2, and PBP3) are physiologically important bifunctional enzymes that catalyze the final stages of peptidoglycan synthesis [6].

In Gram-positive bacteria, such as *S. pneumoniae*, the cell wall is composed mostly of peptidoglycan. *S. pneumoniae* has six PBPs, three of which are bifunctional - PBP1a, PBP2a, and PBP1b [8]. A PBP1a is essential for cell viability. This protein plays a key role in the formation of the cell septum during the bacterial division cycle and is involved in homologous DNA recombination mechanism, repair, and chromosome segregation [2]. To date, the mechanism used by bifunctional PBPs in the development of β-lactam resistance has remained unknown [2]. X-ray studies of soluble forms of pneumococcal PBP1a, both in apo (an inactive form, with no bounded ligand) as well as in antibiotic-bound forms, demonstrate that this protein contains three domains – the central transpeptidase domain flanked N-terminally by a GT/TP interdomain linker region, and C-terminally by a small, β-sheet rich unit. The active site of PBP1a is unusually narrow, suggesting that ligands must initially be threaded into the gorge to be recognized [2].

The search for effective inhibitors of PBP1a protein indicated that among the molecules with significant inhibitory affect there are different metal complexes of 2,2′:6′,2″-terpyridine molecule. The 2,2′:6′,2″-terpyridine (terpy) ligand is tridentate, nearly coplanar, N_3 donor ligand. It has been recognized as a useful ligand for transition metal and rare earth metal ions in inorganic chemistry. Square-planar, square-pyramidal and octahedral metal complexes with terpy ligands have been reported to be of great biological interest [9, 10, 11].

The biologically important metal ions copper(II) and zinc(II) have the ability to coordinate into different

 ISBN 978-86-7466-930-3

geometries depending on the specific arrangement of donor atoms in biomolecules, but strong π-acceptor ability of the tridentate chelate 2,2′:6′,2′′-terpyridine stabilizes the square-pyramidal geometry [10]. Different substituted terpyridene molecules generate complexes with copper(II) and zinc(II) ions, that exert anti-microbial, anti-bacterial, anti-fungal, anti-proliferative and inhibitory activity. For example, terpyridine complexes of Cu(II) and Zn(II), and especially complexes of Cu(TTP)Cl_2 and Zn(TTP)Cl_2 (TTP is 4 -[*p*-tolyl]- 2,2′:6′,2′′-terpyridine) are efficient inhibitors of furin. Furin, a human subtilisin-related proprotein convertase (SPC), is emerging as an important pharmaceutical target because it processes vital proteins of many aggressive pathogens. Inhibition is irreversible, competitive with substrate, and affected by substituents on the chelate. The free chelates are not inhibitors [12]. Complexes of terpyridine-based ligands with Zn(II) as a central metal ion has also shown significant inhibitory activity against B-DNA molecule and similar double helixes, as against penicillin binding protein 2a [9]. This fact indicated the importance of examining the possibility of complexes of terpyridine with Cu(II) and Zn(II) to inhibit PBPa1 protein, which is known to be a protein of great importance in the development of bacteriological infections.

II. Methodology Section

The inhibition potency of copper(II) and zinc(II) terpyridine complexes toward penicillin-binding protein 1A (PBP1a) is investigated using molecular docking analysis. The structures of terpyridine metal complexes are optimized using M06-2X functional [13] in combination with 6-311++G(d,p) basis set implemented in Gaussian 09 program package [14]. Molecular docking simulations were carried out using AutoDock 4.0 software [15]. The three-dimensional (3D) crystal structure of PBP1a protein was downloaded from the Protein Data Bank (PDB ID: 2C6W) [2]. The protein structure is released from the co-crystallized ligand, water molecules, and co-factors and prepared for docking simulations using Discovery Studio 4.0 [16]. The affinity maps of the target protein are established using AGFR (AutoGridFR) software [17]. According to AGFR, binding site with the lowest expected binding energy is grid box with dimensions 98.799Å x 35.214Å x 55.068Å in -x, -y, and -z directions. A grid point spacing of 0.375 Å was used for auto grid runs. The addition of polar hydrogen atoms and the calculation of Kollman charges are done by using AutoDockTools (ADT) graphical interface. The ligands are set to be flexible, while the structure of protein remains standing as rigid. The Lamarckian Genetic Algorithm (LGA) is used for protein-ligand flexible molecular docking simulations. Calculations are performed at a temperature of 298.15 K. Analysis of molecular docking simulation results and visualizations of predicted protein-ligand interactions are performed using BIOVIA Discovery Studio [16].

III. Results and Discussions

Molecular docking analysis is a useful and widely used method for predicting the inhibitory activity of biologically active compounds. Terpyridine metal complexes possess significant anti-bacterial, anti-fungal and anti-cancerous activity [9, 10]. Moreover, recent research has shown that complexes of terpyridine and some its derivatives with different metals show significant inhibitory activity against various protein molecules [18, 19]. Since terpyridine complexes of Cu(II) and Zn(II) are already selected as potential agents against different disease, here is investigated their potency to inhibit PBP1a protein. PBP1a protein is membrane-associated enzyme that plays essential roles in the peptidoglycan biosynthetic process [2]. In this way it enables the proliferation of bacteria *Streptococcus pneumoniae*. The infection caused by this pathogen have been treated with β-lactam antibiotics for almost a century, but the proliferation of strains that are highly resistant to such drugs is a problem of worldwide concern. Although *S. pneumoniae* has six penicillin-binding proteins, PBP1a is essential for the development of high-level resistance to penicillins and cephalosporins [2]. Therefore, the development of agents that enable the inhibition of this protein is of particular interest.

In order to be able to compare the inhibitory activity of terpyridine metal complexes with an activity of a compound already used for these purposes, the inhibitory potency of the drug lactivicin was also examined. Lactivicin is compound that shows moderate activity against Gram-negative and high activity against Gram-positive bacteria. The mechanism of its activity is based on the binding to PBPs and violation of its structure [20]. Structures of copper(II) terpyridine complex, zinc(II) terpyridine complex and lactivicin are shown in Fig. 1.

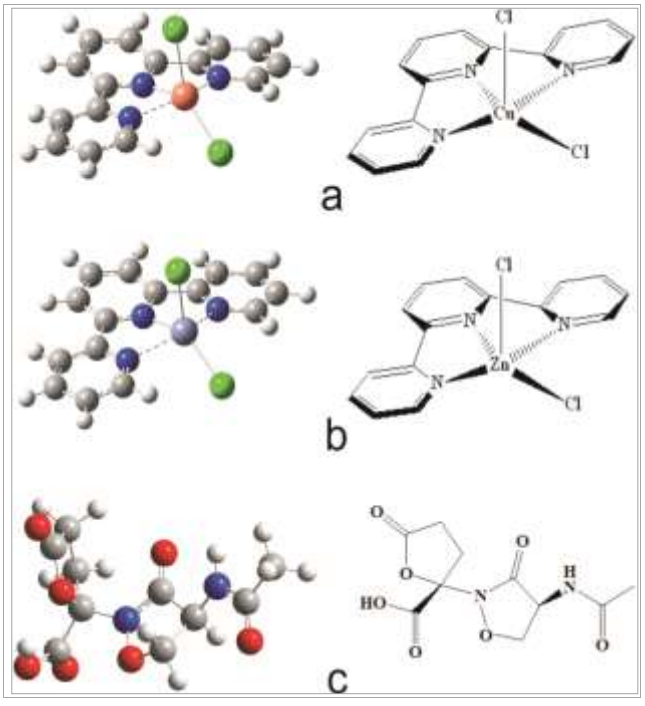

Fig. 1. 2D structures (right) and optimized structures (left) of copper(II) terpyridine complex (a), zinc(II) terpyridine complex (b) and lactivicin (c).

The evaluation of the inhibitory nature of ligand according to PBP1a was performed using molecular docking study. At the beginning of the research, the pockets and binding sites of the targeted protein were determined using the AGFR software [17]. All three estimated ligands showed

 ISBN 978-86-7466-930-3

the highest activity against protein at the same position. Grid box with dimensions 98.799Å x 35.214Å x 55.068Å in -x, -y, and -z directions, and with spacing of 0.375 Å is predicted. For all three estimated ligands it comprises the same pocket of the polypeptide chain (Fig.2).

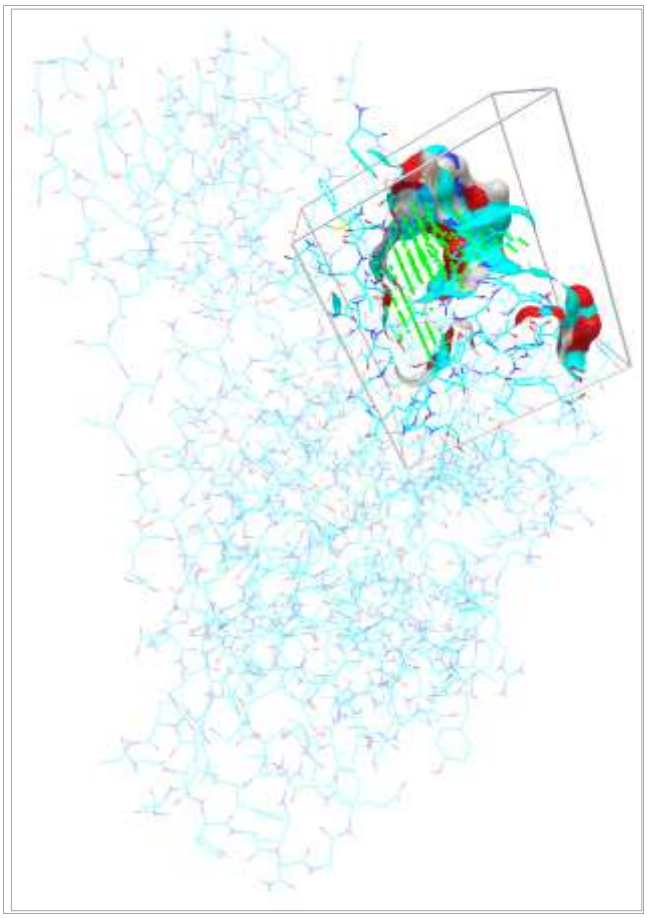

Fig. 2. The location of the most probable binding site of PBP1a for all three estimated ligands.

After configuring and computing affinity maps for a receptor-protein interactions, the one with the lowest binding energy was used for AutoDock4 calculations. Ten different conformations of protein-ligand complexes are set for molecular docking simulations. It should be emphasized that only one conformation has been accomplished when as ligand is used any of estimated terpyridine metal complexes. It can be explained by the complete rigidity of the ligand structure. On the other side, flexible structure of lactivicin allowed formation of ten protein-ligand complexes. The complex conformation that possesses the lowest binding energy was selected for further analysis.

TABLE I

THE IMPORTANT THERMODYNAMICAL PARAMETERS FROM MOLECULAR DOCKING SIMULATIONS BETWEEN PENICILLIN-BINDING PROTEIN 1A (PBP1A) (PDB ID: 2C6W) AND SELECTED COMPOUNDS

Ligand	ΔG_{bind} (kcal/mol)	Ki (μM)
$[CuCl_2(terpy)]$	-6.66	13.11
$[ZnCl_2(terpy)]$	-6.62	13.99
lactivicin	-5.48	95.46

The inhibitory potency of preferred compounds can be estimated based on the thermodynamical parameters obtained by statistical mechanical analysis. Values of the free energy of binding (ΔG_{bind}) expressed in kcal/mol and inhibition constant (Ki) expressed as micromolar concentration, are presented in Table 1. The lowest binding energy indicates to the easiest binding possibility of the investigated ligand. Low values of the inhibition constant indicate that a low concentration of inhibitor is required in order to inhibit the activity of the observed protein. Both ΔG_{bind} and Ki indicate that the highest inhibition potency shows Cu(II)-terpyridine complex. Somewhat lower inhibition potency has Zn(II)-terpyridine complex, while lactivicin shows the least.

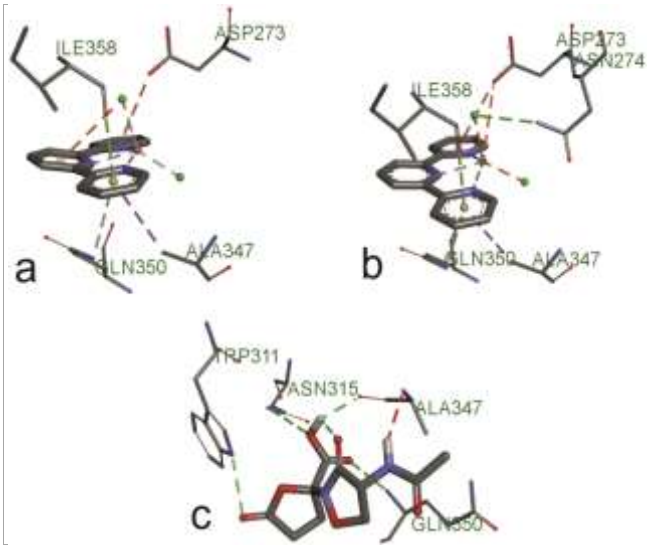

Fig. 3. Docking positions of the Cu(II)-terpyridine complex (a), Zn(II)-terpyridine complex (b) and lactivicin (c), with PBP1a protein.

Each of the three considered ligands achieves at least four protein-ligand interactions. PBP1a protein interact with Cu(II)-terpyridine complex forming π – anion electrostatic interaction via Asp273, then π – lone pair interaction via Ile358, π – donor hydrogen bond via Gln350, and π – σ interaction via Ala347. The interactions achieved by Zn(II)-terpyridine complex with PBP1a are the same as those achieved by the complex with copper, except that Zn-complex achieves another additional conventional hydrogen bond via Asn274 amino acid of PBP1a. Lactivicin generates with the protein four conventional hydrogen bonds, via the amino acids Trp311, Asn315, Ala347 and Gln350. It can be seen that all three ligands interact with PBP1a via Ala347 and Gln350 (Fig. 3). As it can be concluded, the number of ligand-protein interactions is not the only parameter that affects to the strength of inhibition, but it is also the type of interactions. Although conventional hydrogen bonds are among the most significant interactions in protein inhibition, the effect of interactions involving π–electrons derived from terpyridine should not be overlooked.

IV. CONCLUSIONS

Metal complexes of terpyridine are known as compounds with significant anti-bacterial, anti-fungal and anti-

 ISBN 978-86-7466-930-3

cancerous activity [9, 10]. On the other hand, there are numerous infections caused by bacteria *Streptococcus pneumonia*. Penicillin binding proteins (PBPs) play a key role in the proliferation of this bacterium [2]. Therefore, the device of molecules that would lead to the inhibition of this protein could significantly contribute to the treatment of infections caused by *S. pneumonia*.

The potency of Cu(II)-terpyridine complex and Zn(II)-terpyridine complex to inhibit penicillin-binding protein 1A (PBP1a) is investigated in this purpose. Due to it molecular docking simulations are performed. Inhibition potency of $[CuCl_2(terpy)]$ and $[ZnCl_2(terpy)]$ are compared with inhibition potency of lactivicin, molecule that is already used in the treatment of *S. pneumonia*.

The analysis of results obtained by molecular docking simulations indicated that the highest inhibition potency express Cu(II)-terpyridine complex, while Zn(II)-terpyridine complex shows somewhat lower inhibition potency. Both estimated complexes possess higher inhibition potency than lactivicin. All three investigated ligands react with PBP1a at the same reaction position, and in some cases, via the same amino acids of protein. All ligands generate at least four interactions with protein, among the most important are conventional hydrogen bonds, and interactions involving π–electrons from terpyridine.

Comparing inhibition potency of $[CuCl_2(terpy)]$ and $[ZnCl_2(terpy)]$ with inhibition potency of some other complexes of terpyridine and its derivatives with different metals [18, 19], it can be seen that here investigated complexes possess similar or higher inhibition potency toward here estimated protein.

The results of the docking analysis conducted in this study provide significant preliminary results related to the inhibitory activity of the complexes tested here. With all this in mind, the herein discussed metal complexes may be considered as potential agents in the treatment of bacterial infections. Among further studies of the biological activity of the terpyridine complex, *in vivo* studies are certainly the most important.

ACKNOWLEDGMENT

GT Analyzer – A Basic Tool for Handwriting Movement Data

Vladimir Džepina, Nikola Ivančević, Vera Miler-Jerković, Blažo Nikolić, Dejan Stevanović, Jasna Jančić and Milica M. Janković, *Member*, IEEE

***Abstract*—In the presence of neurological and psychiatric diseases, sensorimotor and cognitive skills tend to deteriorate. One of the daily activities that could be easily affected is handwriting. In this paper, we present the open-source software GT Analyzer, developed for visual analysis and feature extraction of the handwriting data acquired by graphic tablet. Data is acquired while patients are working on graphic tasks developed by clinicians. Visual and feature analysis of handwriting data could be of great use in establishing a correct diagnosis or in following the changes during medical therapies for neurological and psychiatric diseases. Furthermore, extracted features can be used later in statistical tools, to improve the classification and determination of therapeutic effects to a greater extent.**

***Index Terms*—handwriting; graphic tablet; depression; Parkinson's disease; open-source**

I. Introduction

Handwriting is a complex motor task consisting of both cognitive and motor processes interplaying together [1, 2]. Computer analysis of handwriting, using a digital writing tablet, has shown its usefulness in clinical studies in the fields of neurology, psychiatry and neuropsychology in both adults and children [3]. Data obtained from handwriting analysis could help clinicians to establish correct diagnosis e.g. in Parkinson's disease and Parkinsonism [4-6], or to track changes in motor functioning and the influence of therapy on it in depression in adult subjects [7] or in attention deficit hyperactivity disorder/ADHD in children [8].

The summary of computer analysis of handwriting is that clinicians are giving patients several specially designed drawing and/or writing tasks, which they have to draw or write on a graphic tablet [2, 3, 4, 6]. During the task, the tablet is acquiring the position of the pen and the pressure with which the pen is pressed on the tablet [2]. Both on-surface and in-air handwriting movements can be analyzed [6]. After the task is completed, acquired data can be operationalized through kinematic handwriting features [2, 4].

This system is favored as it has low complexity of installment, has great ease of use for both patients and clinicians and has low chances of errors while performing the task. Also, kinematic handwriting features acquired using writing tablets show high test-retest reliability [2].

Our previous research [3, 6, 8-10] in the field of handwriting analysis has shown a great need for an open-source, user-friendly software suitable for data acquisition alongside the application software that will be used for later exploration of acquired data. This could help make the research methodology more uniform and to ease data exchange and comparison between different studies.

The aim of this paper is to present a novel, user-friendly, open-source interface for reading, visualization and analysis of data that was acquired during different graphic tasks on digital graphic tablets. This software also stresses out the importance of visual analysis of extracted handwriting features.

The flowchart of the implemented interface and software options are presented in Section II. The software functionality is demonstrated through examples from two different datasets in Section III. A brief overview of software advantages and usage options is presented in the Conclusion section.

II. The Method

Graphic Task Analyzer (GT Analyzer) is an open-source application that enables the reading of recorded pen position (X,Y) and pen pressure (p) data from digital graphic tablets, a simple preview of calculated kinematic features of handwriting over time and export of 173 standard kinematic handwriting features, Fig. 1. An example of visualization for (X,Y,p) input sequence for three drawn figures (figure separators are marked by green arrows) is also presented in Fig. 1.

 ISBN 978-86-7466-930-3

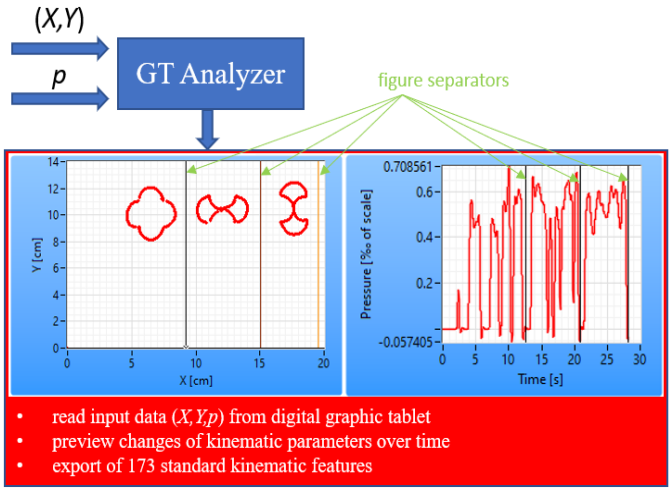

Fig. 1. GT Analyzer software options with preview example of input data (coordinate pair (*X,Y*) and pressure *p* of the pen tip)

A. *Software description*

The application was developed in the LabVIEW 2019 environment (National Instruments, Texas, USA). The code of the software is available at the following Github link: https://github.com/MagnumSinum/GT-Analyzer/blob/main/GT%20Analyzer%20source%20code.rar

B. *Kinematic features*

For each (*X,Y,p*) input sequence, the algorithm calculates the 1st, 2nd and 3rd derivatives. The 1st derivatives of *X(t)* data and *Y(t)* data correspond to the velocity $V_x(t)$ and $V_y(t)$, respectively. The total velocity $V = \sqrt{V_x^2 + V_y^2}$ was also calculated. The 1st derivative of *p(t)* data corresponds to *dp(t)/dt*. The 2nd derivatives of *X(t)* data and *Y(t)* data correspond to the acceleration $A_x(t)$ and $A_y(t)$, respectively. The total acceleration *A(t)* corresponds to the 1st derivative of *V(t)*. The 2nd derivative of *p(t)* data corresponds to $d^2p(t)/dt^2$. The 3rd derivatives of *X(t)* data and *Y(t)* data correspond to the jerk $J_x(t)$ and $J_y(t)$, respectively. The total jerk *J(t)* corresponds to the 2nd derivative of *V(t)*. The 3rd derivative of *p(t)* data corresponds to $d^3p(t)/dt^3$. The list of implemented statistical handwriting features is presented in Table 1.

TABLE I THE LIST OF STATISTICAL HANDWRITING FEATURES

Data	Statistical feature
X(t),Y(t),p(t), $V_x(t),V_y(t)$, *V(t),* *dp(t)/dt,* $A_x(t),A_y(t)$, *A(t),* $d^2p(t)/dt^2$, $J_x(t),J_y(t)$, *J(t),* $d^3p(t)/dt^3$	Median value
	Mean value
	Standard deviation
	Variance
	Coefficient of variation
	Maximum value
	Minimum value
	10th percentile
	25th percentile
	75th percentile
	90th percentile
Total variables =15	*Total number of features=11*

For each figure, 8 kinematic features, so-called "figure features" were calculated. The list of figure features is presented in Table 2.

TABLE II THE LIST OF FIGURE FEATURES

Abbreviation	Figure feature
FL [cm]	Figure length
FT [s]	Figure drawing time
FS [cm/s]	Figure drawing speed
NCV [n.u.]	Number of changes in velocity
RNCV [n.u.]	Number of changes in velocity relative to figure drawing time (NCV/FT)
NST [n.u.]	Time spent during drawing on-surface or in-air normalized by the figure drawing time (ON-SURFACE TIME/FT or IN-AIR TIME/FT)
NCA [n.u.]	Number of changes in acceleration
RNCA [s^{-1}]	Number of changes in acceleration relative to figure drawing time (NCA/FT)

C. *Implementation details*

The expected input file format for GT Analyzer tool is a textual file with 3 columns, each column corresponding to *X(t)*, *Y(t)* and *p(t)* data respectively, obtained by the data acquisition software from the digital graphic tablet. Expected units of the position data (*X,Y*) are meant to be 10^{-5} m. The pressure data *p(t)* is unitless because it is expected to be expressed relative to the full pressure scale of the digital graphic tablet. Also, it is expected that in the input file name first 4 characters are reserved for the subject ID and the last single digit in the file name is reserved for the number of the performed task by the subject. Each task could include up to eight figures.

Within the GT Analyzer tool, the following setting parameters could be selected:

- input file name (two file names could be selected at once in order to compare results for two subjects (e.g. patient vs. healthy data))
- input folder name (with several input files) for the automatic analysis and export of all kinematic features to one excel file per task.
- sample rate (performed by the data acquisition software used for (*X,Y,p*) data recording from the digital graphic tablet)
- lower cut-off frequency that will be performed in (*X,Y*) data processing by the 3rd order low pass Butterworth filter, the default value is set to 2 Hz
- NCV tolerance (minimal difference between two time-adjacent samples of *V(t)* to count it as a change in velocity, the default value is set to 0.1 cm/s)
- NCA tolerance (minimal difference between two time-adjacent samples of *A(t)* to count it as a change in acceleration, the default value is set to 1 cm/s^2)
- *Width* parameter (the number of consecutive data points to be used in the quadratic least-squares fit when the tool is determining local minimums on V_y – local minimums on V_y

 ISBN 978-86-7466-930-3

separate different strides within the figure)

- *Threshold* parameter (maximum value of local minimums that will be accepted when the tool is determining local minimums on V_y).

After the adjustment of parameters, the user can perform the following actions:

- DISPLAY DATA: Process (*X,Y,p*) input sequence from input files – extraction of all features defined in *Section II B Kinematic features*. Display (*X,Y*) data on XY graph, as well as a display of temporal graphics for $p(t)$, $V_y(t)$, $V(t)$, $A(t)$ and $J(t)$ from two selected input files. The software differentiates (*X,Y,p*) samples when the pen was on the surface or in-air and represents it with red and blue color, respectively. Stride ends (found local minimums on V_y) are presented by green circles on $V_y(t)$, $V(t)$, $A(t)$ and $J(t)$ graphics.
- SAVE LIMITS: Figure separators (separators between data for different figures in one task) could be set using cursors on XY graphs (up to eight) and the cursor limits could be saved for each task.
- EXPORT LOADED DATA: Extracted kinematic features could be saved in one .xls file per each selected input file.
- EXPORT FOLDER DATA: Extracted kinematic features could be saved in one .xls file for each file within the selected input folder.

All settings and actions can be repeated while the GT Analyzer application is still running.

D. Dataset description

Two different datasets acquired during graphic tablet tasks have been used to present the functionality of the GT Analyzer software:

- PaHaW adult subjects dataset, presented by Drotar and others [4] - labeled as DS1,
- pediatric subjects dataset used in the Doctoral dissertation of Ivančević N. D. [9] - labeled as DS2.

One pair from each dataset (one healthy and one diseased subject from DS1 and DS2, paired by gender and handedness), was selected to demonstrate the GT Analyzer interface. From DS1, the subject ID 6 (diagnosed with Parkinson's disease) and the healthy subject ID 26 were selected for the "drawing a spiral". During this task, the subject starts the drawing from the center of the spiral. From DS2, the subject ID 17, diagnosed with pediatric-onset major depressive disorder (drug-naive), and the healthy subject ID 25 were selected for the writing of two figures of the consecutive cursive letter "l": 1) figure 1 was drawn in the large rectangle 40x160 mm and 2) figure 2 was drawn in the small rectangle 9x160 mm.

Data acquisition for both DS1 (sample rate 100 Hz) and DS2 (sample rate 200 Hz) was performed using a digital graphic tablet Wacom Intous4 XL (Wacom Europe GmbH, Krefeld, Germany) with the cordless pen that enables on-surface and in-air handwriting. Custom-made data acquisition *LabHand* [10] previously developed in the LabVIEW environment, the same environment as for the GT Analyzer, was used for the data recording.

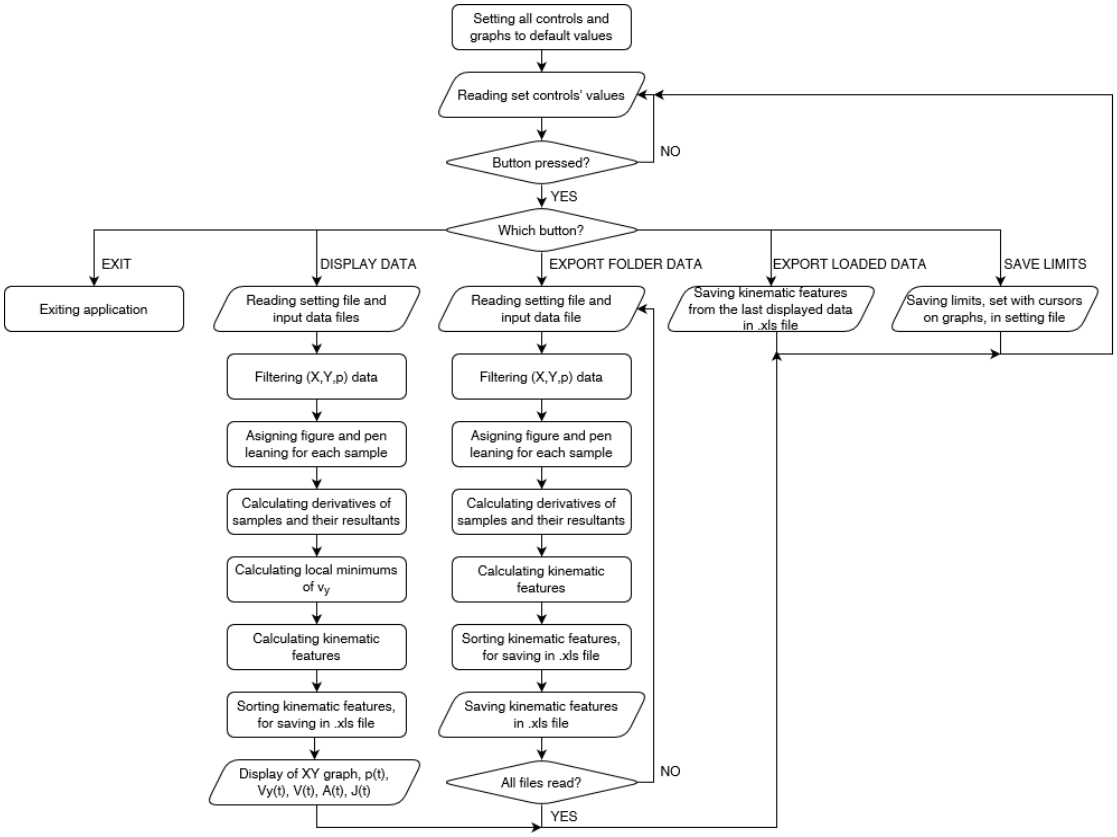

Fig. 2. GT Analyzer flowchart

 ISBN 978-86-7466-930-3

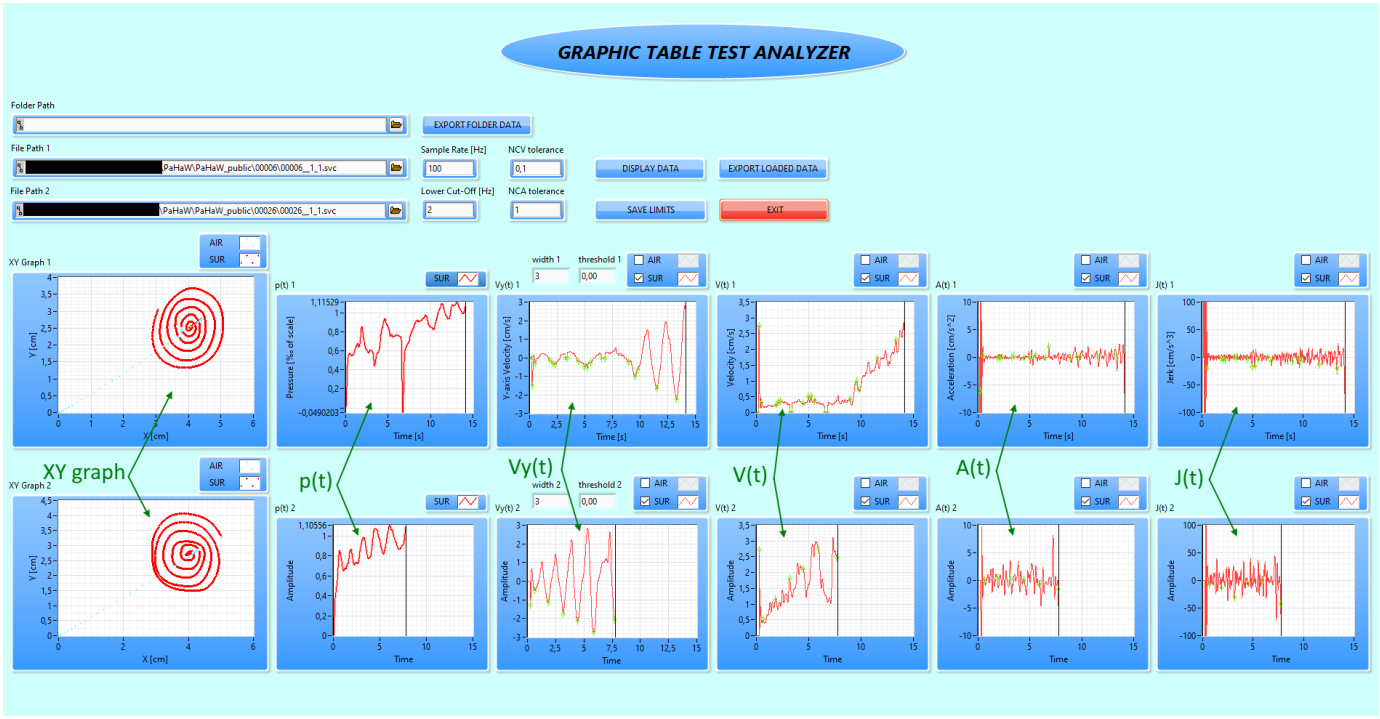

Fig. 3. An example of GT Analyzer interface from DS1 for "drawing a spiral" task (top graphics of subject ID 6 diagnosed with Parkinson's disease and bottom graphics of healthy subject ID 26)

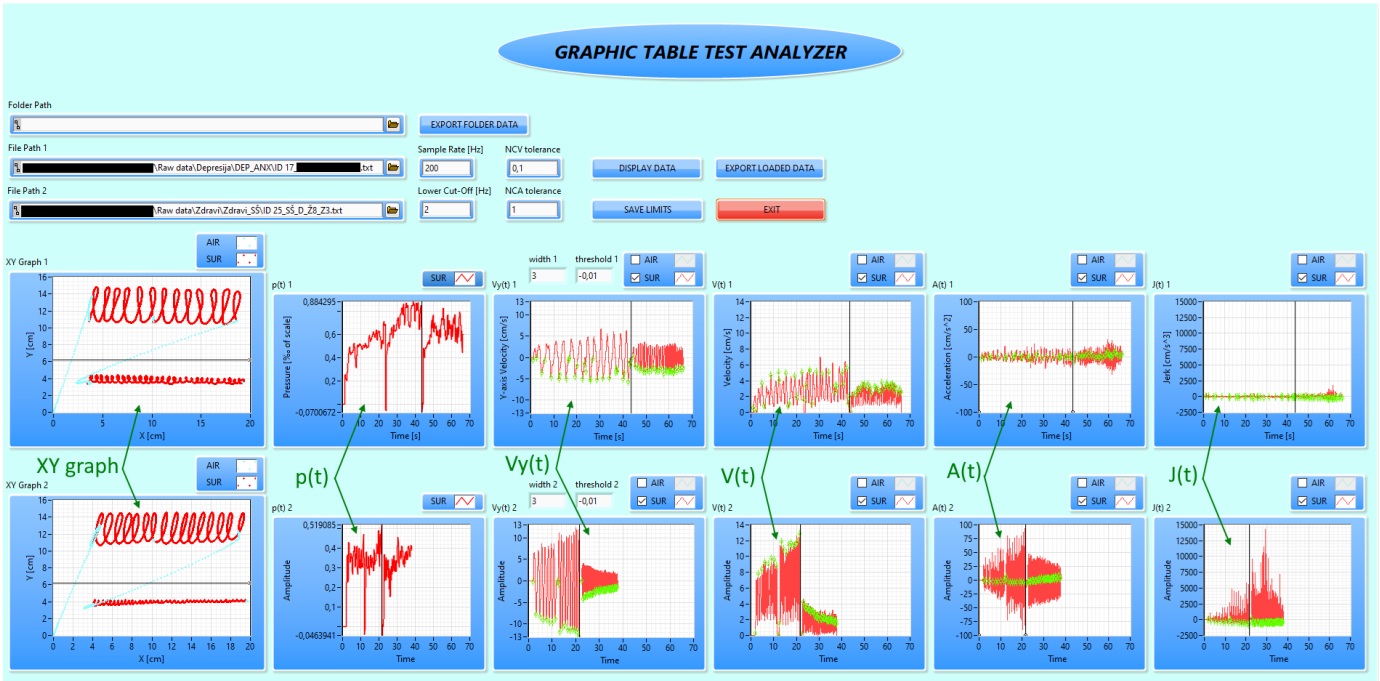

Fig. 4. An example of GT Analyzer interface from DS2 for writing two figures: the cursive letter "l" in 1) large rectangle and 2) small rectangle (top graphics of subject ID 17 diagnosed with major depressive disorder and bottom graphics of healthy subject ID 25)

III. Results

Two examples of the GT Analyzer interface after loading selected subjects from DS1 and DS2 (see *Section II D. Dataset description*) are presented in Fig. 3 and Fig. 4, respectively

In Fig. 3, it is evident that the subject with Parkinson's disease needs more time to finish a task and that he had trouble at the beginning of the task, where fine movements are hampered due to micrographia seen in Parkinson's disease This resulted in a significant increase in local minimums of V_y. Both facts are expected from patients with Parkinson's disease [11].

In Fig. 4, there is a similarity in pressure graphs for the patient with depression and the healthy subject. Both subjects

 ISBN 978-86-7466-930-3

took a break in a similar place while writing the first part of the task (cursive letter "l" in a large rectangle), which is represented as a pressure drop. That is also evident on the XY graph where the blue line presents in-air movement. One of the main kinematic descriptors of depression, psychomotor slowing/retardation, is more pronounced with larger scale movements. That is why a drop in speed amplitude and a significant increase in writing duration are evident in the subject with depression while writing the first part of the task [12].

IV. Conclusion

In this paper, a novel application for visual analysis of handwriting (drawing) tasks is presented. This user-friendly, open-source, clinically validated interface with implemented all standard kinematic features for handwriting analysis has the potential of helping users visually determine differences between healthy and diseased subjects. Furthermore, it can export the conventional kinematic features that can be used later in statistical analysis or classification procedures. The developed analysis software could be integrated with the previously developed data acquisition *LabHand* [10] software as a unique package for the overall handwriting data acquisition, analysis and kinematic feature extraction.

Future work will be focused on greater flexibility and compatibility of the application, as well as on defining and adding new features that will be used for an automatic distinction between different subject groups, including patients with different neurological or psychiatric disorders.

Acknowledgment

The research was supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia (contract 451-03-68/2022-14/200103).

Morphological parameters assessment with a depth camera based measurement system

Olivera Tomašević, Luka Mejić, Darko Stanišić, Nikolina Maravić

***Abstract*—Lately, depth cameras are being widely used for computer vision applications such as human pose estimation, activity recognition, object and people tracking, 3D mapping and localization. Possibilities for depth sensing integration in economy sectors like agriculture and healthcare services are growing as researchers are stating numerous advantages in contactless measurements done by robust low-cost depth camera systems. In this paper, we discuss an application of two different depth-sensing technologies for morphological parameters assessment.**

***Index Terms*— Morphological parameters, active depth-sensing technology, Intel RealSense.**

I. INTRODUCTION

Since computer vision has largely been concerned with obtaining 3D information from 2D images, the invention of low-cost commercial depth sensing cameras made a significant contribution to solving computer vision problems. Derived 3D depth map allowed segmentation of the scene into foreground and background, which facilitated identification and tracking of simple objects. This opened new opportunities for many practical computer vision applications such as human pose estimation [1], activity recognition [2], object and people tracking [3], 3D mapping and localization [4].

Depth maps and resulting 3D reconstructions of objects acquired in real time also enabled non-contact measurement of objects' morphological properties. Researchers have been assessing objects' static properties such as size [5] and volume [6], and dynamic such as breathing patterns [7] in conditions of clinical interest. With this application, depth sensing is likely to gain significant role in economic sectors such as agriculture and healthcare services, but also in industrial and clothing design, and ergonomics.

Namely, in [8] it was concluded that when it came to body measurement, depth camera acquired results close to real data, and as a more affordable method, it could be an appropriate alternative to high cost laser scanner. In similar fashion, in [9] the depth camera based body measurement was shown to be an efficient approach for anthropometric data collection, and in [10] it was demonstrated that low-cost depth camera based system could be used for rapid and robust tracking of body shapes and anthropometric changes in children.

Contactless measurement of body size and volume has also been described as an innovative tool for making management decisions for livestock. In [11], the authors demonstrated an accurate body measurement system based on Microsoft Kinect v2 camera, which was applied to livestock. They successfully validated the quality of generated model against manually measured body references such as height, depth, length, and girth of certain body parts. Similarly, in [12], the authors presented the measurement of body parameters such as linear and integral characteristics along directional lines and local areas, geodesic distances and perimeters of cross sections. While in [13], the measurement system was also based on Microsoft Kinect sensor, the aim was the livestock's growth assessment through the repetitive analysis of 3D models of their certain body portions.

In a similar manner, and in order to optimize the harvesting by the growth state and crop yield assessment, researchers have been measuring structural parameters of fruits and vegetables. For instance, from the segmented lettuce point clouds in [14], they extracted the volume, surface area, leaf cover area, height predictors, and correlated them to the fresh weight. Analysis showed that the calculated surface areas correlated strongly with measured fresh weight. With the similar aim, in [15] the authors used a Microsoft Kinect sensor and reported that accuracy of the 3D models of cauliflower crops deviated from the ground truth measures by less than 2 cm in diameter/height, while the fruit volume estimation showed an error below 0.6% overestimation.

When it comes to expected measurement accuracy, it immensely depends on the choice of depth-sensing technology and application context, particularly lighting conditions and working distance. Namely, depth-sensing technology has been developing for many years in several different forms. Stereo [16] may be the most basic approach for acquiring 3D depth maps. It is a "passive" depth sensing method that uses two or more standard RGB cameras, and calculates depth by finding correspondences between image points. In contrary, "active" [17] approaches use their own light sources, and can potentially overcome the limitations of passive stereo, such as large textureless surfaces and low light levels.

As revised in [18], on the market there are several representatives of state-of-the-art active depth-sensing solutions. Intel RealSense product line is one of them. It supports active depth-sensing technologies that marked the last decade: structured (coded) light (SL), active IR stereo (AIRS), and time-of-flight (TOF). In this paper, we discuss the measurement of morphological parameters using two

 ISBN 978-86-7466-930-3

different Intel RealSense solutions, which we find suitable for close range applications.

The paper is organized as follows. First, we describe the acquisition system and software, then we look at the expected accuracy depending on the chosen device, and in the end, we propose methods for morphological parameters assessment based on a point cloud data.

II. THE METHOD

A. Acquisition system

Namely, Intel RealSense has produced depth cameras through three different series: SR300, D400, and L500. Each series represents a distinct depth sensing technology. What separates them is their ideal operating parameters, along with differences in how accurate the depth information is in different situations [19]. As SR300 and D400 series allow measurements of similar distance ranges, we opted to incorporate a representative of each in our acquisition system, independently.

SR305 camera is Intel RealSense's only representative of SR300 series [20], and thus it's only representative of structured light technology. The camera uses patterned light to determine depth within the scene, thus it is ideal for use in indoor, controlled lighting situations. It is also intended for very short-range applications under one meter, but its operating range goes even up to 2m. It utilizes rolling shutter technology, has a field of view (FOV) of 71.5° x 55° and will provide up to 640×480 resolution depth images at 60 fps.

D435i camera is one of Intel RealSense's representatives that belong to D400 series [21]. It is based on active IR stereo, which uses stereo vision to calculate depth, but also projects an invisible infrared pattern to improve depth accuracy in scenes with low texture. Taken that it is based on stereovision, it is expected to perform equally well in both indoor and outdoor environments. It has an ideal operating range of 0.3m to 3m. It utilizes global shutter technology, has a wide field of view of 85.2° x 58°, and provides up to 1280 x 720 resolution depth images at 90 fps. Since depth camera D435 is another representative in the series that only differs in IMU presence, in the following text we will use the term D435, as equally.

For the purposes of visualization, Intel has developed specialized tools such as Intel RealSense Viewer and Intel RealSense Depth Quality Tool, but has also developed an open source SDK [22] that supports various platforms and programming languages, thus enabling us to build applications for data acquisition and processing adapted to our needs.

B. Acquisition software

Software for data acquisition on PC is written in Matlab (ver. R2021a, MathWorks, USA). It allows acquisition parameters setting, acquisition and processing, and visualization.

Acquisition parameters refer to stream configuration and depth property settings. These parameters are supported by the SDK library, which allows the configuration of the camera with a number of internal settings.

Stream configuration implies settings like stream type, stream format, stream resolution, and sampling frequency. Stream types refer to different types of data provided by RealSense devices. In order to get point cloud that contains RGB information for every data point, our software allowed acquisition of both, depth frame, i.e. data from depth sensor, and color frame, i.e. image from embedded RGB camera. These were thereafter aligned in order to get final point cloud representation of the scene. Available stream format, which identified binary data encoding within a frame, was set to a predefined value, which depended on a type of a stream.

Sampling frequency can take several different predefined values. In cases of dynamic parameter assessment, the sampling frequency value also determined the time resolution of dynamic morphological parameters. Thus, in cases when official documentation did not recommend any value that would ensure good quality depth, we set the highest possible value that still allowed depth and RGB frame alignment. The same applied to stream resolution parameters.

In order to get good quality depth data, we set specific values to a combination of depth property parameters such as depth projector power, accuracy, filter option and depth preset setting. The values were set specifically to achieve as better depth accuracy as possible.

Depth preset setting is a working mode that implies predefined settings for all the depth property parameters that official documentation offers as optimal for certain conditions. Considering that we were after high accuracy mode, if it was supported for given device, we opted for high accuracy preset.

In case of SR305 device, depth accuracy was set through the depth property parameter of the same name, which defined the number of patterns projected per frame. In case of D435 device, high depth accuracy was achieved through the high accuracy preset, which set high confidence threshold value of depth.

Intel SDK library includes post-processing filters to enhance the quality of depth data and reduce noise levels. When done in real time, it negatively affects the temporal resolution of the acquired frames, which should be taken in consideration when assessing dynamic parameters of an object.

As recommended in [23], images acquired with SR305 camera were filtered with default depth filter, which had moderate smoothing effects.

C. Expected accuracy

As said before, expected measurement accuracy immensely depends on application context, particularly lighting conditions and working distance. However, even when these conditions are met in accordance to camera specifications, 3D reconstructed model is still very likely to contain inaccurate, i.e. dimensions that differ from ground truth.

Depth error of SR305 camera is described in [23]. The systematic distance inhomogeneity in case of this camera brings two main systematic error components increasing with distance: non-planarity and depth offset. Non planarity can be explained through error map between the target plane and multiple point clouds acquired with increasing distance from the plane itself, while depth offset can be approximated by a parabolic function with a high coefficient of determination. For instance, for distance of 65 cm, depth offset is somewhat larger than 12 mm.

The error inherent in SR305 camera acquisition is perhaps best portrayed through evaluation of the error introduced in

 ISBN 978-86-7466-930-3

measuring a flat surface that compares SR305 camera model with D415 camera model from D400 series. The comparison can be found in [24]. Namely, D415 has a considerably lower error both in terms of planarity and of distance accuracy.

D435 camera is, on the other hand, a lot more similar to D415 camera - they use the same vision processor to provide RGB-D data. The main difference lays in depth quality, which is usually portrayed through RMS error - the depth noise for a localized plane fit to the depth value. Comparison between the two models can be found in [25]. Namely, the depth RMS error scales as the square of the distance away from the camera, in both cases. However, due to the wider FOV, the smaller baseline, and the smaller sensor resolution, the D435 has more depth noise at any given range. At the same time, this model benefits from having smaller minimum operation distance, which allows acquisition at shorter distances, and global, as opposed to rolling, shutter sensor, so is expected to be more accurate when dealing with dynamic scenes.

D. Data acquisition and processing

The acquisition was performed indoors under artificial lighting conditions. Chosen camera was fixed at a distance of about 50 cm from the horizontal table top on which objects of interest were placed. It was taken into account that placed object should be in the camera's field of view and that all its interest points should also be within the recommended range of distances for a given camera type.

In the case of SR305 camera, RGB-D images were acquired in resolution of 640x480, and with sampling frequency of 60 Hz, and in the case of D435, they were acquired in resolution of 848x480, and with sampling frequency of 30 Hz. Upon the start of acquisition, the first couple of frames were discarded to allow the camera time to settle.

The steps we found useful in the process of parameters extraction were the following:

- points selection within a region of interest in the point cloud so as to lower the computational recources needed for further processing steps
- potential selection of markers that would be used for parameter assessment
- potential rigid transformations so as to align the direction of markers propagation with a certain axes of the camera local coordinate system
- potential plane fitting through the table surface so as to assess camera tilt relative to the table, and perform appropriate tilt correction through rigid transformations
- calculation of the distance between markers based on Euclidean distances between the each two nearest adjacent points
- calculation of surface area in a region of interest based on Delaunay triangulation [26] of point cloud data
- extraction of cross sections defined by the markers trajectory
- calculation of the cross-section area
- in the cases of dynamic parameters assesment, tracking of marker koordinates over succesive frames

III. RESULTS

The point cloud acquisition and calculation of morphological parameters is demonstrated on the cropped RGB-D image of a human body torso. Fig. 1 contains RGB-D image acquired with SR305 (on the left), and with D435 camera (on the right), respectively.

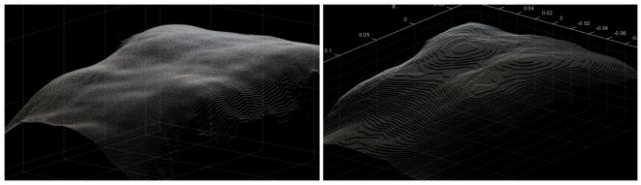

Fig. 1. Cropped RGB-D image of a human body torso captured with SR305 (on the left) and D435 (on the right).

In the case of D435, different levels of depth values are obvious. More specifically, we acquired depth maps with resolution of 1mm, which is a default depth unit of underlying vision processor. In the case of SR305, depth unit is a lot smaller (0.000125 m), thus its depth resolution is higher, as can also be noted in the figure. Other than on visual representation, these differences did not have any significant affect on parameters assessment methods. They are processed in the same manner, and results are stated in the following figures.

Fig. 2 contains example of static morphological parameters derivation based on trajectories in certain directions. Resulting cross-sections are visible in the point cloud (on the left), and isolated so that their length could be assessed (on the right). Top row refers to measurements based on SR305 camera, while bottom row refers to D435 camera. As previously stated, the cross-section lengths were estimated by the calculation of Euclidian distances between the each two nearest adjacent points.

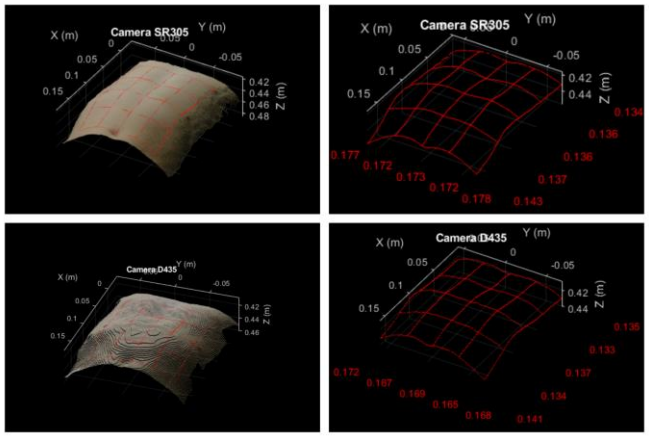

Fig. 2. Static morphological parameters derivation: cross-sections marked in a point cloud (on the left), and extracted cross-sections (on the right) along with their calculated dimensions.

Due to the anatomical planes in which they are located, these cross-sections are referred to as transverse and sagittal cross-sections, respectively. They depended on the marker positions, which were set on nipples and navel, by the user selection. Transverse cross-sections were defined based on direction on which the nipples were lying, and they were equidistantly distributed between the level of the nipples and level of the navel. Sagittal cross-sections were perpendicular with respect to them. The outermost positions of the sagittal cross-sections were left and right nipple location, respectively.

 ISBN 978-86-7466-930-3

These measurements were rounded to a precision of 1 mm. As can be seen on Fig. 2, there are certain differences in the cross-section length measurements that depend on the used camera. They are most prominent in sagittal sections and amount the most in the case of difference of 10 mm in favor of SR305 camera for the outermost left sagittal cross-section (from the perspective of the respondent). We assume that significant part of this difference lays in depth-offset error of camera SR305, which reportedly [23] takes out around 4 mm for the object distance of 400 mm, and 5.433 mm for the object distance of 450 mm.

Extracted cross-sections and their dimensions may indicate local torso characteristics. On the other hand, the object, the torso in this case could also be described globally by parameters such as surface area and volume. An example of surface area calculation is given in Fig. 3. Figure represents marked surface in the region of interest defined by the same markers that defined cross-sections: locations of nipples and navel. The area was estimated on tridimensional polygon mesh generated with Delaunay triangulation applied to the point cloud data illustrated in Fig 4. The resulting surface area is calculated upon all the areas of triangles at the base of the resulting mesh.

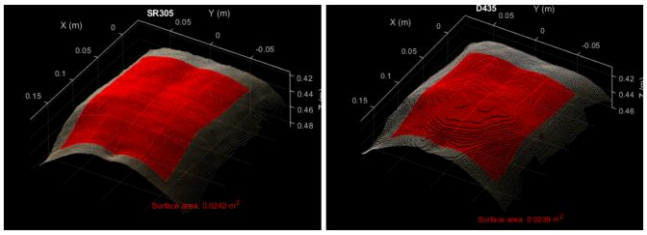

Fig. 3. Static morphological parameters derivation: marked surface in the region of interest – SR305 image (on the left), and D435 image (on the right) along with their respective results.

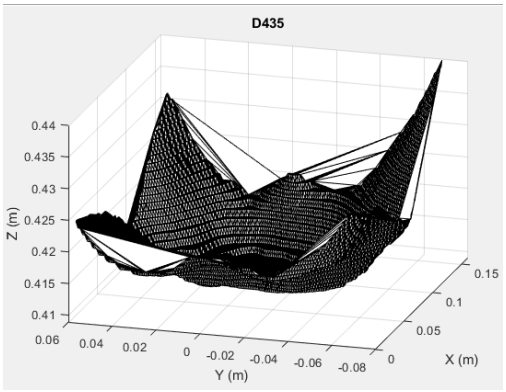

Fig. 4. Tridimensional polygon mesh calculated on the point cloud region of interest. This specific example refers to RGB-D image acquired with camera D435.

As Fig. 3 indicates, the image from SR305 camera resulted in slightly higher value of surface area parameter – 0.0242 m^2 as opposed to 0.0239 m^2 that resulted from D435 acquisition. This is in accordance with the conclusion regarding the length of the cross-sections acquired with these cameras.

Considering that demonstrated parameters can directly allow estimating of the dimensions of either torso or its parts, non-contact measurements of this type could have a purpose in clinical practice.

IV. Discussion

Results above show that visual representation of the scene did not vary significantly depending on the used camera. However, there are certain differences in their performance. Namely, results confirm the higher resolution of camera SR305 compared to D435 model (see Fig. 1). Considering that SR305 is capable of detecting depth with a higher resolution than D435, if the morphological characterization of fine details within small samples was at task, it could be expected that SR305 would be able to better reconstruct the object model, and thus would allow drawing contours that might not be visible in the acquisition with D435 camera.

On the other hand, SR305 has non-planarity and depth offset issues that contraindicate its use in precise measurement systems. As previously stated, in terms of planarity and distance accuracy, SR305 is outperformed by D400 series representatives.

When it comes to D400 series, D415 has more precision than D435. This regularity is accounted to the larger field of view of D435 camera. However, considering that D435 is better suited for dynamic scenes than D415, it could be expected that both these representatives of D400 be equally used in applications concerning morphological parameters assessment.

V. Conclusion

The aim of this study was to demonstrate derivation of morphological parameters with different depth sensing technologies. We discussed acquisition parameters that would allow good depth in static, as well as in dynamic scenes, and gave an example of static parameters calculation that could have a purpose in clinical practice.

As we discussed two different acquisition systems, we can conclude that for this type of application, one should use D400, rather than SR300 series, as it is more likely to provide sufficiently reliable measurements for the task at hand.

Overview of measuring methods and equipment for calibration of instrument transformers

Dragana Naumović-Vuković, *Member, IEEE*

***Abstract*— Instrument transformers are an important and inevitable element of AC current and voltage measurement techniques. They have been in use for more than a century. In parallel with the development of technical characteristics and improvement of instrument transformers measurements, the measurement methods and measuring equipment developed too. The significant parts of the development in this field are measuring methods, measuring devices, and systems for testing the accuracy of measuring transformers. The measurement accuracy is the most important characteristic of instrument transformers since that is the important factor in the accurate billing of electricity. The tradition in the field of testing instrument transformer's accuracy at the Electrical Engineering Institute Nikola Tesla is more than 60 years long. From the very beginning, the experts of the Institute have been active participants in the development of this field, both domestically and internationally. They have contributed to the development of measuring systems and standards for testing and calibration of instrument transformers, which have found application in laboratory calibration of the national metrology laboratories, as well as in industry. This paper provides an overview of the development of measuring methods for testing and calibration of instrument transformers, as well as a wide range of measuring devices and standards based on different measuring methods. The concrete application of measuring methods in the field of calibration in national institutes of metrology and research metrological laboratories is presented. The paper also presents the application of different measuring devices and systems in the industry, for intermediate and final control of measuring transformers as products in the instrument transformer manufacturers. A special review in this paper is dedicated to the contribution of the experts of the Electrical Engineering Institute Nikola Tesla in this field.**

***Index Terms*—Instrument transformers, accuracy, measuring methods, calibration, standard transformers**

I. INTRODUCTION

Instrument transformers are unavoidable elements in the electric circuits and systems for measuring alternating voltage, current, power and energy. Their role is to adjust (transform) the real values of voltage and current (voltages of several hundred and thousands of volts and currents of several hundred to thousands of amperes) to the appropriate optimal levels of measuring, control and protection systems. Furthermore, galvanic separation of the working energy system from the metering and protection system achieves by them.

Dragana Naumović-Vuković is with the Electrical Engineering Institute Nikola Tesla, University of Belgrade, Koste Glavinića 8a, 11000 Belgrade Serbia (e-mail: dragananv@ieent.org), (https://orcid.org/0000-0002-8334-4452).

The electric voltage, current, power and energy measurement, as well as regulation and protection in power facilities, cannot be imagined without the use of instrument transformers.

According to their purpose instrument transformers are divided in two main groups: measuring instrument transformers and protective instrument transformers. In this paper emphasis is on instrument transformers for a measuring purpose.

Their role in the billing metering of electricity is especially important, where the overall accuracy of energy measurement directly depends on the accuracy of measuring transformers [1]. In the production - transmission - distribution chain, electricity is measured at least three times. Therefore, it is also financial interest, especially in the conditions of a deregulated market, to measure energy with the least possible error. Consequently, measuring transformers as well as electricity meters belong to legal metrology. Legal metrology regulations and domestic and international standards precisely define the conditions of application, calibration, as well as the deadlines for periodic review of these types of measuring instruments [2, 3, 4, 5, 6, 7].

The main direction of development of measuring transformers, in addition to improving their reliability, is to reduce the error of transformation of primary quantities into secondary ones. Improving the accuracy of instrument transformers is conditioned by the development of measuring methods and devices for measuring and determining its errors. Historically, the subject of measuring transformers dates back to the beginning of the twentieth century [8, 9]. The development of measuring methods and devices for errors measurement of measuring transformers depended primarily on the technical and technological capabilities of the time in which it took place. Consequently, the first methods and devices were based on a square electrometer [10, 11]. Modern devices have been developed on the most modern microprocessor technologies and virtual instrumentation [12, 13, 14, 15, 16].

The EEINT has the international reputation in the development and application of devices and systems for accuracy testing of instrument transformers for more than 60 years. Devices for accuracy testing of measuring transformers based on different measuring methods, developed at the EEINT, have been used in all manufactories for instrument transformers in the former Yugoslavia, as well as in many other testing laboratories of distribution companies and transmission networks. These devices have shown a number of advantages over other solutions, especially in the on-site

 ISBN 978-86-7466-930-3

testing of measuring transformers, in factory serial quality control, as well as the most accurate measurements [17, 18].

New generations of devices for accuracy testing of the instrument transformers, developed at the EEINT in the last ten years, have been used at the folloving manufacturers: MINEL -FEPO Zrenjanin (Serbia), FMT - Factory of instrument transformers Zajecar (Serbia), "Energoinvest" (Bosnia and Hercegovina), EMO-Ohrid (Macedonia), Končar – Instrument Transformers (Croatia), MBS - Instrument transformers (Germany). In the EEINT special attention is paid to the development of measuring devices for application in the most accurate measurement in this field. Such measuring systems have been developed and made for the National Research Council of Canada (NRC) and the Hydro Qebek High Voltage Testing Laboratory, also in Canada.

II. COMPLEX ERROR

Electric voltage and current are vector quantities. Therefore, their complex transformation error is defined by ratio (amplitude) error and phase displacement. Like any measurement transformation, this one is also followed by certain errors. In a case of vector quantities, discrepancy from the ideal transformation is characterized by a complex error G. The complex error of measuring current and voltage transformers is defined as the fundamental harmonic of current, i.e., voltage. The complex error includes the ratio (amplitude) error, g, and the phase displacement, δ, expressed in mathematical form:

$$\underline{G} = g + j\delta \tag{1}$$

Ratio error of current transformer g in %, in accordance to standard [4] is defined as:

$$g = \frac{K_N \cdot I'' - I'}{I'} \cdot 100 \tag{2}$$

where K_N is the rated transformation ratio.

The phase displacement δ in min (1%=34.4min=1crad), is defined as the phase shift of the secondary current I'' in relation to the primary current I' [4].

The ratio error and phase displacement of the current transformer are defined by its:

- constructive and technological parameters: material, shape and dimensions of the magnetic circuit, number of ampere-turns, length and cross-section of the wire, geometry of the primary and secondary winding;
- operating parameters: secondary load, ratio of measured current to rated, frequency, distortion and shape of measured primary current;
- ambient conditions: temperature and pressure.

The ratio error of voltage transformer g in (%), in accordance to standard [5] is defined as:

$$g = \frac{K_N \cdot U'' - U'}{U'} \cdot 100 \tag{2}$$

where K_N is rated transformation ratio

The phase displacement δ in (min), of voltage transformers is defined as the phase shift of the secondary voltage U'' in relation to the primary voltage U'. The ratio error and phase displacement of the voltage transformer are also defined by its constructive, technological, operating parameters and ambient condition.

The main difference between current and voltage transformers is that the initial design parameter in current transformers is the magnetic excitation force, while in voltage transformers this is the magnetic induction. However, in the constructive, technological and physical sense, there are significant differences between current and voltage transformers, which results from different operating modes. The current transformer operates in the short-circuit mode, and the voltage transformer in the idling mode.

The functional connections between parameters and ratio error and phase displacement are known. Therefore, it is possible to analytically calculate their values for a given current or voltage transformer, which is usually done during design.

The main parameters in designing current and voltage transformers as well as in declaring their errors (accuracy classes) are secondary burden and reference currents and voltages. The limits of errors for declared classes by standard, for current measuring transformers are defined in accordance to percentage of rated currents (i.e., reference currents) and for secondary burden between ¼ and rated value [4]. In the same way, the limits of errors for declared classes for voltage measuring transformers are defined in accordance to percentage of rated voltage (i.e., reference voltage) and also for secondary burden between ¼ and rated value [5]. This method of errors declaring corresponds to their nonlinear character. The accuracy class of measuring transformer directly affects its application.

However, the true (more accurate) error values are obtained only by measuring the accuracy of the measuring transformer.

III. THE MEASURING METHODS AND DEVICES FOR ACCURACY TESTING

From the early beginning of the application of measuring transformers, back in 1892, [19], there was a need for their accuracy testing. The errors of these first current transformers were in the order of about 3% for ratio error and approximately 200 minutes for phase displacement [8]. In that time, these errors had been determined by direct measurement of primary and secondary currents and phase shift. In addition to the error of the measurement method, limitations have also appeared in the application of analog measuring instruments [20]. For example, the limits of current measurement with analog measuring instruments were 200A. Appropriate shunts and pre-resistors were used for currents higher than this value.

With the rapid technological development, the applications

 ISBN 978-86-7466-930-3

of precise standard measuring transformers [21] have begun. With the progress in the production and application of new magnetic materials, in the thirties of the last century, the errors of measuring transformers have been reduced to 0.1% and 5min [22].

A. *Classical methods and devices for accuracy testing of instrument transformers*

The first methods for accuracy testing of instrument transformers appeared at the beginning of the last century [23, 24, 25]. The most important methods, whose influences extend to the present days, are compensation, differential and current comparator methods.

The compensation method, Fig 1, is basically a direct comparison of two alternating voltages generated on precision reference shunts (for current transformer testing) or voltage dividers (for voltage transformers testing), one in the primary circuits and the other in the secondary circuits of the transformer under test, (T_X).

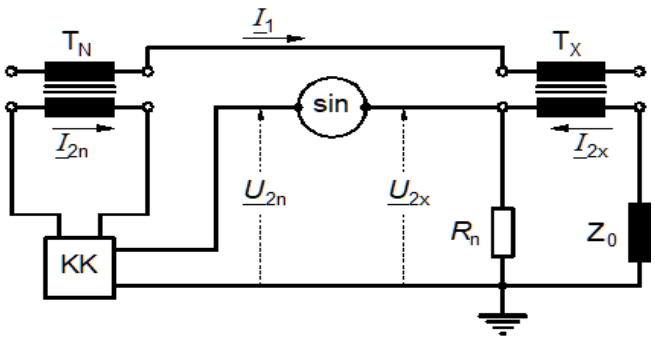

Fig.1. Compensation method for current transformer accuracy testing [17].

The compensating method was usually used in laboratory testing. The main reason for that is demand for satisfactory high accuracy of the elements that is incorporated in complex compensator (precise resistors and voltage dividers), and that are also temperature and time stable. In addition, there is also a problem of additional load in secondary circuits of transformer under test that is not negligible. The main advantage of this method is the ability to accuracy testing of the instrument transformers of non-standard transformation ratio.

The differential method is attributed to F. B. Silsbee and is related to 1917 [23]. This method was perfected by Hole (W. Hohle) in 1934 [26]. The essence of this method, Fig. 2, is to measure the differences between two quantities. In this method the secondary voltages (or currents) of the device under test (current or voltage transformer), (T_X) and of the standard transformer (T_N) of approximately equal transformation ratios are compared. In order to achieve comparison as accurate as possible, the standard current transformer should have a negligibly error.

The basic elements of the devices for accuracy testing based on differential and compensational methods are complex compensator (KK) and selective zero indicator (SIN), Fig. 1, and Fog. 2.

Around 1930, measuring devices based on the compensation method and the complex compensator [27, 28] appeared. The best accuracy of such early commercial devices was about 0.02% and 2 min. There are many solutions of complex compensators, but from the point of view of accuracy testing of instrument transformers, the most significant is certainly the work of scientists Schering and Alberti [24].

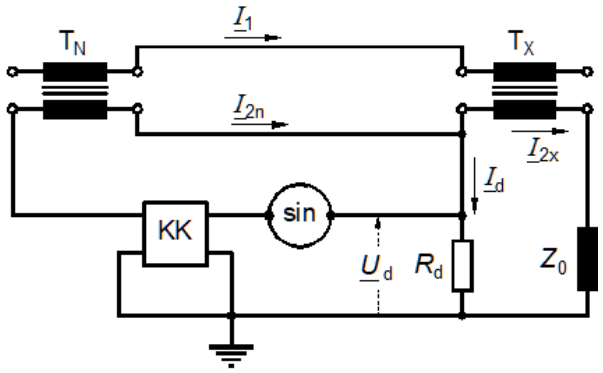

Fig.2. Differential method for current transformer accuracy testing [17].

Measuring device, so-called Hole's compensator based on differential method has also found wide practical application [29].

With the selective zero indicator, the equality of two voltages is determined at a certain (basic) frequency. This implies two requirements: indicator should be sufficiently sensitive to the basic measured voltage and also insensitive to parasitic (disturbing) voltages as well as to higher harmonics of the measured voltage. Two types of selective zero indicators have been used: a classic solution with a vibrating galvanometer and an electronic zero indicator.

Technological improvements and modifications of this compensator and selective indicators, made in the 1930s, especially in the late 1960s, made these instruments indispensable in the laboratories for testing and calibration of measuring transformers, for a long time during the last century.

The third, important measuring method that has remained until today is based on the application of a current comparator. The idea of the current comparator was first presented in 1917 by the American physicist Baker [25]. He suggested measurement of the difference between the two currents by using windings on a magnetic core. The current comparator with a compensating winding was first used in 1930 by the English scientist Bruges [30], and the German physicist Reihe used it as a test device for the accuracy testing of current transformers [31]. This, therefore, long-known but, then technically and technologically imperfect method, experienced its reaffirmation in several metrological laboratories in the 1950s. The current comparator was first used in the comparison of alternating currents, and later for accurate measurement of resistance, capacity, etc. The

 ISBN 978-86-7466-930-3

Electrical Engineering Institute Nikola Tesla (EEINT), mostly thanks to Ilija Obradovic, Petar Miljanic and Srdjan Spiridonovic, is the pioneers in this field. The first device for measuring the accuracy of current transformers is being realized then. This work, which have been continued to these days, is marked by a series of successful results and articles The very name "current comparator", today is internationally accepted technical term, first appeared in the works of experts from the EEINT [32].

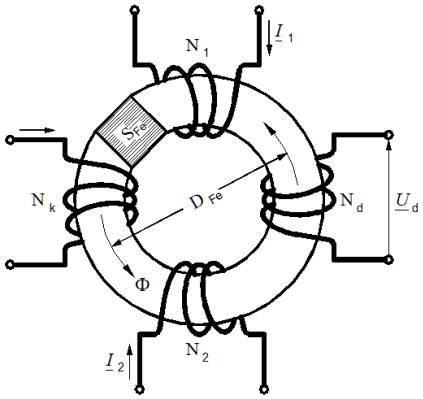

Fig.3. A simplified scheme of current comparator [35].

Significant progress in the construction and manufacture of current comparators has been achieved through the joint work of associates of the Canadian NRC (National Research Council) and the EEINT [33].

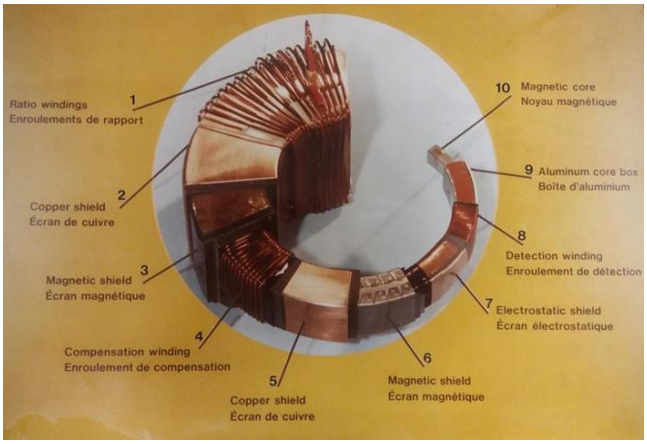

Fig.4 The structure of current comparator [17].

An ideal transformer is a transformer for which the equality of magnetomotive force applies [33]. In reality, a part of the primary magnetomotive force is spent on magnetizing of the core and losses in it. This is the main reason for the error of the current measuring transformer. If the magnetic flux in the core is artificially reduced to zero, then the current transformer becomes ideal. In that way the comparison of the currents reduces to the turn ratio of primary and secondary windings. This ratio is stable during the time and insensitive by temperature changes. This gives the possibility of a very accurate comparison of two alternating currents, which is the basic idea of the current comparator [34].

Fig. 3 shows simplified scheme of a current comparator. To measure the magnetic flux in the core of the current comparator, the detection coil N_d is used, and compensating coil N_k brings the magnetic flux to zero [35]. Practical realization of current comparator is more complex as shown in Fig. 4.

With carefully construction and realization of current comparators, it is possible to achieve its ratio error within the range from 10^{-6} to 10^{-7}, and the phase displacement in the order of 0.01 min.

B. The recent methods and devices for accuracy testing of instrument transformers

In the last years of the 20th century, with the application of modern electronic solutions and microcomputer techniques, measuring methods and devices for accuracy testing of instrument transformers have been significantly improved [36, 37]. Possibilities and advantages of PC hardware and software support are not only in the field of increasing efficiency, or reliability of work, but also in increasing measurement accuracy. Modern devices are based on the general tendency in electronics that the processing of the measuring signal is realized in digital form. The differences between the individual solutions of these devices are most often in the way of further digital processing of measuring signals [17, 38, 39, 40, 41].

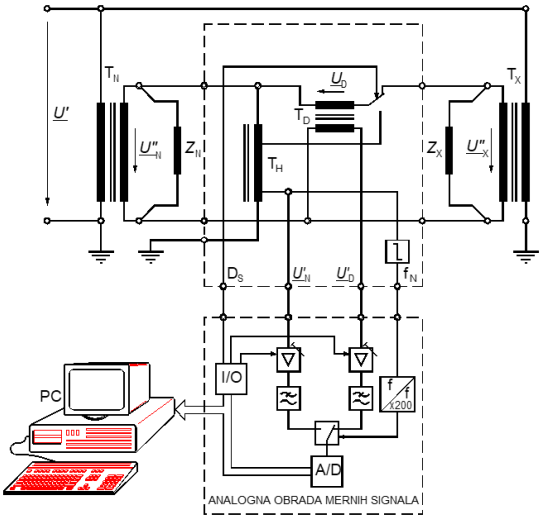

Fig. 5 The structure of DFT measuring method developed by PTB [46].

The application of the measuring method of discrete Fourier transformation (DFT) for the accuracy testing of measuring transformers originates from the laboratory for measuring transformers of the National Metrology Institute of Germany (PTB) which has a long tradition in the field of metrology, even from the early beginning in 1877 [42]. This laboratory has developed several important measuring devices for accuracy testing of the measuring transformers, known as: Schering-Alberti's [24], Hole's [26] and Keller's compensator [43]. PTB experts have significantly contributed to the development of measuring methods and measuring techniques

 ISBN 978-86-7466-930-3

in the field of measuring transformers. As a result of recent research in PTB, the method of discrete Fourier transform was applied, first for testing the accuracy of current measuring transformers [44], and later for testing voltage measuring transformers [45].

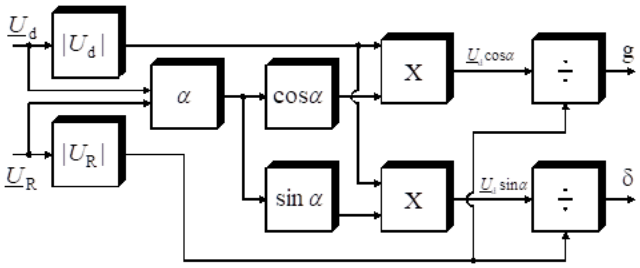

Fig. 6 The structure of measuring method based on orthogonal voltage components [48].

The structure of DFT measuring method developed by PTB experts is shown on Fig. 5 [46]. The device for accuracy testing of instrument transformers based this method, Fig. 5, have following characteristics: measurement range of ± 0,2 % and ± 2 % for ratio error, ± 0,2 crad and ± 2 crad for phase displacement; resolution of 0.000001%, accuracy ± 0,5 % of measuring value and ± 0,05 % of measuring range. This device was capable to measure in a full range from 1% to 200% of rated current, i.e., of rated voltage.

The structure of measuring method based on orthogonal voltage components is shown in Fig. 6

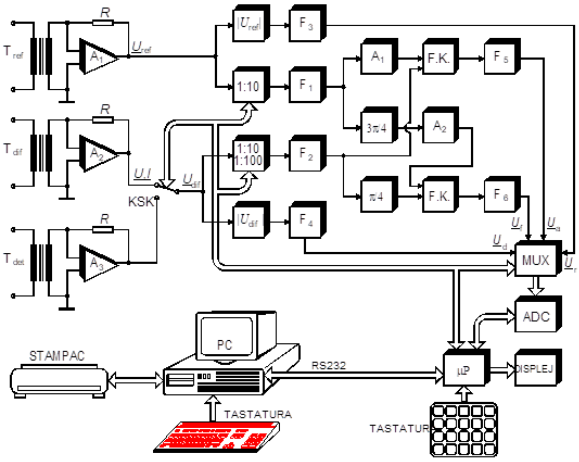

Fig. 7 Block scheme for device for instrument transformer accuracy testing, type INST-2A [47].

Basically, this is a differential method that enables measurement of fundamental harmonic of two voltages and its phase angle, but with some original solutions [47, 48]. The device based on this method is shown in Fig. 7. Novel solution of current-voltage transformer was applied for both differential and detection voltage, as well as for reference voltage. In this way, the adjustment of voltage measured signals to the optimal level was achieved, with minimal degradation of basic signals, and the conversion of current measuring signals into voltages. This initial level of analog processing of measuring signals is very important for the overall accuracy of the device. The second improvement is in electronic bloc that is applied phase regulated rectifier which makes phase shift between $\underline{U}_r$ and $\underline{U}_d$. The phase shift of π/2 by this phase rectifier is obtained as discrepancy between phase shift of 3π/4 for $\underline{U}_r$ and phase shift of 3π/4f or $\underline{U}_d$ [48]. Another recent improvement of differential measuring method is two phase conversion method [49]. The method is based on the measurement of phase angles between three relevant voltages, Fig. 8. The measured ratio error and phase displacement are than presented as a function of two angles. Structure scheme presented in Fig.8 consist of commercial dual channel power analyzer, electronic module and PC. The electronic module integrates: an amplifier, two summing circuits, circuits for π/2 phase shift and multiplexer. The input voltages U_R and U_d are subjected to relatively simple analog processing in the electronic module, and as such, are brought through multiplexer to a dual-channel power analyzer. The PC manages the operation of the electronic module and the dual power analyzer according to the given program [39, 49, 50].

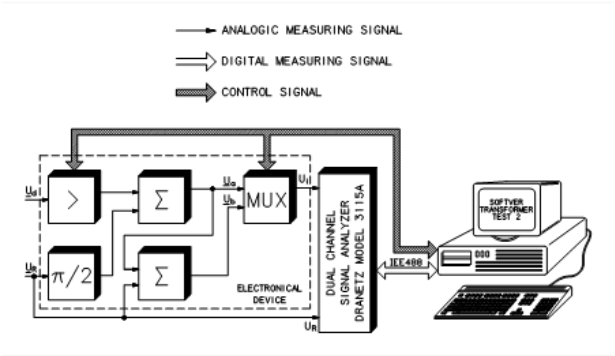

Fig. 8 The structure scheme of two phase conversion method realization [49]

IV. EEINT'S METHODS AND DEVICES

Measuring systems for accuracy testing instrument transformers based on measuring methods mentioned above usually consist of: standard current/voltage transformer, standard current/voltage burden, device for accuracy testing and measuring transformer under test.

In this field of measurement, methods that are used for testing and calibration purpose are basically the same. The difference is in the accuracy of the standard transformer and the device for accuracy testing which is applied [51].

The experts from EEINT continuously follow the development in this field. Devices for accuracy testing of instrument transformers based on different measuring methods as well as standard transformers developed at the EEINT, have been used for manufactory testing, on-site testing in the power and distribution facilities and for calibration in national metrology laboratories.

The first devices for current and voltage measuring transformer testing were developed in seventeens in last century, Fig. 9. These measuring systems are based on current

 ISBN 978-86-7466-930-3

comparator methods.

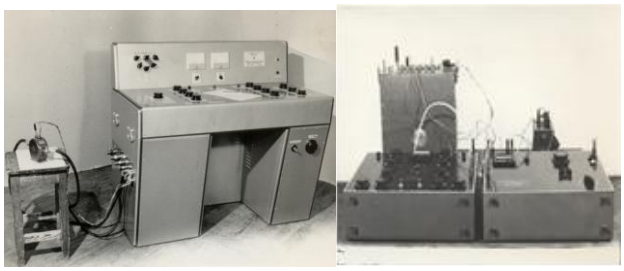

Fig. 9 Devices for current measuring transformer accuracy testing, type KSK-6 (1965) and KSK-7 (1968), respectively.

For accuracy testing of measuring voltage transformers EEINT experts developed measuring system type NIT-2p applied both for laboratory and on-site testing in distribution facilities, Fig 10. The system is based on classical differential method for accuracy testing of voltage transformers that assumed comparison between voltage transformer under test and standard voltage transformer. In that case transformer under test and standard transformer had to have the same transformation ratio.

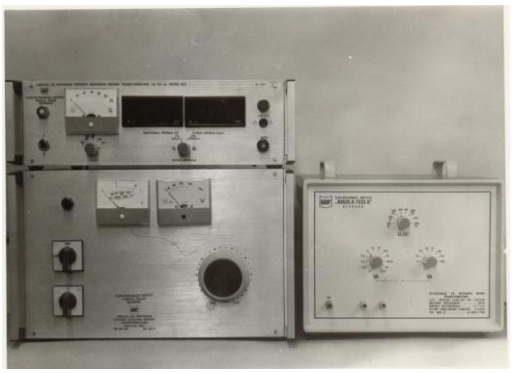

Fig. 10 System for voltage transformers accuracy testing, type NIT-2p (1981.)

With the development of instrument transformers industry in former Yugoslavia, the need for faster and more efficient routine accuracy testing appeared. This demand is satisfied with development of first automatic systems for accuracy testing of current transformers [52, 53], shown in Fig 11 and Fig 12.

Fig. 11 System for automatic accuracy testing of current measuring transformer, type ASK-1 [52]

Fig. 12 System for automatic accuracy testing of current measuring transformer, type ASK-2 [53]

Automatic systems for routine testing of measurement current transformers have been further developed together with new technological achievements. Together with ISKRA AMESI, Slovenia, in 2012, EEINT realized robotized system for routine testing of current transformer, Fig 13. Among the other routine tests according to standard [2], this system can perform accuracy testing of 7 current transformers synchronously. EEINT developed and manufacture the standard transformer, standard burden and device for accuracy testing based modified differential method and multiplexing concept [54].

Fig. 13 Robotized system for current transformers accuracy testing in MBS factory Germany (2012.) [54]

Three years later, for Instrument transformers factory FMT Zajecar, EEINT developed and made device for simultaneously testing of 3 current transformers [55], Fig. 14.

Fig. 14 Automatic device for accuracy testing of 3 current transformers simultaneously [55]

Based on the experience in the realization of different measuring devices in this field, in 2001, EEINT was designed and built a mobile laboratory for on-site accuracy testing of measuring transformers, Fig 15. This mobile laboratory was

 ISBN 978-86-7466-930-3

used by "Elektrostopanstvo", Macedoni, for accuracy testing of measuring transformers in the distribution facilities [56].

Fig. 15 Mobile laboratory for accuracy testing of measuring transformers [56]

Experts from EEINT have made a special contribution to the development of standards and high-precision devices for use in national metrology laboratories. Standard current transformer with electronic compensation of errors type EST-3000 [57] was designed and made together with device for measuring transformers accuracy testing, type INST-2A [47] for Directorate for Measures and Precious Metals (DMDM). This system represents the national standard of Serbia in the field of measuring transformers.

In period from 2016 to 2019 in EEINT three high accuracy systems developed for the needs of National metrology institutes of Canada (NRC) and Singapore (A*Star), as well as for laboratory of power transmission system of Quebec (Hydro Quebec), Canada. In these measuring systems, a differential method with a special construction of a standard transformer and measuring device was applied [58]. The high accuracy of the standard transformer was achieved by an unconventional two stage design. The transformer's detection core is made of high permeability magnetic material, whereas the working core is made of a standard magnetic material for current transformers. The primary and secondary windings are evenly wound around the cores and magnetically and electrostatically shielded. The compensation winding is not connected to the secondary winding but instead to a separate differential transformer winding. This way, the N_{sc} winding of the Ts transformer is not burdened with a voltage created by the full secondary current I_{ss} and the N_{ds} winding impedance, but with a significantly smaller voltage created by a small compensation current I_{sc} and the N_{dc} winding impedance, Fig 16. This makes the impedance seen by the N_{sc} winding smaller and the compensation much thus more effective. This improvement leads to at least two to three times lower measurement errors [58]. The system is verified by simultaneously comparison with NRC system for current transformer accuracy testing – national standard of Canada. The obtained discrepancies in ratio and phase errors were within a few μA/A or μrad, respectively. Practical realization of mentioned measuring system is shown in Fig. 17. The method of simultaneously comparison is developed and firstly applied at EEINT [59].

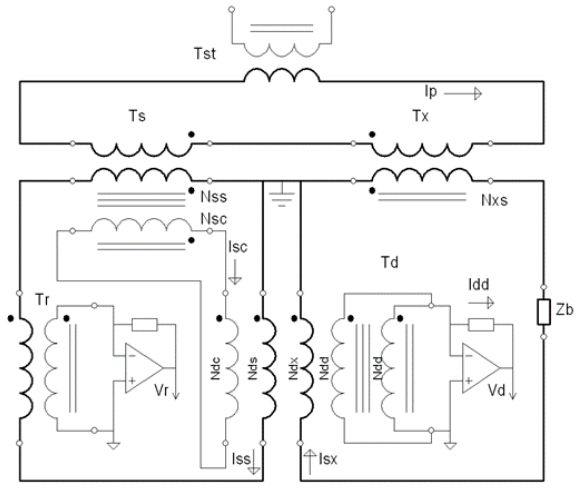

Fig. 16 Block diagram of the differential CT calibration system with special construction of two stage standard transformer T_s and differential T_d transformers [58]

V. NEW GENERATION OF MEASURING TRANSFORMERS

Digitalization of distribution and power facilities is the process that is part of much large movement, the Industrial Revolution 4.0 conventional transformers are no longer suitable for use in such systems. Therefore, new generations of current and voltage transformers and sensors have been developed that can be applied in digitized distribution and power facilities [60, 61, 62]. New types of measuring transformers and sensors require the development of new suitable measuring methods and devices for their testing. Some new proposals for accuracy testing of new generation of instrument transformers, so-cold low power instrument transformers are given in serial of EN/IEC standards [60]. It can be noted that these international standards recommend in the use of current comparators as a part of some proposed measuring systems for accuracy testing of low power instrument transformers.

Fig. 17 Practical realization of NRC measuring system for accuracy testing of current transformer

VI. CONCLUSION

The measurement accuracy is the most important characteristic of measuring transformers since that is the important factor in the accurate measurement of the high

 ISBN 978-86-7466-930-3

voltage and currents. The billing of electricity, as well as the power measurement at low power factors, is the explicit examples where accuracy of instrument transformers has very important role. The need for accurate measurement current and voltage by measuring transformers influenced both the improvement of their characteristics and the development of methods for determining their accuracy. The accuracy of measuring methods and measuring equipment for the accuracy testing of measuring transformers has improved along with technological progress.

This paper presents a historical overview of the development of measuring methods and devices in the field of measuring transformers. Also, the paper presents the most important trends in the development of measuring methods and devices for different applications. The systems for accuracy testing of measuring transformers in manufacturing process as well as high accuracy equipment for laboratory calibration of standard transformers are presented. Special attention was given to the contribution of EEINT experts in this field, both in the past and present.

ACKNOWLEDGMENT

Autor would like to thank dr. Slobodan Skundric for very useful discussion and suggestions regarding to topics that are presented in this paper.

Effects of cryptocurrency mining rig operation on power quality in LV distribution network

Vladimir A. Katić, *Senior Member, IEEE,* Zoltan J. Čorba, *Member, IEEE,* Aleksandar M. Stanisavljević, *Member, IEEE*

***Abstract*—The paper presents the influence of power supply units of a cryptocurrency mining rig on the power quality in a standard low-voltage network. Measurement and monitoring of the power quality indices of one mining rig with an optimized power of 1000W were performed. For comparison, the results of power quality measurement of a group of desktop computers (PC cluster) from a computer centre are presented. It has been observed that the mining rig had a smaller impact on power quality (harmonics) than the PC cluster, but that they represent a significantly higher and almost constant power demand.**

***Index Terms*—Cryptocurrency mining rig; PC cluster; Power quality; Measurements.**

I. Introduction

Widespread use of computers, computer equipment, various digital electronic and mobile devices, consumer electronics, and household appliances, as well as other nonlinear systems based on energy electronic converters, has led to reports of distorted current waveforms in the network, i.e., occurrences of harmonics [1]. The consequence was a reduction in the power quality and the possibility of the appearance of some negative effects on other interconnected loads (linear), but also on the above-mentioned nonlinear ones. Computers and computer equipment are a special problem due to their frequent concentration in large groups (clusters) [2]. As individual loads, they draw pulse current waveforms from the network with a very high level of distortion, so the total harmonic distortion of this current (THDI) may reach more than 120% [1,2]. However, due to group work in different modes, with different individual parameters (diversity factor), as well as due to the phenomenon of harmonic cancellation and attenuation the THDI of a PC cluster is ranged between 30-40% [2,3]. Furthermore, as their power demand is low in relation to the short-circuit power at the connection point, these values are within the limits stipulated by the international standard IEC 61000-3-4 [1,4].

However, in recent years, the use of cryptocurrencies (Bitcoin, Ethereum, Tether, etc.) is growing, as well as the need to verify their transactions on a public digital ledger (public digital book) known as the blockchain. As this process will also create new cryptocurrency values it is called the Bitcoin, or more generally, the cryptocurrency mining [5]. Unlike individual PCs or their groups (PC clusters) where the power varies during operation, cryptocurrency mining is performed with almost constant power, i.e., with a constant engagement of microprocessor resources. In this case, two problems arise. One is the power demand or efficient operation of the device, i.e., its electricity consumption, and the other is the impact on the power quality in the connected network [6,7]. It should be noted that these devices are of low rated power, so they are connected to a low-voltage single-phase network, i.e., one cryptocurrency mining rig represents a set of 6 graphics cards, which are powered via one or two power supply units. The response to both mentioned problems depends on the quality of the rig, i.e., the optimization of its operation, as well as the construction of the power supply (AC/DC converter with PFC).

There are many papers in the scientific literature that treat the first problem, and a lot of articles and reviews on professional sites (blogs) and journalism are dedicated to that. For the sake of objectivity, only those papers that have been published in the reference scientific literature will be considered here [6-11]. The impact of increasing network losses as a result of the operation of these devices was mainly considered in [6], long-term trends related to changes in the amount of energy per transaction in [8], the cost-effectiveness of mining concerning electricity prices in certain countries and environmental factors in [9], and mining of other cryptocurrencies, beside of Bitcoin in [10]. The issue of the effects on the power quality was less prominent and not researched in more detail. Some results presented in [7] show that such a low interest was a consequence of the higher quality power supply unit applications than in standard PCs, so the recorded current distortion had been less than THDI<10% [7]. However, in the case of larger cryptocurrency mining operations, the distortion of electricity may be more significant, even beyond the standards' permissible limits. This was observed in [11], but more detailed measurements and analyses have not been performed.

This paper aims to present the impact of the cryptocurrency mining rigs, i.e., their power supply units, on the power quality in a low-voltage distribution network and to compare it with the effects of conventional desktop (PC) computers. To enable this, the results of multi-day measurements were used, as well as the appropriate analysis of the measured results in the time and frequency domain.

II. MEASUREMENTS OF POWER QUALITY INDICES

Professional device C.A. 8332 by Chauvin Arnoux [12] was used to measure electricity quality indices, which follow the European standard EN 50160 [1,4]. The measurements were performed over a period of seven days, continuously at the place of connection of the device, i.e., at the busbars of the distribution cabinet in the low voltage network. The power quality indices of a PC cluster placed in the computer centre and a cryptocurrency mining rig were measured. The measured values included the effective value of voltage and current, frequency, power, power factor (PF), flicker, harmonics of voltage and current, and k-factor. However, due to limited space, only the most significant measurement results will be presented here, namely, those related to work efficiency (active P, reactive Q, distortive D, and apparent power S, as well as PF), i.e., electricity consumption (kWh, kVAh), and the impact on the power quality (total harmonic distortion of voltage and current, THDU, THDI).

A. Measurement results for the computer centre

As part of the activities on the subject of master's academic studies "Quality of electricity", measurements of power quality indices are regularly conducted on the internal network of the Faculty of Technical Sciences. For the purposes of this paper, obtained measurement results at the distribution cabinet of the computer centre during November/December 2019 will be used. Fig. 1 shows the measuring point, and Fig. 2 shows the waveform of the voltage and current of the single-phase network. In the line shown, 42 computers are connected, which have different power supply units HP Lite-On PA 1181-7 and Fujitsu D12-250 P1A with powers of 180 W and 250W, respectively. During the measurement, not all of them were turned on, that is, 28 computers were working continuously. The operation of these computers is characterized by high current distortion (Fig. 2), so in addition to active and reactive power, there is also distortion power.

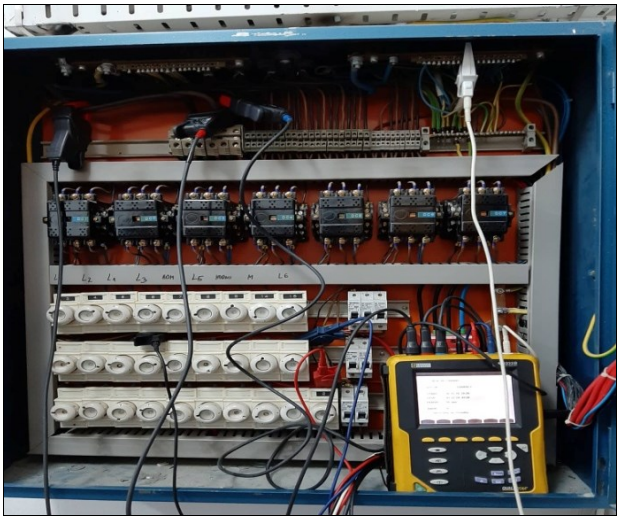

Fig. 1. Photo of measurement location during measurement at the computer centre

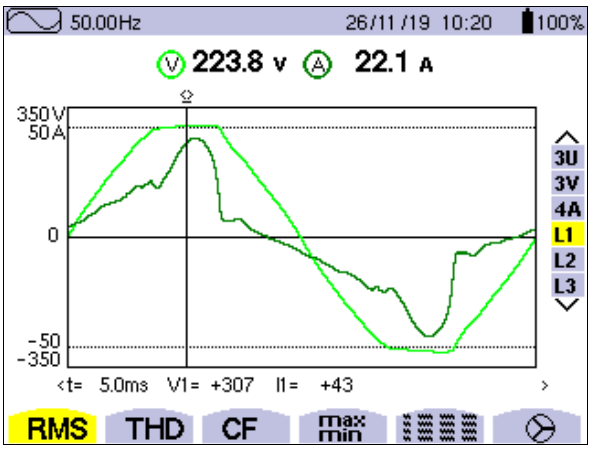

Fig. 2. Voltage and current waveforms of a single phase at the computer centre

Fig. 3 (up) shows the variation of the apparent (S), active (P), and reactive (Q) power, as well as distortion power (D) during a one-week measurement, while Fig. 3 (down) shows their statistical analysis. It can be seen that over 50% of the time computers work in standby (idle) mode, that they are capacitive as the reactive power is Q<0 (this can be also seen from Fig. 2, where the current waveform precedes the voltage one), and that the measured distortion power (D) is negligible. In addition, the measured power factor (PF) presented in Fig.4 indicates significant effects of the PC supply unit capacitance, but also the current harmonic distortion. Fig. 4 shows its variation during the one-week measurement and the statistical analysis. It can be seen that PF was below 0.95 all the time, which indicates a potential problem. In order to better understand all statistical values, Table I gives the most significant results of statistical analysis for all types of power (S, P, Q, and D), as well as for the power factor. It can be seen that power demand is much higher than average power, which shows variation in computers usage.

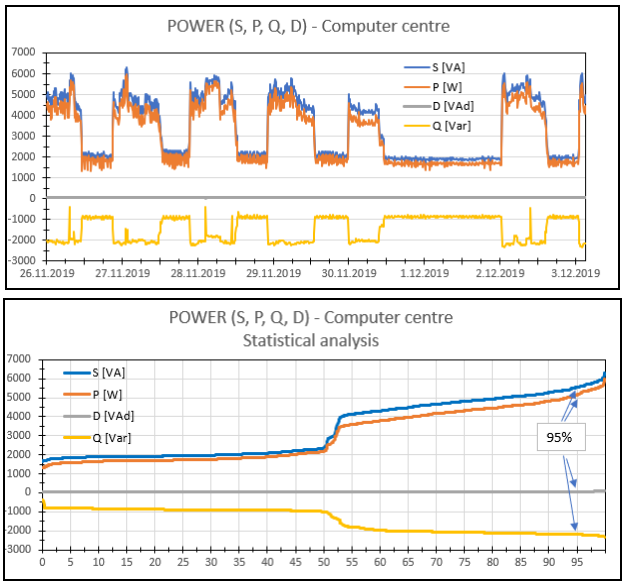

Fig. 3. Variation of the computer centre power demand during one-week measurements: time wave-form (up) and statistical analysis (down)

 ISBN 978-86-7466-930-3

TABLE I
STATISTICS FOR POWER (S,P,Q,D) AND POWER FACTOR OF THE COMPUTER CENTRE

Power	Mini-mum	Median (50%)	Average	95% value	Maximum
S [kVA]	1657.3	2348.4	3373.1	5544.1	6290.9
P [kW]	1337.2	2180.7	3029.3	5157.8	5992.5
Q [kVAr]	-381.1	-995.6	-1448.4	-2195.3	-2328.4
D [kVAd]	39.2	50.9	58.6	73.7	75.7
PF	0.79	0,89	0,889	0,936	0,952

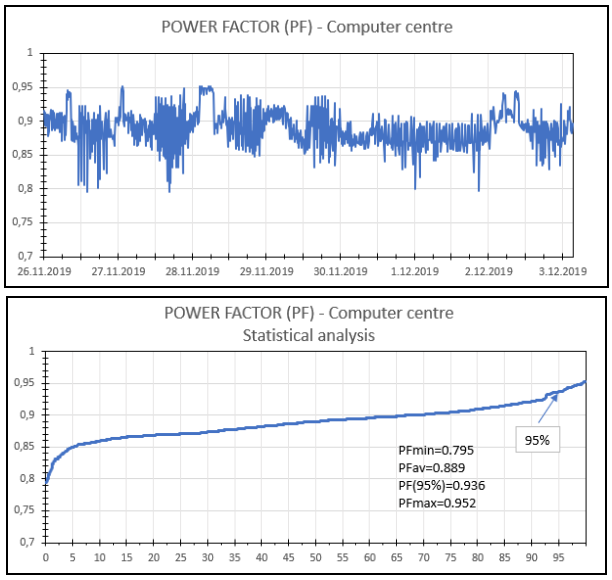

Fig. 4. Variation of the computer centre power factor during one-week measurements: time wave-form (up) and statistical analysis (down)

The observed waveforms of current and voltage (Fig. 2) indicate the existence of harmonic distortion, which is pronounced in the current pulsed waveshape, while in voltage it can be seen as a "flattened top" of the sinusoid. Both distortions are a consequence of the operation of power supply units (in PC and the monitor), which are usually realized as a diode bridge rectifier with a capacitive filtering (for "ironing" of the DC voltage) and additional DC/DC converter (for obtaining different voltage levels). Due to the parallel operation of a large number of computers, the mentioned phenomenon of harmonic cancellation and attenuation is present, so the values of THDI and individual harmonic distortion of the current (HDI) are less than in the case of individual computers. Figs. 5 and 6 show the variation of the THDU (Fig. 5) and THDI (Fig. 6) during one-week measurements. If the results are compared with Fig. 3, it can be seen that the distortions are smaller in the standby ("night" mode) (THDU≈2.2%; THDI≈22%), and that they increase during the working days when the PCs are in active use (THDU≈2.8%; THDI≈45%).

B. Measurement results of cryptocurrency mining rig

Cryptocurrency mining uses a dedicated computer assembly (rig) consisting of a power supply unit, mainboard, and graphics cards. Fig. 7 shows an illustrated block diagram of this device. A set of six graphic card units (GCU) were in operation during the measurement, which was powered by two high-quality power supplies: HPE model "ProLiant" DL580 G7 (1200W, Platinum, η=94%) and "Be Quiet!" model Straight Power 11 (650 W, Platinum, η=94%) connected to a single-phase network (230V, 50 Hz). The maximum power of both supplies is 1850W, but they are optimized to work on 1000W. Fig. 8 shows the photo of the treated rig and the location where C.A 8332 was connected.

The main characteristic of the rig´s operation is the constant engagement of the GCU processor, which leads to higher electricity consumption, but also significant thermal losses. For this reason, applied power supply units are of high efficiency (94% -95%), but also with a more complex schematic. They have an additional power factor correction (PFC) unit, which enables close to unity power factor, but also contributes to the significant reduction of harmonic distortion.

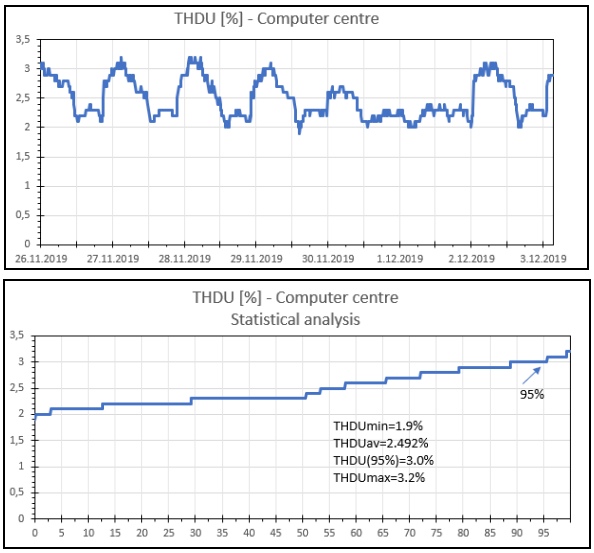

Fig. 5. Variation of the computer centre THDU during one-week measurements: time wave-form (up) and statistical analysis (down)

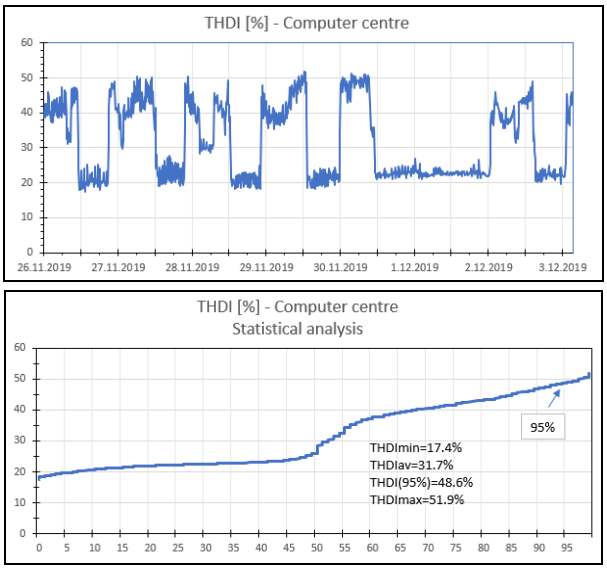

Fig. 6. Variation of the computer centre THDI during one-week measurements: time wave-form (up) and statistical analysis (down)

 ISBN 978-86-7466-930-3

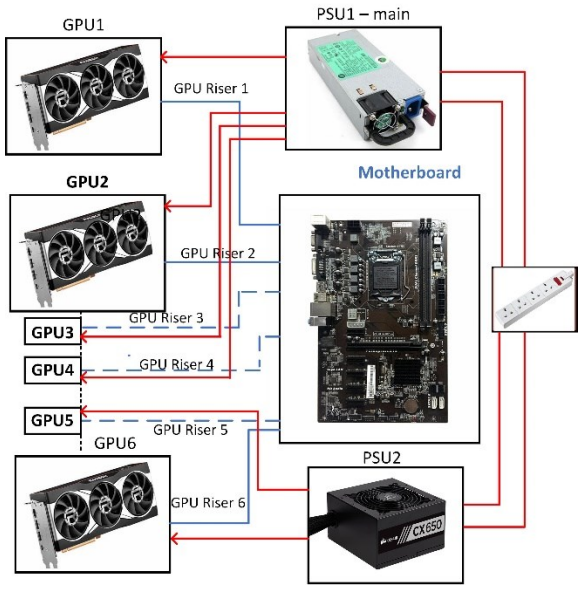

Fig. 7. Block scheme of the cryptocurrency mining rig

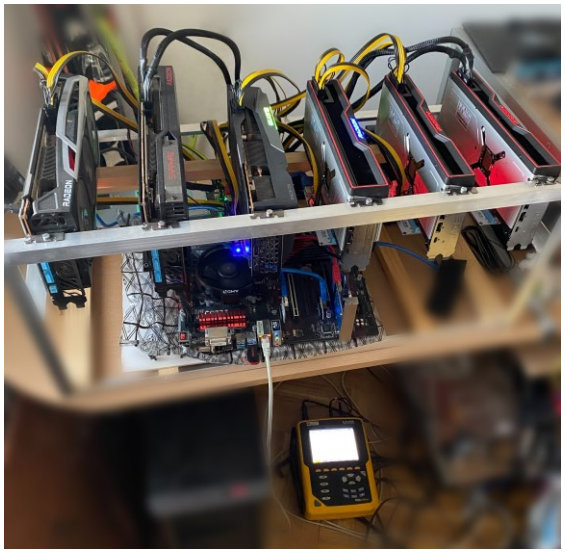

Fig. 8. Photo of measurement location during cryptocurrency mining rig measurement

The measurement results are shown in Figs. 9-14. Fig. 9 shows the waveforms of voltage and current, which are characterized by the flatness of the sinusoidal top and very low current distortion and displacement. Fig. 10 shows the measurement results for different types of power, while Fig. 11 the power factor. It can be seen that there were some short periods with lower power demand, which corresponds to some problems with the Internet and shutting down at the end of the measurement. In order to better understand the statistical values, Table II gives the most significant results of statistical analysis of measured power and power factors for the cryptocurrency mining rig. It can be noticed that the rig works with practically constant power and a close to unity power factor (0.988).

Figs. 12 and 13 show the results of the voltage and current harmonic distortion of the cryptocurrency mining rig. The variation of the THDU during one-week measurements is shown in Fig. 12, while the THDI is in Fig. 13. A low voltage and current distortion can be observed. However, significant increases in current distortion can be observed during the measurement and at the end (Fig.13). These are the periods when there was a significant reduction in processor activity of the GCU i.e., in the mining, when the system operates with lower power (see Fig. 10) and outside the optimal parameters. However, these periods do not significantly affect the overall assessment of current distortion.

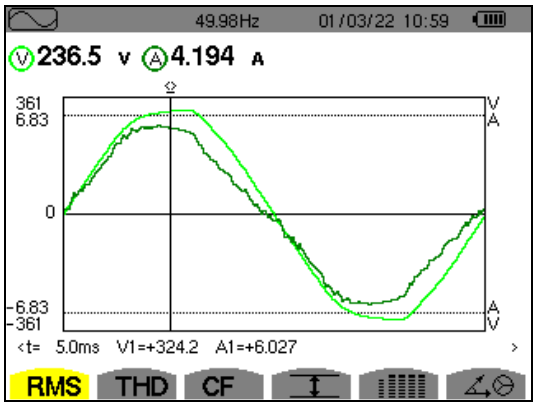

Fig. 9. Voltage and current waveforms of the cryptocurrency mining rig

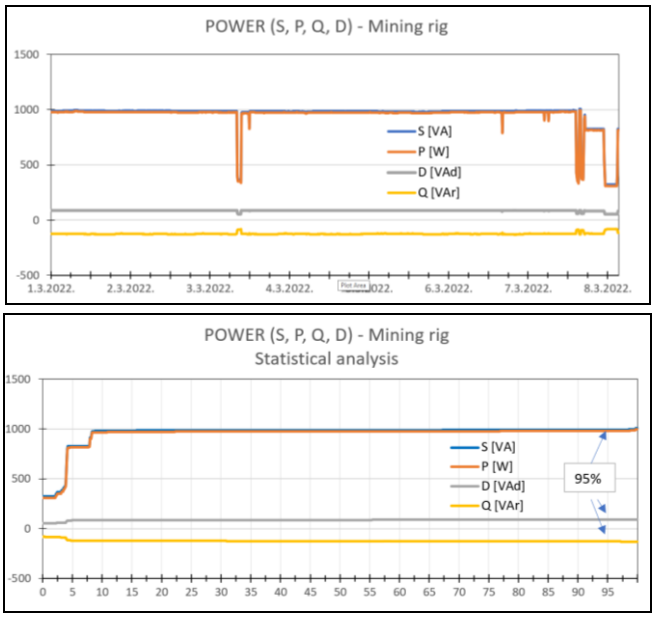

Fig. 10. Variation of the cryptocurrency mining rig power demand during one-week measurement: time wave-form (up) and statistical analysis (down)

III. Discussion

A. Comparison of PC cluster and Mining rig by distortion

Commercial PCs, which are widespread and present in many locations are well-known as current and voltage distortion sources in low voltage distribution networks [1]. If they are clustered, the distortion is much less than if a single one is considered [2]. Yet, the current harmonic distortion limits stipulated by international standards are not surpassed.

 ISBN 978-86-7466-930-3

Still, the voltage distortion is increased (depending on the power demand of the PC cluster) and may contribute to the appearance of some negative effects at other connected loads. The remaining problems are high and distorted current in the neutral conductor and poor power factor.

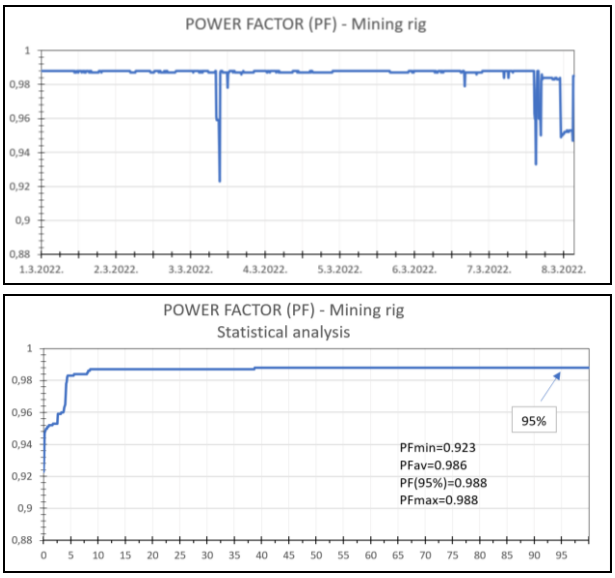

Fig. 11. Variation of the cryptocurrency mining rig power factor during one-week measurements: time wave-form (up) and statistical analysis (down)

TABLE II
STATISTICS OF POWERS (S,P,Q,D) AND POWER FACTOR OF THE CRYPTOCURRENCY MINING RIG

Power	Mini-mum	Median (50%)	Average	95% value	Maximum
S [VA]	323.8	987.8	956.1	992.7	1007.0
P [W]	308.4	975.7	943.9	980.9	994.9
Q [VAr]	-81.3	-125.4	-123.9	-128.6	-1431.3
D [VAd]	53.3	87.8	86.3	88.5	89.6
PF	0.923	0.988	0.986	0.988	0.988

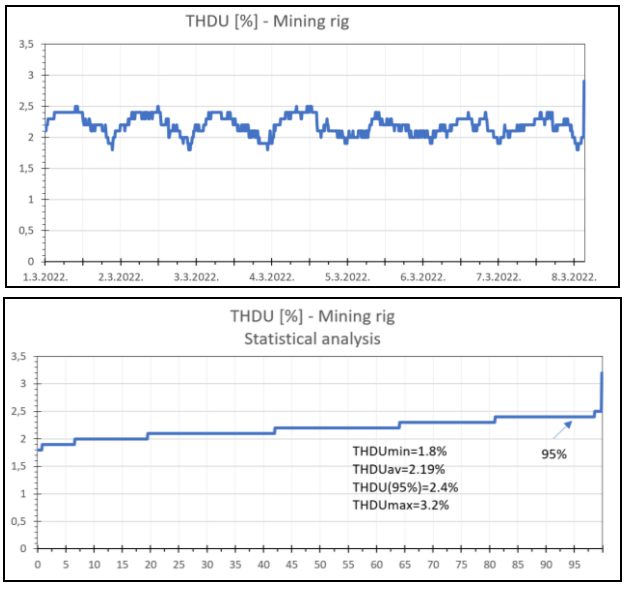

Fig. 12. Variation of the cryptocurrency mining rig THDU during one-week measurements: time wave-form (up) and statistical analysis (down)

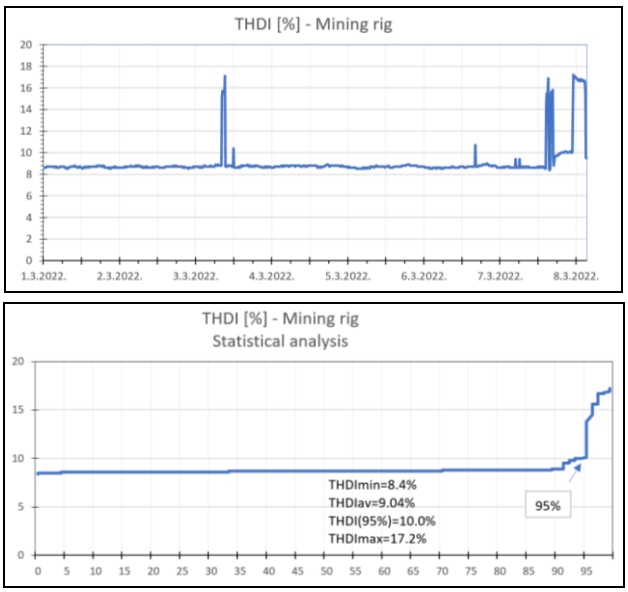

Fig. 13. Variation of the cryptocurrency mining rig THDI during one-week measurements: time wave-form (up) and statistical analysis (down)

In the case of the connection of the cryptocurrency mining rig to the low voltage distribution network the measured harmonic distortion factors and power factor are good and in accordance with international standards. It shows that the power supply units of the rig are carefully selected to enable optimum operation.

Table III shows a comparison of main power quality indicators recorded during measurements of the PC cluster and the cryptocurrency mining rig. It can be seen that the cryptocurrency mining rig has superior performance. Such a conclusion is not a surprise as the power supply units of the mining rig are of much higher quality than the ones of the PC in the cluster.

TABLE III
COMPARISON OF DISTORTION FACTORS AND POWER FACTORS OF THE PC CLUSTER AND THE MINING RIG

	THDU (95%)	THDU (Max.)	THDI (95%)	THDI (Max)	PF 95%	PF (Max)
PC cluster	3.0%	3.2%	48.6%	51.9%	0,936	0,952
Mining rig	2.4%	3.2%	10.0%	17.3%	0.988	0.988

B. Comparison of PC cluster and Mining rig by power and electricity consumption

The PC cluster and the cryptocurrency mining rig comparison by power demand and electricity consumption is more interesting. The measurement results show that the power demand of the cryptocurrency mining rig is much higher. Moreover, it is constant over time, so the low-voltage distribution network may see it as a high (~1000W) load of a resistive nature (like some heater).

Fig. 14 (up) shows a comparison of a PC cluster and the cryptocurrency mining rig's active power demand. The power demand of the PC cluster is downsized to the one comparable with the cryptocurrency mining rig (~1000 W). Fig.14 (down)

 ISBN 978-86-7466-930-3

shows the same comparison, but regarding the electricity consumption. It can be seen that the power demand of the cryptocurrency mining rig was in some periods much higher, while in others similar to the PC cluster. Regarding electricity, the consumption was much higher (almost twice).

C. *Effects on voltage distortion (THDU)*

Considering the above observations, it is rational to assume that the operation of the PC cluster, as well as the cryptocurrency mining rig, may have some effects on the low-voltage distribution network voltage harmonics. From Fig.5 it can be seen that there is a high difference between the voltage harmonic levels during the night (PCs are in idle mode) and during the day. It can be estimated that the PC cluster operation increase voltage harmonics from $THDU_{night}$=2.3% to $THDU_{day(95\%)}$=3.0%, i.e., for 30%, up to $THDU_{day(max)}$=3.2%, i.e., for almost 40%.

In the case of the cryptocurrency mining rig, there are no differences between night and day, so it is difficult to estimate the rig´s effect on voltage harmonics. Still, from Figs.10 and 14, it can be noticed some periods with low power operation (when the mining process has been ended and the rig had continued operation in an idle mode), i.e., with a reduced effect on voltage harmonics. Therefore, observing corresponding Fig.12 it can be estimated that the cryptocurrency mining rig operation increase voltage harmonics from $THDU_{min}$=1.8% to $THDU_{day(95\%)}$=2.4%, i.e., for around 33%, up to $THDU_{day(max)}$=3.2%, i.e., 78%!

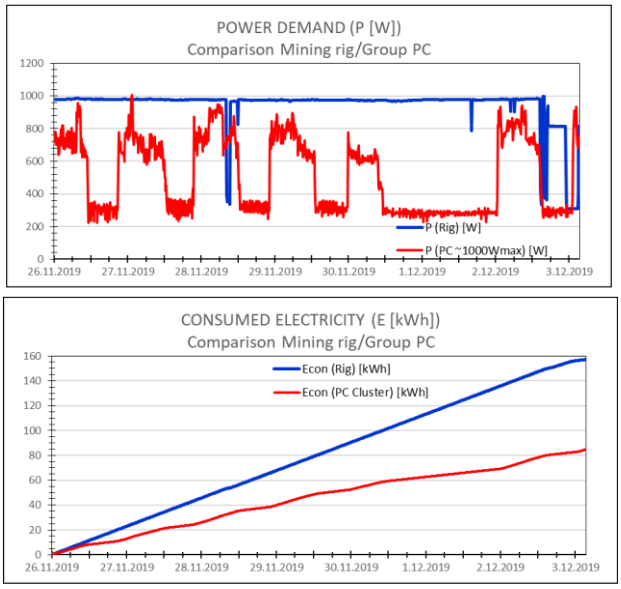

Fig.14. Comparison of the cryptocurrency mining rig and a PC cluster of the same size: of power demand (up) and consumed electricity (down)

IV. Conclusion

The paper presents research results of the cryptocurrency mining rig's effects on the power quality at the low-voltage distribution network. The most important power quality indices obtained during one-week measurements are recorded and discussed. For comparison, similar research has been worked out for a PC cluster.

The research results show that cryptocurrency mining rig has higher power demand and electricity consumption than the similar-sized PC cluster. The power factor is much better (close to unity) than the PC cluster has (below 0.95). It has a lower effect on current distortion (THDI), while the effects on voltage distortion (THDU) are similar to the PC cluster ones.

However, the THDU of the cryptocurrency mining rig might increase significantly if more rigs are connected at the same bus and endangered power (voltage) quality for other loads. Further research will be focused on this problem.

Prediction of voltage dips characteristics in IEEE 13-bus test grid using harmonic footprint

Aleksandar M. Stanisavljević, *Member, IEEE,* and Vladimir A. Katić, *Senior Member, IEEE*

***Abstract*—In this paper, the method of harmonic footprint (HF), as a significant feature of voltage dip is applied for a dip characterization. The dips are generated using an internationally verified test grid, the IEEE 13-bus test grid. First, the method of the HF is presented and described. Then, the IEEE 13-bus test grid modified by adding the distributed generators (wind or solar power) is described. Faults were simulated in the test network, and the values of the HF parameters were determined. The results were used for the voltage dips characteristics prediction. The results of simulation and prediction were compared and the mutual deviation (error) was determined. It is shown that the HF can be used for the early voltage dips characteristic prediction and further applied for training a deep-learning algorithm. Some limitations have been observed and their mitigation will be a topic of future research.**

***Index Terms*—Electric power quality, Voltage Dips, Harmonic footprint, Test grids**

I. Introduction

In recent years, power quality issues have become more relevant, and significant attention had been paid to the related topics. In addition to the quality of delivery, the quality of delivered electrical energy is also important, which is often recognized as the quality of voltage. Voltage dips or sags are a consequence of disturbances in the operation of the power system and may have serious negative effects on industrial loads and connected distributed generation (DG) [1]. Particularly inconvenient are outages of industrial plants or the shutdown of small power plants in the distribution network, which can have major financial consequences. For these reasons, great research efforts are focused on the rapid detection and successful characterization of voltage dips [2, 3] and techniques of its compensation [4].

One of the successful methods for the dip's characterization is the application of harmonic footprint [5]. It provides the possibility for early characterization of a voltage dip so that in the first phase of fault its characteristics can be predicted with high probability [5, 6, 7]. For the sake of more accurate categorization and faster response, it is convenient to apply some of the methods of artificial intelligence, i.e., machine learning or deep learning [8, 9]. However, the main problem is the training, i.e., providing a huge number of adequate and different cases of voltage dips. Voltage dips occurrence in real grids is relatively rare, so long-term measurements are needed, which is costly and requires specialized equipment. Therefore, the use of synthetic dips based on mathematical calculations or simulated ones, based on the response from the grid simulation model are possible solutions.

This paper aims to test the application of the harmonic footprint method for the prediction of the voltage dip characteristics and to discuss such an approach for training a deep learning algorithm. The testing is based on recognizable and internationally verified references or test grids [10]. First, the method of harmonic imprinting is presented and described. Then, the IEEE 13-bus test grid is described, which is modified by additional distributed generators (wind and solar power plants). Faults were simulated in the test grid, and the values of the harmonic footprint parameters were determined for the various types of voltage dips thus obtained. The results of modeling and prediction of the voltage dips characteristics were compared and the mutual deviation (error) was determined.

II. Harmonic footprint

It is generally known that voltage dips are a consequence of faults in the network, high-power motor drive starting, or power transformer energizing [1]. During these events, a sudden rise of current may be observed, which distorts the voltage waveform all over a huge area of the grid. If the Fourier transformation is performed, the second and several other low-order harmonics may be noticed [1, 5]. If they are traced as a group, which consists of the 2nd, the 3rd, then 5th, and the 7th harmonics, and monitored throughout a voltage dip, a specific waveform may be observed [5]. It was named harmonic footprint (HF) [5]. Its mathematical representation is:

$$HF = \frac{\sqrt{\sum_{n=2,3,5,7} U_n^2}}{U_1^2} \cdot 100 \quad [\%] \tag{1}$$

where n is harmonic order, and U_n is r.m.s. value of the *n-th* harmonic.

The harmonic footprint is an important feature of a voltage dip. It appears at each voltage dip transition state, i.e., at the start of the dip and its end. Additionally, the HF may be recorded if the dip progresses from single-ground one to two-phase to ground or if some other voltage transition occurs. It

Aleksandar M. Stanisavljević with the University of Novi Sad, Faculty of Technical Sciences, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (e-mail: acas@uns.ac.rs).

Vladimir A. Katić is with the University of Novi Sad, Faculty of Technical Sciences, Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (e-mail: katav@uns.ac.rs).

 ISBN 978-86-7466-930-3

can be obtained in a few milliseconds, so the HF method represents one of the fastest tools [11].

The main parameters of an HF are its initialization (start-up), maximum value (MHF), and width (wHF). They may be used for voltage dip detection (start-up moment) and prediction of voltage dip magnitude (depth), and duration, i.e., for fast and accurate characterization [5, 6, 7]. The HF and its parameters are presented graphically in Fig.1.

The HF method was tested with voltage dips recorded in various real distribution grids, and the configurations of the different distribution grids did not significantly affect the accuracy of the algorithm [5, 6, 7]. Furthermore, it can be noted that stochastic quantities, like fault resistance and fault inception angle, have some influences on the HF, but their effects are combined with the distance from the fault (line impedance between the fault location and voltage dip recording point). Generally, the total impedance has an inversely proportional effect, i.e., if it is higher, the HF is usually of a smaller value. The fault inception angle does not influence the precision of the method, as it is tested with real faults, which had different fault inception angles.

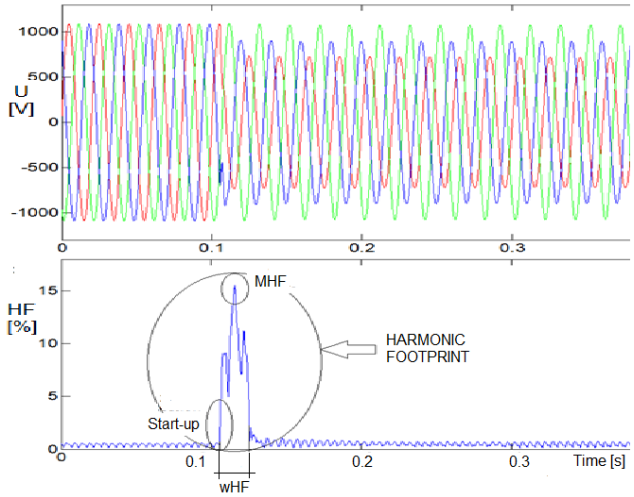

Fig.1.Harmonic footprint characteristics

III. MODIFIED IEEE 13-BUS TEST GRID

There are several different test grids available for the simulations of voltage disturbances in a grid [10]. In this paper, the IEEE 13-bus test grid will be used. It represents a sample of the North American distribution grid consisting of three-phase lines, with two-phase and single-phase ones close to the ends of feeder laterals (load side). The supply voltage is 155 kV, while the distribution voltage is 4.16 kV. The grid is loaded with constant current, constant impedance, and constant power consumers, so that the total load is 3.466 MW. Unity power factor is assumed.

The test grid was modified with the addition of DGs, to make a better representation of a modern distribution grid. The optimal DG size is 2.5 MW connected at bus #633 [12], but in this paper, it will not be concentrated. A 2 MW wind plant was added at bus #633, and a 0.5 MW solar PV system at bus #652. The wind plant consists of four wind generators of 0.5 MW each interconnected with the grid via a power transformer and a one-kilometer-long power line. The solar PV plant is an on-grid solar PV system of 0.5 MW connected to the grid at bus #652 via a power transformer, which is further connected to the mainline at bus #648 via a 2 km line. These plants are dispatchable, but also comply with low-voltage ride-through (LVRT) requirements [13]. Therefore, they can support the grid during the duration of a voltage dip.

The IEEE 13-bus test grid is available as the Matlab/Simulink simulation model in [14]. Its modification is also done in Matlab/Simulink and its one-line diagram is presented in Fig.2.

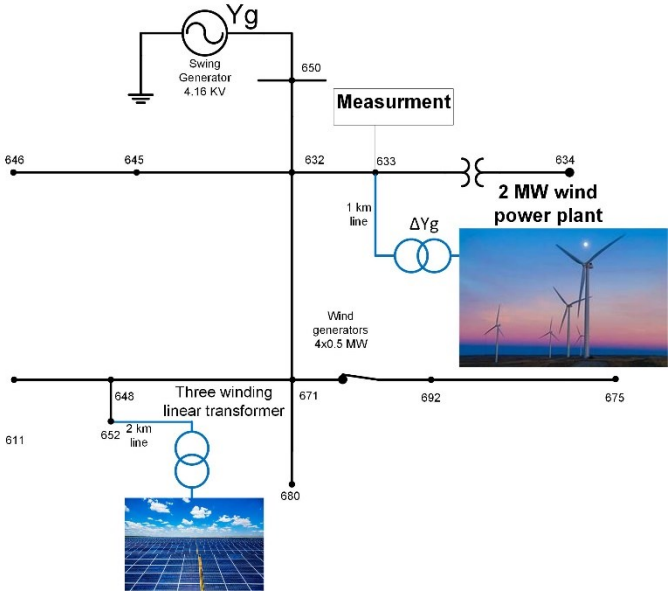

Fig.2. Modified IEEE 13-bus test grid with added DGs

IV. VOLTAGE DIPS SIMULATIONS

The simulated voltage dips are the result of hypothetical faults in the test grid. The faults are generated at buses #692, #633, and #671 with a rated voltage of 4.16 kV. Different faults are simulated: single-phase to the ground (line-to-ground), two-phase faults (line-to-line), and a three-phase to the ground.

The voltage dips are measured (recorded) at bus #633. Two main features are monitored, the magnitude of voltage dip (MoVD) and duration.

The magnitude of a voltage dip represents the voltage during the dip as a percentage of the rated voltage, i.e., it is defined as:

$$MoVD = \frac{U_{rem.}}{U_r} \cdot 100 \ [\%] \tag{2}$$

where U_{rem} is the remaining voltage during the voltage dip at the observing bus and U_r is the rated voltage.

The duration of a voltage dip is defined as a period when the voltage at the observing bus is lower than $0.9U_r$.

 ISBN 978-86-7466-930-3

Fig. 3 shows an example of the single-phase (line-to-ground) voltage dip recorded at bus #633. The fault occurred on line 1 (L1, the blue line) at bus #671. As the result, the voltage at observing bus #633 suddenly decreases from the rated to 5% of the rated, i.e., the MoVD=5%. The voltages of the other two lines (L2, the red one, and L3, the green one) experience voltage swells, i.e., increased by around 15%. The duration of the voltage dip was 0.16 seconds. After that, the fault was cleared and all voltages returned to the rated values. It can be easily observed that significant voltage distortion occurred during the voltage transient states, i.e., when a fault and corresponding voltage dip initiated (started) and when it ended. In these periods the HF appears, and it can be calculated and recorded.

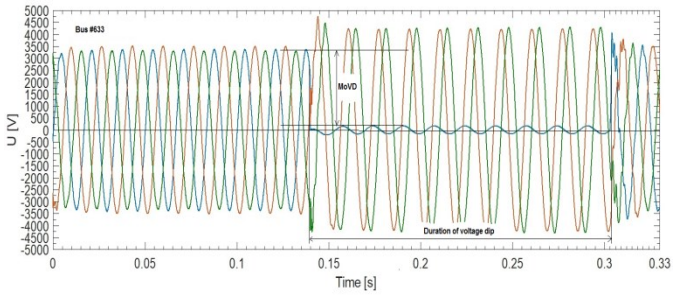

Fig. 3. Single-phase voltage dip recorded at bus #633.

Beside the single-phase to the ground (line-to-ground) fault and corresponding voltage dip presented in Fig. 3, six more cases of different faults were simulated. They are presented in Table I. It can be seen that three single-phase to the ground faults which occurred on the busses #692, #671, and #648 were simulated, together with the additional three phase-to-phase (line-to-line) faults on the same busses and one three-phase to the ground on bus #643. In total, seven faults were tested.

The recorded voltage dips on bus #633 were also summarized in Table I. It shows the main characteristics of the simulated voltage dips, their magnitude (given by MoVD), and their duration. It can be seen that for single-phase to the ground faults the MoVDs are very small, as well as for the three-phase to the ground fault, while in cases of phase-to-phase faults the MoVD values are around 50%.

V. HARMONIC FOOTPRINT PARAMETERS DETERMINATION

The harmonic analysis of the tested voltage dips resulting in their harmonic footprint was performed. An example of the HF for the case of the voltage dip presented in Fig. 3 (fault No.2 in Table I) is shown in Fig. 4. It can be seen that there are two HFs, one at the beginning of the dip and the other at its end. For further analysis, the first one will be considered. Specific parameters of the harmonic footprint can be distinguished, its MHF and wHF. For the voltage dip characterization, the MHF is important. It can be seen that the MHF value in this case (single-phase to the ground fault) is 36%.

A similar analysis is done for all other recorded voltage dips cases. Due to limited space, the HF diagrams for the other cases will not be shown here. The results for the MHF are presented in Table I (column to the right). It can be seen that in the cases of the low MoVD values (deep voltage dips) the MHF values are above 30%, while for the higher MoVDs the MHF is lower.

TABLE I
SIMULATED VOLTAGE DIPS CHARACTERISTICS

No.	Type of faults / Voltage dip characteristics	MoVD [%]	Duration [s]	MHF [%]
1	Single-phase to the ground at bus #692	7	0.18	37
2	Single phase to ground at bus #671	5	0.16	36
3	Single-phase to the ground at bus #648	8	0.20	35
4	Phase A and B at bus #692	48	0.30	24
5	Phase A and C at bus #671	49	0.33	25
6	Phase C and B at bus #648	62	0.50	18
7	Three-phase to ground at bus #643	9	0.80	32

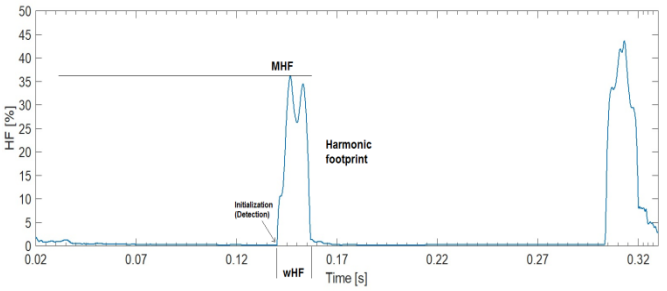

Fig. 4. The HF for the case of the single-phase voltage dip recorded at bus #633 for fault No. 2 in Table I

VI. ESTIMATION OF THE VOLTAGE DIPS CHARACTERISTICS

The obtained HF parameters can be used for the early prediction of the voltage dip characteristics, its magnitude (MoVD), and its duration. These characteristics can be predicted using the maximum value of the HF (MHF) according to the expressions given in [6, 7].

The prediction function calculates voltage magnitude as a function of the maximum value of the HF:

$$MoVD^* = f(MHF) \tag{3}$$

where $MoVD^*$ is the predicted value of the voltage dip magnitude, and MHF is a global maximum of the HF during the first transient stage. The voltage dip magnitude can be calculated using the following expression [6]:

$$\log_{10}(MoVD^*) = 1.913 + 0.00284 \cdot MHF + \\ + 0.000036 \cdot MHF^2 - 0.000024 \cdot MHF^3 \tag{4}$$

The results of the calculations are presented in Table II. For the generated faults (Table I) the values of the predicted MoVD* are presented in the second column of Table II. For comparison, the simulated (recorded) MoVD values are given

 ISBN 978-86-7466-930-3

in the third column (repeated from Table I). It can be seen that predicted values are close to the actual (simulated) ones. The absolute errors of prediction are given in the third column of Table II. It can be seen that these errors are below 9 percent. The average absolute error of the prediction is 4.2%, while r.m.s. error is 5.12%. It can be concluded that the prediction can be successfully performed with an acceptable error of prediction.

For prediction of the voltage dip duration, the method presented in [7] is used. The method uses the *MHF* values to calculate the probability function *f(MHF)* [7]:

$$f(MHF) = (1 + e^{9.15 - 0.2320 MHF})^{-1} \quad (5)$$

The probability function determines the probability of the voltage dip duration being predicted as momentary or temporary. It is a sigmoid function, so two zones (momentary or temporary) can be distinguished easily. If the *f(MHF)* is less than 0.4, which corresponds to MHF<37.7% the voltage dip is momentary, i.e., less than 3 seconds. If the *f(MHF)* is above 0.6 (MHF>41.2%) then the voltage dip is temporary, i.e., longer than 3 s. In between is uncertainty or border zone, where both solutions are possible.

The probability function is calculated for the obtained MHF values and presented in Table III. It can be seen that for all observed cases of the voltage dips predicted duration was "momentary", i.e., less than 3 s, which is in accordance with the actual duration. Therefore, the prediction was true.

TABLE II
VOLTAGE DIPS MAGNITUDE PREDICTION AND PREDICTION ERROR

Fault No.	Predicted MoVD* [%]	Simulated MoVD [%]	Absolute Error [%]
1	7.11	7	0.11
2	8.75	5	3.75
3	10.65	8	2.65
4	46.79	48	1.21
5	42.81	49	6.19
6	68.52	62	6.52
7	17.96	9	8.96
The average absolute error of prediction			4.20
Root mean squared error			5.12

TABLE III
VOLTAGE DIPS DURATION PREDICTION AND PREDICTION ACCURACY

Fault No.	Probability function *f(MHF)*	Predicted VD DURATION [S]	Simulated VD DURATION [s]	Prediction accuracy
1	0.362	Momentary (<3s)	0.18	TRUE
2	0.311	Momentary (<3s)	0.16	TRUE
3	0.263	Momentary (<3s)	0.20	TRUE
4	0.027	Momentary (<3s)	0.30	TRUE
5	0.034	Momentary (<3s)	0.33	TRUE
6	0.001	Momentary (<3s)	0.50	TRUE
7	0.101	Momentary (<3s)	0.80	TRUE

VII. DISCUSSION

The harmonic footprint presents a unique feature of a voltage dip, which may be used for the prediction of its characteristics. Moreover, it offers the possibility of dip detection and obtaining its early characterization. The presented results show that the simulated voltage dips have been analyzed adequately and that the predicted characteristics are true and acceptable regarding prediction error.

The predicted dip magnitudes correspond to the simulated ones with the r.m.s. error of 5.12%, which is acceptable in engineering practice. The predicted dip durations were true, but the prediction was limited to only two options – momentary (less than 3 s) and temporary (more than 3 s). Additional problem is that the HF is not able to predict the exact duration of voltage sag, so the whole period of voltage sag should be recorded. In that case, the two HFs should be calculated (at the beginning and the end of a voltage dip) and their detection times compared (see Fig.4). Other possible solutions will be sawn in future research.

The results also show that simulated voltage dips may be used for creating a database for the training of a deep learning algorithm. Available reference or test grids (IEEE or others) are adequate and suitable, so many different cases may be simulated.

Still, the number of simulated cases is limited, as for the deep-learning algorithm or any other machine learning one high number of input data is needed. One solution is to use the test grids with more buses (feeders) where there are more options to generate the faults and obtain voltage dips. There are other options and they will be the topic of future research.

VIII. CONCLUSION

The voltage dips characterization is an important task for modern industrial or other loads, as well as for distributed generation and protection of the distribution network. The use of artificial intelligence and deep-learning algorithms for solving this task proved a good solution but require a huge database for the algorithm training process.

In previous papers, the authors have presented that the harmonic footprint, as a voltage dip feature, can be successfully implemented for the prediction of voltage dip characteristics. These results were based on the measurement results obtained in the real grid.

The result of this paper shows that simulation in the referenced test grids can be also used for that purpose. The harmonic footprint has been successfully applied for a voltage dip early characterization. It proves that such an approach can be also applied for the generation of an artificial (simulated) set of voltage dip cases (characteristics) and used for deep-learning algorithm training. Some limitations of this method have been observed, so future work will focus on their mitigation.

Optimal Power Dispatch in Distribution Networks with PV Generation and Battery Storage

Jordan Radosavljević, Miloš Milovanović, Nebojša Arsić, Andrijana Jovanović, Bojan Perović and Jovan Vukašinović

***Abstract*—Numerous researchers in the last two decades have intensively dealt with various aspects of the integration of renewable energy sources (RES) into distribution networks (DNs). It has been shown that optimal planning and operation of RES can achieve positive effects, both in terms of technical performance of the system, and from the environmental and economic aspects. However, the uncontrollability and stochastic nature of wind speed and solar irradiance as the primary sources of RES remained their main shortcomings. The energy crisis that has been present lately imposes the need for much more flexible use of RES. This means finding technically efficient and economically acceptable solutions for energy storage, in order to fully exploit the potential of RES integrated into the system. This paper deals with the issues of the optimal operation and management of rechargeable batteries for energy storage in DNs with PV generation.**

***Index Terms*—Distribution networks, Renewable energy sources, Battery energy storage, Optimal power flow**

I. INTRODUCTION

In the last twenty years, we have witnessed the expansion of renewable energy sources (RES), primarily wind and solar photovoltaic (PV) power plants. The development and application of these technologies have several causes. First of all, it is the constant growth of the electricity consumption and need for new generation capacities. Another, no less important cause, is the ultimative request to limit the use thermal power plants in order to reduce global warming due to CO_2 emissions. In addition, the deregulation and liberalization of electricity market and preferential prices for green energy have contributed rapid growth of RES in the last two decades [1].

Wind and solar technology is becoming cheaper year by year [2], which makes it widely available. There are wind and solar power plants with installed capacity of several hundred MW connected to the transmission network. In addition, there has long been a trend of building smaller so-called distributed energy sources from several kW to several MW, which are integrated into distribution networks (DNs).

A large number of papers have been written on the topic of the distributed energy sources. Various aspects in their planning, operation and control have been explored. It has been shown that optimal planning and control can maximize their positive effects, such as reducing power losses, improving voltage profiles, increasing the supply reliability in DNs, reducing greenhouse gas emissions, etc. However, the uncontrollability and stochastic nature of wind speed and solar irradiance as primary sources of RES remained their main shortcomings.

The energy crisis that has been present recently, imposes the need for much more flexible use of RES. This means finding (using) technically efficient and economically acceptable solutions for energy storage, in order to fully use the potential of RES integrated into the DN.

There is no way to directly store active electricity. There are more or less developed technologies and solutions for indirect storage of the electricity, i.e. converting the electricity into another type of the energy that can be stored in a certain medium. The energy stored in this way is, when necessary, converted back into the electricity, which is injected into the transmission or distribution system.

At the level of DNs, the battery energy storage systems (BESS) are imposed as a solution. For their application in DNs with significant penetration level of RES, type WT and PV, it is necessary to solve two questions beforehand. The first one refers to the optimal planning of the BESS, which includes the choice of capacity, rated power and location in the DN. The second one is the optimal exploitation, i.e. determination of the BESS operation mode in a given period of time, usually 24 h. This implies defining the charging/discharging regime, i.e. the time schedule and the charging/discharging power of the BESS in accordance with the adopted function that it should perform in the DN. These functions can be [3-7]: (i) providing energy management and optimal power flow for reducing the cost for electricity, minimizing power losses, and improving the power quality, (ii) enable/facilitate the

 ISBN 978-86-7466-930-3

realization of smart grids, (iii) meeting peak electrical load demands, (iv) increasing the reliability of power supply. The mode of operation of the BESS is determined taking into account variable load, as well as the variable and stochastic power of RES (PV and WT).

In essence, this is a problem of optimal power dispatch in DNs. Given the specificity of the BESS, i.e. the limitation related to the state of charge (SoC), which directly affects the battery status in the next time segment (charging/discharging and power level), the problem of optimal power dispatch must be observed in a certain (given) time horizon, usually a period of 24 hours. Therefore, the problem of optimal power dispatch becomes a dynamic problem on a certain time horizon. The solution of this problem is performed by time segments (e.g. from 1 to 24 h), where the solution in a given segment (t) is conditioned by the solution obtained for the previous segment (t-1).

This paper presents a two-stage procedure for optimal dispatch of active and reactive power in DNs with PV sources and BESS. In the first stage, the optimal active power dispatch in DN is determined, based on the classical model of dynamic economic dispatch with neglected power losses. The aim is minimizing costs for electricity from the source (upstream) grid. After that, the problem of optimal reactive power dispatch in DN is solved to minimize energy losses and voltage deviation.

II. Models of PV, Load and Battery Storage

A. PV Model

The power generated by a PV unit is dependent on the solar irradiance. Beta PDF is suitable to modeling the stochastic nature of the solar irradiance. The solar irradiance measurements are made available with the sampling time of 1-10 min. Therefore, the mean and standard deviation of the solar irradiance can be calculated from measured data which correspond to the certain time interval τ (e.g. 1 h). Based on the mean and standard deviation of the solar irradiance, the shape parameters of Beta PDF can be calculated [8].

To realize Beta PDF in discrete form, the time interval τ is divided into N_s states, where the corresponding solar irradiance and probability for each state ($g = 1 \div N_s$) can be calculated. The output power of PV is then estimated taking into account the probabilities of all solar irradiance states in the observed time interval, as explained in [8,9].

B. Load Model

It is assumed that the load diagram is the same for active and reactive power. The load is assumed to be a random variable following the same normal PDF within each hour of a given daily load diagram.

To realize the normal PDF load function, the hour t is divided into N_L states, and the corresponding loads and probabilities for each state ($g = 1: N_L$) are calculated.

The level of the load in the certain time segment t is determined based on the probability of all possible conditions within that hour [9].

C. BESS Model

The BESS model is conditioned by a continuous change in the state of charge (SoC). This means that the value of the SoC at a given time-hour (t) depends on its value in the previous time segment (t-Δt or t-1). Mathematically, this can be expressed as follows [10]:

$$SoC(t) = SoC(t - \Delta t) + \Delta SoC\,, \tag{1}$$

$$\Delta SoC = \frac{P_{bat}(t-1)\cdot \Delta t}{C_B}\,, \tag{2}$$

where C_B is the total capacity of the battery, Δt is the time segment (1 h), and P_{bat} is the power of the battery.

BESS mode means the time schedule and dynamics of charging/discharging of the battery during the considered time period (e.g. 24 h). The mode of the operation of the BESS in each time segment of the observed period is determined in accordance with the adopted function of the BESS in the DN. This can be, for example, minimizing the cost for electricity from the source grid, reducing peak loads, maximizing the use of the energy from RES to supply local loads in the DN, etc. The power of the BESS at time t depends on the adopted battery mode operation. At the same time, the following limits must be met:

$$-P_{bat,n} \le P_{bat}(t) \le P_{bat,n}\,, \tag{3}$$

$$SoC^{\min} \le SoC(t) \le SoC^{\max}\,, \tag{4}$$

where $SoC^{\min}$ and $SoC^{\max}$ are the predefined minimum and maximum charge levels, respectively, and $P_{bat,n}$ is the rated power of the BESS.

III. Optimal Active Power Dispatch

It seems that the minimization of the cost for electricity from the source grid is most appropriate function of BESS in the DN:

$$Cost = \sum_{t=1}^{24} P_g(t)\cdot C_{en}(t)\,, \tag{5}$$

where $P_g(t)$ is the active power from/to the source grid at the hour t, $C_{en}(t)$ is the electricity price in the hour t.

This means that during periods of the day when the electricity price is low, the BESS is used to store the energy from RES and the source grid, working in the charging mode. During periods of the day with a high price of the energy from the source grid, the BESS is used as an additional power source, i.e. it operates in the discharge mode. It is assumed that the electricity price from the source grid changes during the day according to a predetermined diagram, i.e. the electricity price is known in each time segment (hour) of the considered time period.

It is clear that in the charging mode BESS behaves as a

 ISBN 978-86-7466-930-3

load, and that according to the adopted reference directions the battery power is positive, and in the discharge mode BESS acts as a generator in the DN and the power P_{bat} is negative. In order to define the terms "high price" and "low price", it is assumed that the electricity price at a given time t is high if it is higher than the mean price in the observed time period (day), and that the electricity price at the given time t is small if it is less than the mean value of the electricity price in the considered period.

In order to define the charging/discharging power of the BESS, i.e. to define the value of $P_{bat}(t)$, the principle was adopted is that the greater difference in the energy price at a given moment t, $C_{en}(t)$, in relation to the mean electricity price during the day, it is also the higher power of the battery $P_{bat}(t)$ in relation to the rated power of the battery $P_{bat,n}$. Therefore, the BESS mode at the time t can be defined as follows:

$$P_{bat}(t)=\begin{cases} 0 & \text{if} \quad SoC(t)=SoC_{\max} \\ & \text{and} \quad SoC(t)=SoC_{\max} \\ a_f(t)\cdot P_{bat,n} & \text{if} \quad C_{en}(t)\le C_{en,sr} \\ & \text{and} \quad SoC_{\min}\le SoC(t)<SoC_{\max} \\ 0 & \text{if} \quad C_{en}(t)>C_{en,sr} \\ & \text{and} \quad SoC(t)=SoC_{\min} \\ -a_f(t)\cdot P_{bat,n} & \text{if} \quad C_{en}(t)>C_{en,sr} \\ & \text{and} \quad SoC_{\min}<SoC(t)\le SoC_{\max} \end{cases} \tag{6}$$

where the coefficient a_f shows the difference in the electricity price at the time t from the mean value during the observed day:

$$a_f(t)=\frac{\left|C_{en}(t)-C_{en,mean}\right|}{C_{en,\max}}, \tag{7}$$

$C_{en,mean}$ and $C_{en,\max}$ are mean and maximum electricity price during the day, respectively.

The constraint related to the power balance in the DN for each time interval t, without considering power losses, can be expressed as folows:

$$P_g(t)=P_{load}(t)-P_{PV}(t)+P_{bat}(t), \tag{8}$$

where $P_{load}(t)$ is the total power of loads in the DN at the hour t, $P_{PV}(t)$ is the total power generation of PV sources at the hour t, while $P_{bat}(t)$ is the power of the BESS at the hour t determined according to (6).

The DN operating conditions are defined through the predicted daily load curve and PV source generation profile. In this model, the power losses in the DN are not taken into account, nor the cost of the BESS operation, and the cost of the PV generation.

IV. Optimal Distribution of Reactive Powers

PV sources and BESS are connected to the DN through three-phase inverters. Inverters have the ability to control the reactive power. Assuming that the rated power of the corresponding inverter is slightly higher (e.g. 10%) than the rated power of the PV source and BESS, it means that inverters can be used as an additional control resource in the DN. It is clear that the range of the reactive power is determined by the rated apparent power of the inverter and the active power that is transmitted through the inverter at a given moment. This can be expressed by the following relation [10]:

$$Q_{inv}^{\max}(t)=\pm\sqrt{S_{inv,n}^2-P_{PV}^2(t)}, \tag{9}$$

where $Q_{inv}^{\max}(t)$ is the maximum (minimum) reactive power of the inverter at the time t, $S_{inv,n}$ is the rated power of the inverter, and $P_{PV}(t)$ is the active power of the PV source at the time t. Equation (9) also applies to the BESS.

The optimal reactive power dispatch can be considered as a problem of determining the optimal values of the reactive powers of inverters with a certain objective function, such as minimizing power loss and/or voltage deviation in DN. Mathematically, this can be formulated as follows:

$$\min\ F(\mathbf{x},\mathbf{u}), \tag{10}$$

with constraints:

$$g(\mathbf{x},\mathbf{u})=0, \tag{11}$$

$$h(\mathbf{x},\mathbf{u})\le 0, \tag{12}$$

$$\mathbf{u}\in\mathbf{U}, \tag{13}$$

where $\mathbf{x}$ is the vector of dependent variables, $\mathbf{u}$ is the vector of control variables, and F is the objective function.

The vector of dependent variables $\mathbf{x}$ consists of the slack bus power (P_0), load bus voltages (V_L), and line loadings (S_l). On the other hand, the vector of control variables $\mathbf{u}$ consists of the inverters reactive powers (Q_{inv}), and slack bus voltage (V_0). The equality constraints (11) are the typical nonlinear power flow equations. Inequality constraints (12) are the functional operating constraints, such as: slack bus active power limits, load bus voltage limits, and branch flow limits. Constraints (13) define the feasibility region of the problem control variables, i.e. inverter reactive power limits, and slack bus voltage limits.

It is worth mentioning that the control variables are self-constrained. The inequality constraints of dependent variables are incorporated in the objective function (10) as quadratic penalty terms [11].

To solve this nonlinear optimization problem with constraints, a large number of classical and metaheuristic methods are available. In this paper, the hybrid metaheuristic method PSOS-CGSA was applied [12].

 ISBN 978-86-7466-930-3

V. Simulation Results

The proposed procedure was applied to a modified IEEE 69-bus test system [13]. Modification of the original IEEE 69-bus system is reflected in the fact that in buses 16 and 61, according to the results in [1], are connected PV sources, as shown in Fig. 1. Both PV sources have the same rated power of 1.8 MW, and they are connected to the network through inverters whose apparent powers are 10% higher than the rated powers of the PV sources. In the bus 4 is connected a BESS, rated power of 2 MW, and capacity of 8 MWh. The apparent power of the BESS converter is also 10% higher than the rated power of the BESS.

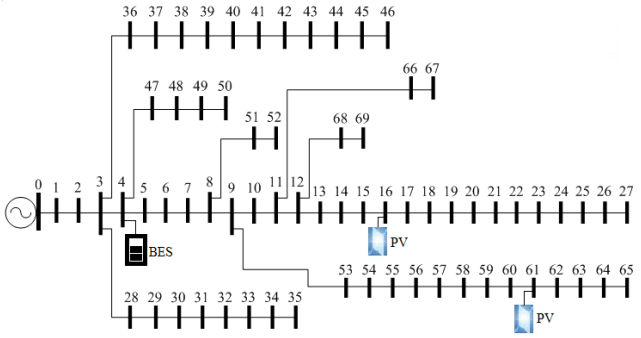

Fig. 1. Single-line diagram of the modified IEEE 69-bus test system.

It is assumed that all loads have the same daily load diagram, as shown in Fig. 2. The rated powers of loads are given in [13]. Also, it was adopted that the change of the solar irradiation is the same in the whole area of the DN, so that the powers of both PV sources change according to the same dynamics during the day, as in Fig. 2. The procedure for determining the optimal active power dispatch was carried out according to the algorithm described in Section III. The daily diagram of the change in the energy price from the source grid, expressed in p.u., is also shown in Fig. 2. The base energy price is 100 €/MWh [14]. It was adopted that SoC_{min} is 30%, SoC_{max} is 100%, and the initial state of charge is 30%.

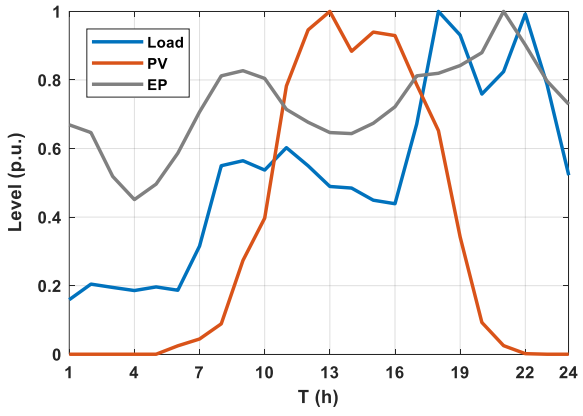

Fig. 2. Load, PV generation, and energy price (EP) profiles.

After determining the optimal active power dispatch, the procedure for determining the optimal reactive power dispatch was carried out for three types of the objective function, as follows:

- Case 1: Minimization of energy losses during the day
- Case 2: Minimization of load buses voltage deviation
- Case 3: Simultaneously minimization of energy losses and voltage deviation

It was adopted that the allowable voltage limits at load buses are from 0.95-1.05 p.u. The voltage magnitude at the slack bus is considered in the range 0.9 -1.1 p.u., whereas the reactive power limits of the inverters are changeable, according to (9).

A. Optimal Active Power Dispatch

In order to compare the results, the base case was adopted when PV sources are connected to the DN but there is no the BESS. Fig. 3 shows the costs for electricity from the source grid in the case when there is no the BESS and in the case when there is the BESS with the optimal active power dispatch obtained according to the algorithm described in Section III.

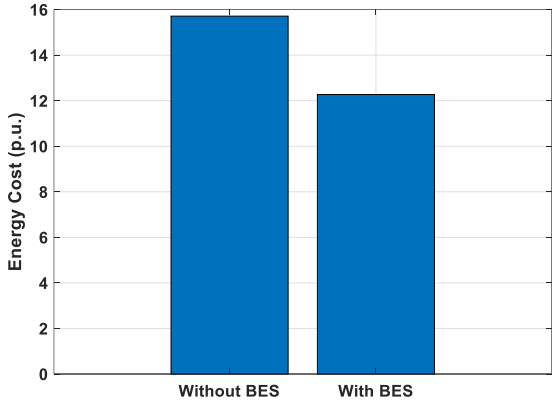

Fig. 3. Comparison of costs for energy purchased from the source grid.

As results of the optimal active power dispatch, daily diagrams of the active power and SoC of the BESS were obtained, as shown in Figs. 4 and 5, respectively.

Based on the results in Figure 3, it is clear that the integration of BESS and application of the proposed algorithm for optimal active power dispatch lead to a significant reduction in costs for electricity from the source grid. This conclusion is derived with the notation that the operating costs of the PV source and the BESS were not considered in this case.

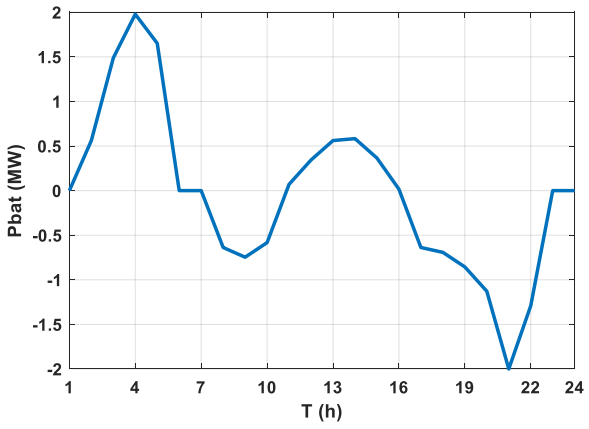

Fig. 4. The power change of the battery during the day.

 ISBN 978-86-7466-930-3

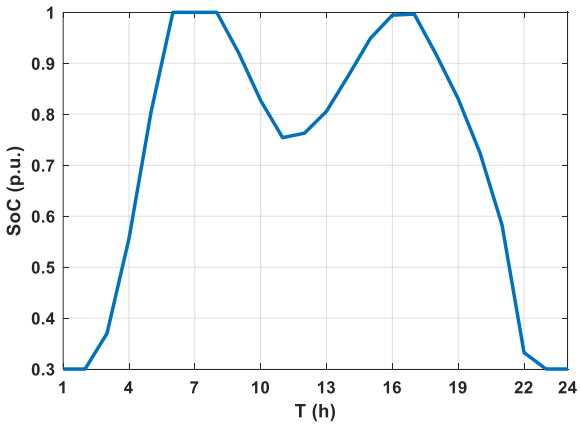

Fig. 5. The S_OC change of the battery during the day.

B. *Optimal Distribution of Reactive Powers*

The results of the optimal reactive power dispatch are given in Table I. The base case is taken when PV sources and BESS operate with unity power factor, and the slack bus voltage is equal to 1 p.u. The table shows the values of the active energy losses during the day (W_{loss}), the sum of voltage deviations at load buses during the day (ΔV_{pq}) and the maximum values of voltage deviations during the day in the whole DN. It is obvious that the proposed approach for the optimal reactive power dispatch in Case 1 achieves a significant reduction in energy losses, and in Case 2 a reduction in voltage deviations in the network. As expected, a compromise solution was obtained in Case 3. The optimal values of the control variables for Case 1 and Case 3 are shown in Figs. 6 and 7, respectively.

TABLE I
RESULTS OF THE OPTIMAL DISTRIBUTION OF REACTIVE POWERS

	Case			
	Base case	Case 1	Case 2	Case 3
W_{loss} (MWh)	2.33	2.04	2.93	2.15
sum(ΔV_{pq}) (p.u.)	22.60	57.19	16.88	19.78
max(ΔV_{pq}) (p.u.)	0.09	0.05	0.05	0.05

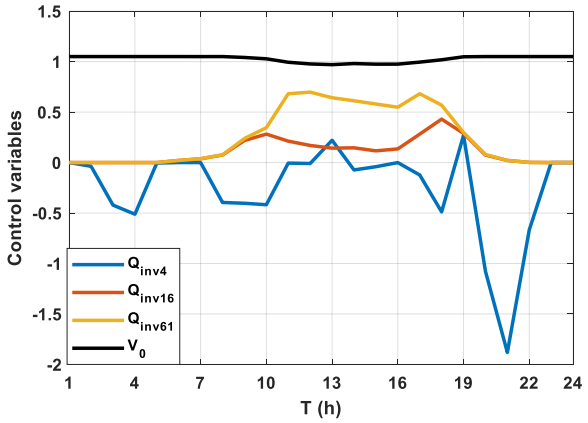

Fig. 6. Optimal values of control variables in Case 1.

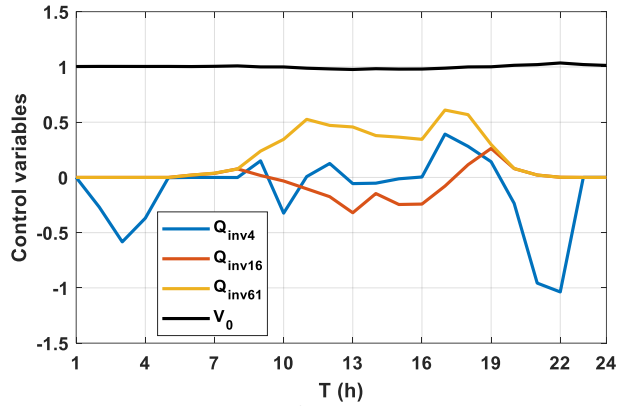

Fig. 7. Optimal values of control variables in Case 3.

The voltage profiles of the DN for the 24-hour period corresponding to the optimal active/reactive power dispatch for Cases 1-3 are shown in Figs. 8-10, respectively.

Based on these results, it can be seen a significant voltage deviation for Case 1 compared to the base case and Cases 2 and 3. This is a consequence of presenting loads with the constant power model; to minimizing the power losses in Case 1, control variables are optimized so that load voltages have higher values within the permissible limits to minimize branch currents, and thus power losses in the DN.

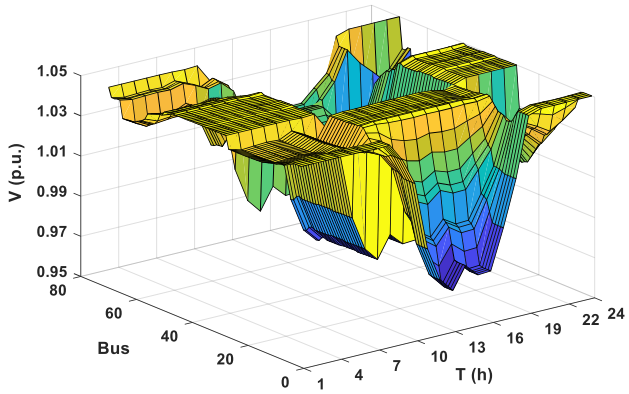

Fig. 8. Voltage profiles for Case 1.

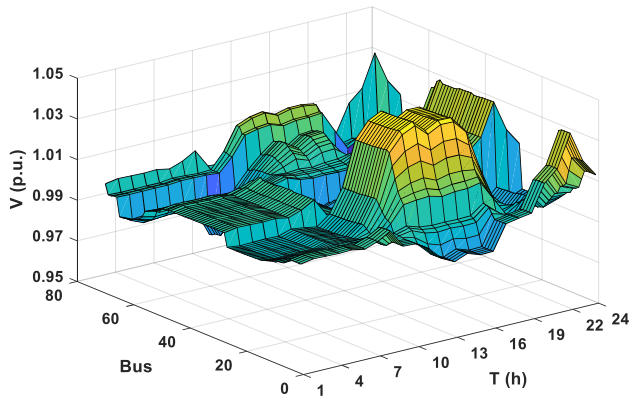

Fig. 9. Voltage profiles for Case 2.

 ISBN 978-86-7466-930-3

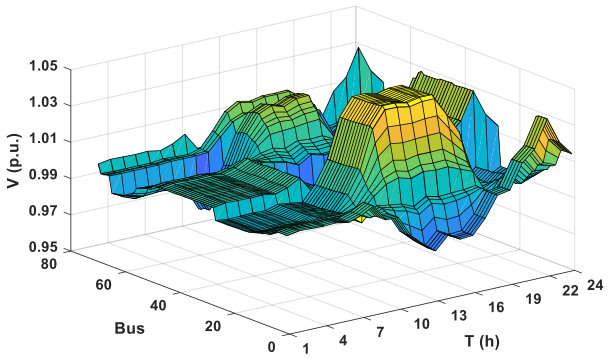

Fig. 10. Voltage profiles for Case 3.

VI. Conclusion

In this paper, a two-stage active/reactive power dispatch approach for DNs with high penetration of PV generation and BESS has been considered. The proposed procedure has been tested on the IEEE 69-bus test system with two PV sources and one BESS. The simulation results lead to conclusions that can be summarized as follows:

- Integration of BESS and application of proposed algorithm for optimal active power dispatch lead to a significant reduction in costs for electricity from the source grid. In this particular case, the results showed that it is possible to achieve a reduction in the energy cost by about 22%, compared with the base case without BESS.
- It has been shown that PV and BESS inverters can serve as additional control resources for reactive power. By applying the proposed algorithm for optimal reactive power dispatch, a significant reduction in active power losses and voltage deviations in DNs can be achieved. Specifically, in comparison with the base case, the solutions obtained by the proposed algorithm provide a reduction in energy losses of 12.45% for Case 1, and a reduction in voltage deviations of 25.31% for Case 2.

Modeling of High-Voltage Induction Machines with Fallen-out Magnetic Slot Wedges

Milica Banović, Kristina Vujkov, *Student Member, IEEE*, Mladen Terzić, *Member, IEEE*, Dejan Jerkan, *Member, IEEE*

***Abstract*— lectrical machines of medium to high voltage range are commonly fabricated with wide stator slot openings which often lead to the increase of noise, vibrations and power losses. The use of magnetic slot wedges is intended to minimize these effects.**

posure to high magnetic and mechanical forces may cause magnetic wedge fall-outs. In this paper, a dynamical model of an induction machine was developed in order to investigate the influence of stator slot magnetic wedge failures on the machine's performance. Through observation of the machine's terminal quantity disturbances, the model demonstrated remar able differences in steady-state rated operation, regarding stator line currents, rotor loop currents and generated electromagnetic toque, in case of healthy and faulty machine.

***Index Terms*—induction machine; magnetic slot wedges; finite element analysis; CCA; motor faults.**

I. Introduction

Induction machines (IMs) designed for use in modern drives and industry must cope with ever-growing demands for increased efficiency and high performance. Furthermore, there are strong requirements for the reduction of noise pollution and vibrations which represent one of the most common issues in today's motor drives. For high and medium voltage IMs, it is reported that wide open stator slots are the main cause of those issues [1-3]. A well-known means to mitigate suggested problems in medium and high voltage motors is to install magnetic stator slot wedges.

Most magnetic slot wedges are made from iron powder (~ 75%), glass fabric and epoxy resin binders, and therefore, have larger relative permeability (less than 10) compared to epoxy edges [4]. Their higher relative permeability compared to classical non-magnetic wedges reduces the flux fluctuations on the rotor core surface and decreases the effective air gap width. The smoothened flux [6] in the air gap reduces the surface core losses, acoustic noise and improves the torque characteristics [4, 5]. Therefore, magnetic slot wedges also improve motor efficiency, power factor and power density.

Since the iron powder in the magnetic wedges makes them mechanically weakened, they are more prone to failures (fall-outs) caused by exposure to high magnetic and mechanical forces. There are many cases of wedge failures in medium (high) voltage motors (above 3.3 kV) reported, where up to 50% of the wedges were lost within 3 years of service [4].

Magnetic wedge fall-outs impact the machine's performance and are observable through the IM terminal quantity disturbances. Numerical modeling of this phenomenon may be used as a starting point for the evaluation of this type of fault and investigation of reliable fault indicators.

For this purpose, a dynamical model of an IM, based on Multiple Coupled Circuit Approach (MCCA) and Finite Element Analysis (FEA) analysis [7-9] is developed in Section II. FEA calculations of IM inductances for the healthy and faulty machine are illustrated and discussed in Section III and then used for MCCA model inductance matrices formation. MCCA model simulation results, presented in Section IV clearly demonstrate the influence of magnetic slot wedge fall-outs through unbalanced stator line currents, distorted rotor bar currents and increased torque pulsation. Conclusion of this paper with further research topics suggestions is given in Section V.

II. Mathematical Representation of Mcca Model Of Squirrel-Cage Induction Motor

MCCA model of squirrel-cage IM is used to model energy conversion process in the machine, taking into account higher-order harmonic components in the magnetic field, induced voltages and currents. The nonsinusoidal electromagnetic field in the machine can be incorporated effectively by the rotor position-dependent variation of elements in MCCA model inductance matrices.

In this paper, the inductance matrix is reconstructed using series of linear 2-D FEA magneto-static simulations [7]. Discrete values of inductances obtained by this method are then represented via Fourier series, allowing the choice of harmonic components from the series which will be afterward used in the MCCA model.

The squirrel-cage rotor can be represented as identical and equally spaced rotor loops. Rotor loop consists of two neighboring rotors bars and adjacent end-ring segments. Fig. 1 shows three neighboring rotor loops (detail of rotor cage).

 ISBN 978-86-7466-930-3

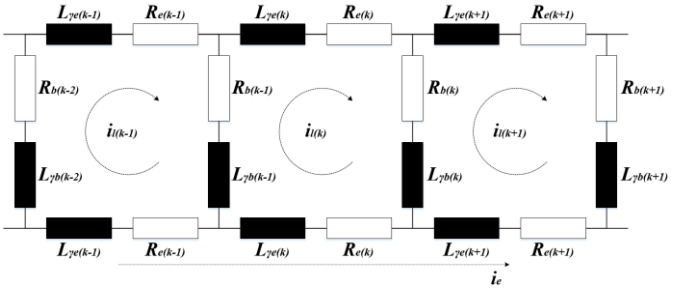

Fig. 1. Detail of squirrel-cage electrical circuit.

The mathematical model of the squirrel-cage IM can be formulated as:

$$\boldsymbol{V} = \boldsymbol{RI} + \frac{d}{dt}(\boldsymbol{LI}). \tag{1}$$

Voltage vector $\boldsymbol{V}$ consists of stator ($\boldsymbol{V_s}$) and rotor ($\boldsymbol{V_r}$) voltage vectors:

$$\begin{aligned} &\boldsymbol{V} = [\boldsymbol{V_s}\ \boldsymbol{V_r}]^T, \\ &\boldsymbol{V_s} = [v_a \quad v_b \quad v_c], \quad , \\ &\boldsymbol{V_r} = [0 \quad 0 \ldots 0 \quad 0]_{n_B+1.} \end{aligned} \tag{2}$$

where v_a, v_b, and v_c are three stator voltages and n_B is the number of rotor bars. There are $(n_B + 1)$ rotor voltages equal to zero for $(n_B + 1)$ independent current loops in the rotor cage which stand for n_B rotor bars and two end rings. Likewise voltage vector $\boldsymbol{V}$, current vector $\boldsymbol{I}$ in (1) consists of stator ($\boldsymbol{I_s}$) and rotor ($\boldsymbol{I_r}$) current vectors:

$$\begin{aligned} &\boldsymbol{I} = [\boldsymbol{I_s}\ \boldsymbol{I_r}]^T, \\ &\boldsymbol{I_s} = [i_a \quad i_b \quad i_c], \quad . \\ &\boldsymbol{I_r} = [i_{l1} \quad i_{l2} \ldots i_{ln_B} \quad i_e]_{n_B+1,} \end{aligned} \tag{3}$$

where $\boldsymbol{I_s}$ is the stator current vector for three stator phase windings i_a, i_b, and i_c. Rotor current vector $\boldsymbol{I_r}$ includes n_B rotor loops currents i_{r1}, i_{l2}, …, i_{ln_B} and one end-ring current i_e.

Diagonal 3x3 stator resistance matrix $\boldsymbol{R_s}$ and rotor resistance symmetrical matrix $\boldsymbol{R_r}$ comprise resistance matrix $\boldsymbol{R}$ from (1):

$$\begin{aligned} &\boldsymbol{R} = \begin{bmatrix} \boldsymbol{R_s} & \\ & \boldsymbol{R_r} \end{bmatrix}, \\ &\boldsymbol{R_s} = \begin{bmatrix} R_s & & \\ & R_s & \\ & & R_s \end{bmatrix}, \\ &\boldsymbol{R_r} = \begin{bmatrix} R_{l1} & -R_{b2} & \ldots & -R_{bn_B} & -R_{e1} \\ -R_{b1} & R_{l2} & \ldots & 0 & -R_{e2} \\ \vdots & \vdots & \ldots & \vdots & \vdots \\ \vdots & \vdots & \ldots & \vdots & \vdots \\ 0 & 0 & \ldots & -R_{bn_B} & -R_{e(n_B-1)} \\ -R_{b1} & 0 & \ldots & R_{ln_B} & -R_{en_B} \\ -R_{e1} & -R_{e2} & \ldots & -R_{en_B} & \sum_{i=1}^{N_B} R_{ei} \end{bmatrix}_{(n_B+1)\mathrm{x}(n_B+1)} \end{aligned} \quad , \tag{4}$$

where R_{lk} represents resistance of rotor k loop, defined as $R_{lk} = R_{bk} + R_{b(k+1)} + 2R_{ek}$ with R_{bk} as k bar resistance and R_{ek} end-ring k segment resistance.

Interaction between neighboring rotor loops and end-ring segments shown in Fig. 1 are reflected in the resistance matrix $\boldsymbol{R_r}$. Voltage equation for arbitrarily k rotor loop ($1 < k \leq N_B$) (Fig. 1) has the following form:

$$\begin{aligned} R_{ek} i_{rlk} + R_{bk}\left(i_{rlk} - i_{rl(k+1)}\right) + R_{ek}(i_{rlk} - i_e) - \\ R_{b(k-1)}\left(i_{rl(k-1)} - i_{rlk}\right) + \frac{d\Psi_{\mathrm{rlk}}}{dt} = 0, \end{aligned} \tag{5}$$

It can be noticed that negative elements in the matrix $\boldsymbol{R_r}$ (4) result from interactions between neighboring rotor loops and end ring.

Rotor bar current i_{bk} can be expressed through neighboring rotor loop currents as follows:

$$i_{bk} = i_{lk} - i_{l(k+1)}. \tag{7}$$

Inductance matrix $\boldsymbol{L}$ is a periodic function of rotor angular position θ, and it consists of four sub-matrices:

$$\boldsymbol{L}(\theta) = \begin{bmatrix} \boldsymbol{L_{ss}}(\theta) & \boldsymbol{L_{sr}}(\theta) \\ \boldsymbol{L_{rs}}(\theta) & \boldsymbol{L_{rr}}(\theta) \end{bmatrix}. \tag{8}$$

Stator inductance matrix $\boldsymbol{L_{ss}}$ is θ-dependent 3x3 matrix which defines magnetic coupling between stator phases:

$$\boldsymbol{L_{ss}}(\theta) = \begin{bmatrix} L_a & M_{ab} & M_{ac} \\ M_{ba} & L_b & M_{bc} \\ M_{ca} & M_{cb} & L_c \end{bmatrix}. \tag{9}$$

Rotor inductance matrix $\boldsymbol{L_{rr}}$ is a $(n_B + 1)$x$(n_B + 1)$ position-varying matrix generated similarly to rotor resistance matrix with one major difference; any rotor loop is magnetically coupled with all the other loops and generally there are no zero elements in it:

$$\boldsymbol{L_{rr}}(\theta) = \begin{bmatrix} L_{l1} & \ldots & M_{r1n_B} - L_{bn_B} & -L_{\gamma e1} \\ M_{r21} - L_{b1} & \ldots & M_{r2n_B} & -L_{\gamma e2} \\ \vdots & \ldots & \vdots & \vdots \\ \vdots & \ldots & \vdots & \vdots \\ M_{r(n_B-1)1} & \ldots & M_{r(n_B-1)n_B} - L_{bn_B} & -L_{\gamma e(n_B-1)} \\ M_{rn_B1} - L_{b1} & \ldots & L_{ln_B} & -L_{en_B} \\ -L_{e1} & \ldots & -L_{en_B} & \sum_{i=1}^{n_B} L_{ei} \end{bmatrix}. \tag{10}$$

Rotor k loop inductance L_{lk} ($1 \leq k \leq n_B$) is defined as $L_{lk} = L_k + L_{\gamma bk} + L_{\gamma b(k+1)} + 2L_{\gamma ek}$, where L_k is k loop self-inductance, $L_{\gamma bk}$ is rotor k bar leakage inductance, and $L_{\gamma ek}$ is rotor end-ring k segment leakage inductance. Mutual inductances between arbitrary rotor loops m and n are labeled as M_{rmn} ($1 \leq m, n \leq n_B \wedge m \neq n$).

Stator-rotor inductance matrix $\boldsymbol{L_{sr}}$ is defined as:

 ISBN 978-86-7466-930-3

$$\boldsymbol{L_{sr}}(\theta) = \begin{bmatrix} M_{al1} & M_{al2} & \dots & M_{al_{n_B}} & 0 \\ M_{bl1} & M_{bl2} & \dots & M_{bl_{n_B}} & 0 \\ M_{cl1} & M_{cl2} & \dots & M_{cl_{n_B}} & 0 \end{bmatrix}, \quad (11)$$

Mutual inductance between arbitrarily stator phase x and rotor loop k is labeled as M_{xlk}, where $x \in \{a, b, c\}, 1 \leq k \leq n_B$. Rotor-stator inductance matrix $\boldsymbol{L_{rs}}$ can be derived from (11), by transposition of stator-rotor inductance matrix $\boldsymbol{L_{rs}} = \boldsymbol{L_{sr}^T}$.

The calculation of torque T_e in the MCCA model is based on the virtual work principle (p is pole pairs number):

$$T_e = \frac{1}{2} p \begin{bmatrix} \boldsymbol{I_s} \\ \boldsymbol{I_r} \end{bmatrix}^T \frac{d}{d\theta} \left(\begin{bmatrix} \boldsymbol{L_{ss}} & \boldsymbol{L_{sr}} \\ \boldsymbol{L_{rs}} & \boldsymbol{L_{rr}} \end{bmatrix} \right) \begin{bmatrix} \boldsymbol{I_s} \\ \boldsymbol{I_r} \end{bmatrix}. \quad (12)$$

III. Inductance Calculation of Healthy and Faulty IM

After derivation of MCCA model in Section II, inductance calculation method shall be presented in the following. Modeled induction machine is a 2-pole, 6 kV high voltage motor with rated output power of 1.03 MW (detailed machine data are given in Appendix). Magnetic slot wedges of relative permeability 5 are used to close stator slot openings.

Linear magneto-static 2-D FEA simulations are used to compute discrete values of machine's inductances relative to absolute rotor angular position. Saturation effect is neglected. In the calculated inductance waveforms, only harmonics provoked by geometry variations and presence/absence of the magnetic wedges are investigated. These harmonics are independent from saturation-induced harmonics and can be treated separately.

In order to obtain self- and mutual inductances of an arbitrary winding for a fixed rotor position, only the winding itself is supplied with 1 A direct current. After single magneto-static simulation is completed, flux linkages of all windings in the machine are determined and used for single discrete value inductance calculation. Next magneto-static simulation is performed in the same manner after fixed-valued angle increment of rotor position. The value of angle increment determines the precision of inductances waveforms.

One full revolution of rotor is necessary for complete inductance matric reconstruction. Derived discrete waveforms are then represented with Fourier series coefficients in the MATLAB&Simulink model.

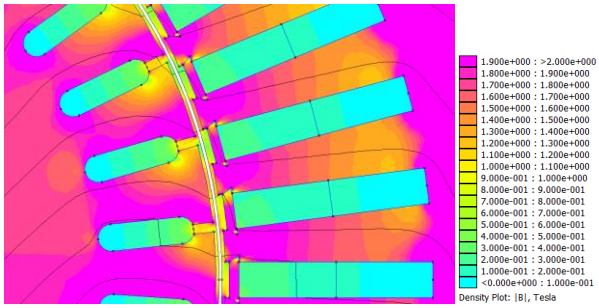

Fig. 2. Discrete magneto-static simulation of healthy IM

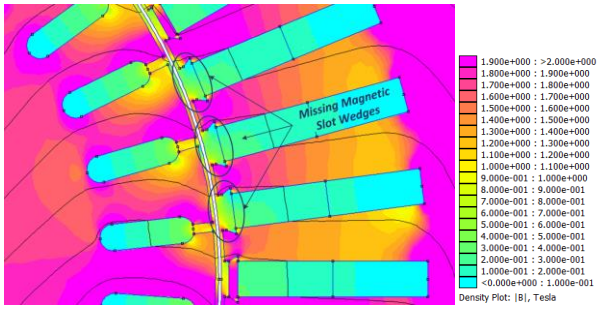

Fig. 3. Discrete magneto-static simulation of faulty IM (three consecutive fallen-out wedges)

Detail of magneto-static simulation for healthy and faulty IM is given in Fig. 2 and Fig. 3, respectively. The analyzed fault is modeled by three consecutive completely fallen-out wedges. As can be seen from the figures magnetic flux lines crossing the air gap from rotor to stator have significantly more homogeneous flow in the healthy motor compared to the one with missing wedges. Represented local distortion of flux lines will lead to deformation of machine inductances in case of fault occurrence.

Stator phase *A* self-inductance as a function of rotor angular position is shown in Fig. 4. Minor oscillations around the constant value of stator self-inductance are the result of air gap equivalent permeability variations caused by rotor slotting. Since analyzed IM has 36 rotor slots all three stator self-inductances have identical waveforms and their minor oscillations are in phase.

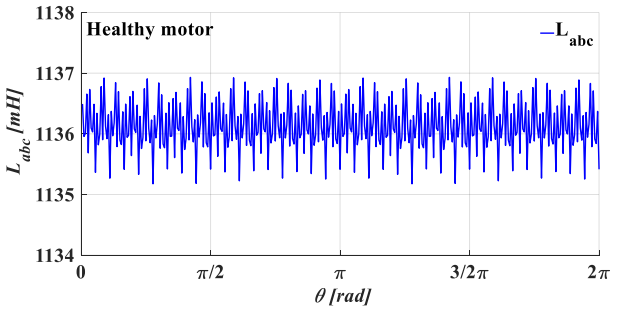

Fig. 4. Stator phase A self-inductance waveform – healthy motor

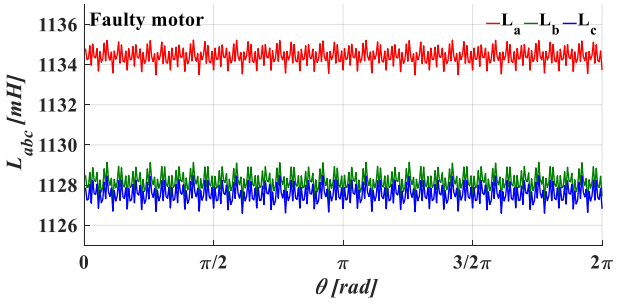

Fig. 5. Stator phases self-inductances waveform – faulty motor

In case of fallen-out wedges, the balance of stator

 ISBN 978-86-7466-930-3

windings is corrupted. This leads to different mean values of stator self inductances for phase *A*, *B*, and *C*. Modeled missing wedges are in close vicinity of phase *B* and *C* winding axes. Lack of ferromagnetic material caused by fallen-out magnetic wedges decreases inductances of most affected windings - Fig. 5.

Similar phenomena can be observed in stator mutual inductance waveforms. All stator mutual inductances are identical in case of healthy motor (Fig. 6), while in the event of fault (Fig. 7), all mutual inductances suffer in mean value reduction. Mutual inductances involving phase *A* are less influenced by the fault, as expected.

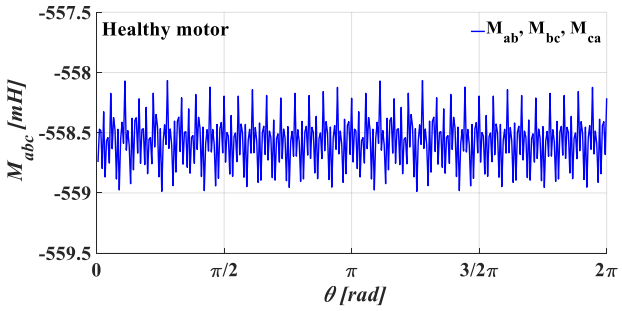

Fig. 6. Stator phases mutual inductances waveform – healthy motor

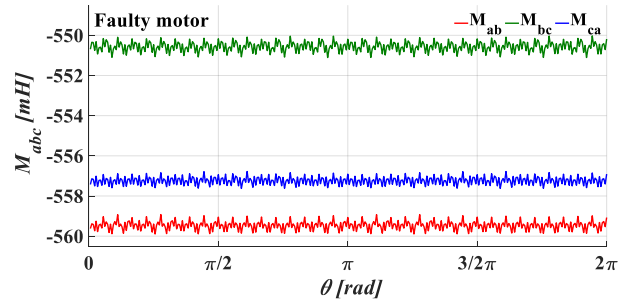

Fig. 7. Stator phases mutual inductances waveform – faulty motor

Stator-rotor inductances of IM are the main contributors to torque generation. For healthy motor, they are symmetrical, alternating, rotor angular position-dependent functions with characteristic trapezoidal shape (Fig. 8 – blue line). Therefore, spectrum of trapezoidal inductance signal contains only odd higher-order harmonics (Fig. 9 – blue bars). However, in the presence of slot wedge faults, a local dip in the waveform is formed each time specific rotor loop passes by stator slots with missing wedges (Fig. 8 – red line). As a result, new even harmonic components in the Fourier series appear (Fig. 9 – red bars). These additional components will further induce characteristic harmonics in flux linkages and consequently, in induced voltages and currents. This will affect torque production by causing unwanted pulsations.

The fallen-out magnetic slot wedges also have impact on rotor inductance matrix. Similar to stator inductances, rotor inductances in the healthy machine are fairly constant quantities with small oscillations around the mean value. These oscillations are the consequences of stator slotting. Slot wedges reduce these oscillations by making stator inner circumference more magnetically uniformed.

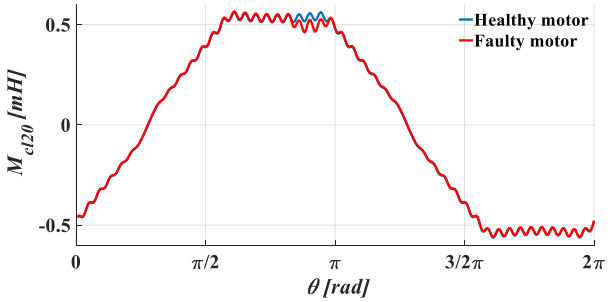

Fig. 8. Mutual inductance between stator phase C and rotor loop 20

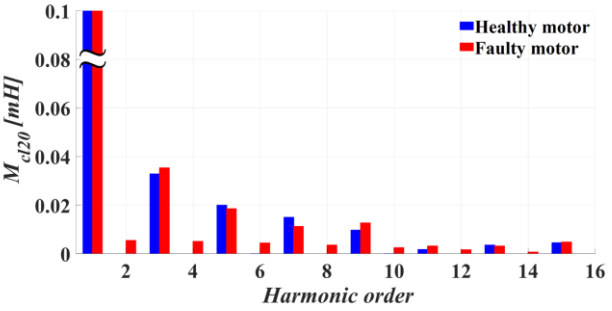

Fig. 9. Mutual inductance between stator phase C and rotor loop 20 - Fourier series coefficients

In Fig. 10 blue line illustrates rotor loop self-inductance waveform in healthy motor. There are exactly 48 oscillations in one rotor revolution due to the number of stator slots. When slot wedges are missing stator magnetic uniformity is lost which will locally diminish rotor self-inductance just as rotor loop passes by faulty slots. Since three neighboring slots are impacted by the fault, there will be three more prominent oscillations combined with lower mean value in the inductance waveform (Fig. 10 – red line).

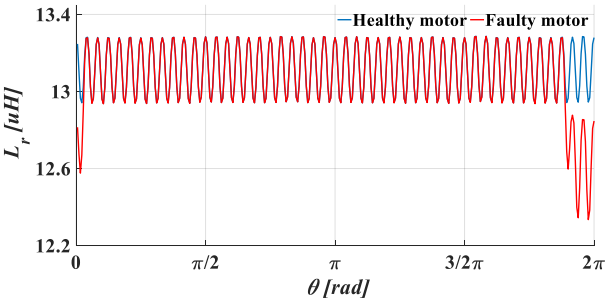

Fig. 10. Rotor loop self-inductance

A detail of rotor self-inductance spectrum, both for healthy and faulty motor, is shown in Fig. 11. In order to emphasize the emergence of additional spectral components, dominant mean value is excluded from the figure. Despite their small magnitudes, higher-order components have a significant impact on the energy conversion process which will be

 ISBN 978-86-7466-930-3

illustrated and discussed in the next Section.

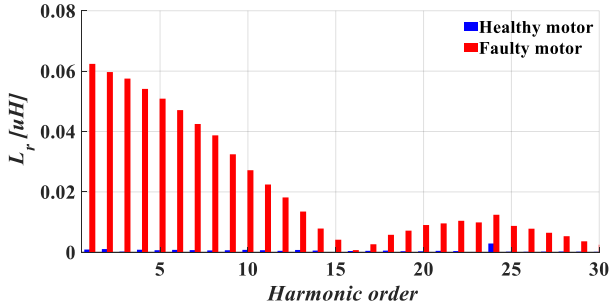

Fig. 11. Rotor loop self-inductance – spectrum with mean value excluded

As the last characteristic example of the magnetic wedge fall-outs impact on machine's inductances, mutual inductance between arbitrarily chosen rotor loops is shown in Fig. 11 (healthy machine in blue and faulty in red line). Magnetic coupling between two rotor loops subjects to complex mechanisms of flux lines formation and it is dependent on relative rotor position and the mutual position of the loops themselves. The situation grows even more puzzling when slot wedge fault is present, as observable in Fig. 11- red line.

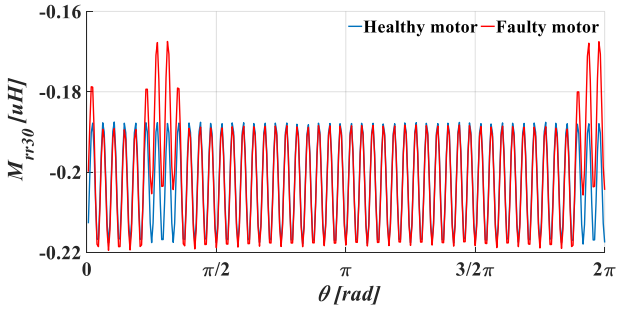

Fig. 12. Mutual inductance between first and 31st rotor loop

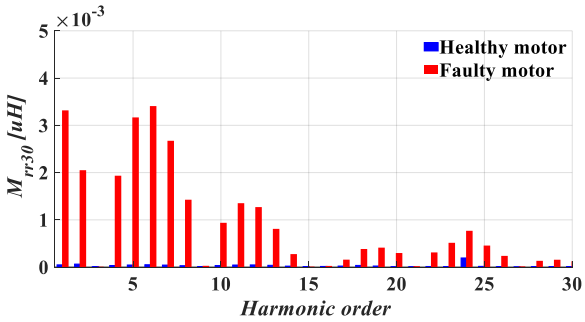

Fig. 13. Mutual inductance between first and 31st rotor loop – spectrum with mean value excluded

Singled out higher-order components of the mutual inductance between first and 31st rotor loop, shown in Fig. 13 are compliant with the expected increase in number and magnitude of additional components in the spectrum, similar to elaborated phenomena in Fig. 11.

IV. Simulation Results

Based on FEA calculation of machine's inductances presented in Section III and MCCA model derived in Section II MATLAB&Simulink model of the machine under investigation (Appendix) was developed.

The output of FEA computations i.e. waveforms of machine inductances are firstly represented with Fourier series coefficients. These coefficients are then used for the formation of time and position varying inductance matrices of dynamic MCCA machine model. Inductances independent from geometry variations which cannot be calculated using 2-D representation of the machine: stator end-winding and rotor end-ring leakage inductances are added to the MCCA model inductance matrices as constant values. Their values are provided from separate simulations performed using commercial FEA software with such built-in options. MCCA model is able to simulate transient behavior of the machine under arbitrary supply and loading conditions, similar to conventional dq models, but with much more insight into construction-dependent properties of the specific machine.

Stator line currents during steady-state operation under the rated load of healthy machine are illustrated in Fig. 14. The machine was supplied from three-phase balanced voltage source of 6 kV at rated frequency of 50 Hz. Rated speed of the machine was 2985 rpm, rated torque 3.23 kNm and rated output power 1.03 MW. As expected, line currents are balanced in the case of healthy machine.

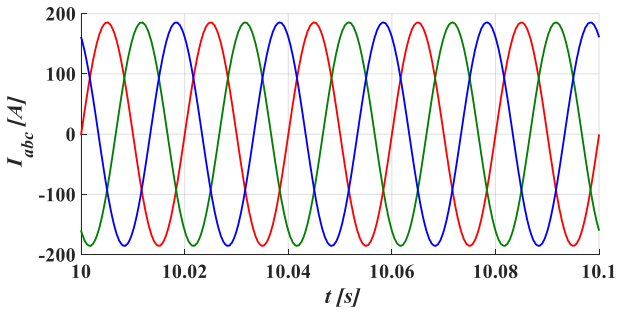

Fig. 14. Stator line currents under full load – healthy machine

Under the same supply and loading conditions, but with magnetic wedge fault present, unbalance in stator line currents is clearly visible in Fig. 15. Fallen-out magnetic wedges led to unbalanced inductances of stator phase windings (Fig. 5 and 7) which consequently caused noticeable imbalance in the currents as well.

Fig. 16 shows differences between arbitrary rotor loop current waveforms in case of the healthy and faulty machine. It is noticeable that, in the event of fault, rotor loop current waveform will contain more prominent oscillations which were expected as the result of emergence of additional components in the inductance spectrum of the faulty machine.

 ISBN 978-86-7466-930-3

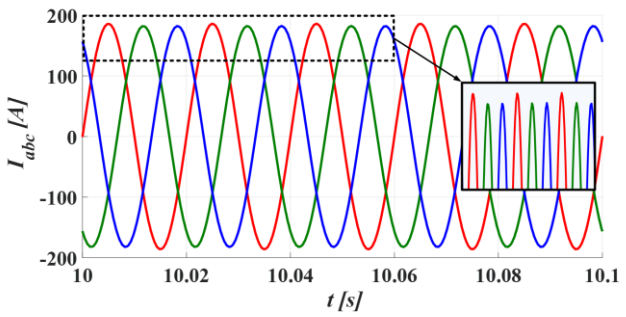

Fig. 15. Stator line currents under full load – faulty machine

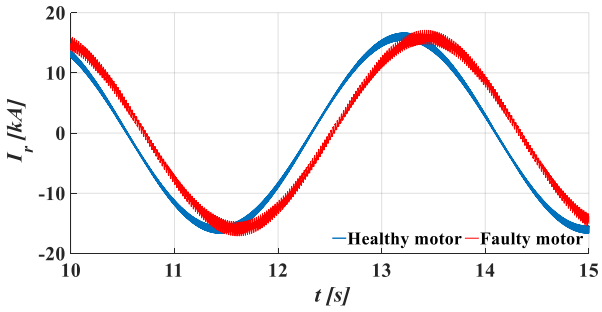

Fig. 16. Current waveform of arbitrary rotor loop under full load

Parasitic torque pulsations are direct outcome of increased oscillations in the machine inductances and currents. In the Fig. 17, the machine toque waveform is illustrated for rated operational mode with and without fault. Increased torque pulsations may provoke an unwanted mechanical response from the machine which could reflect on the level of noise and vibrations. Exceeding level of vibration can have great impact on bearing deterioration, may cause cracks in the winding insulation and tightness of the lamination stack.

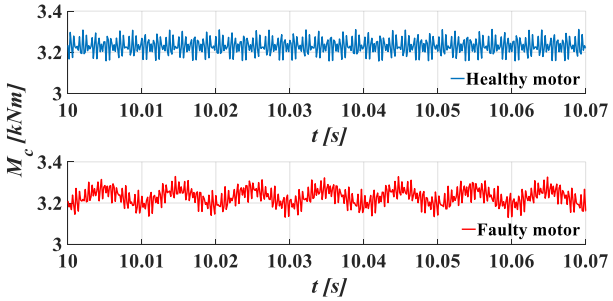

Fig. 17. Rated electromagnetic torque

V. Conclusion

In this paper MCCA model of high voltage squirrel-cage induction machine is used to investigate the influence of stator slot magnetic wedge failures on machine's performance. Series of magneto-static FEA simulations illustrated differences in waveforms of characteristic inductances of the machine in case of healthy machine and the machine with three consecutive fallen-out stator magnetic wedges. FEA results provided input data for MCCA inductance matrices formation, using the Fourier series coefficient. Through observation of the machine's terminal quantity disturbances, performed simulations in MATLAB&Simulink dynamic MCCA model of IM demonstrated remarkable differences in steady-state rated operation, regarding stator line currents, rotor loop currents and generated electromagnetic toque. Further research may include targeted thorough analysis of the terminal quantities in the interest of reliable and non-invasive detection of fallen-out wedges.

Time-domain Simulation of Electric Circuit with Nonlinear Hysteretic Inductor

Srđan Divac and Branko Koprivica

***Abstract*—The aim of this paper is to present a method for simulation of electric circuits with nonlinear inductor with hysteresis in time domain. The method is based on solving equation derived from Kirchhoff's law of the considered electric circuit through a series of successive iterations. Electric circuit consisting of AC voltage source connected in series with linear resistor, linear inductor and nonlinear inductor with hysteresis has been considered. Simulations have been performed for four cases of the considered electric circuit – without linear elements, with one and both linear elements, for sinusoidal voltage source amplitudes from 2 V to 10 V with the step of 2 V. Detailed simulation procedure, measurement and simulation results, as well as adequate discussion, have been presented.**

***Index Terms*—Simulation method, electric circuit, nonlinear inductor, magnetic hysteresis, time domain.**

I. Introduction

SOLVING an electric circuit with nonlinear inductor with hysteresis is very challenging due to the appearance of higher harmonics in the electric current, due to distorted waveform of the magnetic field (strength) of considered inductor [1]. Methods used in power engineering are commonly obtained by substituting the inductor with an equivalent *RL* circuit (consisting of a single nonlinear inductor represented by magnetising curve in parallel with linear or nonlinear resistor to represent hysteresis power loss) and solving the circuit [2]. However, this method cannot accurately solve electric circuits in time domain. Better results in time domain can be obtained by varying the resistance and the inductance of the elements in time, as proposed by De Leon [3]. More complex solutions of the electric circuit implement the use of one of the hysteresis models to represent the inductor with hysteresis [4]. Some of the commonly used models are: Preisach [5], Jilles-Atherton [6], Neural Network based models [7] and others. This method gives better results in time domain but the mathematics behind the model itself can be quite complex and its parameters difficult to obtain.

Presented simulation method is based on solving equation derived from Kirchhoff's law for the considered electric circuit through series of successive iterations. Electric circuit consisting of AC voltage source connected in series with linear resistor, linear inductor and nonlinear inductor with hysteresis. Influence of the inductor with hysteresis has been accounted for by calculating circuit current from dynamic magnetic field waveform $H_{dyn}(t)$ of the inductor. Dynamic field $H_{dyn}(t)$ has been obtained by following the simulation method for dynamic hysteresis loops and rate-independent property of the quasistatic hysteresis loops [8, 9]. This has been done by considering three components of $H_{dyn}(t)$ - quasistatic field $H_{qs}(t)$, eddy current field $H_{eddy}(t)$ and excess field $H_{exc}(t)$ [10].

Measurements of the magnetic field waveform $H(t)$ and magnetic flux density waveform $B(t)$ have been made using the measurement method based on data acquisition with PC [1]. Waveforms have been measured at frequency of 1 Hz for amplitudes of sinusoidal $B(t)$ from 0.2 T to 1.6 T with measurement step of 0.2 T. Also, measurement has been made at frequency of 50 Hz for sinusoidal $B(t)$ with the amplitude of 1 T. This measurement has been used for calculation of phenomenological parameters of $H_{exc}(t)$ by fitting the calculated excess power loss to measured excess loss. Fitting has been performed using the criteria of least root mean square deviation (RMSD [11, 12]) between excess power loss.

Simulations have been made for four cases of the considered electric circuit - without linear elements, with one and both elements, for sinusoidal input voltage with amplitudes from 2 V to 10 V with the step of 2 V.

A description of the simulation procedure, presentation of measurement and simulation results, as well as adequate discussion have been given in the paper.

II. Measurement Results

Measurements of magnetic field $H(t)$ and magnetic flux density $B(t)$ waveforms have been performed by using measurement method based on data acquisition and PC [1]. Measurements have been made with toroidal shaped sample made of electrical steel sheet 27PH100 (manufactured by POSCO). Parameters of used toroidal sample can be found in Table I. All measurements have been made with 1000 data points.

frequency of 1 Hz for controlled sinusoidal shape of $B(t)$ (voltage induced at the secondary winding). Measurements have been made for $B(t)$ amplitudes ranging from 0.2 T to 1.6 T with step of 0.2 T. The obtained hysteresis loops are presented in Fig. 1. Also, $H(t)$ and B(t) have been measured at 50 Hz and 1 T to obtain a dynamic hysteresis loop needed for calculation of phenomenological parameters of $H_{exc}(t)$. This hysteresis loop is shown in Fig. 1 as dashed line.

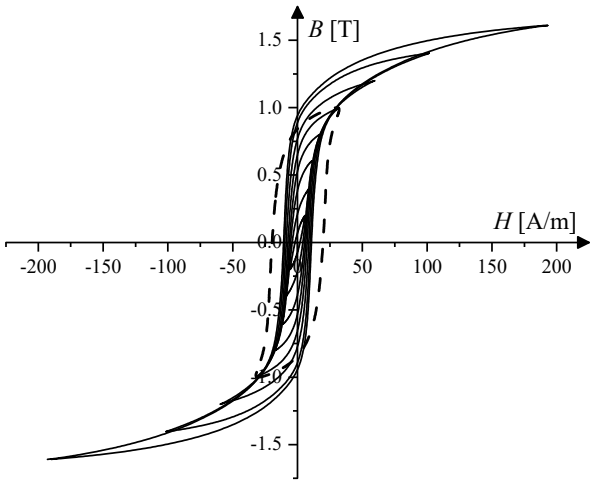

Fig. 1. Measured hysteresis loops for sinusoidal shape of $B(t)$.

III. Simulation Procedure

Considered electric circuit consisting of voltage source $u(t)$ in series with linear resistor R, linear inductor L and nonlinear inductive element exhibiting hysteretic properties L_h is presented in Fig. 2.

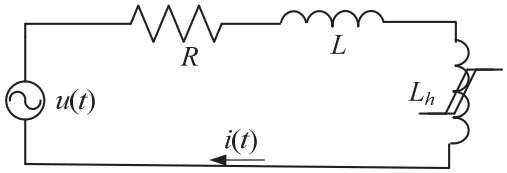

Fig. 2. Electric AC circuit with linear R and L elements and nonlinear L_h element with hysteresis.

Solving of this circuit means the calculation of its electric current $i(t)$, which depends on elements R, L and L_h and their characteristics. Obtaining dynamic solution is complicated due to the nonlinear and hysteretic characteristic of L_h. Its characteristic is usually represented with the dynamic hysteresis loops (the dynamic magnetic field $H_{dyn}(t)$ and magnetic flux density $B(t)$).

A. Calculation of dynamic magnetic field $H_{dyn}(t)$

Dynamic magnetic field $H_{dyn}(t)$ can be obtained by calculating its quasistatic $H_{qs}(t)$, eddy current $H_{eddy}(t)$ and excess $H_{exc}(t)$ components, and summing them up [10, 12]:

$$H_{dyn}(t) = H_{qs}(t) + H_{eddy}(t) + H_{exc}(t) \qquad (1)$$

Calculation of $H_{qs}(t)$ requires two steps. First, quasistatic field $H_{int}(t)$ needs to be calculated for sinusoidal $B(t)$, $B_{int}(t)$, with the amplitude $B_{\max}$ of interest. So, N harmonic components (amplitudes and phases) of measured quasistatic $H(t)$ need to be calculated at particular amplitudes of $B(t)$ for each measured quasistatic loop, Fig. 1. For new $B_{\max}$ of interest, N new harmonics of $H_{int}(t)$ can be calculated by linear or higher order polynomial interpolation of previously calculated harmonics [8]. Further, $H_{int}(t)$ and a new quasistatic hysteresis loop formed by $H_{int}(t)$ and sinusoidal $B_{int}(t)$ can be obtained. In the second step, a general solution for $H_{qs}(t)$ for non-sinusoidal $B(t)$, $B_{Lh}(t)$, with the amplitude of $B_{\max}$, can be obtained by using inverted hysteresis loop $H_{int}(B_{int})$, which can be considered as rate-independent (having fixed shape) at the frequency of 1 Hz. The shape of that hysteresis loop is only determined by the amplitudes of $H(t)$ and $B(t)$ and not by the shape of their waveforms [9]. Thus, $H_{qs}(t)$ can be obtained by reconstructing data points for $B_{Lh}(t)$ over data points for $H_{int}(B_{int})$ [13]. This procedure is illustrated in Fig. 3.

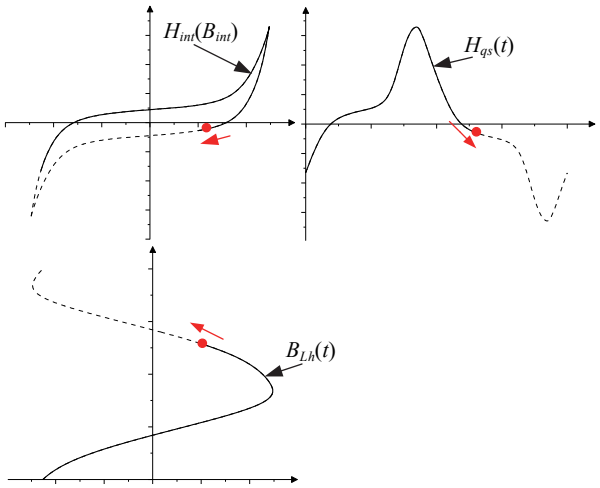

Fig. 3. Illustration of obtaining $H_{qs}(t)$ by reconstructing of non-sinusoidal $B_{Lh}(t)$ over the quasistatic hysteresis loop $H_{int}(B_{int})$.

Calculation errors may occur during this step due to the phase difference between $B_{Lh}(t)$ and B_{int}(t). This phase difference can be taken into account by delaying $B_{Lh}(t)$ for the period of Δt, $B_{Lh}(t+\Delta t)$, and proceed further with the calculations. Delaying period should be chosen so that the minimum and maximum values of $B_{Lh}(t+\Delta t)$ occur at the same time as for $B_{int}(t)$. Resulting $H_{qs}(t+\Delta t)$ should be delayed for the period of $-\Delta t$ to obtain $H_{qs}(t)$.

Waveform of $H_{eddy}(t)$ can be calculated from well-known analytical expression [10]:

$$H_{eddy}(t) = \frac{\sigma d^2}{12}\frac{\mathrm{d}B_{Lh}(t)}{\mathrm{d}t}, \qquad (2)$$

where σ is the conductivity of steel sheet and d is its thickness.

 ISBN 978-86-7466-930-3

Calculation of $H_{exc}(t)$ can be made using the following expression [10]:

$$H_{exc}(t)=\frac{n_0V_0}{2}\left(\sqrt{1+\frac{4\sigma GS}{{n_0}^2V_0}\frac{\mathrm{d}B_{Lh}(t)}{\mathrm{d}t}}-1\right), \quad (3)$$

where G is equal to 0.1356 and n_0 and V_0 are phenomenological parameters of material.

Consideration of hysteresis loop measured at 1 Hz as rate-independent is not completely correct (accurate), as there would always exist some difference between such loop and true static loop due to the existence of the dynamic components of the field ($H_{eddy}(t)$ and $H_{exc}(t)$). Dynamic components at 1 Hz participate with several percent in the quasi-static field and power loss under sinusoidal and non-sinusoidal conditions [14]. However, these components are much smaller at 1 Hz than at 50 Hz, considered in the simulations. Accordingly, the accuracy of the simulation would not be significantly affected with such consideration (approximation).

It should be noted that all quantities measured and calculated (magnetic field and flux density) are averaged for the considered mean magnetic path length and cross-section area of the toroidal sample. Actually, these quantities vary with the radial distance from the sample longitudinal axis (over the radius). However, the variations are not too high when the outer to inner radius ratio (r_2/ r_1) is low, as in the case of used sample (see Table I). The results of the simulation relate to the sample as a whole, as a part of the considered electric circuit, neglecting inhomogeneity of the magnetic field, which is acceptable in most of the practical applications. Accordingly, expressions (2) and (3) do not depend on the toroid dimensions (radiuses r_1 and r_2 and width w).

B. Iterative procedure

Proposed iterative algorithm for solving the circuit presented in Fig. 2 can be divided into the following steps:

1) calculating of the voltage at L_h for (i+1)-th iteration, $u_{Lh,i+1}(t)$, using II Kirchhoff's law [15]:

$$u_{Lh,i+1}(t)=u(t)-Ri_i(t)-L\frac{\mathrm{d}i_i(t)}{\mathrm{d}t}, \quad (4)$$

where $i_i(t)$ is the current derived from i-th iteration, t is the time, R and L are the resistance and inductance of the considered linear elements,

2) calculation of $B_{Lh,i+1}(t)$ from $u_{Lh,i+1}(t)$ using Faraday's law [15], as follows:

$$B_{Lh,i+1}(t)=\frac{1}{N_1S}\int_0^t u_{Lh,i+1}(t)\mathrm{d}t, \quad (5)$$

where N_1 is the number of turns in the magnetising coil and S is the cross-section area of magnetic core of L_h,

3) calculation of $H_{dyn,i+1}(t)$ for non-sinusoidal $B_{Lh,i+1}(t)$ using the procedure explained in subsection A,

4) calculation of $i_{i+1}(t)$ using Ampere's law [15]:

$$i_{i+1}(t)=\frac{H_{dyn,i+1}(t)}{N_1}l_c, \quad (6)$$

where l_c is the mean magnetising path length of L_h,

5) steps 1-4 should be repeated until condition (7) is met:

$$\frac{\max\{|i_i(t)|\}-\max\{|i_{i+1}(t)|\}}{\max\{|i_{i+1}(t)|\}}100\%<\varepsilon, \quad (7)$$

where ε is predetermined limit, which is not so rigorous.

Iterative procedure starts with $i_0(t)$=0 A for each time sample of t>0 and amplitude of $u(t)$ factorised by K>1 to minimise the oscilations and time shifts between iterations, such that:

$$U_{m,k}=\frac{U_m}{K}k, \quad (8)$$

where k=1, 2, 3,…, K. Solution of the k-th step is the new initial condition $i_k(t)$ for the (k+1)-th step. The value of K should be chosen high enough to allow for good convergence of the iterative procedure, but low enough to keep required computation time acceptable.

After finishing the iterative procedure, obtained waveforms of $H_{dyn}(t)$ and $B_{Lh}(t)$ can be used to plot dynamic hysteresis loop of L_h. Also, the specific power loss of L_h (corresponding to the area of the dynamic hysteresis loop), expressed in W/kg, can be calculated as:

$$P_s=\frac{1}{mT}\int_0^T u_{L_h}(t)i(t)\mathrm{d}t=\frac{Sl_c}{mT}\int_0^T\frac{\mathrm{d}B_{L_h}(t)}{\mathrm{d}t}H_{dyn}(t)\mathrm{d}t, \quad (9)$$

where T=1/f is the period and m is the mass.

IV. SIMULATION RESULTS

Four cases of the electric circuit presented in Fig. 2 have been considered:

I. with R=0 Ω and L=0 H;
II. with R=48 Ω and L=0 H;
III. with R=0 Ω and L=20 mH and
IV. with R=48 Ω and L=20 mH.

A sinusoidal voltage source with U_m from 2 V to 10 V with the step of 2 V and frequency of 50 Hz has been used for all performed simulations. All simulations have been made using 1000 data points.

Other, lower or higher frequencies can also be used in simulations. However, the frequency of 50 Hz is of particular importance, as it is used as the working frequency in most of the basic electric circuits, as considered one. Consideration of higher frequencies would also be interesting for some advanced applications of electric machines and drives, power

 ISBN 978-86-7466-930-3

electronics and other. However, that is beyond of the scope of this paper.

Total of N=35 harmonics of measured quasistatic $H(t)$ have been used during the 4th step of the simulation process. This number of harmonics has been found to be optimal in case of U_m=10 V, therefore, less harmonics could be used for lower U_m.

Parameters of the electrical steel σ and d, used to calculate the magnetic field of eddy currents in (2), have been provided by the manufacturer and amount 2083 kS/m and 0.27 mm, respectively. Other parameters of the material given by the producer are: density ρ=7650 kg/m^3, B_{max}=1.90 T for H_{max}=800 A/m, specific power loss at 50 Hz is 0.72 W/kg for 1.5 T and 0.95 for 1.7 T, maximum of the relative permeability is around 70000 for static fields, coercive field goes up to 10 A/m for static field and up to 25 A/m for field at 50 Hz under sinusoidal $B(t)$.

Parameters n_0=908 and V_0=0.08 A/m in (3) have been obtained by fitting the excess power loss caused by $H_{exc}(t)$ for sinusoidal shape of $B(t)$ at 1 T to the excess power loss calculated from measurements for the same $B(t)$ [12], taking into account both hysteresis and dynamic loss (given by the hysteresis loops measured at 1 Hz and 50 Hz) and eddy current loss calculated using $H_{eddy}(t)$ given by (2) at 50 Hz. Fitting has been performed using the criteria of RMSD between excess power loss produced by fitted and calculated excess magnetic field. Both parameters have been kept constant in all performed simulations.

Predetermined limit ε has been set to 0.5%. This value has been chosen in order to obtain best convergence of the simulation procedure. Parameter K has been set to 30 to obtain best solutions in case III for U_m=10 V and has been kept at this value for all simulations. It has been found that total number of iterations for K steps is 36, 30, 31 and 30, for each of the considered cases at U_m=10 V, respectively.

Results for $i(t)$ for case IV of electric circuit for all considered values of U_m are presented in Fig. 4.

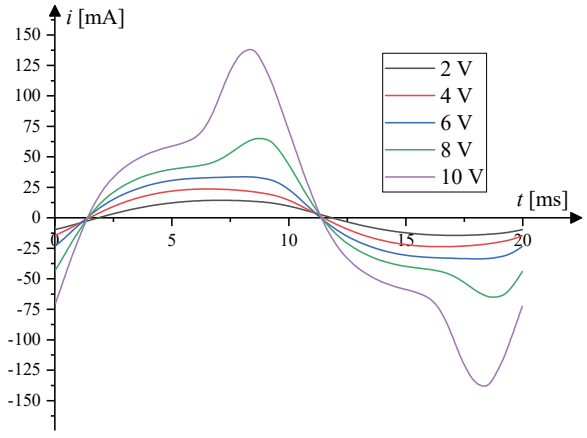

Fig. 4. Simulated $i(t)$ waveforms for the case of R=48 Ω and L=20 mH, for all considered values of U_m.

Influence of linear circuit elements R and L to the solution of the circuit for considered cases I-IV is better seen in observing the hysteresis loops of L_h than in observing $i(t)$. Therefore, a number of simulated hysteresis loops has been constructed and the loops have been compared to observe such influence.

Simulated hysteresis loops for each of the considered cases of circuit and all values of U_m are presented in Fig. 5-8, respectively. Scales are the same in all these figures for better illustration of R and L influence.

It can be seen that in all of the presented cases simulated hysteresis loops for lower U_m are fully encompassed by the hysteresis loops of higher U_m. This is in accordance with the hysteresis theory which states that hysteresis loops obtained for higher voltages, under same conditions, should encompass the ones at lower voltages [10].

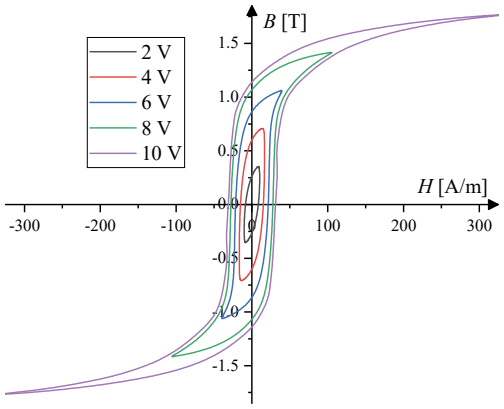

Fig. 5. Simulated hysteresis loops for the case of R=0 Ω and L=0 mH, for all considered values of U_m.

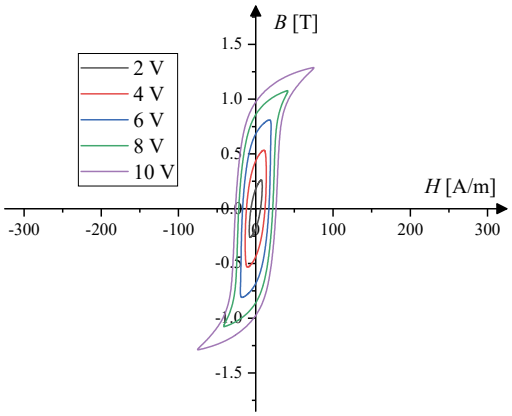

Fig. 6. Simulated hysteresis loops for the case of R=48 Ω and L=0 mH, for all considered values of U_m.

Hysteresis loops for all considered cases of electric circuit at particular values of U_m are presented in Fig. 9-13, respectively.

At lower voltages, Figs. 9 and 10, the used electrical steel exhibits almost linear behaviour, therefore resulting in almost elliptical loops and sinusoidal $i(t)$. This limits the influence of L in (4) since its voltage is proportion to the rate of change of $i(t)$. Also, adding R in the electric circuit results in lover voltage levels at L_h. Its influence is more noticeable than the L's, since the voltage over the resistor is proportional to the $i(t)$.

 ISBN 978-86-7466-930-3

Simulations at higher voltages, Figs. 11-13, show greater influence of nonlinearity of the material, causing the significant peaks in the $i(t)$. Influence of L is more prominent under these conditions, resulting in smoother $i(t)$ in case III than in case I by effectively lowering its peaks. Choking of the current [15] is less prominent in case IV since in this case linear R causes lower voltage levels at L_h-lesser influence of nonlinearity on the shape of $i(t)$, making it smoother.

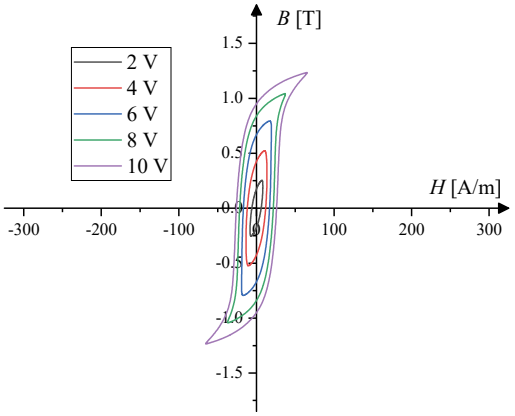

Fig. 7. Simulated hysteresis loops for the case of R=0 Ω and L=20 mH, for all considered values of U_m.

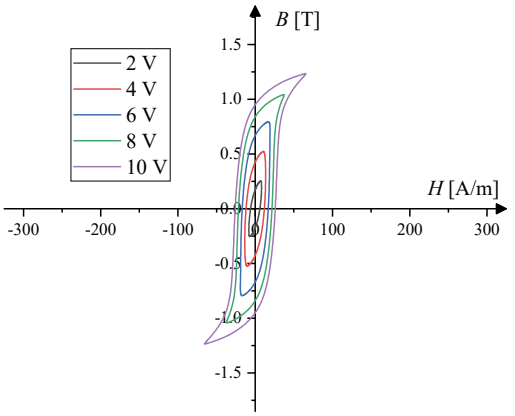

Fig. 8. Simulated hysteresis loops for the case of R=48 Ω and L=20 mH, for all considered values of U_m.

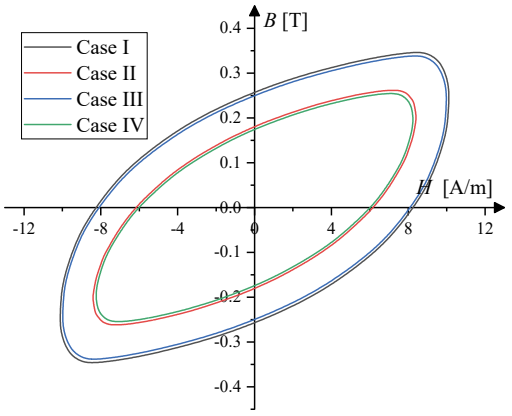

Fig. 9. Simulated hysteresis loops for U_m=2 V for all considered cases of electric circuit.

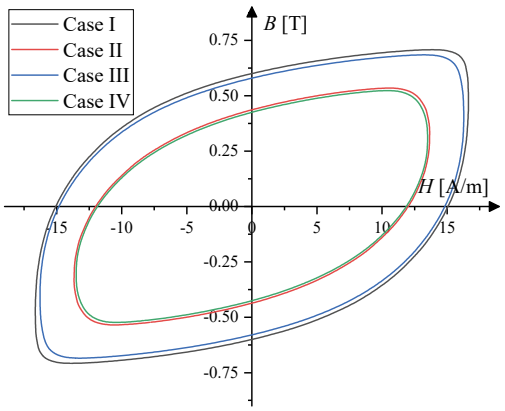

Fig. 10. Simulated hysteresis loops for U_m=4 V for all considered cases of electric circuit.

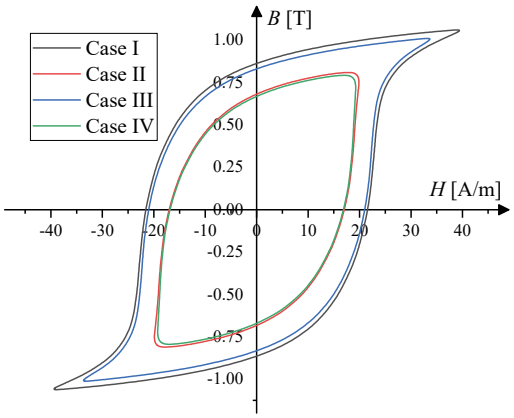

Fig. 11. Simulated hysteresis loops for U_m=6 V for all considered cases of electric circuit.

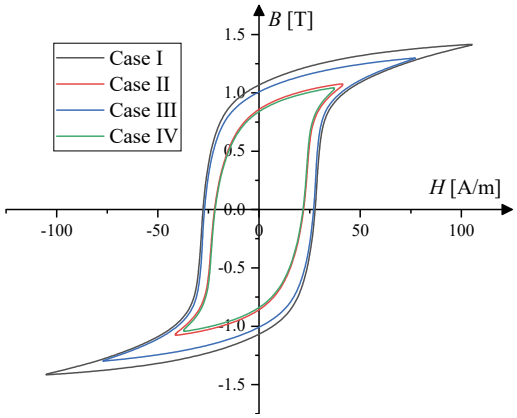

Fig. 12. Simulated hysteresis loops for U_m=8 V for all considered cases of electric circuit.

According to the results presented, simulation method presented could be suitable for solving electric circuits with L_h for sinusoidal $u(t)$ in the steady state time domain. The simulation method presented has not been tested in simulation of transient processes.

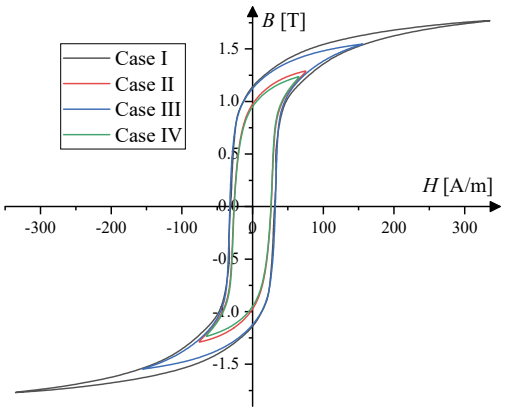

Fig. 13. Simulated hysteresis loops for U_m=10 V for all considered cases of electric circuit.

V. Conclusion

A simulation method for solving electric circuits with nonlinear inductor with hysteresis in time domain has been resented in this paper. The considered electric circuit consisted of AC voltage source connected in series with linear resistor, linear inductor and nonlinear inductor with hysteresis. Proposed calculation procedure has been based on solving an equation derived from Kirchhoff's law through series of successive iterations. Influence of the inductor with hysteresis has been accounted for by calculating current in the electric circuit from its $H_{dyn}(t)$ corresponding to the $B_{Lh}(t)$ from iteration. Waveform of $H_{dyn}(t)$ has been calculated as the sum of its quasistatic, eddy current and excess magnetic field components. Each component has been calculated separately for the considered $B_{Lh}(t)$.

Measurements have been made for $H(t)$ at low frequency of 1 Hz for sinusoidal shape of $B(t)$ for amplitude from 0.2 T to 1.6 T with the measurement step of 0.2 T. Also, measurements have been made at 50 Hz for the sinusoidal $B(t)$ of 1 T.

Simulations have been performed for sinusoidal voltage source with the amplitudes from 2 V to 10 V with the step of 2 V. Also, four cases of the electric circuit have been considered for each of the voltages-without, with one and with both linear elements. Based on the simulation result and their discussion, it can be concluded that the presented simulation method could be suitable for solving electric circuits with nonlinear inductors with hysteresis in steady state time domain.

A Comparative Analysis of Three-Phase Phase-Locked Loops for Grid-Connected Systems

Filip Bakić, Lazar Stojanović, Katarina Obradović, Emilija Lukić

***Abstract*—In renewable power generation system, synchronization of the inverter and the power grid is essential for the stable control of grid-connected inverters. Phase-Locked Loops (PLL) are widely used for grid synchronization due to simple implementation and robust performance against the grid disturbances. The main goal of this paper is to present a survey of the comparative performance evaluation among the synchronous reference frame PLL (SRF-PLL), Lag-PLL, stationary-frame based enhanced PLL (SF-EPLL) and double second-order generalized integrator PLL (DSOGI-PLL) under disturbances such as frequency changes, voltage sags and harmonic distortion. System structures and working principles are presented. Moreover, the parameters design for each algorithm are proposed. Dynamic analysis and experimental results of steady state performance of PLLs are observed and compared to verify and validate theoretical comparative analysis.**

***Index Terms*—Phase-locked loop, grid synchronization, frequency estimation, three-phase**

I. Introduction

Over the past couple of decades, there is a clear trend of switching from fossil fuels to renewable energy sources (RES) in electricity production. Furthermore, distributed generation (DG) of RES and their wide prevalence created a possibility to work independently from the grid i.e. in islanded mode, but also as generating units that inject active or reactive power directly to the grid. Many such grid-tied solutions rely on the proper usage of DC-AC power converters in order to successfully connect to the power system. Hence, advancing both hardware and control solutions has become a great deal.

The process of connecting the inverter to the grid is called synchronization of the inverter. In order to achieve successful synchronization, it is important that amplitude, phase and the frequency of the inverter's and the grid's voltages are precisely determined. In case of small DG such as rooftop solar PV systems intended to connect to weak distribution grid, parameters and quality of grid's voltage can vary significantly due to constant change of load. Thus, robust, efficient and precise controlling scheme becomes even more important.

The research work for the most suitable way for synchronizing inverters with the grid has resulted in numerous solutions. In general, all these methods could be classified as either single phase or three-phase based methods. Some of them, such as open transition transfer, are less applicable due to reduced reliability of the power system. On the other side, others, such as passive synchronization, imply usage of synchoncheck relay for synchronization check of voltage, frequency and phase [1]. Although passive synchronization methods do not require control mechanism, using this type of synchronization results in longer reconnecting process. Nevertheless, the most commonly used synchronization method is active synchronization. With implementation of controlling mechanisms, synchronization can be done by controlling the frequency and voltage. The most acknowledged concepts nowadays are Frequency Locked Loop [2], Droop Control [3], [4] and Phase Locked Loop (PLL). Due to simplicity, robustness and effectiveness in various grid conditions, PLL is the most commonly used synchronization method. To improve PLL performances under various grid conditions, numerous modifications have been done, such as Synchronous Reference Frame PLL (SRF-PLL) [5], enhanced PLL (EPLL), fixed-reference frame PLL (FRF-PLL) [6], Lag-PLL, SF-EPLL and DSOGI-PLL [7] .

In this paper, multiple PLL solutions are introduced and discussed. In the third paragraph PLL algorithms Synchronous Reference Frame PLL (SRF-PLL), Lag-PLL, SF-EPLL and DSOGI-PLL are analyzed. Then, Paragraph IV The process of selection of the adequate parameters for each algorithm is explained. Finally, experimental results were conducted on real prototype of grid-connected inverter.

II. Generalized structure of PLL

Basic structure of every PLL can be organized in three sections, Fig. 1:

1) Phase detector (PD): It compares generated signal with desired one and generates corresponding error. For three-phase systems, voltages u_{abc} in a stationary reference frame are transformed in a synchronous rotating frame, where sinusoidal voltages are represented as DC values u_{dq}.
2) Low-Pass filter (LPF): Some phase detectors generate undesired high frequency signals that need to be filtered. For three-phase systems, LPF is often designed as PI controller which input is q component of the voltage. The goal for PI controller is to bring q component to zero. This will ensure that phase is aligned with d axis.
3) Voltage controlled oscillator (VCO): After the angular frequency is estimated, it is integrated to get phase. This phase is then sent to phase detector to finish one iteration of PLL.

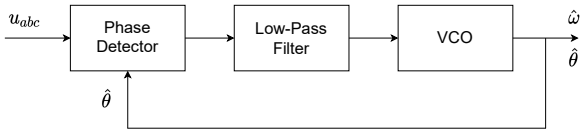

Fig. 1. Basic structure of PLL

III. Overview of the Three-Phase PLL Algorithms

A. SRF-PLL

Synchronous Reference Frame PLL is one of most commonly used algorithm due to its low complexity and easy digital realization. Conventional scheme of the SRF-PLL is shown on Fig.2. Phase detector is cascade Clark (1) and Park (2) transformation. Angle used in Park transformation θ is one estimated from algorithm in previous cycle.

$$T_{abc/\alpha\beta} = \begin{bmatrix}\alpha\\ \beta\end{bmatrix} = \frac{2}{3}\begin{bmatrix}1 & -\frac{1}{2} & -\frac{1}{2}\\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2}\end{bmatrix}\begin{bmatrix}a\\ b\\ c\end{bmatrix} \tag{1}$$

$$T_{\alpha\beta/dq} = \begin{bmatrix}d\\ q\end{bmatrix} = \begin{bmatrix}\cos(\theta) & \sin(\theta)\\ -\sin(\theta) & \cos(\theta)\end{bmatrix}\begin{bmatrix}\alpha\\ \beta\end{bmatrix} \tag{2}$$

The goal of this PLL is to bring q component to zero and align the voltage vector with d axis. It is achieved by utilizing PI controller which output is angular frequency. A stationary value of frequency is added to ensure faster phase tracking. Frequency is then integrated to obtain phase, which is then used in PD.

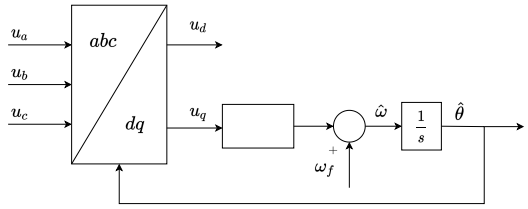

Fig. 2. Scheme of SRF-PLL

B. Lag-PLL

Another implementation of the PLL is shown in Fig.3 as proposed in [8] and referred as Lag-PLL, is derived from SRF-PLL by passing u_q through low-pass filter prior to the PI regulator. The intention of signal filtering is to improve PLL performance when sensing noise and higher harmonics are present in grid voltages.

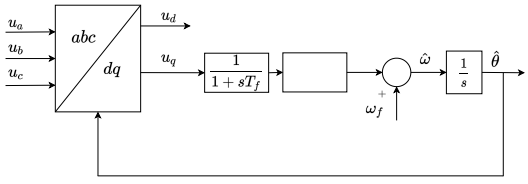

Fig. 3. Scheme of Lag-PLL

C. SF-EPLL

Since standard EPLL algorithm is implemented in a three-phase stationary it is relatively complex due to trigonometric and multiplying operations, the presented algorithm reduces complexity by transforming voltages in $\alpha\beta$ frame. Fig.4 shows the three-phase implementation of the enhanced PLL which was proposed in [9]. Besides estimating phase and frequency, EPLL add amplitude loop in PLL scheme. After the three-phase signals are transformed into u_α and u_β are subtracted by the estimated components y_α and y_β to obtain the estimated errors e_α and e_β. Amplitude and frequency error are defined as

$$e_v = e_\alpha sin(\tilde{\theta}) + e_\beta sin(\tilde{\theta} - 90°) \tag{3}$$

$$e_w = e_\alpha cos(\tilde{\theta}) - e_\beta cos(\tilde{\theta} - 90°) \tag{4}$$

They are, respectively, integrated to obtain amplitude and passed to the PI controller for frequency estimation. By integrating $\tilde{\omega}$ estimated angle is obtained.

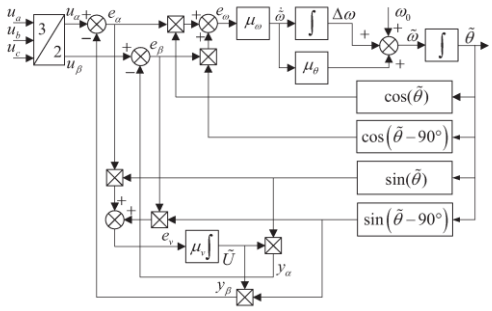

Fig. 4. Scheme of SF-EPLL [9]

D. DSOGI-PLL

Instead of filtering q component, DSOGI algorithm is designed in a way to prefilter $\alpha\beta$ components. Besides that, by dual integration, it is able to conserve information from positive sequenced harmonics by canceling negative sequenced harmonics in u'_α and u'_β by dividing with 2 voltage amplitude is preserved. Then u'_α and u'_β are transformed in dq components which further can be pass to standard SRF-PLL for frequency and phase estimation.

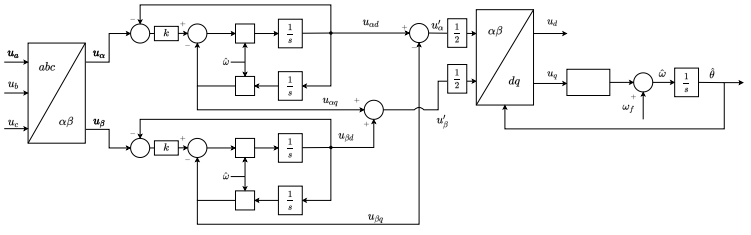

Fig. 5. Scheme of DSOGI-PLL

 ISBN 978-86-7466-930-3

IV. Selection of Parameters

A. SRF-PLL

Because of nonlinear structure of phase detector analysis and parameters selection would be complicated so model is linearized Fig. 6. From the obtained linear model, we can select parameters of PI controller to achieve desired response. Open loop transfer function is equal to:

$$W_{open}(s) = \frac{\varphi_{PLL}}{\varphi_{grid}} = \frac{sK_pK_{pd} + K_iK_{pd}}{s^2} \tag{5}$$

from which closed loop function is equal to:

$$W_{close}(s) = \frac{sK_pK_{pd} + K_iK_{pd}}{s^2 + sK_pK_{pd} + K_iK_{pd}} \tag{6}$$

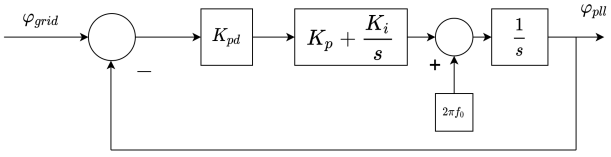

Fig. 6. Linearized model of SRF PLL

Where K_p, K_i are parameters of PI controller and Kpd represents amplitude of three-phase voltage. Selecting of parameters K_p and K_i is done to achieve desired bandwidth and damping by selecting coefficients to meet standard second order polynomial.

$$s^2 + 2\xi\omega_n s + \omega_n^2 = s^2 + sK_pK_{pd} + K_iK_{pd} \tag{7}$$

From where we can obtain parameters as:

$$K_i = \frac{\omega_n^2}{K_{pd}},\ K_p = \frac{2\xi\omega_n}{K_{pd}} \tag{8}$$

in this study, we chose $\xi = 1$ and $w_n = 37.7$ rad/s which corresponds with desired closed loop bandwidth of 6 Hz and absence of oscillations in response.

B. LAG-PLL

The idea of this PLL is to better filter higher harmonics than SRF. Since it only differs from SRF in added filter, we can use K_i and K_p used for SRF PLL. T_f is selected to minimize effect on system response. Open loop transfer function is equal to:

$$W_{open}(s) = \frac{\varphi_{PLL}}{\varphi_{grid}} = \frac{sK_pK_{pd} + K_iK_{pd}}{s^3T_f + s^2} \tag{9}$$

To find poles positions of closed loop in depending on T_f we used modified transfer function W_{mod}

$$W_{mod}(s) = \frac{T_f s^3}{s^2 + sK_pK_{pd} + K_iK_{pd}} \tag{10}$$

because closed loop poles for both transfer functions are the same. Poles position with respect to different value of T_f is shown in Fig. 7.T_f must be small enough to not interfere with system dynamics and large enough to filter higher harmonics. As a good compromise, T_f is selected to filter dynamics over 100Hz so $T_f = \frac{1}{200\pi}$.

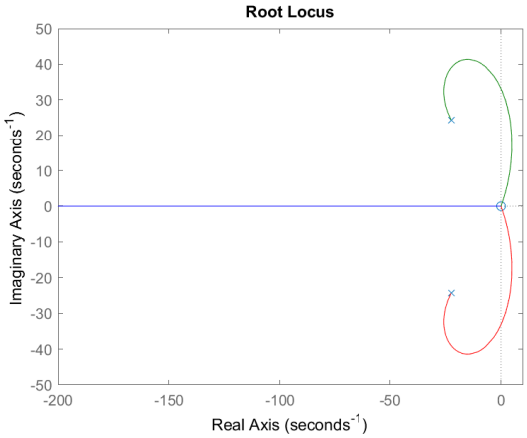

Fig. 7. Pole position for different values of T_f

C. DSOGI

Filtering power of dual integrator is determined by parameter, k which can we see in transfer functions from u_α to $u_{\alpha d}$ and u_α to $u_{\alpha q}$

$$G_d(s) = \frac{u_{\alpha d}}{u_\alpha} = \frac{k\omega_1 s}{s^2 + k\omega_1 s + \omega_1^2} \tag{11}$$

$$G_q(s) = \frac{u_{\alpha q}}{u_\alpha} = \frac{k\omega_1^2}{s^2 + k\omega_1 s + \omega_1^2} \tag{12}$$

transfer functions from u_β to $u_{\beta d}$ and u_β to $u_{\beta q}$ are the same.

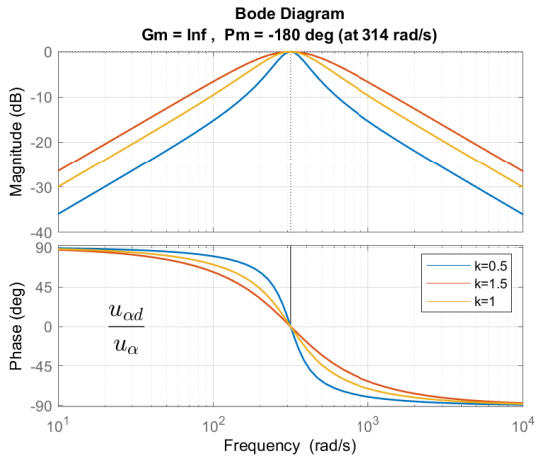

Fig. 8. Bode plot G_d in function of k

As it is shown on Fig. 8 and Fig. 9 increasing k give better attenuation of harmonics but also causes higher overshoot and greater settling time of estimation. For best trade-off $k = 1$ is selected. Parameters of PI controller K_i and K_p are same as in SRF and Lag-PLL.

D. SF-EPLL

For this PLL parameters for amplitude and frequency estimation can be chosen separately. For amplitude loop time

 ISBN 978-86-7466-930-3

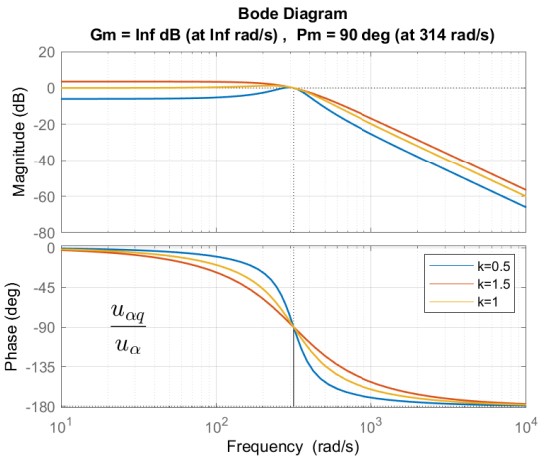

Fig. 9. Bode plot of G_q in function of k

constant of response is the same as $1/\mu_v$, from setting time of 50ms and $T_{sett} = 5/\mu_v$ we chose $\mu_v = 100$. Dynamic model of this PLL are provided in [9] from where $\mu_\theta = 2\xi/w_n$ and $\mu_\omega = w_n/\mu_\theta/U$ where U is estimate amplitude of grid voltage.

V. Simulation Results

Modeling of different PLLs and simulation is done by using Matlab and Simulink software.

Dynamic response of different PLLs is examined by step frequency change. As shown in Fig. 10 PLLs have similar rise time which means that regulation bandwidth is roughly the same. Despite, $\psi = 1$ overshoot is present due to the presence of dominant zero. Difference in overshoot is not crucial for performance of PLL.

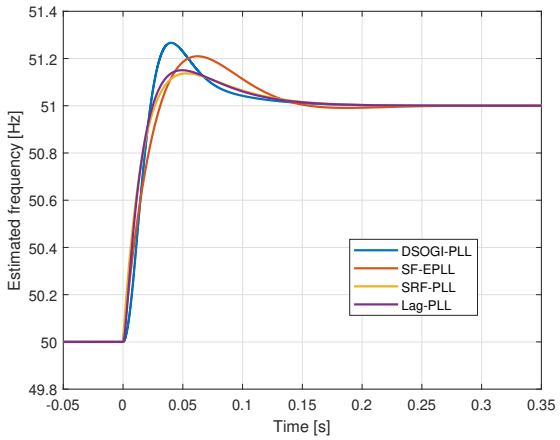

Fig. 10. Response on step frequency change

Unbalanced three-phase system is a problem for PLLs because it introduces ripple in frequency estimation. Unbalanced grid voltage used for simulation is shown in Fig. 11. Unbalanced grid conditions have the largest impact on SRF PLL. On the other hand, DSOGI is unaffected by distortions.

TABLE I
Performance comparison on step frequency change

PLL	Overshoot [%]	2% settling time [s]
SRF	13.70	0.143
Lag	15.05	0.140
SF-EPLL	20.95	0.138
DSOGI	26.65	0.130

Performance comparison in unbalanced conditions

PLL	Steady oscillation amplitude [Hz]
SRF	0.828
Lag	0.622
SF-EPLL	0.560
DSOGI	0

VI. Experimental Results

Experimental results were conducted of grid-connected inverter prototype. The prototype was designed for a grid with 208 V line voltage, so tests were conducted on that voltage. The algorithm is implemented on TMS320F28379D microcontroller. Experimental setup is shown on Fig. 13. The idea of this test is to show influence of real implementation

 ISBN 978-86-7466-930-3

and grid conditions on performance of PLL algorithms. Grid voltage with THD of 3.67% is shown on Fig. 14. Performance of different algorithms can be seen on Fig. 15 and Table III.

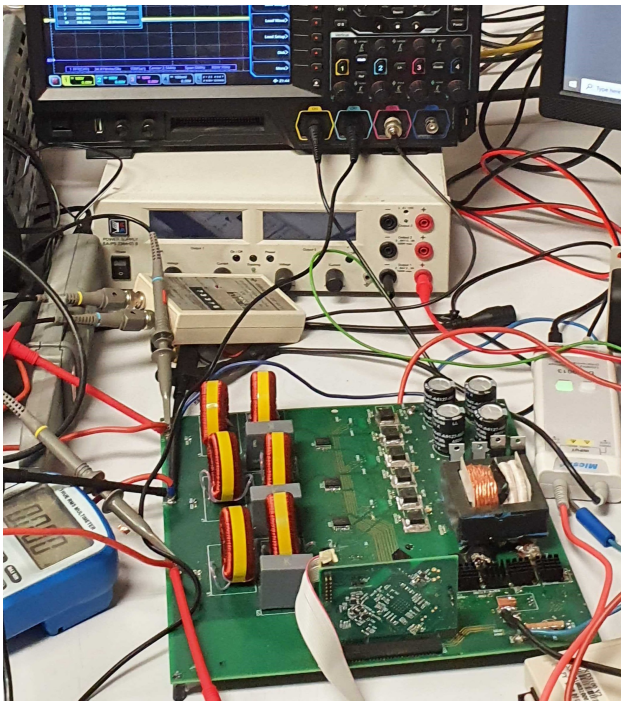

Fig. 13. Experimental setup

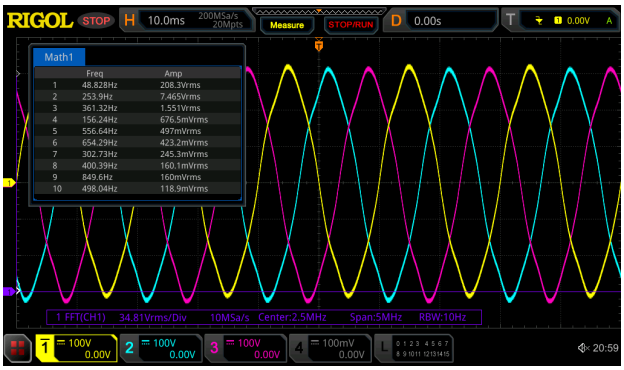

Fig. 14. Grid voltage

TABLE III
PERFORMANCE COMPARISON IN EXPERIMENTAL CONDITIONS

PLL	Maximum error [Hz]	Mean error [Hz]
SRF	0.771	0.439
Lag	0.675	0.4153
SF-EPLL	0.509	0.2930
DSOGI	0.357	0.224

VII. CONCLUSION

Analysis and performance comparison of four three-phase PLL structures have been simulated and tested on real prototype. From the presented comparison, it is found that DSOGI-PLL has the best performance in all three scenarios, providing the most accurate frequency estimation. Worst results are obtained with SRF-PLL which was expected knowing that all other PLLs presents modification of this algorithm in desire to achieve better performance. Future analysis will focus on quality of current injected to grid by inverter knowing the dynamic and performance of frequency estimation, which is essential for accurate grid synchronization.

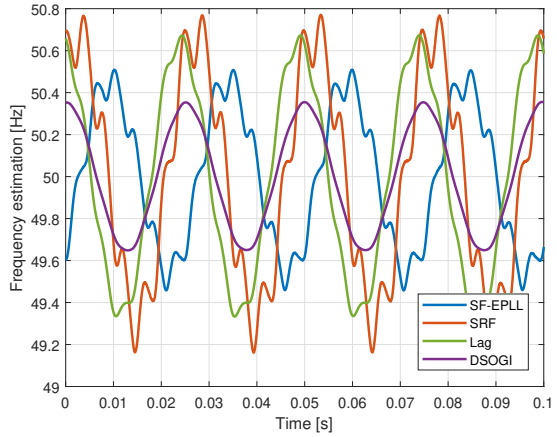

Fig. 15. Frequency estimation

ACKNOWLEDGMENT

We are grateful to Laboratory of the Digital Drive Control in the School of Electrical Engineering, University of Belgrade for testing equipment. Also, we are grateful to all H-Bridges team members for developing and implementation of this prototype.

Parameter estimation of induction motors using Wild Horse Optimizer

Jovan Vukašinović, Miloš Milovanović, Nebojša Arsić, Jordan Radosavljević, Saša Štatkić, Bojan Perović and Andrijana Jovanović

***Abstract*—In this paper, a new metaheuristic algorithm called the Wild Horse Optimizer (WHO) is for the first time proposed for estimation of the equivalent circuit parameters of the single-cage induction motors. The parameters of the motors are found as a result of the error minimization function between the calculated and manufacturer data. Simulation results obtained using the WHO algorithm are compared to the results obtained using other optimization methods applied in solving the induction motor parameter estimation problem. The performances of the methods are evaluated using the motors of different powers (i.e. 5 HP and 40 HP), based on the statistical analysis of the results obtained in several independent runs of the methods. It is shown that the proposed WHO algorithm has better performance, i.e. it is able to provide quality solutions with faster convergence speed and better statistical indicators.**

***Index Terms*—Induction motors, Parameter estimation, Optimization, Metaheuristic, Wild Horse Optimizer (WHO)**

I. INTRODUCTION

Induction motors are the most widespread electric motors in the world, and as such they represent one of the largest consumers of the electricity. Today, induction motors consume between 35% and 40% of the world's total electricity production. Knowing the parameters of the equivalent circuit of an induction motor is of great importance for drive control processes, as well as for fault diagnosis of the induction motor.

Classical methods for determining the parameters of the equivalent circuits of induction motors are based on no-load and short-circuit experiments. Because these tests are very difficult to perform in cases where the motor is already connected to a mechanical load, these methods are not always easily applicable in industry. For these reasons, in the recent years, many analytical and optimization methods have been proposed to estimate the parameters of induction motors. Some of the commonly used methods for estimation the parameters of induction motors that can be found in the literature are: Particle Swarm Optimization (PSO) [1], Genetic Algorithm (GA) [2], Charged System Search (CSS) [3], hybrid GA and PSO (HGAPSO) [4], Gravitational Search Algorithm (GSA) [5], hybrid Phasor Particle Swarm Optimization and Gravitational Search Algorithm (PPSOGSA) [6], and Shuffled Frog Leaping Algorithm (SFLA) [7].

In this paper, the Wild Horse Optimizer (WHO) [8] is for the first time proposed for estimating the single-cage induction motors parameters. It could be regarded as the main contribution of the paper. In the scientific literature, there is no research that deals with the direct application of the WHO algorithm for solving any problem of induction motor parameter estimation. The WHO algorithm has shown very good results in solving different complex benchmark functions, as pointed out in [8], and practical engineering problems, such as the problems of the parameter estimation of diode PV models [9], static/dynamic PV models [10], and damage identification in steel plates [11]. For this reason, the authors of this paper have decided to use the WHO algorithm.

II. PROBLEM FORMULATION

In order to optimize the values of the electrical parameters, the formulation of the objective function is required. In this case the objective function has the following form [7]:

$$OF = F_1^2 + F_2^2 + F_3^2 + F_4^2, \tag{1}$$

where

$$F_1 = \frac{T_{fl.cal} - T_{fl.mf}}{T_{fl.mf}}, \tag{2}$$

$$F_2 = \frac{T_{st.cal} - T_{st.mf}}{T_{st.mf}}, \tag{3}$$

$$F_3 = \frac{T_{\max.cal} - T_{\max.mf}}{T_{\max.mf}}, \tag{4}$$

Andrijana Jovanović is with the Faculty of Technical Sciences, University of Priština in Kosovska Mitrovica, 7 Knjaza Miloša, 38220 Kosovska Mitrovica, Serbia (e-mail: andrijana.jovanovic@pr.ac.rs).

 ISBN 978-86-7466-930-3

$$F_4 = \frac{pf_{fl.cal} - pf_{fl.mf}}{pf_{fl.mf}}. \quad (5)$$

In (1) – (5) variables have the following meaning: *OF* is the objective function, F_i (i = 1,2,…,4) is the i-th component of the objective function (i.e., it is an error between the calculated and manufacturer value), T is a torque, I is a current, *pf* is a power factor, subscripts *st*, *fl* and max correspond to the start load, full load, and maximum load, respectively. Also, subscripts *cal* and *mf* are used for the calculated and manufacturer data.

According to Fig. 1, the stator ($\underline{I}_s$) and rotor ($\underline{I}_r$) currents in terms of slip (s) can be calculated using the following equations:

$$\underline{I}_s(s) = \frac{\underline{V}_{ph}}{R_s + jX_s + \underline{Z}_p(s)}, \quad (6)$$

$$\underline{I}_r(s) = \frac{\underline{Z}_p(s) \cdot \underline{I}_s(s)}{\frac{R_r}{s} + jX_r}, \quad (7)$$

where $\underline{V}_{ph}$ is the stator phase voltage, R_s is the stator resistance, R_r is the rotor resistance, X_s is the stator leakage reactance, X_r is the rotor leakage reactance, and X_m is the magnetizing leakage reactance.

The equivalent impedance ($\underline{Z}_p$) and Thevenin's equivalent impedance ($\underline{Z}_{Th}$) are:

$$\underline{Z}_p(s) = \frac{1}{\frac{1}{jX_m} + \frac{1}{\frac{R_r}{s} + jX_r}}, \quad (8)$$

$$\underline{Z}_{Th} = R_{Th} + jX_{Th} = \frac{1}{\frac{1}{R_s + jX_s} + \frac{1}{jX_m}}. \quad (9)$$

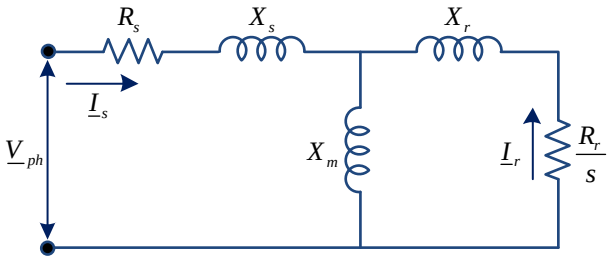

Fig. 1. One phase steady-state equivalent circuit of a single-cage three-phase induction motor.

The torque in terms of slip can be obtained by using the following equation:

$$T(s) = \frac{3p}{\omega_s}\left[I_r(s)\right]^2 \frac{R_r}{s}. \quad (10)$$

Thus, $T_{fl} = T(s_{fl})$, $T_{st} = T(1)$, and $T_{\max} = T(s_{\max})$, where the maximum torque slip (s_{max}) is given by (11).

$$s_{\max} = \frac{R_r}{\sqrt{R_{Th}^2 + \left(X_{Th} + X_r\right)^2}}. \quad (11)$$

The apparent, active and reactive powers are:

$$\underline{S}(s_{fl}) = 3 \cdot \underline{V}_{ph} \cdot \left[\underline{I}_s(s_{fl})\right]^*, \quad (12)$$

$$P_{fl} = \mathrm{Re}\left\{\underline{S}(s_{fl})\right\}, \quad Q_{fl} = \mathrm{Im}\left\{\underline{S}(s_{fl})\right\}. \quad (13)$$

Finally, the power factor can be calculated:

$$pf_{fl} = \arctan\left(\frac{Q_{fl}}{P_{fl}}\right). \quad (14)$$

According to [6, 7], the following constraints are taken into account:

$$R_s, R_r, X_s, X_r, X_m > 0, \quad (15)$$

$$X_s = X_r. \quad (16)$$

III. Solution Method

The WHO algorithm [8] is a recently proposed metaheuristic algorithm developed by Naruei and Keynia. This algorithm is inspired by the social life behavior of wild horses in the nature. Wild horses exhibit different group behaviors, such as grazing, chasing, mating, dominance and leadership.

The WHO algorithm consists of the following steps [8]:

A. Creating an Initial Population and Forming Horse Groups, and Selecting Leaders

The WHO begins with an initial population of N agents, $\mathbf{POP}(1) = \left[\mathbf{X}_1(1), \mathbf{X}_2(1), ..., \mathbf{X}_N(1)\right]^T \subseteq \mathbf{U}$. In the initial iteration, the ith agent $\mathbf{X}_i(1)$ can be expressed as: $\mathbf{X}_i(1) = \left[X_i^1(1), ..., X_i^d(1), ..., X_i^n(1)\right]$, where X_i^d is the position of the ith agent in the dth dimension, n is the dimension of the problem, while $\mathbf{U}$ is the space of possible solutions. The initial population is divided into several groups. Each group has only one leader (stallion) and one or more mares and foals.

B. Grazing of Horses

The following equation is used to simulate the grazing:

$$\mathbf{X}_{i,G}^j(t+1) = 2 \cdot \mathbf{Z}(t) \cdot \cos\left(2 \cdot \pi \cdot R \cdot \mathbf{Z}(t)\right) \times \\ \times \left(\mathbf{Stallion}^j(t) - \mathbf{X}_{i,G}^j(t)\right) + \mathbf{Stallion}^j(t) \quad (17)$$

where $\mathbf{X}_{i,G}^j(t)$ and $\mathbf{X}_{i,G}^j(t+1)$ are the current position and new position of the foal or mare, respectively; t is the current iteration; $t + 1$ is the next iteration; $\mathbf{Stallion}^j(t)$ is the current position of the stallion; R is a uniform random number between [-2,2], and $\mathbf{Z}(t)$ is an adaptive mechanism described in [8].

 ISBN 978-86-7466-930-3

C. Horse Mating Behavior

To simulate the departure and mating of horses, the following formula can be used:

$$\mathbf{X}_{G,k}^{p} = \text{crossover}\left(\mathbf{X}_{G,i}^{q}, \mathbf{X}_{G,j}^{z}\right);\ \ i \neq j \neq k; \quad p = q = \text{end};\ \ \text{crossover} = \text{mean} \tag{18}$$

where $\mathbf{X}_{G,k}^{p}$, $\mathbf{X}_{G,i}^{q}$ and $\mathbf{X}_{G,j}^{z}$ are the positions of horses *p*, *q* and *z* from groups *k*, *i* and *j*, respectively.

D. Leadership and Leading the Group by the Leader

The mathematical model of leading the group by the stallion can be described by (19).

E. Exchange and Selection of Leaders

In this step, the leaders of the groups – stallions are selected. Firstly, to preserve the stochastic nature of the algorithm, the leaders are selected randomly. In the later stages of the iteration process, the leaders are selected based on their fitness values using (20).

$$\mathbf{Stallion}_{G,i}(t+1) = \begin{cases} 2\cdot\mathbf{Z}(t)\cdot\cos\left(2\cdot\pi\cdot R\cdot\mathbf{Z}(t)\right)\times\left(\mathbf{WH}(t)-\mathbf{Stallion}_{G,i}(t)\right)+\mathbf{WH}(t) & \text{if}\ \ R_2 > 0.5 \\ 2\cdot\mathbf{Z}(t)\cdot\cos\left(2\cdot\pi\cdot R\cdot\mathbf{Z}(t)\right)\times\left(\mathbf{WH}(t)-\mathbf{Stallion}_{G,i}(t)\right)-\mathbf{WH}(t) & \text{if}\ \ R_2 \leq 0.5 \end{cases}, \tag{19}$$

$$\mathbf{Stallion}_{G,i}(t+1) = \begin{cases} \mathbf{X}_{G,i}(t+1) & \text{if}\ \ \text{cost}\left(\mathbf{X}_{G,i}(t+1)\right) < \text{cost}\left(\mathbf{Stallion}_{G,i}(t)\right) \\ \mathbf{Stallion}_{G,i}(t) & \text{if}\ \ \text{cost}\left(\mathbf{X}_{G,i}(t+1)\right) \geq \text{cost}\left(\mathbf{Stallion}_{G,i}(t)\right) \end{cases}. \tag{20}$$

In (19) and (20), **WH**(*t*) presents the position of the water hole (i.e. the global best position). More details about the WHO algorithm can be found in the paper [8].

As for any other optimization problem, a potential solution can be presented by a vector consisting of a combination of control variables, i.e., in this case, corresponding induction motor parameters. The electrical parameters of the single-cage motors are the following: R_s, R_r, X_s, X_r, and X_m. Generally, it is supposed that the stator and rotor leakage reactances are equal: $X_s = X_r$. Therefore, the position of the agent *i* can be defined as follows:

$$\mathbf{X}_i = \left[R_{s,i}, R_{r,i}, X_{s,i}, X_{m,i}\right]. \tag{21}$$

The flowchart of the WHO algorithm is given in Fig. 2.

IV. Simulation Results and Discussion

The proposed WHO method is tested on two three-phase single-cage induction motors. The manufacturer data of the test motors are shown in Table I.

TABLE I
MANUFACTURER DATA OF THE TEST MOTORS [6,7]

Parameters	Values	
Rated power P_n (HP)	5	40
Rated voltage U_n (V)	400	400
Rated frequency f_n (Hz)	50	50
Starting current I_{st} (A)	22	180
Full-load current I_{fl} (A)	8	45
Number of pole pairs *p*	2	2
Starting torque T_{st} (N·m)	15	260
Full-load torque T_{fl} (N·m)	25	190
Maximum torque T_{max} (N·m)	42	370
Full-load power factor pf_{fl}	0.8	0.8
Slip at full load s_{fl}	0.07	0.09

The following parameter ranges are considered:

- For the motor of 5 HP:

$$0.1 \leq R_s \leq 5,\ 1 \leq X_s \leq 15,\ 50 \leq X_m \leq 150,$$
$$0.5 \leq R_r \leq 10,\ 1 \leq X_r \leq 15$$

- For the motor of 40 HP:

$$0.01 \leq R_s \leq 0.5,\ 0.1 \leq X_s \leq 2,\ 5 \leq X_m \leq 15,$$
$$0.05 \leq R_r \leq 1,\ 0.1 \leq X_r \leq 2$$

The algorithm was developed in the MATLAB computing environment. To examine the effectiveness of the proposed WHO algorithm, the same problem was solved using the PPSOGSA algorithm [6] (which proved to be effective in solving problems in this area). The obtained results are compared with those obtained using the other methods reported in the literature.

The algorithms are implemented with the following control parameters: for the PPSOGSA [6], c_1 and c_2 are set to 2, α is set to 25, and G_0 is set to 1; for the WHO [8], the crossover process is carried out using the mean value of corresponding group members (mean crossover type), crossover percentage is set to 0.1, and the percentage of stallions in the total population (*PS*) is set to 0.2. For both algorithms, the population size (*N*) and the maximum number of iterations (t_{max}) are set to 300 and 100, respectively.

The results of WHO and PPSOGSA are obtained after fifty consecutive test runs. The best results achieved over these runs are presented in Tables II and III. Also, the tables show the results obtained by other optimization methods. The corresponding steady-state equivalent circuit electrical parameters of the test motors are presented in Table IV.

By comparing the results from Tables II and III, it can be seen that the values of the objective function (*OF*) obtained with the WHO are lower than those obtained by other methods, except the MSFLA [7] for the motor of 5 HP. In [7], a larger range of control variables was taken into consideration, i.e. the optimal value of the stator resistance was 0.0037 Ω, which is far less than the value of 0.3 Ω obtained by the WHO, as presented in Table IV; that may be a possible reason why the *OF* value obtained using the MSFLA is less than the value obtained by the WHO.

The convergence profiles of the WHO and PPSOGSA for the motors of 5 HP and 40 HP are shown in Figs. 3 and 4, respectively. The figures indicate that the proposed WHO algorithm converges to the optimal solution in lower iterations in comparison to the PPSOGSA algorithm.

 ISBN 978-86-7466-930-3

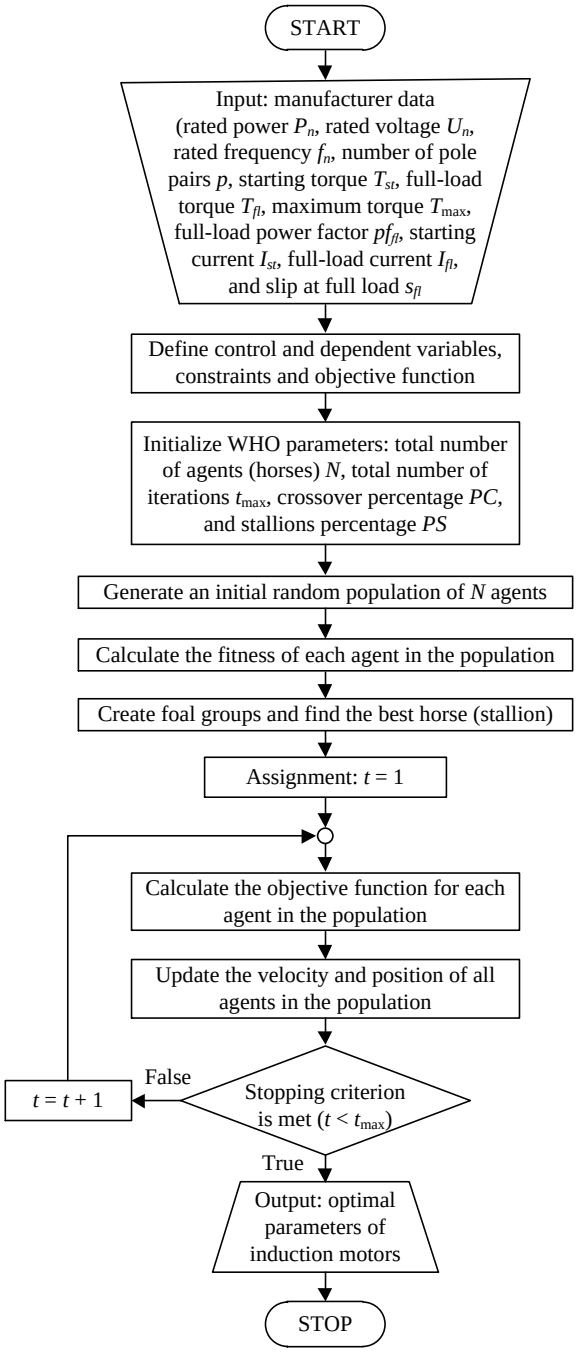

Fig. 2. The flowchart of the WHO algorithm in solving the induction motor parameter estimation problem.

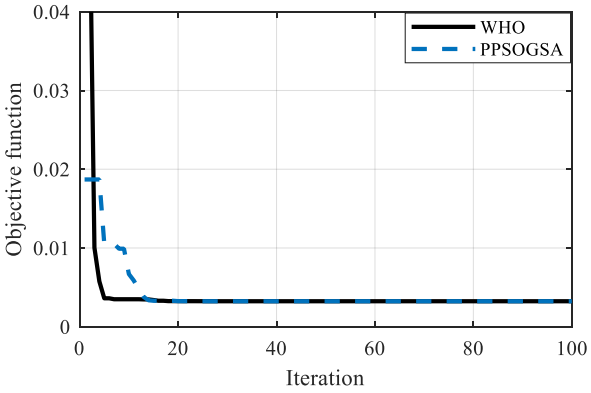

Fig. 3. Convergence profiles obtained for the motor of 5 HP.

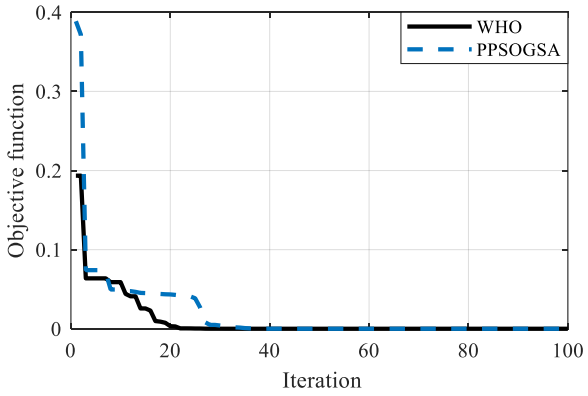

Fig. 4. Convergence profiles obtained for the motor of 40 HP.

Torque-slip characteristics of the motors of 5 HP and 40 HP obtained using the WHO algorithm are presented in Figs. 5 and 6, respectively. From these figures, it is evident that the results obtained by the WHO are in very good agreement with the manufacturer values.

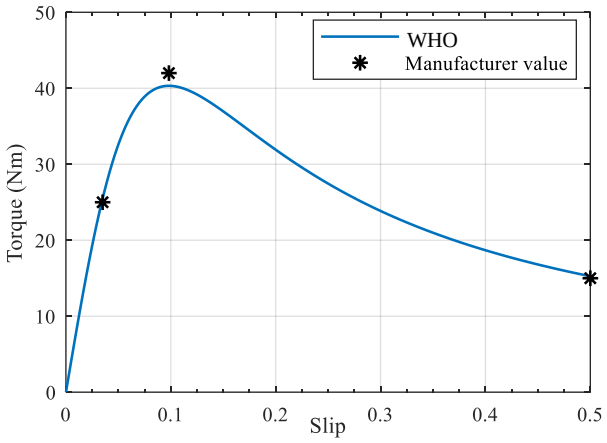

Fig. 5. Torque versus slip curve for the motor of 5 HP.

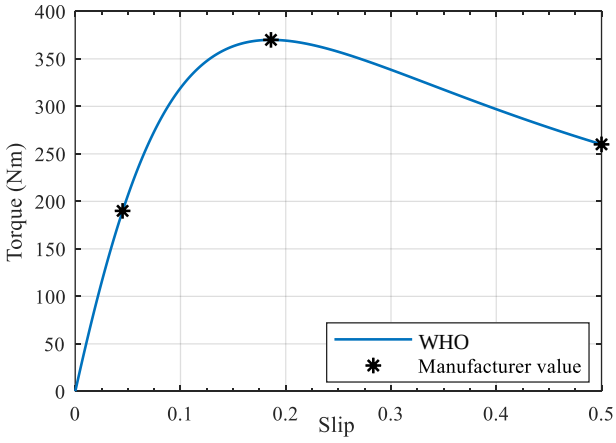

Fig. 6. Torque versus slip curve for the motor of 40 HP.

The statistical parameters of the results (i.e. minimum, maximum and mean values of the objective function, as well as the standard deviations) obtained by the WHO and PPSOGSA over fifty runs for the both test motors are presented in Table V. The results from Table V show that the proposed WHO algorithm is more robust compared to the PPSOGSA. From the aspect of running, the running time of the WHO is a little shorter than the time of the PPSOGSA.

V. CONCLUSION

The main conclusions that can be drawn from the presented results and discussion of them are the follows:

- By comparing the results obtained using the WHO algorithm with those obtained using other algorithms (i.e. using the PSO, SFLA, MSFLA, and PPSOGSA algorithms), it is found that the WHO provides effective, robust and high-quality solutions.
- It is shown that the results obtained by the WHO algorithm are in very good agreement with the manufacturer data. The maximum relative deviations are less than 5%.
- The average running time of the WHO algorithm for both test motors was less than 2 s. This means that the calculation speed of the WHO algorithm is high.
- It is found that the WHO algorithm has better performance than the PPSOGSA algorithm in terms of the solution quality and convergence speed.

ACKNOWLEDGMENT

The research for this article was carried out with ERASMUS + project: “Knowledge triangle for a low carbon economy (KALCEA)” and with scientific project the TR 33016 – “Research, development and implementation of programs and procedures Energy efficiency of electric drives” funded by the Ministry of Education, Science and Technological Development of the Republic of Serbia.

Damper Winding Inductances Calculation by Winding Function Approach

Aldin Kajević, Gojko Joksimović, *Senior Member, IEEE*

***Abstract*—The paper presents a procedure for dq model parameters calculation of a synchronous turbogenerator using winding function theory, with special emphasis on the damper winding. The advantage of this procedure is that the real spatial distribution of all windings in the machine is taken into account, therefore, taking into account all spatial harmonics simultaneously. A real synchronous turbogenerator of type TBB-200-2A was analyzed as a case study.**

***Index Terms*—Damper winding, Inductance, Synchronous machine, Turbo-generator, Winding function.**

I. Introduction

Mathematical model of synchronous machine projected on two mutually orthogonal axes, *dq* model, is the most common dynamic model of synchronous machine, [1], [2]. Although the model itself is often found in the literature, in rare cases attention is paid to determining the parameters that appear in the model itself. Additionally, model parameters are most often given in unit values. The key parameters of the model that are at the same time the most demanding to determine are the self and mutual inductances of the windings. Analytical expressions that assume an ideal, sinusoidal spatial distribution of windings are often used when determining these parameters, or, which is the same, only the fundamental harmonic of the real spatial winding distribution is taken into account, [3], [4]. In this paper, using the theory of the winding functions, [5], [6], [7], [8], all spatial harmonics of the magnetomotive force (mmf) of the real winding are taken into account simultaneously.

The generic synchronous machine is characterized by the existence of three symmetrical armature phase windings as well as the field and damper winding on the rotor.

The paper presents a methodology that allows direct and fairly intuitive determination of self and mutual inductances of windings, inductances that appear as parameters of the *dq* model of the machine. The first step in order to calculate inductances is to determine the winding functions of the stator windings and the damper windings of the machine in the natural frame of reference. However, the following convention should be introduced here: in order to avoid rugged constructions as "winding function of field winding" or "winding function of stator phase winding", etc. a simpler sentence construction will be used – simply "field winding function" or "damper winding function" or "stator phase winding function". When the winding functions are known, then in the case of stator phase windings, their equivalent winding functions are determined in a rotating *dqn* reference frame fixed to the rotor. The role of these functions is twofold. Firstly, they enable obtaining self and mutual inductances of the stator windings directly in the *dqn* system. Secondly, their existence enables, in combination with the damper winding functions along the *d* and *q* axes, the direct calculation of its mutual inductances. The procedure for obtaining the damper winding functions along the *d* and *q* axes is also presented in this paper and these functions represent one of the main results of this paper.

The whole procedure is illustrated on the example of a synchronous turbogenerator of type TBB-200-2A. As a final result, all self and mutual inductances that appears as the parameters of the *dq* model are determined. A comparison of the obtained parameters concerning the stator windings with the factory data of the generator was performed and a high degree of agreement was observed.

II. DQ Model of Synchronous Machine

The voltage equations of a synchronous turbogenerator in matrix form are given below, [1]. The indexes *a*, *b* and *c* are associated with the values concerning the three phase windings of the stator, in the natural (*abc*) frame of reference. The indexes *d* and *q* are associated with the damper winding along the *d* and *q* axes, respectively. Index *f* refers to the field winding. The indexes *s* and *r* refer to the stator and rotor, respectively.

$$[U_{abcs}] = [R_s][i_{abcs}] + \frac{d}{dt}[\psi_{abcs}] \tag{1}$$

$$[U_{dqfr}] = [R_r][i_{dqfr}] + \frac{d}{dt}[\psi_{dqfr}] \tag{2}$$

The equations of magnetic coupling for the stator and rotor windings, in matrix form, are:

$$[\psi_{abcs}] = [L_{abcs}][i_{abcs}] + [L_{abcsr}][i_{dqfr}] \tag{3}$$

 ISBN 978-86-7466-930-3

$$\left[\psi_{dqfr}\right]=\left[L_{abcsr}\right]^{T}\left[i_{abcs}\right]+\left[L_{dqfr}\right]\left[i_{dqfr}\right] \quad (4)$$

Vectors of voltages, currents and fluxes that appear in the previous expressions together with the matrices of inductance and resistance are given in the Appendix. The same will be done with the vectors and matrices in the continuation of the work.

It is now necessary to transform the previous equations from the natural (*abc*) frame of reference to the rotating *dqn* coordinate system. The transformation will be done using the transformation matrix [$T(\theta)$]. The angle θ in the transformation matrix is the angle that the rotating reference frame, fixed to the rotor, occupies at a certain point in time in relation to the reference, i.e. initial position. For a coordinate system that rotates with an arbitrary angular velocity ω, assuming that the initial angle is equal to zero, at time t=0, the following holds:

$$\theta=\omega t \quad (5)$$

After the transformation of equations, procedure of which will not be presented in detail here, the following equations are obtained in the *dqn* system,

$$\left[U_{dqns}\right]=\left[R_{s}\right]\left[i_{dqns}\right]+\frac{d\left(\left[\psi_{dqns}\right]\right)}{dt}+\left[\omega x\right]\left[\psi_{dqns}\right] \quad (6)$$

$$\left[U_{dqfr}\right]=\left[R_{r}\right]\left[i_{dqfr}\right]+\frac{d}{dt}\left[\psi_{dqfr}\right] \quad (7)$$

$$\left[\psi_{dqns}\right]=\left[L_{dqns}\right]\left[i_{dqns}\right]+\left[L_{dqnsr}\right]\left[i_{dqfr}\right] \quad (8)$$

$$\left[\psi_{dqfr}\right]=\frac{3}{2}\left[L_{dqnsr}\right]^{T}\left[i_{dqns}\right]+\left[L_{dqfr}\right]\left[i_{dqfr}\right] \quad (9)$$

where:

$$\left[L_{dqns}\right]=\left[T\left(\theta\right)\right]\left[L_{abcs}\right]\left[T\left(\theta\right)\right]^{-1} \quad (10)$$

$$\left[L_{dqnsr}\right]=\left[T\left(\theta\right)\right]\left[L_{abcsr}\right] \quad (11)$$

III. WINDING FUNCTIONS IN DQ SYSTEM, INDUCTANCES AND METHOD OF THEIR DETERMINATION

The stator winding functions in the *dqn* system are given in expression (12). There $N_a(\theta_m)$, $N_b(\theta_m)$ and $N_c(\theta_m)$ are the stator phase windings functions in the natural frame of reference, and θ_m is the mechanical angle.

In addition to the previously listed winding functions, it is necessary to determine the function of the field winding $N_{fr}(\theta_m)$, as well as the damper winding functions along the *d* and *q* axes, $N_{dr}(\theta_m)$ and $N_{qr}(\theta_m)$, respectively. All these functions will be determined in the following by applying the winding function theory on the example of a real synchronous turbogenerator of type TBB-200-2A.

When the winding functions for all windings are determined then self and mutual inductances in the model matrices can be obtained by numerical integration. Some of the inductances in the matrices [L_{dqns}], [L_{dqnsr}] and [L_{dqfr}] are given by expressions (15) - (20), just for illustration purposes.

$$N_{ds}=\frac{2}{3}\left(N_a\left(\theta_m\right)\sin\left(\theta\right)+N_b\left(\theta_m\right)\sin\left(\theta-\frac{2\pi}{3}\right)+N_c\left(\theta_m\right)\sin\left(\theta+\frac{2\pi}{3}\right)\right) \quad (12)$$

$$N_{qs}=\frac{2}{3}\left(N_a\left(\theta_m\right)\cos\left(\theta\right)+N_b\left(\theta_m\right)\cos\left(\theta-\frac{2\pi}{3}\right)+N_c\left(\theta_m\right)\cos\left(\theta+\frac{2\pi}{3}\right)\right) \quad (13)$$

$$N_{ns}=\frac{\sqrt{2}}{3}\left(N_a\left(\theta_m\right)+N_b\left(\theta_m\right)+N_c\left(\theta_m\right)\right) \quad (14)$$

$$L_{dsds}=\frac{3\mu_0 rl}{2g}\int_0^{2\pi}N_{ds}^2\left(\theta_m,\theta\right)d\theta_m \quad (15)$$

$$L_{dsqs}=\frac{3\mu_0 rl}{2g}\int_0^{2\pi}N_{ds}\left(\theta_m,\theta\right)N_{qs}\left(\theta_m,\theta\right)d\theta_m \quad (16)$$

$$L_{dsdr}=\frac{\mu_0 rl}{g}\int_0^{2\pi}N_{ds}\left(\theta_m,\theta\right)N_{dr}\left(\theta_m,\theta_r\right)d\theta_m \quad (17)$$

$$L_{dsqr}=\frac{\mu_0 rl}{g}\int_0^{2\pi}N_{ds}\left(\theta_m,\theta\right)N_{qr}\left(\theta_m,\theta_r\right)d\theta_m \quad (18)$$

$$L_{drdr}=\frac{\mu_0 rl}{g}\int_0^{2\pi}N_{dr}^2\left(\theta_m,\theta\right)d\theta_m \quad (19)$$

$$L_{drqr}=\frac{\mu_0 rl}{g}\int_0^{2\pi}N_{dr}\left(\theta_m,\theta\right)N_{qr}\left(\theta_m,\theta_r\right)d\theta_m \quad (20)$$

etc.

IV. STATOR PHASE WINDING AND FIELD WINDING FUNCTIONS

The synchronous generator of type TBB-200-2A is a turbogenerator that is cooled by water and hydrogen. Its rated active power is 200 MW, rated voltage is 15.75 kV, rated frequency 50 Hz. It is a two-pole generator. On the stator of this generator, there exists 60 slots in which the stator winding is manufactured. The stator winding consists of three symmetrical phase windings. Each phase winding additionally consists of two half-windings connected in parallel. The phase windings are connected in star conection. Due to the existence of two parallel connected half-windings, this conection is also known as a double star conection. The three-phase stator winding consists of sixty coil groups with one coil, or twenty coils per phase - ten per half-winding. In Fig. 1 all slots and all coil groups on the stator and rotor are shown and numbered. On the stator, the shades of red represent the conductors of the phase A winding. More intense red color shows the first and lighter one the second half-winding. The other two phases are represented by shades of yellow and green - phase B in yellow and phase C in green. All slots, coil

 ISBN 978-86-7466-930-3

groups are clearly numbered and the adopted reference directions of currents and mechanical angle are shown. Based on the previous data, the functions of the phase windings can be determined, [5]-[8]. Thus, the winding function of phase A is given in Fig. 2.

Field and damper winding are mounted in 36 rotor slots. The rotor slot pitch is $\tau_r=2\pi/52$. The field winding consists of 18 coil groups, and each coil group consists of seven coils. Coil groups of the field winding are marked in green and red on the rotor, Fig. 1. Damper winding consists of conductive wedges made of aluminum alloy which close the slots in which the field winding is located. These bars are short-circuited on the front and back sides by a conductive tension rings. They are shown in blue in Fig. 1 The waveform of the field winding function is given on Fig. 3 – that is at the same time the waveform of the field winding mmf for a unit current, [1].

The functions of the fictive stator windings in the rotating frame of reference fixed to the rotor are obtained from the original functions of the phase windings using expresions (12)-(14). The winding functions obtained in this way, under the *d* and *q* axes, are given in Fig. 4 for the case $\theta=0^o$.

All of these functions will be used in the following paragraphs to calculate the inductances that appear in the *dq* model.

The function of the field winding that is located on the rotor does not need to be reduced because the rotating frame of reference is already fixed to the rotor. The magnetic axis of this winding is the *d* axis, Fig. 1.

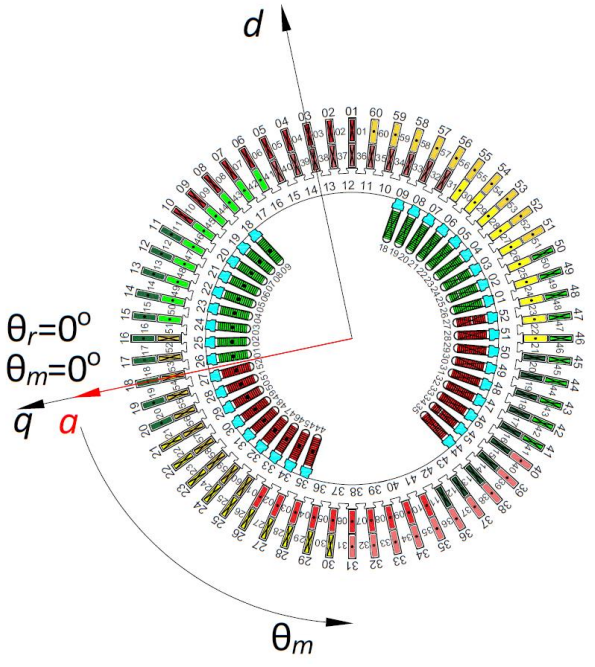

Fig.1. Design of phase, field and damper windings of the TBB-200-2A turbogenerator

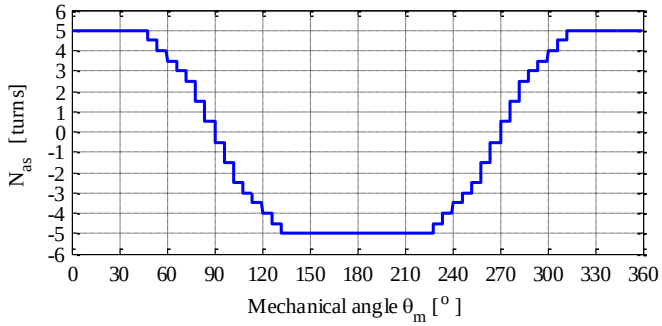

Fig.2. Stator phase A - winding function

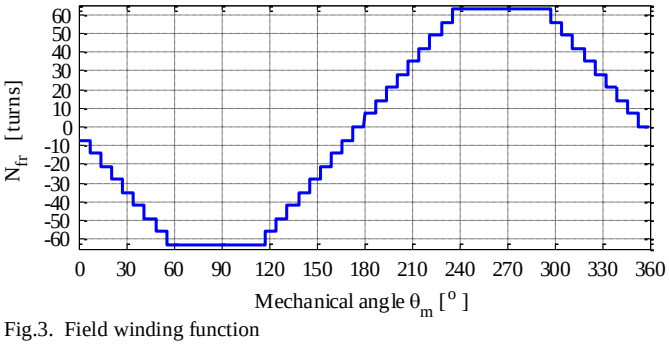

Fig.3. Field winding function

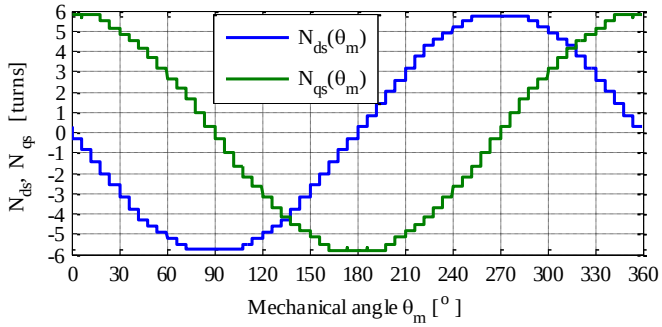

Fig.4. Fictive stator winding functions reduced to a rotating frame of reference, $\theta=0^o$

V. DAMPER WINDING FUNCTIONS

Structurally, the damper winding consists of conductive bars located in the top of the rotor slots. These bars are short-circuited on the front and back sides by the conductive tension rings. From the construction of the damper winding itself, it is clear that the same currents do not flow in short-circuited conducting bars, which, at first glance, makes this winding complicated for analysis using the concept of winding function. Namely, in order to be able to apply the definition of the winding function, it is necessary that one and the same current flows through that winding, [1]. This condition is met for armature phase windings and the field winding. This difficulty in determining the function of the damping winding can be overcome by taking into account some assumptions and neglections. As the bars on the rotor are short-circuited, currents in them are induced as a result of time-varying magnetic flux generated by currents in the phase windings of the stator. Due to the symmetry of the phase windings, it is sufficient to observe the case of induced currents resulting from the magnetic flux generated by one of the armature

 ISBN 978-86-7466-930-3

phase windings. The phase A winding will be observed here. Based on the currents induced in the bars as a consequence of the current in the phase winding, a usable damper winding function along the *d* and *q* axes can be obtained.

In order to determine the function of the damper winding along the *d* axis, Fig. 5 shows the developed scheme of the damper winding for the case when the *d* axis is in the same position as the axis of the phase A winding, i.e. the *d* axis is below the maximum value of fundamental harmonic of winding A mmf wave.

The N_{as} function shown in red in Fig. 5 represents the fundamental harmonic of the phase A winding function. Multiplying function $N_{as}(\theta_m)=N_m\cos(\theta_m)$ by the sinusoidal current in the winding, $I_a\sin(\omega_e t)$, gives a pulsating mmf. As the air-gap in the turbogenerator is uniform (ignoring the stator and rotor slots), the magnetic flux density wave created by the phase A winding will also be sinusoidal along the rotor circumference. Due to the existence of symmetry, the induced currents in bars 1 and 1' are the same but of opposite polarity, so these two bars can be considered as one fictious coil. The same situation is with 2-2', 3-3' pair of bars, etc. which are under same pole. The magnetic fluxes coupled by these fictitious coils are given by the following expressions,

$$\phi_{11'}=\frac{2\mu_0 N_m I_a r l \sin(9z/2)}{g}\sin(\omega_e t) \qquad (21)$$

$$\phi_{22'}=\frac{2\mu_0 N_m I_a r l \sin(11z/2)}{g}\sin(\omega_e t) \qquad (22)$$

etc.

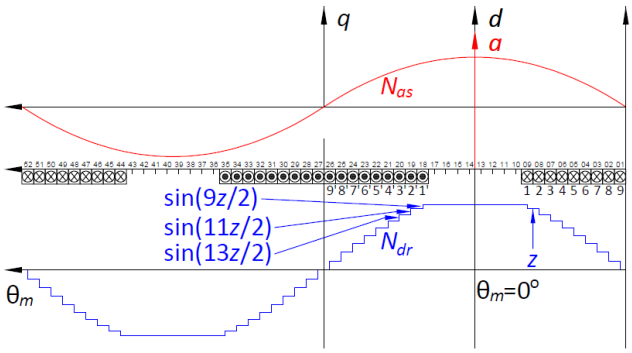

Fig.5. Damper winding function along the *d* axes

What can be seen from the previous expressions is the fact that the fluxes in the fictious coils differ only by the factors sin(9z/2), sin(11z/2), ... This difference is due to the difference in the area occupied by these coils, or differences in coil step. The induced electromotive forces in them differ for the same factors. The resistance and leakage inductance of each bar is the same. The resistance and leakage inductance of the ring segments connecting the two bars of the fictitious coil is different for each coil due to the difference in length. However, as the resistance and leakage inductance of the ring segments are usually very small, [1], around thousend times smaller than values for bars, they will not be considered here. As a consequence of the previously mentioned neglection, the currents in the fictitious windings will be the ratio of the induced electromotive force and the double impedance of the bar. Based on the above, it is concluded that the currents will differ only by the factors sin(9z/2), sin(11z/2), ..., too. Now the damper winding can be viewed as a fictive, concentrated winding through whose coils flows the same current. However, each coil has a number of conductors that differs by a factor of sin(9z/2), sin(11z/2), ... etc. In this way the mmf of the damper winding remains unchanged. The damper winding function obtained in this way is sketched in Fig. 5, in blue. Fig. 7 shows the exact shape of the damper winding function along the *d* axis, for the analysed machine, taking the position of the *q* axis as the starting position for the mechanical angle when it is in the same position as the phase A winding axis, $\theta_r=0^o$.

The procedure for obtaining the damper winding function along the *q* axis is similar to the previous procedure. Now, Fig. 6, *q* axis is placed in a position that coincides with the magnetic axis of the phase A winding. Due to the obvious symmetry the currents induced in bars 1 and 1' are the same in magnitude but opposite in direction, so these two bars can be viewed as a fictive coil. The situation is similar with other pairs of bars 2-2', 3-3', etc. The magnetic fluxes coupled by these fictive coils are:

$$\phi_{11'}=\frac{2\mu_0 N_m I_a r l \sin(z/2)}{g}\sin(\omega_e t) \qquad (23)$$

$$\phi_{22'}=\frac{2\mu_0 N_m I_a r l \sin(3z/2)}{g}\sin(\omega_e t) \qquad (24)$$

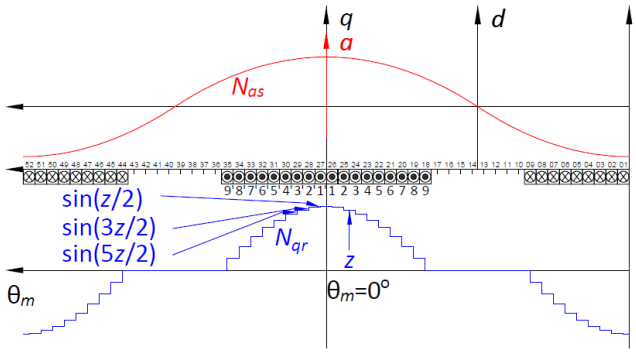

Fig.6. Damper winding function along the *q* axes

Now the factors are sin(z/2), sin(3z/2), etc. As before, ignoring the impedances of the ring segments that connect the corresponding bars, one can conclude that the currents will differ from each other only by the factors sin(z/2), sin(3z/2), etc. Now the damper winding along the *q* axis can be considered as fictitious concentrated winding through whose coils the same current flows, but each of the coils has different number of conductors. In this way the mmf of the damper winding remains unchanged. The function of the damper winding along the *q* axis is sketched in Fig. 7 in blue. Fig. 8 gives the exact waveform of the damper winding function along the *q* axis, for the analyzed machine and for the adopted reference directions from Fig. 1.

 ISBN 978-86-7466-930-3

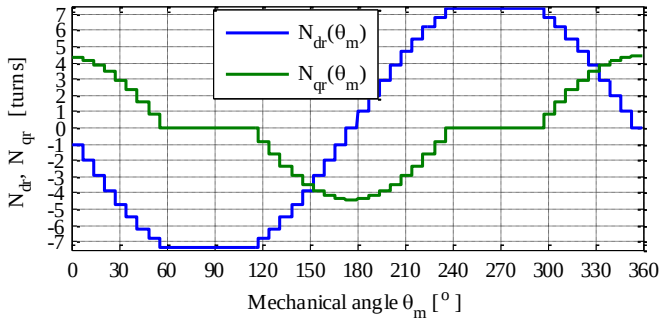

Fig.7. Damper winding functions along the *d* and *q* axes

VI. Results

The winding functions defined in the previous paragraphs enable the determination of all inductances that appear in the equations of the *dq* model. As the rotating frame of reference is fixed to the rotor all the inductances of the model are constant valued. The values of inductances obtained on the example of the analyzed generator are given in Table I.

TABLE I
CALCULATED INDUCTANCES FOR ANALYSED MACHINE

L_{dsds}	L_{qsqs}	L_{dsqs}	L_{dsns}	L_{qsns}	L_{dsdr}	L_{qsqr}	L_{dsqr}
mH	mH	mH	mH	mH	mH	mH	mH
6.6	6.6	0.0017	0.0	0.0	5.9	2.65	0.16
L_{qsdr}	L_{dsfr}	L_{qsfr}	L_{drdr}	L_{qrqr}	L_{drqr}	L_{drfr}	L_{qrfr}
mH	mH	mH	mH	mH	mH	mH	mH
–0.36	48.8	–2.95	8.0	1.8	0.0	65.9	–0.0023

What can be noticed from the previous Table is that there is a certain magnetic coupling between those windings that are located on orthogonal axes (except on the fictitious *n* axis which is normal to the plane formed by the *d* and *q* axes). This magnetic coupling is, however, very weak, as illustrated by the obtained values of the mutual inductances of the windings along these axes: L_{dsqs}, L_{dsqr}, L_{qsdr}, L_{qsfr} and L_{qrfr}. The existence of these mutual inductances is a consequence of higher spatial harmonics which are taken into account by the winding functions.

By adding the leakage inductance of armature phase winding, which for this generator is 0.5 mH to the inductance L_{dsds}, synchronous inductance along the *d* axis is 7.1 mH. Multiplying this value by the electric angular frequency results in a synchronous reactance along the *d* axis of this generator: X_d =2.2305 Ω. By dividing this reactance with the base impedance of the generator, Z_b=1.0556 Ω, unit value of synchronous reactance along the *d* axis can be obtained: x_d=2.113. The unit value of synchronous reactance given in the "passport" of this generator is x_d =2.106. This very good match, testifies to the usefulness of this procedure in determining the parameters of the *dq* model.

VII. Conclusion

The method of determining the parameters of the *dq* model of a synchronous generator using winding function theory is presented in this paper. The procedure enables direct obtaining of parameters without the need for a large number of mathematical manipulations over matrix equations. The method of determining the functions of the damper winding along the *d* and *q* axes, which enables its modeling, is also presented. The procedure is illustrated on a real synchronous turbogenerator of type TBB-200-2A.

Plan for future research is to develop software that will enable obtaining electromagnetic torque, stator, field and damper windings curents in the time domain using the parameters obtained by the explained procedure.

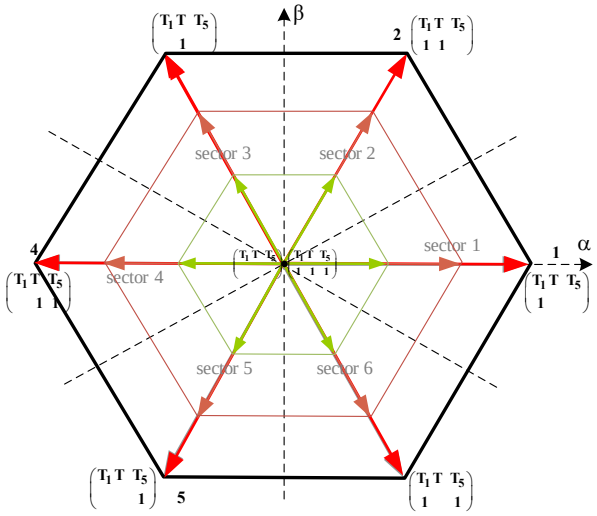
I. UVOD

Principi konvencionalne direktne kontrole momenta (cDTC) su dobro poznati i prezentovani u brojnoj naučnoj i stručnoj literaturi. Jednostavnost i dobre dinamičke osobine ovog vida kontrole čine ga i dalje aktuelnim u savremenim industrijskim pretvaračima. Kada se radi o metodama DTC zasnovane na prekidačkim tabelama, ripl momenta kao najveći nedostatak ove metode, pored ostalog, u najvećoj meri zavisi od broja raspoloživih naponskih vektora. Sa povećanjem broja raspoloživih naponskih vektora, korišćenjem invertora sa više nivoa ili kombinacije aktivnih naponskih vektora, DTC algoritmi zahtevaju definisanje nove, složenije prekidačke table koja zavisi od broja aktivnih naponskih vektora i brzine obrtanja motora [1, 2].



Sa druge strane, savremeni upravljački algoritmi, pored osnovnog dela, zahtevaju implementaciju i brojnih pratećih algoritamskih struktura kao što su estimacija parametara mašine u toku rada, self-tuning metode, napredni estimatori fluksa, opserveri stanja, kompenzacija efekta mrtvog vremena [3-5], itd. Iako ovi prateći algoritmi doprinose kvalitetu i stabilnosti pogona u širokom opsegu radnih brzina i režima rada, oni povećavaju ukupno proračunsko vreme algoritma (T_s ≈ 50-100 μs) smanjujući frekvenciju izvršavanja algoritma odnosno ograničavaju propusni opseg regulisane veličine. Iz tog razloga potrebno je da glavni deo algoritma bude što je moguće jednostavniji i manje vremenski zahtevan kako se ne bi umanjile dinamičke karakteristike sistema.

Industrija 4.0 takođe zahteva razvoj inteligentnih elektromotornih pogona sposobnih da izvrše samo evaluaciju, procenu stanja i životnog veka, autodetekciju kvara itd. [6-7]. Iz tog razloga upravljački algoritmi sa jedne strane treba da imaju sposobnost brze optimizacije i modifikacije u toku rada, a sa druge strane proračunsku jednostavnost i efikasnost koja ostavlja dovoljno prostora za implementaciju pomenutih pratećih kompenzacionih algoritamskih struktura.

Imajući u vidu navedeno, postoji potreba za robusnim, što jednostavnijim algoritmima, kao što je cDTC, sa visokim dinamičkim osobinama i malim riplom struje / momenta. Ovaj rad prezentuje karakteristike DTC algoritma baziranog na prekidačkoj tabeli sa mogućnošću njegove automatske adaptacije u cilju smanjenja ripla momenta, a u zavisnosti od broja raspoloživih diskretizovanih naponskih intenziteta (DVI). Definisanje broja naponskih intenziteta moguće je ručno (od strane korisnika) ili automatski, u zavisnosti od definisane maksimalne vrednosti ripla momenta u pogonu i ne zahteva izmene konvencionalne prekidačke tabele.

II. TEORIJSKA POZADINA DVI-DTC ALGORITMA

DVI-DTC metod baziran je na primeni više diskretizovanih naponskih intenziteta u svakom od šest osnovnih pravaca kod standardnog naponskog invertora kao što je prikazano na Sl.1.

Sl. 1. Rezolucija naponskih vektora u αβ ravni sa definisana 3 naponska int.

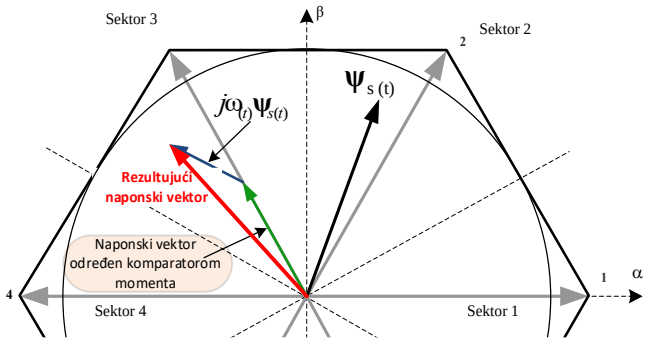
Marko Rosić – Fakultet tehničkih nauka Čačak, Univerzitet u Kragujevcu, Sv. Save 65, 32000 Čačak, Srbija (e-mail: marko.rosic@ftn.kg.ac.rs).

 ISBN 978-86-7466-930-3

U zavisnosti od definisanog broja naponskih intenziteta formira se odgovarajući komparator momenta. Komparator fluksa i prekidačka tabela (Tabela I) ostaju isti kao kod cDTC nezavisno od broja naponskih intenziteta . Ova osobina DVI-DTC omogućava da se broj naponskih vektora može jednostavno definisati ili promeniti bez potrebe za izmenom prekidačke tabele, kao što je to slučaj u [2, 8] gde je potrebno definisati novu prekidačku tabelu pri svakoj promeni broja raspoloživih naponskih intenziteta (vektora).

TABELA I – KONVENCIONALNA PREKIDAČKA TABELA

ψ	T		
	1	0	-1
1	k+1	7 or 8	k-1
-1	k+2	7 or 8	k-2

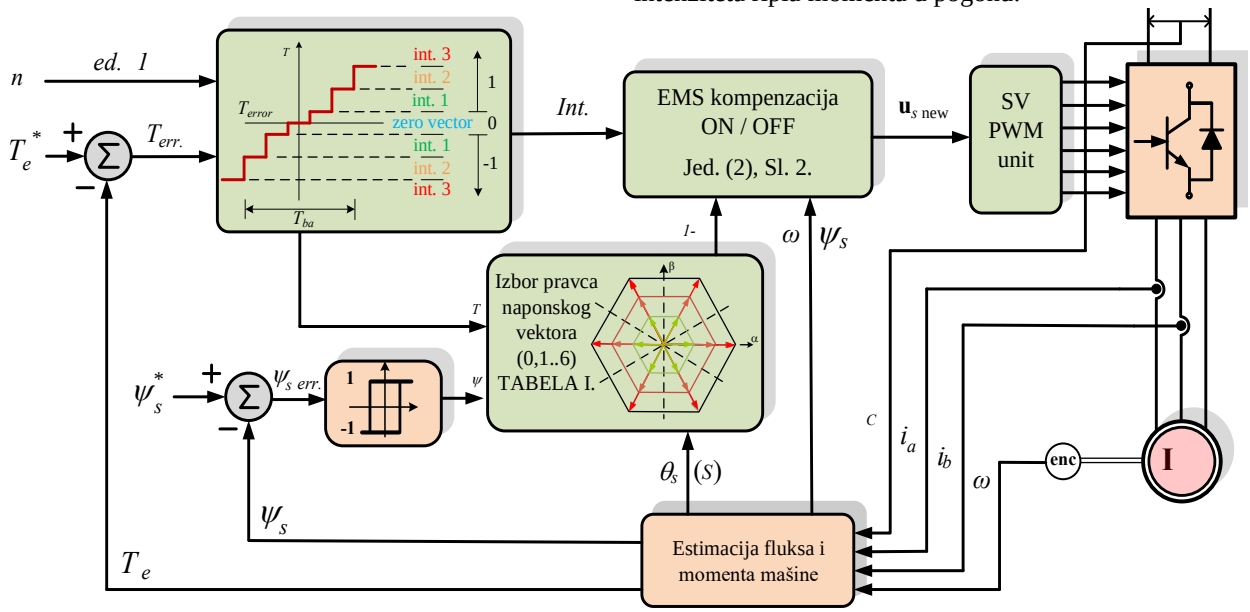


Izmene u broju naponskih intenziteta n kod DVI-DTC zahtevaju samo redefinisanje granica novog komparatora momenta T_{ba}, koja se može izvršiti prema (1).

$$T_{ba} = \frac{T_{ba_c}}{3} \cdot i = \frac{T_{ba_c}}{3} \cdot (2 \cdot n + 1) \qquad (1)$$

Negativan efekat indukovane elektromotorne sile (EMS) na inkremente momenta pri visokim (dokumentovan u [9]) može se jednostavno kompenzovati prema (2).

$$\begin{aligned} \mathbf{u}_{s\,\text{new}} &= \mathbf{u}_s + \mathbf{u}_{\text{add.}} \\ &= \mathbf{u}_s + j\omega\boldsymbol{\psi}_s = u_{\alpha s} + ju_{\beta s} + j\omega\left(\psi_{\alpha s} + j\psi_{\beta s}\right) \\ &= \underbrace{u_{\alpha s} - \omega\psi_{\beta s}}_{\text{Re}(\mathbf{u}_{s\,\text{new}})} + j\underbrace{(u_{\beta s} + \omega\psi_{\alpha s})}_{\text{Im}(\mathbf{u}_{s\,\text{new}})} \end{aligned} \qquad (2)$$



Vrednost indukovane EMS potrebno je dodati prethodno izabranom naponskom vektoru odgovarajućeg intenziteta (kao izlaza iz komparatora momenta) formirajući rezultujući naponski vektor, kao što je to prikazano na slici 2. Blok dijagram DVI-DTC algoritma prikazan je na slici 3, gde su zelenom bojom obeleženi delovi koji su izmenjeni u odnosu na cDTC.

Sl. 2. Kompenzacija EMS i formiranje rezultujućeg naponskog vektora

Broj definisanih naponskih intenziteta teorijski može varirati od 2 pa do maksimalnog broja ograničenog brojačem DSP. Ipak, u [10] pokazano je da ripl momenta eksponencijalno opada sa povećanjem broja naponskih intenziteta i da je sa 6 naponskih intenziteta ripl smanjen 8 puta u poređenju sa riplom momenta koji se ima kod cDTC.

DVI-DT može biti dalje unapređen definisanjem više pravaca (8, 12, 16 ili više) naponskih vektora dalje povećavajući prostornu rezoluciju vektora statorskog napona. U tom slučaju bilo bi potrebno modifikovati prekidačku tabelu u zavisnosti od definisanog broja pravaca. Ipak, rezultati prezentovani u [11] pokazuju da stepen smanjenja ripla momenta kod DT algoritama baziranih na prekidačkim tabelama ne zavisi u velikoj meri od izabranog pravca naponskog vektora koliko od njegovog intenziteta. Stoga, zadržavanje konvencionalne prekidačke table sa 6 aktivnih naponskih vektora se čini opravdanim. Zahvaljujući odsustvu koordinatnih transformacija, složenih matematičkih operacija, PI regulatora itd., DVI-DTC algoritam ima veoma malo vreme izvršavanja i zadržava visoke dinamičke osobine karakteristične za cDTC. Navedene osobine promovišu DVI-DTC algoritam kao pogodnog kandidata za implementaciju u savremenim upravljačkim sistemima koji zahtevaju širok propusni opseg po momentu i kontrolu maksimalnog intenziteta ripla momenta u pogonu.

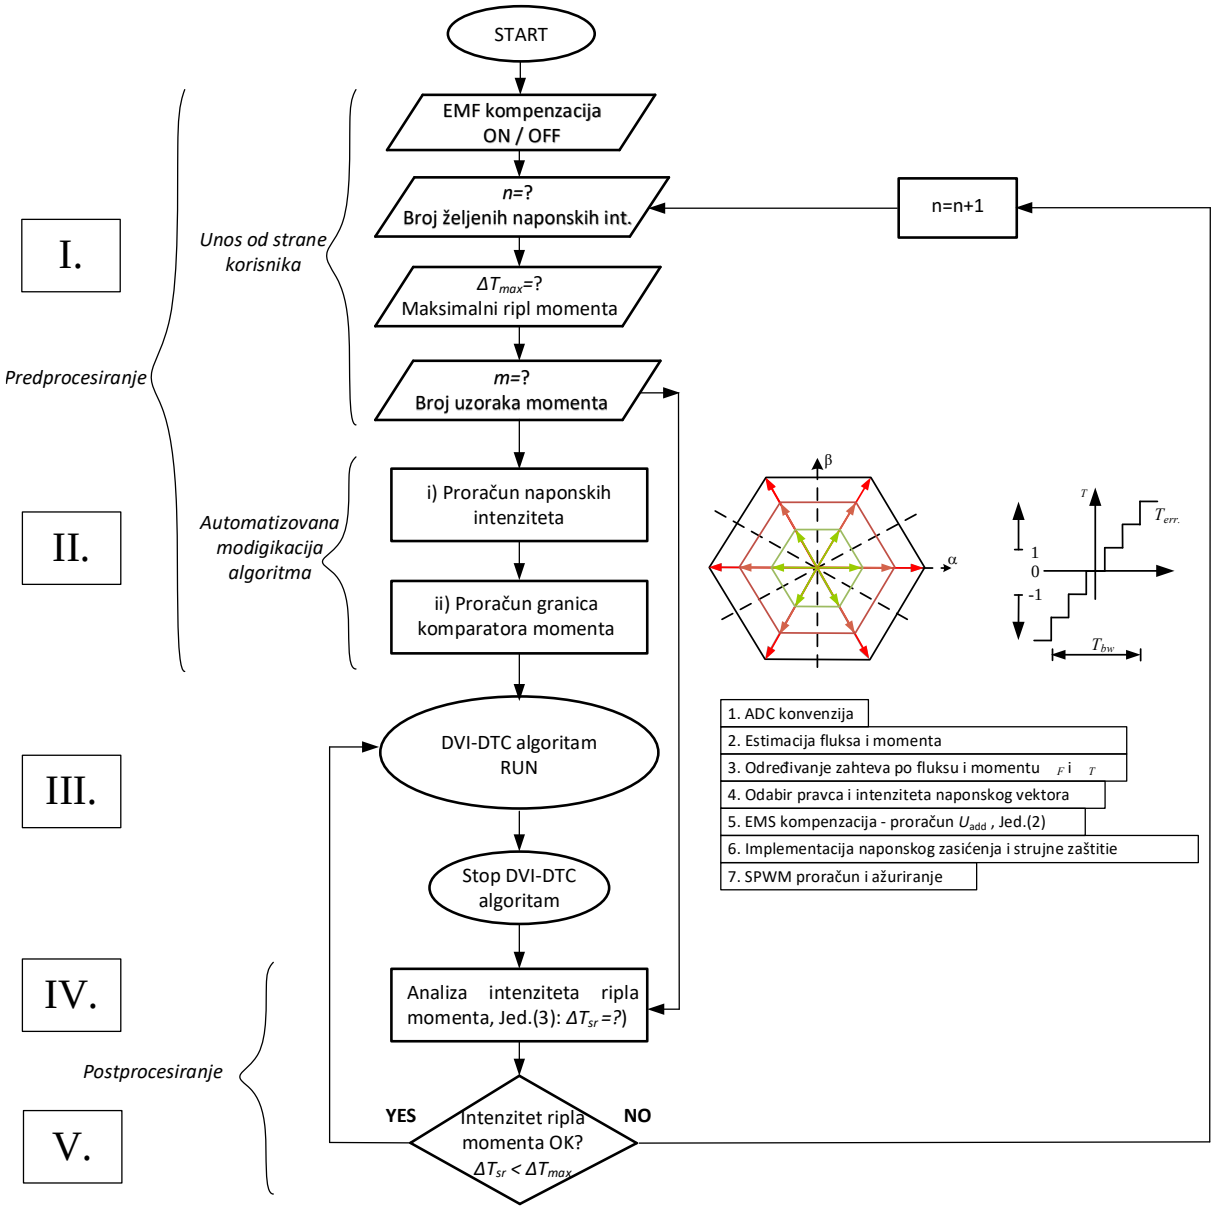
Sl. 2. Blok struktura DVI-DTC algoritma

 ISBN 978-86-7466-930-3

III. AUTOMATSKA MODIFIKACIJA DVI-DTC ALGORITMA

U cilju adekvatnog smanjenja ripla momenta, broj diskretizovanih naponskih intenziteta može biti definisan na dva načina:

- Od strane korisnika (ručno) ili
- Automatski, od strane algoritma, bazirano na estimiranim vrednostima momenta i ripla.



Na početku algoritma korisnik definiše broj naponskih intenziteta *n,* na osnovu koga se DVI-DTC algoritam dalje modifikuje pre starta. Pored ovoga, potrebno je definisati i maksimalno dozvoljeni intenzitet ripla momenta u pogonu ΔT_{ma} , kao i broj uzoraka estimiranog momenta *m* na osnovnu koga će biti određen trenutna vrednost ripla momenta. Ukoliko je ripl momenta veći od definisane vrednosti ΔT_{ma} , broj naponskih intenziteta se uvećava za jedan i algoritam nanovo modifikuje pre sledećeg starta. Slika 3 daje prikaz kompletnog algoritma inteligentnog DVI-DTC algoritma.

Inteligentni DVI-DTC algoritam je podeljen na 5 sekcija. U sekciji I zahteva se definisanje inicijalnih karakteristika pogona kao što su početni broj naponskih intenziteta i opcija kompenzacije EMS (uključena ON ili isključena OFF) od strane korisnika. Takođe u sekciji I definišu se i vrednosti za ΔT_{ma} i *m* potrebne za analizu ripla momenta u sekciji IV.

Kao što je rečeno, uvećanje broja naponskih intenziteta ne zahteva izmene u prekidačkoj tabeli. Dalja automatska modifikacija algoritma svodi se na sledeća dva koraka:

- predefinisanje odgovarajućih naponskih intenziteta u SVPWM jedinici i
- modifikacije granica komparatora momenta sa *n* nivoa.

Ova dva koraka, definisana u sekciji II, predstavljaju glavni deo automatske modifikacije DVI-DTC algoritma. Jednostavna automatizovana modifikacija u dva koraka omogućena je zahvaljujući raspregnutom izboru pravca i (prekidačka tabela) i intenziteta (komparator momenta sa *n* nivoa) kao glavnoj prednosti DVI-DTC algoritma.

Sl. 3. Inteligentni DVI-DTC algoritam

 ISBN 978-86-7466-930-3

Predefinisanje odgovarajućih naponskih intenziteta podrazumeva podelu punog opsega SVPWM generisanog naponskog vektora na jednake delove. Izuzimajući oblast nadmodulacije i negativan efekat mrtvog vremena, maksimalni intenzitet naponskog vektora generisanog uz SVPWM ograničen je radijusom upisanog kruga u heksagon koga formiraju šest aktivnih naponskih vektora (Sl.1), što predstavlja 86.7% od intenziteta maksimalnog naponskog vektora. Dalje se ovaj intenzitet deli na jednake delove na osnovu čega se definišu odgovarajuća vremena vođenja prekidačkih elemenata kod SVPWM. Odgovarajući komparator momenta i njegove granice određene su prema (1) ravnomernom raspodelom nivoa komparatora i odgovarajućih naponskih intenziteta u okviru širine komparatora T_{ba}.

Kako se opisane sekcije algoritma I i II izvršavaju pre starta glavnog dela DVI-DTC algoritma definisani su kao predpocesiranje. Ovo omogućava da glavni deo algoritma (sekcija III) zadrži proračunsku jednostavnost sličnu kao kod cDTC. Glavni deo DVI-DTC algoritma startuje sa ADC konverzijom statorskih struja i prikazan je na slici 3 koracima od 1 do 7.

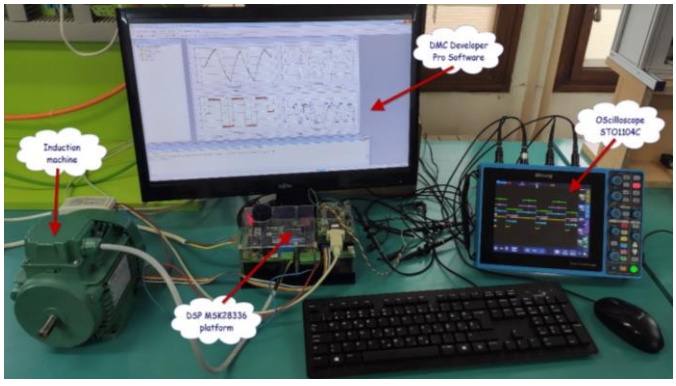
Postprocesiranje odnosi se na sekcije IV i V koji se realizuju nakon zaustavljanja glavnog dela DVI-DTC algoritma. Ovaj deo zadužen je za analizu rezultata (ripla momenta) i odgovarajuće donošenje odluka u sekciji V. Ukoliko je rezultujući ripl momenta u okviru definisanih granica DVI-DTC algoritam može biti startovan opet. U suprotnom, broj definisanih naponskih intenziteta će biti uvećan u okviru sekcije I. Ova petlja (od sekcije V do sekcije I) omogućava uvećanje broja predefinisanih naponskih vektora za jedan nakon čega se na odgovarajući način algoritam automatski modifikuje u sekciji II. Odluka da li trenutna vrednost ripla momenta zadovoljava maksimalno definisanu vrednost ΔT_{ma} (definisanu od strane korisnika u sekciji I) donosi se na osnovu proračuna procentualne srednje vrednosti ripla momenta ΔT_{sr} u odnosu na nominalnu vrednost momenta motora T_n prema (3).

$$\Delta T_{sr} = \frac{\sqrt{\frac{1}{m}\sum_{=1}^{m}\left(T - T_{ref.}\right)^2}}{T_n} \cdot 100 \quad [\%] \qquad (3)$$

Gde je m broj semplova estimiranog momenta prikupljenih u cilju analize ripla momenta T, a $T_{ref.}$ predstavlja aktuelnu referentnu vrednost momenta. U cilju što objektivnije ocene srednje vrednosti ripla momenta $\Delta T_{sr.}$, i odabira odgovarajućeg broja potrebnih naponskih intenziteta, potrebno je da budu ispunjeni sledeći uslovi:

- kompenzacija EMS mora biti uključena (ON)
- broj semplova estimiranog momenta m treba da obuhvata vrednosti momenta pri konstantnoj referentnoj vrednosti momenta.

Ova dva uslova obezbeđuju eliminisanje greške momenta kao posledice uticaja EMF (naročito pri visokim brzinama) i trenutne greške momenta koja se javlja kao posledica nagle promene referentne vrednosti i kašnjenja usled ograničene dinamike odziva momenta kao i kašnjenja usled digitalne implementacije.



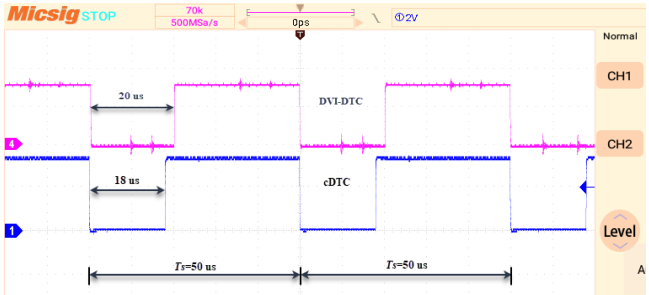
Očigledno, ova petlja zahteva da DVI-DTC algoritam najpre bude stopiran sa svakom novom iteracijom sve dok uslov maksimalnog ripla momenta ne bude ispunjen (sekcija V). Razlog ovome leži u činjenici što su delovi algoritma koji nisu prioritetni izmešteni u predprocesiranje i postprocesiranje i kao takvi pogodni su za implementaciju zajedno sa drugim *self-tuning* algoritmima opisanim u uvodu. Sa druge strane, ovim je omogućeno očuvanje jednostavnosti glavnog dela DVI-DTC algoritma.

Automatska regulacija ripla momenta moguća je i bez zaustavljanja DVI-DTC pogona u slučaju kada se sekcije I, II, IV i V izvršavaju paralelno sa sekcijom III. Ovo bi zahtevalo implementaciju ovih delova koda koji se izvršavaju sa manjom frekvencijom kao što su poziciona ili brzinska petlja. Drugi način odnosi se na implementaciju ovih delova u posebne delove koji se izvršavaju na zahtev korisnika ili nadređene upravljačke strukture.

DVI-DTC algoritam pretenduje da pokaže svoj pun potencijal sa višefaznim mašinama i odgovarajućim višefaznim pretvaračima gde mogu biti implementirani ne narušavajući originalnu jednostavnost. Prirodno veća prostorna rezolucija naponskog vektora kod višefaznih pretvarača može biti dalje umnožena uvođenjem diskretizovanih naponskih intenziteta što bi dovelo većeg stepena redukcije ripla momenta. Takođe implementacija DVI-DTC algoritma sa višefaznim mašinama bi omogućila unapređenje robusnosti i otpornosti sistema (eng. *fault tolerant*) na potencijalne kvarove na pojedinačnim fazama.

IV. EKSPERIMENTALNI REZULTATI

DVI-DTC algoritam implementiran je i testiran na MSK28335 DSP digitalnoj platformi u EMPA laboratoriji Fakulteta tehničkih nauka u Čačku. DSP platforma sastoji se od TMS320F28335 procesora sa pokretnom tačkom, 150 MHz, konvencionalnog naponskih invertora sa 6 IGBT 750 W i 310 V DC kolom. Eksperimentalna platforma je prikazana na slici 4 dok su podaci motora dati u prilozima.



Sl. 4. Eksperimentalna postavka sa merenjem vremena izvršavanja

Prekidačka frekvencija je definisana na 20kHz, ostavljajući na raspolaganju T_s 50 μs za izvršenje DTC algoritma.

 ISBN 978-86-7466-930-3

Estimacija fluksa realizovana je sa *Gopinath* fluks opserverom [12] koji kombinuje strujni i naponski model mašine. Osciloskop STO1104C je korišćen za snimanje vremena izvršavanja pojedinih DVI-DTC algoritma praćenjem digitalnog izlaza procesora koji pri startu praćenog dela algoritma daje logičku nulu a pri završetku se opet vraća na nivo logičke jedinice. Vremena trajanja cDTC i DVI-DTC su snimljena i prikazana na slici 5.

Sl. 5. Vremena izvršavanja DVI-DTC (gore) i cDTC algoritama (dole)

Slika 5 potvrđuje da glavni deo DVI-DTC algoritma zahvaljujući svojoj jednostavnosti ima oko 2 μs (≈10%) duže vreme izvršavanja u poređenju sa cDTC. Pri aktiviranju kompenzacije EMS (ON), ovo vreme izvršavanja DVI-DTC produžava se oko 7 μs kao što je prikazano na slici 6.

Sl. 6. Vremena izvršavanja delova DVI-DTC algoritma (sekcija III) sa uključenom kompenzacijom EMS

Eksperimentalni rezultati DVI-DTC sa 3, 4, 5 i 6 naponskih intenzitete sa ili bez kompenzacije indukovane EMS prikazani su na slici 7. Vremenska osa odgovara uzorkovanju rezultata na 1 ms. Na brzinskoj osi 15 pulseva odgovara brzini od 900 min^{-1} dok je osa momenta izražena u Nm. Rezultati prikazani na slici 7 potvrđuju da se ripl momenta značajno smanjuje sa rastom broja definisanih naponskih intenziteta.

V. Zaključak

Ovaj rad prezentuje inteligentni DTC algoritam baziran na diskretizovanim naponskim intenzitetima koji ima mogućnost se automatske adaptacije u zavisnosti od intenziteta ripla momenta. Odgovarajući broj naponskih intenziteta može biti definisan od strane korisnika ili automatski kroz iterativni postupak u cilju zadovoljenja definisanom maksimalnog ripla momenta u pogonu. Originalna jednostavnost i dobre dinamičke osobine koje karakterišu cDTC su zadržane kod DVI-DTC. Dobijeni eksperimentalni rezultati potvrđuju proračunsku jednostavnost DVI-DTC algoritma u poređenju sa konvencionalnom DTC i značajno smanjenje ripla momenta sa porastom broja predefinisanih diskretizovanih naponskih intenziteta. Navedene karakteristike DVI-DTC sa mogućnošću automatske modifikacije u cilju redukcije ripla momenta čine ovaj metod kontrole pogodan za implementaciju u pametnim pogonima sledeće generacije.

ABSTRACT

The paper presents characteristic of direct torque control method based on discretised voltage intensities with possibilities of automatic algorithm modification in terms of torque ripple reduction. The algorithm uses the conventional switching table with an arbitrary number of discretized voltage intensities allowing higher space-voltage resolution and consequently lower torque ripple. The number of available voltage intensities can be easily changed without the need to modify the conventional switching table. Depending on the number of defined, discretized voltage intensities corresponding algorithm structures are automatized, making this kind of control method simple, effective, and suitable for upcoming smart drives in the rapidly growing industry 4.0. Experimental validation presented in the paper confirms improvements in torque ripple reduction retaining the simple and time-effective control structure of the induction machine DTC drive.

Intelligent DTC algorithm with automatic reorganisation based on the torque ripple intensity

Primjena električnih vozila za smanjenje deficita snage u sistemu

Uroš Ognjenović[1], Saša Mujović[1], Lazar Šćekić[1]
[1]*Univerzitet Crne Gore, Elektrotehnički fakultet, Bulevar Dž. Vašingtona bb, Podgorica, Crna Gora*

***Apstrakt*—Električna vozila (EVs – electric vehicles) su jedan od vodećih trendova u svijetu kada je u pitanju održivi razvoj i smanjenje emisije štetnih gasova. Prodor električnih vozila u elektroenergetski sistem znači povećano opterećenje, ali i omogućava plansko punjenje i pražnjenje ovih vozila uz benefit po sistem i korisnike električnih vozila. U ovom radu analizirana je primjena planskog punjenja i pražnjenja električnih vozila zasnovana na metodi igara na sreću, u cilju smanjenja deficita snage u sistemu.**

***Ključne riječi*—električna vozila; agregator; plansko pražnjenje; plansko punjenje**

I. UVOD

Električna vozila cjelokupnu snagu ili jedan njen dio obezbjeđuju iz električne mreže i dijele se na potpuno električna vozila (AEVs – all-electric vehicles) i hibridna vozila (PHEVs – plug-in hybrid electric vehicles). Potpuno električna vozila su pokretana od strane jednog ili više električnih motora. Energiju obezbjeđuju punjenjem sa električne mreže i njenim čuvanjem u baterijama. Ne troše fosilna goriva i ne proizvode toksične gasove niti gasove sa efektom staklene bašte. Hibridna vozila koriste baterije za napajanje električnog motora, ali pored toga posjeduju i motor sa unutrašnjim sagorijevanjem (ICE – internal combustion engine).

Nagli rast interesovanja za razvoj električnih vozila je dobrim dijelom rezultat negativnog uticaja na životnu sredinu usljed industrijskog razvoja, konflikta u zemljama izvoznicama nafte na Bliskom Istoku i sa tim u vezi visokom cijenom nafte. Finansijska ulaganja i podsticaji za razvoj i posjedovanje električnih vozila su zasnovani na percepciji da su električna vozila ekološki prihvatljiv vid transporta u budućnosti.

Električna vozila su tek na početku svog ubrzanog razvoja i prodora na tržište (iako je prvo električno vozilo proizvedeno davne 1832.) što znači da će međusobni uticaj električnih vozila i EES-a (elektroenergetskog sistema) da raste u narednom periodu što potvrđuju sledeće zanimljivosti:

- 2,6% prodatih automobila u svijetu u 2019. su bila električna vozila, što predstavlja značajan porast u odnosu na 2017. kada je taj udio bio 1%.
- Norveška planira da u potpunosti izbaci iz upotrebe vozila sa motorom sa unutrašnjim sagorijevanjem do 2025., dok Francuska i Velika Britanija to planiraju da urade do 2040.
- Broj stanica za punjenje u Holandiji je u februaru 2020. iznosio nešto više od 37.000 (jedna stanica na 459 stanovnika) što Holandiju pozicionira na prvo mjesto u svijetu.
- Od ukupne potrošnje energije u Sjedinjenim Američkim Državama u 2005. u iznosu od 29.000 TWh, 28% odnosno 4.953 TWh je utrošeno u sektoru transporta. Ukoliko se pretpostavi da je ova energija utrošena isključivo u automobilima, dolazi se do zaključka da bi SAD trebalo da obezbijede energiju koja je veća od njene ukupne godišnje proizvodnje električne energije u istoj godini (4.055 TWh) za potpuni prelazak na električna vozila.

Imajući u vidu mogućnost kontrolisanog punjenja i pražnjenja, električna vozila se mogu posmatrati kao pokretni upravljivi sistemi za skladištenje električne energije. Interes korisnika električnih vozila je razlika između cijene električne energije predate u mrežu i cijene električne energije za punjenje. Kao rezultat učešća u V2G, dolazi do degradacije baterije tako da novčane naknade korisnicima moraju biti veće od troškova usljed degradacije baterije.

Ostatak rada je organizovan na sledeći način. U drugom poglavlju je objašnjen problem planskog pražnjenja vozila. Metod igara na sreću, proces aukcije i benefit korisnika su opisani u trećem poglavlju. Rezultati proračuna potencijala upotrebe električnih vozila za smanjenje deficita snage u primorskoj regiji Crne Gore su dati u poglavlju broj četiri. Peto poglavlje sumira ovaj rad. Na kraju rada je dat spisak korišćene literature.

II. ELEKTRIČNA VOZILA U ELEKTROENERGETSKOM SISTEMU

Istraživanja pokazuju da su špic sati za dolazak na posao električnim vozilom između 7:00 i 8:00 i da je vrijeme punjenja tokom radnih sati. Špic sati za povratak sa posla električnim vozilom su između 17:00 i 19:00 i vrijeme punjenja je između 19:00 i 6:00 narednog dana. Dakle, električno vozilo se može povezati na mrežu dva puta dnevno [1]. Pored toga, više od 90% vozila je parkirano negdje i 50% kod kuće tokom dana, što otvara mogućnost za ispomoć električnoj mreži ukoliko postoji odgovarajući stimulans [2]. Konkretno, zabrana prodaje automobila na benzin i dizel koja je predložena u nekim zemljama će promovisati prodor električnih vozila, tako da imaju veliki potencijal kao kontrolisano opterećenje [3].

Obzirom da se električna vozila mogu posmatrati kao distribuirani izvor energije i kao opterećenje koje može biti planirano, stvorena je ideja o sistemu vozilo-ka-mreži (V2G –

 ISBN 978-86-7466-930-3

vehicle-to-grid). U V2G sistemu, energija može da teče između električne mreže i električnog vozila [1].

Za koordinaciju punjenja i pražnjenja električnih vozila se koristi agregator. Agregator je centralni entitet koji koordiniše i planira status električnih vozila. Očekuje se da će u budućnosti većina električnih vozila biti povezana na Internet preko VANET-a (Vehicular ad hoc network – Bežična ad-hok mreža), Wi-Fi-ja ili mobilne mreže. Električna vozila mogu da prenose informacije kao što je tip vozila, kapacitet baterije, neophodno punjenje, ruta, itd. agregatoru [4]. Sva električna vozila karakteriše i status napunjenosti (SoC – State of Charge) koji je nivo napunjenosti u odnosu na kapacitet baterije (između 0% i 100%).

Za određivanje uticaja električnih vozila na elektroenergetski sistem neophodno je razumjeti različite statuse koje električna vozila mogu imati u bilo kom trenutku. Razlikuje se 5 statusa [5]:

- Električna vozila na punjenju: Električna vozila su priključena na mrežu i preuzimaju energiju za punjenje njihovih baterija.
- Električna vozila u V2G sistemu: Električna vozila predaju energiju mreži.
- Električna vozila kao eksplicitna rezerva: Električna vozila su priključena na mrežu, ali ne preuzimaju niti injektiraju energiju u mrežu. U ovom slučaju, električna vozila mogu započeti proces punjenja ili pražnjenja na zahtjev agregatora, uzimajući u obzir trenutno stanje baterije.
- Električna vozila koja se koriste za transport. U ovom modu električna vozila nijesu priključena na mrežu, već se koriste za transport i troše energiju skladištenu u baterijama.
- Neiskorištena električna vozila: Električna vozila su priključena na mrežu, ali agregator odlučuje da ne koristi ova vozila za punjenje, V2G niti kao rezervu.

III. METOD IGARA NA SREĆU

Za učešće u V2G sistemu se primjenjuje mehanizam aukcije po prvoj cijeni (first-price auction). Pobjednici aukcije su učesnici koji su dali najviše ponude i oni plaćaju iznose koje su ponudili. Kao benefit ostvaruju razliku između cijene električne energije za punjenje električnih vozila i ponude, sa jedne strane, i cijene električne energije predate u mrežu, sa druge strane. Učesnici aukcije nisu upoznati sa ponudama drugih učesnika (sealed-bid auction – aukcija sa zatvorenim ponudama). Potrošači, odnosno učesnici aukcije koji ne žele da pobijede na aukciji i time učestvuju u V2G sistemu, mogu da daju ponudu za koju vjeruju da neće biti najviša. Time se obezbjeđuje autonomija – potrošači bi trebalo da sami odlučuju da li da učestvuju u V2G poređenjem benefita V2G i mobilnosti [3].

Aukcija se vrši za svaki 60-minutni interval pojedinačno za naredni dan. Na osnovu prognoze proizvodnje i potrošnje za naredni dan, $P_{pro}(t)$ i $P_{pot}(t)$, se određuje deficit snage po satima $P_{def}(t)$, gdje je t indeks intervala ($t \in \{1,2,...,T\}$, gdje je T poslednji interval). Ovaj podatak se koristi za dobijanje podataka o idealnom broju idealnih vozila (idealna vozila su vozila čiji status baterije omogućava predaju određene količine energije mreži tokom odgovarajućeg intervala pri određenoj snazi) $N_{ide}(t)$ koja bi predala električnu energiju sistemu. Ukoliko su sva električna vozila istih karakteristika, $N_{ide}(t)$ se dobija po formuli:

$$N_{ide}(t) = floor(\frac{P_{def}(t)}{P_{pra}}), t = 1,2,..., T, \quad (1)$$

gdje je P_{pra} snaga kojom električna vozila predaju električnu energiju mreži [kW]. Floor($P_{def}(t)/P_{pra}$) označava prvu manju cijelu vrijednost količnika $P_{def}(t)/P_{pra}$ – zaokruženu vrijednost.

V2G se realizuje kada se, na osnovu prognoze proizvodnje i potrošnje električne energije za naredni dan ustanovi da se makar u jednom od intervala javlja deficit snage $P_{def}(t)$ i kada je taj deficit veći od P_{pra}. Ovaj uslov se može predstaviti relacijom:

$$\sum_{t=1}^{T} N_{id}(t) \geq 1. \quad (2)$$

Neka se u nekom EES-u nalazi N električnih vozila. Broj vozila $N_{ide}(t)$ za određeni interval može biti veći, jednak, ili manji od stvarnog broja vozila u sistemu. U slučaju da je $N_{ide}(t)$ veće od ili jednako N, svi korisnici električnih vozila mogu da učestvuju u V2G, čime se gubi potreba za održavanjem aukcije u odgovarajućem intervalu. U ovoj situaciji, agregator određuje vrijednost po kojoj se električna energija otkupljuje od korisnika električnih vozila. Ova vrijednost se određuje po relaciji:

$$C_{otk} = k_1 C_{maks}, \quad (3)$$

gdje je:

C_{otk} – cijena otkupljene električne energije od potrošača [EUR/kWh]

k_1 – koeficijent kojim se obezbjeđuje benefit potrošaču u najnepovoljnijem slučaju kada je električno vozilo punjeno tokom perioda maksimalne cijene električne energije i koji je veći od 1 (npr. 1,1), za slučaj kada je $N_{ide}(t)$ veće od jednako N.

C_{maks} – maksimalna cijena električne energije tokom dana [EUR/kWh]

Kada je $N_{ide}(t)$ manje od N, odnosno kada je deficit u sistemu moguće pokriti sa brojem vozila koji je manji od stvarnog broja vozila u sistemu, održava se aukcija kako bi se odredio broj korisnika električnih vozila koji žele da učestvuju u V2G. Da bi korisnici električnih vozila ostvarili benefit pri učestvovanju u aukciji, moraju biti upoznati sa cijenom otkupa električne energije koja se može razlikovati od slučaja kada je $N_{ide}(t)$ veće od ili jednako N. Na osnovu ovog podatka, određuje se maksimalna moguća ponuda korisnika *maksPonuda* [EUR] koja donosi benefit po relaciji:

$$maksPonuda = floor(P_{pra}(k_2 - 1)C_{maks}), \quad (4)$$

gdje je k_2 koeficijent kojim se obezbjeđuje benefit potrošaču, za slučaj kada je $N_{ide}(t)$ manje od N.

U realnosti, električna vozila nisu idealna, već ih karakteriše SoC između 0% i 100% što direktno utiče na

 ISBN 978-86-7466-930-3

mogućnosti isporuke električne energije mreži. Štaviše, usljed degradacije baterije, ne preporučuje se punjenje iznad 80% za model Nissan Leaf. Uvodi se i zahtjev da baterija nijednog električnog vozila ni u jednom trenutku ne smije da dostigne status napunjenosti manji od b kapaciteta baterije [r.j. – relativne jedinice] čime jedan dio korisnika automatski gubi mogućnost za učešće u V2G, a koji je rezultat upotrebe električnih vozila u prethodnom periodu (ovaj uslov se može eliminisati ako se uzme da je b jednako nuli što znači da se električna vozila mogu potpuno isprazniti ako se koriste za ispomoć mreži). Ovaj uslov se uvodi usljed činjenice da je glavna uloga električnih vozila transport pa se podrazumijeva da se baterija ne smije potpuno isprazniti. Neka je EV niz kapaciteta baterija svih električnih vozila u sistemu. Uslov za određivanje niza potencijalnih električnih vozila EV_{pot}, dužine N_{pot}, od svih vozila u sistemu, za učešće u planskom pražnjenju je sledeći:

$$EV(n) \geq bE_{bat} + P_{pra}, n = 1,2,\ldots,N \tag{5}$$

gdje je E_{bat} kapacitet baterije [kWh].

Dakle, električna vozila koja mogu da učestvuju u V2G su ona vozila koja imaju skladištenu minimalnu količinu energije plus količinu energiju koju mogu predati mreži tokom jednog sata pri snazi pražnjenja P_{pra}. Od niza svih električnih vozila u sistemu se dobija niz potencijalnih vozila EV_{pot} čija je dužina N_{pot} manja od ili jednaka N. Ovaj niz sadrži podatke o vozilima u sistemu koja zadovoljavaju (5).

Treba imati u vidu da vozila $EV_{pot}(j)$ (j=1,2,...,N_{pot}) zadovoljavaju (5) samo za prvi interval posmatranog dana. Na kraju tog intervala, a u zavisnosti od upotrebe električnog vozila (punjenje, plansko pražnjenje, vožnja, itd.), električna vozila karakteriše SoC koji se razlikuje od SoC na početku intervala. Dakle, (5) je neophodno provjeriti za svaki od intervala za posmatrani dan.

Obzirom da se aukcija održava za naredni dan, tačni SoC električnih vozila u t-om intervalu nije poznat ni agregatoru ni korisniku. Međutim, SoC na početku dana se za proračune može opisati normalnom raspodjelom N(0,6, 0,01) [1].

Iz niza EV_{pot}, na osnovu ponuda učesnika aukcije za učešće u V2G za odgovarajući interval, agregator određuje niz dobitnika aukcije EV_{dob}. Ovi korisnici su dužni da u datom intervalu obezbijede dogovorenu količinu energije mreži. U slučaju da korisnik, koji je pobijedio na aukciji za određeni interval, odluči da isključi vozilo sa mreže tokom tog istog intervala, što se u praksi može desiti, dužan je da plaća penale čiji iznos određuje sistem operator i čiji detalji su precizirani u ugovoru između ove dvije strane.

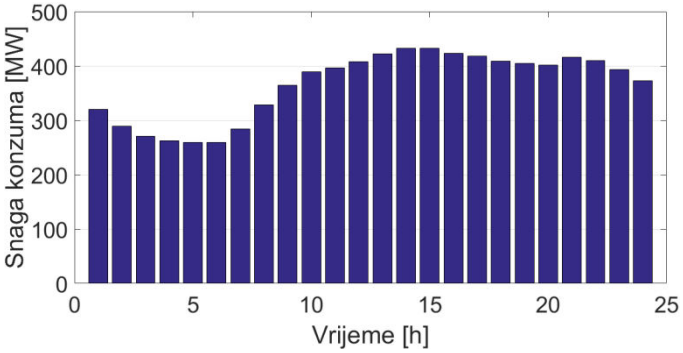
Obzirom na ograničeni kapacitet baterije, korisnici električnih vozila nisu u mogućnosti da učestvuju u V2G u svim mogućim intervalima. Za svakog pobjednika agregator vrši proračun dostupnog kapaciteta kako bi se odredio zahtijevani plan pražnjenja. Ukoliko agregator odredi da u k-tom (k=1,2,...,T) intervalu dobitnik aukcije nije u mogućnosti da učestvuje u V2G, provjerava se da li je u t-im (t=1,2,...,k-1) intervalima moguće dopuniti električno vozilo energijom neophodnom za učešće u planskom pražnjenju u k-tom intervalu. Opcije su sledeće:

- Ukoliko to jeste moguće, korisnik donosi odluku da priključi vozilo na mrežu u zahtijevanom intervalu ili da se povuče iz aukcije. U slučaju da odluči da se povuče iz aukcije, prvi gubitnik aukcije dobija priliku da učestvuje V2G.
- Ukoliko to nije moguće, prvi gubitnik aukcije dobija priliku da učestvuje u V2G.
- Agregator automatski isključuje datog korisnika iz planskog pražnjenja za posmatrani interval i prvi gubitnik aukcije dobija priliku da učestvuje u V2G.

Pored određivanja plana pražnjenja, agregator može kao izlazni podatak da daje i dostupni kapacitet baterije u nekom trenutku, što bi korisnicima olakšalo planiranje upotrebe električnog vozila.

Za interakciju između agregatora (sistema) i korisnika električnih vozila je neophodno izgraditi odgovarajuću komunikacionu infrastrukturu.

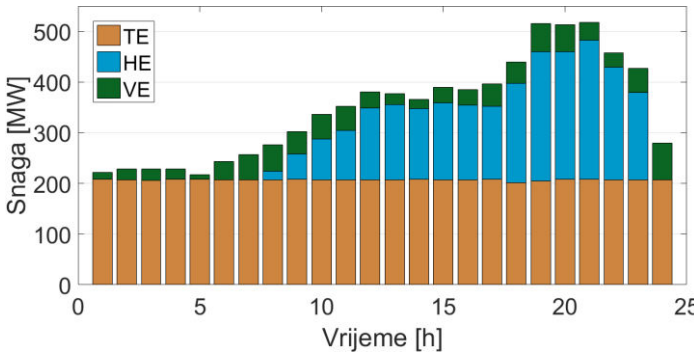
IV. NUMERIČKI REZULTATI



Posmatra se EES Crne Gore. Elektrane od velikog značaja za EES Crne Gore i njihove karakteristike su prikazane u tabeli I.

TABELA I
Velike elektrane u EES-u Crne Gore

Elektrana	Tip	Instalisana snaga [MW]
HE Piva	Akumulaciona hidroelektrana	342
HE Perućica	Protočna hidroelektrana	307
TE Pljevlja	Termoelektrana na ugalj	210
VE Krnovo	Vjetroelektrana	72
VE Možura	Vjetroelektrana	46

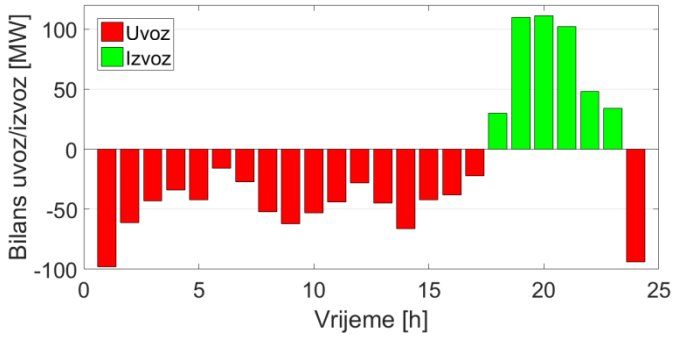


EES Crne Gore je pretežno hidro sistem sa instalisanom snagom velikih hidroagregata od 649 MW što predstavlja 66,43%, odnosno približno dvije trećine ukupnih kapaciteta (nisu uračunate male hidroelektrane).

Ljetnje mjesece u EES-u Crne Gore karakteriše naročito povećanje opterećenja u južnoj regiji kao rezultat izraženih turističkih aktivnosti. Na slici 1 je dat dijagram opterećenja konzuma, a na slici 2 proizvodnja proizvodnih jedinica Crne Gore na dan 27.07.2020.

Sl. 1. Konzum Crne Gore na dan 27.07.2020. (izvor ENTSO-E Transparency)

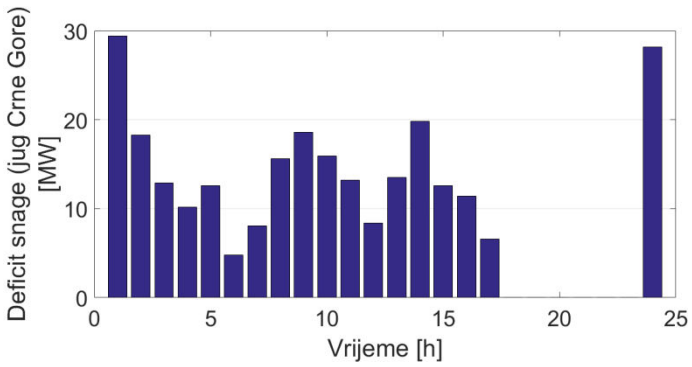
 ISBN 978-86-7466-930-3



Sl. 2. Proizvodnja na dan 27.07.2020. (izvor ENTSO-E Transparency)

Na osnovu podataka sa slike 1 i 2 se zaključuje sledeće:

– TE Pljevlja tokom cijelog 24-časovnog perioda radi sa snagom koja je približno jednaka njenoj instalisanoj snazi od 210 MW i ta snaga se kreće u opsegu od 201 MW do 208 MW. Maksimalno se koristi raspoloživa snaga TE i tokom cijelog dana se javlja opterećenje koje je veće od tehničkog minimuma TE Pljevlja pa se ne javlja potreba za isključenje date elektrane sa mreže.
– Energija vjetra se koristi u onoj mjeri u kojoj je to moguće – teži se što boljem iskorišćenju raspoložive energije.



Na slici 3 dat je bilans snaga u EES-u Crne Gore na dan 27.07.2020.

Sl. 3. Bilans snaga uvoz/izvoz na dan 27.07.2020.

Električna energija se uvozi u periodu između 00:00 i 17:00, kao i između 23:00 i 00:00, dok se izvozi u periodu između 17:00 i 23:00 časa. Višak proizvodnje u sistemu tokom ovog perioda se može iskoristiti za punjenje električnih vozila, koja se u preostalim intervalima (kada se javlja manjak snage) mogu ponašati kao generatori električne energije. Izvezena količina električne energije tokom posmatranog dana iznosi 435 MWh, dok je uvezena količina približno dva puta veća i iznosi 867 MWh.

Ukoliko se uvede pretpostavka da, od ukupne nedostajuće količine energije, odnosno snage, 30% otpada na južnu regiju, dolazi se do podataka o deficitu snage prikazanih na slici 4.

Sl. 4. Nedostajuća snaga u južnoj regiji Crne Gore na dan 27.07.2020. (aproksimacija od 30% ukupne nedostajuće snage u EES-u)

Na osnovu ovih podataka, ukupna nedostajuća količina energije u južnoj regiji Crne Gore na dan 27.07.2020. je 260,1 MWh (približno 260 MWh), a prosječna nedostajuća snaga je 14,45 MW. Nedostajuća količina energije bi mogla biti nadoknađena iz baterija električnih vozila za šta bi bilo neophodno priključiti na mrežu 5.200 vozila sa kapacitetom baterija 50 kWh i potpuno ih isprazniti. Međutim, električna vozila se koriste za transport tako da se uzima u obzir da ni u jednom trenutku ni jedno električno vozilo ne smije biti u potpunosti ispražnjeno. Time se zaključuje da u EES-u Crne Gore, tj u južnoj regiji, treba da postoji 6.500 električnih vozila sa baterijama kapaciteta 50 kWh koje ni u jednom trenutku ne padaju ispod stanja napunjenosti od 20%, odnosno 10 kWh, kako bi se pokrio deficit električne energije. U 2019. je u gradovima južne regije Crne Gore registrovano ukupno 66.410 vozila (Bar 17.232; Budva 11.922; Kotor 9.961; Tivat 7.397; Ulcinj 7.781; Herceg Novi 12.117) tako da se zaključuje da svako deseto vozilo treba da bude električno sa odgovarajućim karakteristikama.

U proračunu potencijala upotrebe električnih vozila u V2G sistemu u EES-u Crne Gore posmatraju se četiri stepena prisustva električnih vozila u južnoj regiji i to: 1.000 vozila, 5.000 vozila, 10.000 vozila i 20.000 vozila. Smatra se da su sva vozila istih karakteristika i to:

– Baterije su kapaciteta 50 kWh
– Snaga punjenja je 10 kW
– Snaga pražnjenja je 5 kW

Koeficijenti k_1 i k_2 su 1,1 i 1,2, respektivno. Na osnovu (5), minimalna količina energije neophodne za učešće u V2G, sa koeficijentom b=0,2, je 15 kWh.

SoC na početku dana se opisuje normalnom raspodjelom sa koeficijentima μ=0,6 i σ=0,1. Zaključuje se da 99,87% vozila ispunjava (5), što nema značajniji uticaj na sistem (u odnosu na slučaj kada bi 100% vozila ispunjavala dati uslov), ali je poželjno voditi računa o pomenutom uslovu radi maksimalne udobnosti korisnika koji električno vozilo koriste prije svega za transport.

Po dvotarifnom modelu u Crnoj Gori, maksimalna cijena električne energije je jednaka cijeni električne energije tokom perioda visoke tarife i iznosi približno 0,103 EUR/kWh.

Električna vozila nijesu generatori električne energije, već pokretne baterije za njeno skladištenje. Dakle, pored V2G sistema, mora se uzeti u obzir i pitanje punjenja električnih

 ISBN 978-86-7466-930-3

vozila tokom posmatranog dana sa ciljem bolje procjene njihovog uticaja na sistem. Iz ovog razloga, za svaki stepen prisustva električnih vozila se posmatraju dva podslučaja:

1. Kada korisnici električna vozila pune onda kada žele.
2. Kada korisnici električna vozila pune u periodu viška snage u sistemu.

Svi proračuni koji zavise od odluka potrošača koje imaju dva ishoda su izvedeni upotrebom funkcije koja nasumično generiše date odluke (npr. da li napuniti vozilo u posmatranom intervalu ili ne).

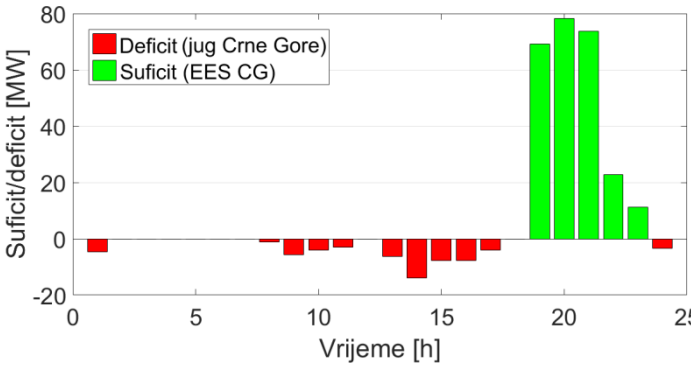
U tabelama II i III prikazani su rezultati proračuna za 8 posmatranih slučajeva. Date veličine su sledeće:

- Deficit energije u sistemu sa električnim vozilima [MWh] i u odnosu na deficit energije u originalnom sistemu [%]
- Suficit energije u sistemu sa električnim vozilima [MWh] i u odnosu na suficit energije u originalnom sistemu [%]
- Prosječna zarada planskog pražnjenja [EUR/kWh]
- Prosječna energija vozila na kraju dana [kWh]
- Prosječno pokrivanje deficita snage po satima [%] daje podatak o učešću električnih vozila u pokrivanju nedostatka snage u sistemu. Negativna vrijednost označava povećanje prosječnog pokrivanja deficita i javlja se isključivo kada korisnici vozila pune kada žele
- Prosječno pokrivanje suficita snage po satima [%] daje podatak o učešću električnih vozila (punjenju) u preuzimanju viška snage u sistemu

TABELA II
Rezultati proračuna (prvi dio)

Broj vozila	Deficit energije [MWh] ([%])	Suficit energije [MWh] ([%])	Prosječna zarada pražnjenja [EUR]
1.000 (1.)	258,62 (99,43)	425,39 (97,79)	0,0103
1.000 (2.)	239,64 (92,14)	416,6 (95,77)	0,0102
5.000 (1.)	259,03 (99,59)	390,50 (89,77)	0,0097
5.000 (2.)	158,30 (60,86)	338,24 (77,75)	0,0098
10.000 (1.)	305,88 (117,60)	378,82 (87,08)	0,0097
10.000 (2.)	61,325 (23,57)	254,97 (58,61)	0,0096
20.000 (1.)	444,45 (170,87)	374,50 (86,09)	0,0096
20.000 (2.)	0,025 (0,0096)	141,33 (32,49)	0,0097

TABELA III
Rezultati proračuna (drugi dio)



Broj vozila	Prosječna energija vozila na kraju dana [kWh]	Prosječno pokrivanje deficita snage po satima [%]	Prosječno pokrivanje suficita snage po satima [%]
1.000 (1.)	38,13	-0,15	3,03
1.000 (2.)	27,94	9	6
5.000 (1.)	38,6690	-9,58	13,84
5.000 (2.)	28,9750	34,79	31,05
10.000 (1.)	40,1900	-43,62	17,58
10.000 (2.)	28,1195	65,06	42,86
20.000 (1.)	42,2390	-106,37	18,71
20.000 (2.)	31,6760	99,95	66,27

Na osnovu podataka iz tabela II i III se zaključuje sledeće:

- Uvođenjem električnih vozila u sistem se povećava deficit snage u sistemu kada korisnici električna vozila pune onda kada to smatraju za shodno (slučajevi 1.), a pritom ne dolazi do značajnijeg smanjenja suficita što je rezultat ravnomjernog punjenja vozila tokom cijelog dana.
- Kada se V2G kombinuje sa planskim punjenjem (slučajevi 2.), dolazi do znatnog smanjenja deficita snage sa povećanjem prisustva električnih vozila u sistemu.
- Prosječna energija skladištena u baterijama električnih vozila na kraju dana u slučajevima 2. iznosi u prosjeku 29,21 kWh, odnosno 97,37% prosječnog kapaciteta energije na početku dana, što govori da je V2G sistem u kombinaciji sa planskim punjenjem održiv i kada se primijeni na periode duže od jednog dana. U proračunima međutim nije uzeto u obzir korišćenje električnih vozila za prevoz, odnosno smanjenje dostupne energije u baterijama električnih vozila tokom dana.
- Kombinovanje V2G sistema i planskog punjenja pozitivno utiče na sistem, jer u suprotnom električna vozila praktično međusobno izmjenjuju električnu energiju (kada jedno električno vozilo predaje energiju mreži, drugo se puni, pa je uticaj na sistem manji nego kada bi se punjenje električnih vozila prebacilo u interval viška snage u sistemu).

Na slici 5 dat je prikaz deficita snage na jugu Crne Gore po satima i ukupan deficit u sistemu sa 10.000 električnih vozila koja se pune tokom perioda viška snage (slučaj 2.).

 ISBN 978-86-7466-930-3

Sl. 5. Deficit snage na jugu Crne Gore i ukupni suficit u sistemu sa 10,000 (2.) električnih vozila na dan 27.07.2020.

Poredeći podatke sa slike 5 i podatke sa slike 3 i 4, zaključuje se da je deficit snage na jugu Crne Gore (pretpostavka o 30% deficita snage na nivou EES-a) značajno smanjen uvođenjem plana planskog pražnjenja vozila. U periodu između 1 i 6 časova u jutarnjim satima bilans snaga je jednak nuli. Primjećuje se i da je uticaj električnih vozila manji u kasnijim satima usljed pretpostavke da se električna vozila tokom posmatranog dana pune isključivo tokom perioda viška snage u sistemu, kada opet dostižu minimalnu količinu energije za učešće u V2G. Suficit snage u sistemu u periodu između 17 i 23 časa je takođe smanjen planskim punjenjem vozila. U intervalu između 17 i 18 časova se u potpunosti absorbuje višak proizvodne snage.

U proračunima o mogućem učešću električnih vozila u EES-u Crne Gore je zanemareno postojeće stanje. Naime, u 2018. godini je, od ukupnog broja registrovanih vozila od oko 235.000, registrovano tek nešto više od 100 električnih vozila, odnosno približno 0,043 %. Poredeći ovaj podatak i podatak o neophodnom broju vozila za pokrivanje nedostajuće snage u južnoj regiji Crne Gore, zaključuje se da se broj električnih vozila u ovoj regiji mora uvećati više od 300 puta.

Glavni uslov za prodor električnih vozila na tržište Crne Gore je uvođenje podsticajnih mjera za njihovu kupovinu i posjedovanje poput ukidanja poreza pri kupovini, besplatne registracije i parkinga, kao i izgradnje mreže stanica za punjenje. Pritom treba imati u vidu da su električna vozila još uvijek znatno skuplja od tradicionalnih vozila sa motorom sa unutrašnjim sagorijevanjem i da je kupovna moć građana Crne Gore znatno manja od kupovne moći zemalja koje su lideri u prelasku na električna vozila.

V. ZAKLJUČAK

U ovom radu je obrađen problem primjene električnih vozila kao pokretnih upravljivih sistema za skladištenje električne energije i predaju energije mreži (V2G sistem) sa osvrtom i na pitanje planskog punjenja električnih vozila, a sa ciljem smanjenja deficita snage u sistemu. Izvedeni su proračuni za različite nivoe prisustva električnih vozila u elektroenergetskom sistemu Crne Gore za tipičan ljetnji dan koji karakteriše relativno visoko opterećenje tokom cijelog dana i smjena intervala manjka i viška proizvodne snage u sistemu.

Iako V2G sistem dobija puni smisao kada se električna vozila pune tokom perioda niskih opterećenja i predaju energiju mreži tokom vrhova opterećenja, ovaj rad tretira pitanje upotrebe električnih vozila za davanje ispomoći sistemu onda kada mu je to potrebno, nezavisno od doba dana i trenutnog opterećenja. Za primjenu V2G sistema za pokrivanje deficita snage u realnim uslovima je neophodno uzeti u obzir brojne faktore koji utiču na stepen ispomoći mreži kao što su: prisustvo vozila u EES-u i očekivani udio ovih vozila u budućnosti, upotreba električnih vozila za transport i matematički modeli koji opisuju ovaj mod, održivost, odnosno ekonomska isplativost otkupa električne energije od korisnika električnih vozila, itd.

ABSTRACT

EVs (electric vehicles) are one of the leading trends in the world when it comes to sustainable growth and reducing impact on the environment. EV penetration in power systems means an increased load, but it allows for planned charging and discharging which benefit both the system and the owners of EVs. This paper proposes the use of planned charging and discharging of EVs based on game theory, with the aim to reduce the power deficit in a system.

Index terms—electric vehicles; aggregator; planned discharging; planned charging

Use of Electric Vehicles for Reduction of Power Deficit in System

Realizacija laboratorijskog sistema za bežični prenos energije

Dejan Janjić, Alenka Milovanović i Branko Koprivica

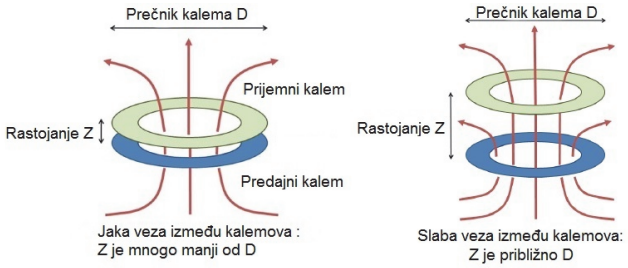
***Apstrakt*—Cilj ovog rada je prikaz teorijskih osnova i realizacije laboratorijskog sistema za bežični prenos električne energije. Na početku će biti razmotreni osnovni principi induktivnog i rezonantnog bežičnog prenosa energije i biće navedene njihove osnovne prednosti i mane. Dalje, biće detaljnije opisana rezonantna metoda realizovanog sistema, uključujući: šemu veza i opis principa rada predajnog i prijemnog dela sistema, tehničke podatke, prikaz realizovanog laboratorijskog sistema, kao i rezultate merenja i odgovarajuću analizu.**

***Ključne reči*—Bežični prenos energije; rezonantna metoda; rezonantna frekvencija, redno-paralelna kompenzacija.**

I. Uvod

Metodologiju za bežični prenos električne energije je predložio Nikola Tesla, krajem 19. veka [1, 2]. Prve realizacije takvih sistema se javljaju na početku 21. veka, kada MIT realizuje prenos električne energije na rastojanje od 2 m za napajanje sijalice [3], kao i INTEL [4], a SONY predstavlja prvi bežični televizor [5]. Bežični prenos energije je sada već realnost koja se dalje razvija kroz različite primene, u medicini, robotici, za napajanje kućnih uređaja ili punjenje baterija prenosnih uređaja, električnih bicikli i mopeda, a očekuje se da će uskoro ući u primenu i bežični sistemi za punjenje električnih automobila.

Dosadašnja istraživanja u Srbiji u oblasti bežičnog prenosa električne energije (koliko je autorima poznato) odnose se na analizu i izradu Teslinog transformatora, ali ne i na realizacije sistema za napajanje uređaja [6, 7].



U ovom radu će biti date osnove teorije bežičnog prenosa energije bazirane na induktivnoj i rezonantnoj metodi i biće analizirane njihove prednosti i nedostaci. Zatim će biti analizirana rezonantna metoda sa redno-paralelnom kompenzacijom, koja se dobija dodavanjem kondenzatora [8]. Biće prikazana i praktična realizacija sistema, kao i rezultati merenja dobijeni u toku testiranja sistema.

II. Osnovi bežičnog prenosa energije

Postoje dve glavne tehnologije koje se trenutno koriste za implementaciju bežičnog prenosa energije:

- induktivna i
- rezonantna.

Obe tehnologije rade po principu sprezanja predajnog i prijemnog namotaja u bliskom elektromagnetskom polju i koriste magnetsku spregu da prenesu električnu energiju. Glavna razlika je u tome koliko su namotaji međusobno udaljeni i da li su izrađeni tako da se javlja rezonancija ili ne, kao što je prikazano na Slici 1.

a) *b*)

Sl. 1. Ilustracija položaja kalemova za *a*) induktivnu i *b*) rezonantnu metodu.

Induktivni prenos energije podrazumeva blisku magnetsku spregu između predajnog kalema i prijemnog kalema na relativno malom rastojanju, reda nekoliko milimetara ili centimetara. Ovaj prenos energije se naziva i prenos energije sa jakom spregom. Predajni kalem je povezan na izvor naizmeničnog napona (najčešće u opsegu 100-400 kHz) koji generiše naizmeničnu struju kroz kalem i tako stvara magnetsko polje. Promenljivo magnetsko polje predajnog kalema se obuhvata prijemnim kalemom u kojem se indukuje naizmenični napon po Faradejevom zakonu, a samim tim i struja prijemnika. Količina prenete energije/snage se kontroliše promenom frekvencije napona u predajnom kalemu. Ova vrsta prenosa električne energije se može uporediti sa prenosom energije pomoću transformatora sa magnetskim jezgrom.

Rezonantna metoda prenosa električne energije se zasniva na magnetskoj rezonanciji između predajnog i prijemnog kalema. Predajni i prijemni kalem mogu biti i više desetina puta udaljeniji nego kod induktivnog prenosa, što karakteriše slabo spregnute kalemove za bežični prenos energije. Ova vrsta prenosa električne energije se može uporediti sa radio prenosom.

Rezonantni bežični prenos energije ima brojne prednosti u odnosu na induktivni, kao što su:

1. veće rastojanje između predajnog i prijemnog kalema,
2. veće osno odstupanje između predajnog i prijemnog kalema koji ne moraju biti postavljeni u osi, kao što je slučaj sa induktivnim prenosom,

Dejan Janjić – Tehnički remontni zavod Čačak, Dr Dragiše Mišovića 167, 32000 Čačak, Srbija (e-mail: dzandz@gmail.com).

Alenka Milovanović – Univerzitet u Kragujevcu, Fakultet tehničkih nauka u Čačku, Svetog Save 65, 32000 Čačak, Srbija (e-mail: alenka.milovanovic@ftn.kg.ac.rs).

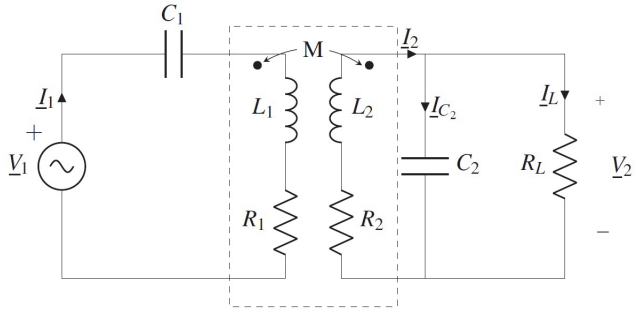
 ISBN 978-86-7466-930-3



3. jedan predajni kalem može preneti energiju/snagu na više prijemnih kalemova, dok induktivni prenos zahteva više predajnih kalemova, što omogućava prenos snage na više uređaja sa različitim opterećenjima (uređaji sa različitom snagom).

Nedostatak rezonantnog prenosa u nekim slučajevima je niža efikasnost u poređenju sa induktivnim prenosom. Razlog je to što se veći deo polja rasipa oko prijemnog kalema, zbog povećane udaljenosti, što nije slučaj kod induktivne metode.

III. Rezonantna metoda sa kompenzacijom

Za razliku od induktivne metode, rezonantna metoda se zasniva na postojanju reaktivnih (induktivnih i kapacitivnih) delova u predajnom i prijemnom kalema, kako bi sistem radio u rezonantnim uslovima. Zbog dimenzija kalemova, parazitna kapacitivnost nije dovoljna da obezbedi rezonanciju u radnom opsegu frekvencija, određenog primenom sistema za bežični prenos. U skladu sa tim, za postizanje rezonancije u željenom opsegu frekvencija potrebno je na predajnoj i prijemnoj strani dodati reaktivne elemente (najčešće kondenzatore), što se karakteriše kao dodatna kompenzaciona mreža. Tako se mogu realizovati redno-redna, redno-paralelna, paralelno-redna i paralelno-paralelna kompenzaciona metoda.

Šema veza rezonantnog kola sa redno-paralelnom kompenzacijom je prikazan na Slici 2.

Sl. 2. Šema veza rezonantnog kola sa redno-paralelnom kompenzacijom.

Za spregnuto kolo sa Slike 2 se mogu napisati sledeće jednačine po I i II Kirhofovom zakonu i to:

$$\underline{V}_1 = \left(R_1 + \mathrm{j}\omega L_1 + \frac{1}{\mathrm{j}\omega C_1}\right)\underline{I}_1 - \mathrm{j}\omega M\underline{I}_2\,, \tag{1}$$

$$\underline{V}_2 = -\left(R_2 + \mathrm{j}\omega L_2\right)\underline{I}_2 + \mathrm{j}\omega M\underline{I}_1 = R_L\underline{I}_L = \frac{\underline{I}_{C_2}}{\mathrm{j}\omega C_2}\,, \tag{2}$$

$$\underline{I}_2 = \underline{I}_{C2} + \underline{I}_L\,, \tag{3}$$

$$\underline{I}_2 = \mathrm{j}\omega R_L C_2 \underline{I}_L\,, \tag{4}$$

gde je ω kružna učestanost i $\mathrm{j}^2 = -1$.

Izjednačavanjem imaginarnog dela ulazne impedanse:

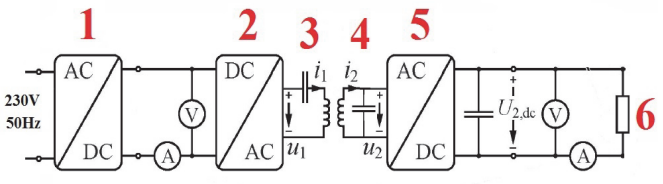
$$\underline{Z}_{ul} = \frac{\underline{V}_1}{\underline{I}_1} = \left(R_1 + \mathrm{j}\omega L_1 + \frac{1}{\mathrm{j}\omega C_1}\right) + \frac{\omega^2 M^2\left(\mathrm{j}\omega C_2 R_L + 1\right)}{R_L + \left(R_2 + \mathrm{j}\omega L_2\right)\left(\mathrm{j}\omega C_2 R_L + 1\right)}\,, \tag{5}$$

sa nulom, može se odrediti rezonantna učestanost kola ω_r.

Međutim, u praksi se rezonantna učestanost podešava pomoću parametara prijemnog kola (induktivnosti L_2 prijemnog kalema i kompenzacione kapacitivnosti C_2) tako da ona bude jednaka:

$$\omega_r = \frac{1}{\sqrt{L_2 C_2}}\,. \tag{6}$$

Kada kolo radi u režimu rezonancije važe sledeći izrazi [8]:

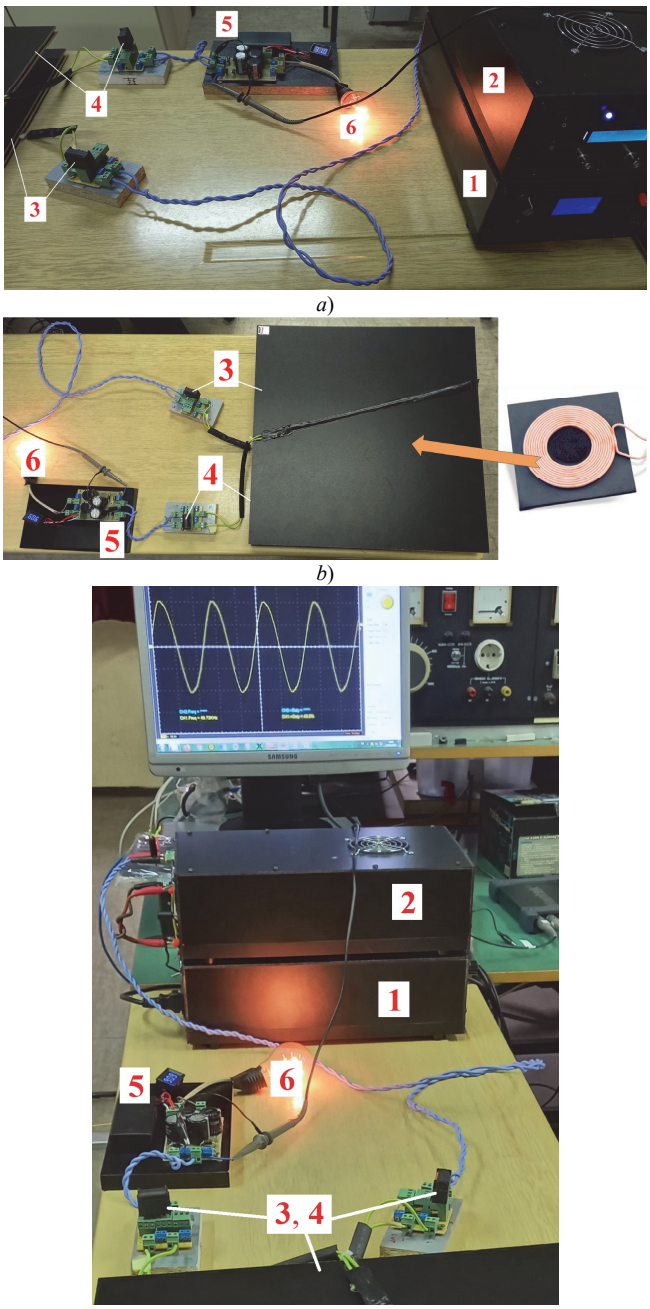


$$\omega_r L_1 - \frac{1}{\omega_r C_1} \approx \frac{\omega_r M^2}{L_2}\,, \tag{7}$$

$$C_1 \approx \frac{L_2^2 C_2}{L_1 L_2 - M^2}\,. \tag{8}$$

Izrazom (8) je približno određena vrednost kompenzacione kapacitivnosti C_1 za odabranu induktivnost predajnog kalema L_1. U slučaju kada je međusobna induktivnost M mnogo manja od induktivnosti kalemova, odnos kapacitivnosti C_1 i C_2 će biti približno srazmeran odnosu induktivnosti L_2 i L_1.

IV. Realizacija laboratorijskog sistema



Sistem za bežični prenos energije rezonantnom metodom sa redno-paralelnom kompenzacijom (Slika 1) je realizovan u laboratorijskim uslovima. Sistem se sastoji od: 1) ispravljača naizmeničnog napona 230 V, 50 Hz, 2) pretvarača stalnog napona u naizmenični napon više frekvencije realizovan kao mostni invertor sa MOSFET tranzistorima [9], 3) predajnog kalema sa kompenzacionim kondenzatorom, 4) prijemnog kalema sa kompenzacionim kondenzatorom, 5) ispravljača naizmeničnog napona više frekvencije realizovanog kao Grecov spoj sa brzim diodama i kondenzatorom [9] i 6) aktivnog opterećenja (sijalica sa užarenim vlaknom). Blok šema ovog sistema je prikazana na Slici 3, a odgovarajuće fotografije na Slici 4.

Sl. 3. Blok šema sistema za bežični prenos energije.

Sistem radi tako što se priključni napon od 230 V, 50 Hz ispravlja pomoću ispravljača 1 i na njegovom izlazu podešava na nivo od 30 V do 50 V, a zatim se taj stalni napon dovodi na ulaz DC u AC pretvarača 2 koji na svom izlazu generiše pravougaoni impulsni napon u_1 amplitude 30-50 V u opsegu frekvencija od 15 kHz do 120 kHz. Tako generisani napon se dovodi na rednu vezu predajnog kalema i kompenzacionog kondenzatora 3. Na izlazu prijemnog kalema 4 se indukuje naizmenični napon u_2 maksimalne amplitude 250-300 V za odabrano opterećenje, frekvencije jednake frekvenciji napona priključenog na predajni kalem 3. Indukovani naizmenični napon se ispravlja pomoću ispravljača 5 i priključuje na prijemnik 6. Ispravljanje napona u_2 je potrebno za većinu praktičnih primena, kao što su napajanje elektronskih uređaja ili punjenje njihovih baterija.

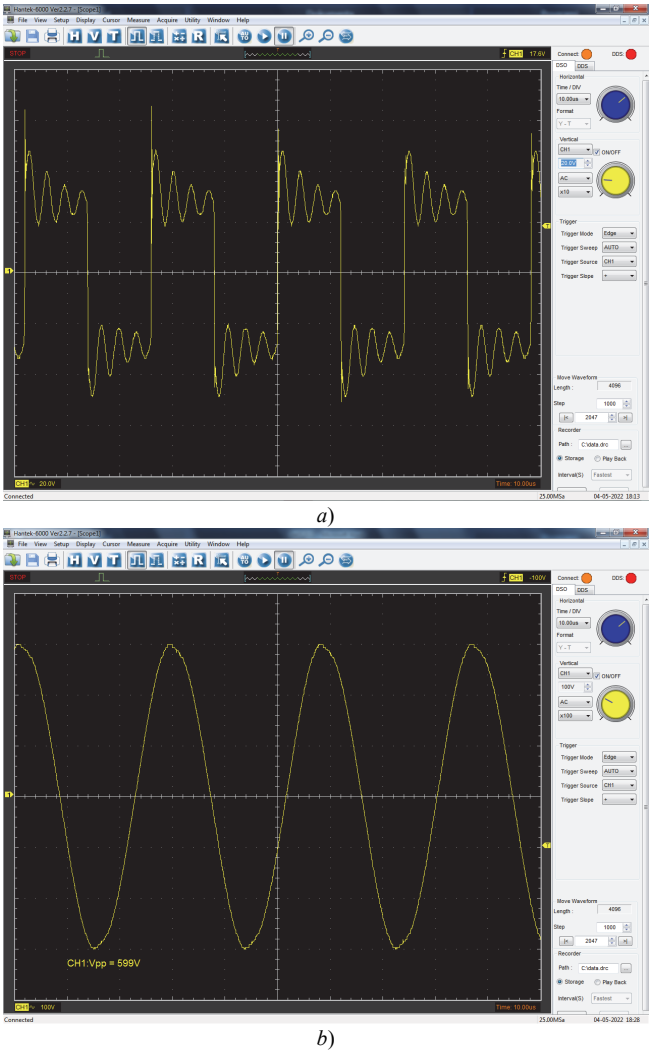
 ISBN 978-86-7466-930-3

Sl. 4. Fotografije realizovanog laboratorijskog sistema i kalema.

Predajni i prijemni kalem su namotani tako da imaju iste dimenzije i induktivnost, pa su i kompenzacioni kondenzatori izabrani tako da imaju istu kapacitivnost (zanemarujući uticaj međusobne induktivnosti). Podaci o dimenzijama i električnim parametrima sistema su date u Tabeli I.

TABELA I
PARAMETRI SISTEMA

Unutrašnji prečnik kalemova	375 mm
Spoljašnji prečnik kalemova	440 mm
L_1, L_2	100 μH
C_1, C_2	300 nF



Na osnovu izraza (6) i vrednosti parametara L_2 i C_2 datih u Tabeli 1 određena je rezonantna frekvencija sistema, koja iznosi približno 29,06 kHz.

V. REZULTATI ISPITIVANJA SISTEMA

Ispitivanje rada realizovanog sistema za bežični prenos energije je urađeno sa aktivnim opterećenjem, sa jednom ili dve redno vezane sijalice sa užarenim vlaknom od po 100 W. Kalemovi su bili postavljeni na međusodnom rastojanjima od 7 cm do 23 cm.

Merenja napona su vršena pomoću četvorokanalnog USB osciloskopa Hantek 6074 DB. Mereni su stalni naponi na izlazu ispravljača 1, pravougaoni impulsni napon u_1 na izlazu pretvarača 2 i naizmenični napon u_2 na krajevima prijemnog kalema 4. Dodatno, digitalnim voltmetrom je meren stalni napon na izlazu ispravljača 5, što je i napon prijemnika 6.

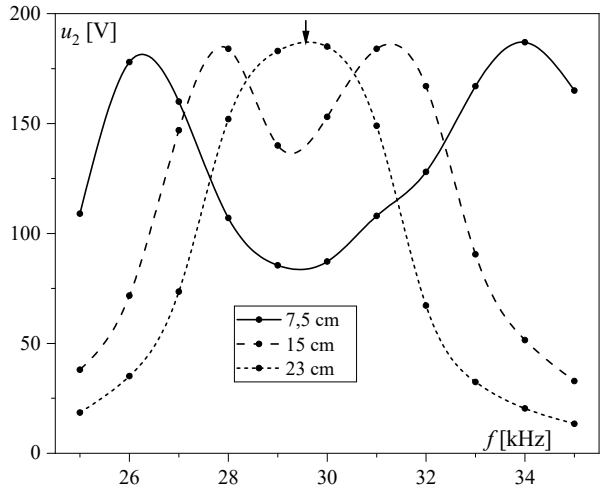
Na Slici 5 su prikazani snimci ekrana pri merenju napona na pretvaraču 2 i prijemnom kalemu 4.

Sl. 5. Snimci ekrana pri merenju osciloskopom: *a*) napon u_1 na pretvaraču 2 i *b*) napon u_2 na prijemnom kalemu 4.

Uočava se da napon u_1 nema sasvim pravougaoni oblik, što je posledica oscilatornog karaktera struje kroz kalem L_1 i

 ISBN 978-86-7466-930-3

kondenzator C_1 koji su priključeni na taj napon. Sa druge strane napon u_2 ima skoro pravilan sinusoidalan oblik, a frekvencija mu je jednaka frekvenciji napona u_1.



U Tabeli 2 su dati rezultati merenja stalnog napona U_2 i struje I_2 prijemnika, kao i ostvarene aktivne snage P_2. Prijemnik je realizovan rednom vezom dve sijalice sa užarenim vlaknom naznačene snage od 100 W.

TABELA II
REZULTATI MERENJA

I_2 [A]	U_2 [V]	P_2 [W]
0,1	14,8	1,48
0,2	82,0	16,4
0,3	193,0	57,9
0,4	334,0	155,6

Detaljnije ispitivanje rada sistema su izvršena sa ciljem određivanja rezonantne učestanosti sistema merenjem napona na prijemniku za različite frekvencije izlaznog napona pretvarača 2. U toku ovakvog merenja se može očekivati da će se najveći napon izmeriti onda kada frekvencija napona pretvarača 2 odgovara rezonantnoj učestanosti sistema. S obzirom na to da je izračunata rezonantna frekvencija približno jednaka 29 kHz, ispitivanja su vršena u frekventnom opsegu od 25 kHz do 35 kHz.

Promena izmerenog napona sa frekvencijom za tri međusobna rastojanja između kalemova je prikazana na Slici 6. Strelicom je označen vrh rezonantne krive, na frekvenciji od 29,57 kHz, dobijene za najveće rastojanje između kalemova. Dobijena vrednost rezonantne frekvencije je veoma bliska proračunatoj vrednosti (29,06 kHz). Na manjim rastojanjima dolazi do razdvajanja maksimuma, koji se postižu za dve frekvencije, jednoj manjoj i jednoj većoj od proračunate. Razlika frekvencija za koje se postižu maksimumi se povećava sa smanjenjem rastojanja između kalemova. Ova pojava je povezana sa vrednošću međusobne induktivnosti M, koja se povećava sa smanjenjem rastojanja, pa se povećava i njen uticaj na vrednost rezonantne frekvencije, odnosno učestanosti ω_r, približno određenu izrazom (7).

Sl. 6. Promena napona na prijemnom kalemu sa frekvencijom.

VI. ZAKLJUČAK

U ovom radu su dati osnovi metodologije bežičnog prenosa električne energije pomoću spregnutih kalemova i pri tome su ukratko analizirane prednosti i nedostaci induktivne i rezonantne metode. Detaljnije je analiziran slučaj rezonantnog kola sa redno-paralelnom kompenzacijom i određena je rezonantna učestanost kola za poznate parametre kalemova i kompenzacionih kondenzatora. Proračunom je utvrđeno da rezonantna frekvencija iznosi približno 29 kHz.

U radu je prikazana i realizacija laboratorijskog sistema za bežični prenos energije rezonantnim kolom sa redno-paralelnom kompenzacijom. Sistem je testiran u frekventnom opsegu 25-35 kHz, bliskim proračunatoj rezonantnoj frekvenciji. Pri tome su mereni naponi na predajnom i prijemnom kalemu. Rad sistema na frekvencijama od 15 kHz do 120 kHz omogućava njegovo ispitivanje u skladu sa međunarodnim standardima (IEC, ISO, SAE i drugi) u oblasti bežičnog prenosa energije.

Detaljnije ispitivanje sistema je izvršeno za tri međusobna rastojanja između kalemova, pri čemu je meren napon na prijemnom kalemu u odabranom frekventnom opsegu. Pokazana je promena tog napona sa frekvencijom za tri slučaja i utvrđeno je da se maksimum može postići za dve frekvencije kada je rastojanje relativno malo i kada je uticaj međusobne induktivnosti značajan. Sa povećanjem rastojanja se smanjuje uticaj međusobne induktivnosti, pa se maksimum napona dobija na frekvenciji vrlo bliskoj proračunatoj rezonantnoj frekvenciji.

Realizovani laboratorijski sistem za bežični prenos energije će poslužiti kao osnova za nova istraživanja u oblasti koja je veoma aktuelna u svetu, a koja je još uvek nedovoljno istražena. Cilje daljih istraživanja će biti nalaženja novih praktičnih primena bežičnog prenosa energije u elektroenergetici.

ZAHVALNICA

Istraživanja prezentovana u ovom radu su delimično finansirana sredstvima Ministarstva prosvete, nauke i tehnološkog razvoja RS, ugovor br.451-03-68/2022-14/200132 čiji je realizator Fakultet tehničkih nauka u Čačku - Univerziteta u Kragujevcu.

ABSTRACT

The aim of this paper is to present the theoretical foundations and realization of the laboratory system for wireless transfer of electric energy. At the beginning, the basic principles of inductive and resonant wireless energy transfer will be considered and their basic advantages and disadvantages will be stated. Further, the resonant method of the implemented system will be described in more details, including the connection scheme and description of the principles of operation of the transmitting and receiving part of the system, its technical data, presentation of the implemented laboratory system, as well as measurement results and appropriate analysis.

Realization of laboratory system for wireless energy transmission

Pravci istraživanja u elektroenergetici kroz tematsku orijentaciju radova sa skupova CIRED Srbija i ETRAN/IcETRAN

Zoran J. Simendić i Vladimir A. Katić, *Senior Member, IEEE*

***Apstrakt*—U radu su razmatrani pravci istraživanja kroz radove na dva značajna naučno-stručna skupa, koja se održavaju u Srbiji, savetovanje CIRED Srbija i konferencije ETRAN/IcETRAN. Detaljnije je predstavljena struktura oba skupa, kao i ključne teme, koje se na njima razmatraju. Kod savetovanja CIRED Srbije teme su vezane za problematiku elektrodistribucije, preko stalnih studijskih komiteta i njihovih preferencijalnih tema, dok su kod konferencija ETRAN/IcETRAN one vezane i pokrivaju kompletnu oblast elektroenergetike. Na bazi toga razmatrana je zainteresovanost učesnika ovih skupova za predstavljanje svojih rezultata kroz brojnost prezentovanih naučno-stručnih radova u odgovarajućim tematskim oblastima. Zaključeno je da su najzastupljenije teme iz oblasti generisanja električne energije, distribuirane proizvodnje, primene obnovljivih izvora energije, priključenja električnih vozila, te upravljanja takvom proizvodnjom i pridruženim merenjima. Ovo ukazuje da istraživači u Srbiji obrađuju najnovije prodore u nauci i struci, te da razmatrani skupovi daju adekvatan prikaz o najnovijim dostignućima iz ovih oblasti.**

***Ključne reči*—Pravci istraživanja, Naučno-stručni radovi, Savetovanje CIRED Srbija, Konferencije ETRAN/IcETRAN.**

I. Uvod

Elektroenergetski sistem u Srbiji je obuhvaćen delovanjem tri velika državna preduzeća, Elektroprivreda Srbije (EPS), Elektromreže Srbije (EMS) i Elektrodistribucija Srbije (ODS), koja su proistekla i ranijeg centralizovanog sistema EPS-a. Pored toga niz privatnih domaćih i stranih kompanija se bavi proizvodnjom električne energije uglavnom na bazi obnovljivih izvora, kao i proizvodnjom i ugradnjom elektroenergetske opreme. Takođe, niz firmi se bavi projektovanjem i izgradnjom elektroenergetskih objekata i mreže. U svim ovim preduzećima radi impozantan broj inženjera i tehničara, kao i veći broj magistara i doktora nauka. S druge strane, rad i tehnički napredak ovih firmi neraskidivo su vezani za usvajanje i primenu novih tehničkih i tehnoloških rešenja, stručnih inovacija i originalnih tehničkih unapređenja i patenata. Sve to motiviše zaposlene, odnosno pruža dobru osnovu za prikazivanje postignutog na redovnim dvogodišnjim savetovanjima sa regionalnim učešćem CIRED Srbije. Na njima se uglavnom prikazuju radovi iz oblasti elektrodistribucije, odnosno vezani za rad, planiranje i održavanje elektrodistributivnih mreža. Ova savetovanja organizuje udruženje CIRED Srbije, koje je nacionalni komitet u sklopu međunarodnog udruženja CIRED sa sedištem u Liježu (*Liege*), Belgija [1].

Društvo za elektroniku, telekomunikacije, računarstvo, automatiku i nuklearnu tehniku (Društvo za ETRAN), kao jedno od najstarijih društava iz oblasti elektrotehnike u Srbiji, koje ove godine organizuje svoju LXVI konferenciju, od 1994. godine neguje sekciju Elektroenergetika [2]. U njoj se uglavnom prezentuju radovi iz akademskog okruženja, odnosno od strane autora sa univerziteta u Beogradu, Novom Sadu, Nišu i Kragujevcu. Od 2014. god. ETRAN ima i svoje međunarodno izdanje, IcETRAN (International Conference on ETRAN), na kom se predstavljaju radovi na engleskom jeziku. Na obe konferencije se prikazuju radovi iz svih oblasti elektroenergetike, ali je najčešća tematika vezana za elektroenergetske mreže, industrijsku elektroenergetiku i električne potrošače.

Cilj ovog rada je da predstavi pregled stručne problematike i glavnih tema istraživanja iz oblasti elektroenergetike u Srbiji u poslednjih sedam godina (2014. – 2021. god.) čiji rezultati su predstavljeni na savetovanjima CIRED Srbije, odnosno konferencijama ETRAN/IcETRAN. Na taj način autori žele da ukažu na moguću spregu istraživača sa univerziteta i iz privrede u formulisanju najboljih rešenja za rad elektrodistributivnog sistema.

II. Savetovanja CIRED Srbija

Savetovanje CIRED Srbija održavaju se dvogodišnje, svake parne godine i na njima se okupi oko 500 učesnika iz zemlje i regiona. Pored naučno-stručnog dela u kom se izlaži prijavljeni radovi, organizuje se i velika izložba kompanija i preduzeća iz oblasti, kao i tematski okrugli stolovi. Tako struktuirano, savetovanje je pre svega namenjeno stručnjacima iz privrede, koji na njemu mogu da vide najnovija tehnička i tehnološka dostignuća, kao i da dobiju pregled naučnih istraživanja u oblasti. Pored toga, značajno je prisustvo i prezentacije istraživača sa univerziteta i naučnih instituta, kroz koje se mogu videti i pravci istraživanja i moguće primeene u praksi.

Rezultati istraživanja prikazani u naučnim ili stručnim radovima (referatima ili informacijama) svrstani su tematski

Zoran J. Simendić – Predsednik CIRED Srbija, Elektrodistribucija Srbije d.o.o. Beograd, Ogranak Elektrodistribucija Sombor, Apatinski put bb, 25101 Sombor, Srbija (e-mail: Zoran.Simendic@epsdistribucija.rs)

Vladimir A. Katić – Predsednik Društva za ETRAN, Univerzitet u Novom Sadu, Fakultet tehničkih nauka, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: katav@uns.ac.rs)

 ISBN 978-86-7466-930-3

prema preferencijalnim temama. Ove teme za svako savetovanje definišu odgovarajući studijski komiteti CIRED Srbije. Postoji šest stalnih studijskih komiteta (STK), čije delovanje obuhvata najaktuelnije teme vezane za savremene elektrodistributivne sisteme. To su:

STK 1 – Komponente mreža,

STK 2 – Kvalitet električne energije u elektrodistributivnim sistemima,

STK 3 – Zaštita i upravljanje elektroenergetskim mrežama,

STK 4 – Distribuirana proizvodnja i efikasno korišćenje električne energije,

STK 5 – Planiranje distributivnih sistema, i

STK 6 – Tržište električne energije i deregulacija.

A. Preferencijalne teme CIDER Srbija 2022

Preferencijalne teme (PFT) daju bliže odrednice tematike referata i definišu se u skladu sa razvojem nauke i struke. Za ovogodišnje savetovanje CIRED Srbija 2022 predložene preferencijalne teme obuhvataju sledeće problematike navedenih studijskih komiteta (ovde su teme navedene u skraćenom obliku, a kompletne se mogu naći u [1]):

STK 1:

- PFT 1.1 - Savremene konstrukcije, primena novih tehničkih rešenja i održavanje komponenti elektrodistributivnih mreža;
- PFT 1.2 - Testiranje, monitoring, dijagnostika i strategija održavanja komponenti elektrodistributivnih mreža;
- PFT 1.3 - Modelovanje i primena savremenih softverskih alata za analizu komponenti elektrodistributivnih mreža;
- PFT 1.4 - Uticaj komponenti elektrodistributivnih mreža na životnu i radnu sredinu;
- PFT 1.5 - Tehnička regulativa iz domena komponenti elektro-distributivnih mreža.

STK 2:

- PFT 2.1 - Kvalitet isporuke i kvalitet isporučene električne energije – uzroci, prostiranje, imunitet, eliminisanje, analize, iskustva;
- PFT 2.2 - Uređaji i metode za merenje i praćenje parametara kvaliteta električne energije (dijagnostičke metode, oprema, postupci i sl.);
- PFT 2.3 - Domaća i evropska tehnička regulativa o kvalitetu električne energije (standardizacija, tehnički propisi i postupci);
- PFT 2.4 - Uticaj distribuiranih generatora na kvalitet električne energije (naponski nivoi, struje kratkih spojeva, harmonici, podrška mreži – LVRT i sl.);
- PFT 2.5 - Uslovi priključenja nelinearnih potrošača i distribuiranih generatora, elektromagnetna kompatibilnost, bezbednost i interferencija;
- PFT 2.6 - Uticaj nedovoljnog kvaliteta u mreži na rad potrošača ili distribuiranih generatora (tehnički problemi, energetska efikasnost, pouzdanost, finansijski efekti, odnosi sa potrošačima...);
- PFT 2.7 - Prenaponi i zaštita od prenapona u distributivnim mrežama, poremećaji u uzemljenju i uticaj na kvalitet električne energije i druge povezane teme.

STK 3:

- PFT 3.1 - Ekploatacija (Strategije održavanja i procena stanja, tehnike i alati za upravljanje radnom snagom, zahtevi u pogledu upravljanja podacima, strategije upravljanja kriznim situacijama, eksploatacija industrijskih mreža);
- PFT 3.2 - Zaštita (Strategije pri zameni i rekonstrukciji zaštite, sistemi za nadzor i upravljanje u transformatorskim stanicama, uticaj distribuirane proizvodnje, nove zaštitne šeme i funkcije, simulacioni modeli, alati i nove funkcije, aspekti pouzdanosti, ispitivanje relejne zaštite, funkcija i sistema, analiza pojave kvarova i registrovanih zapisa);
- PFT 3.3 - Upravljanje i komunikacije (Automatizacija ED mreža, upravljanje u tržišnim uslovima, primena energetskih aplikacija, uvođenje sistemskih usluga, regulacija napona u SN i NN mrežama, primena komunikacionih sistema, sigurnosni aspekti pristupa informacijama, komunikacione tehnike i protokoli za realizaciju inteligentnih mreža, međusobna zavisnost).

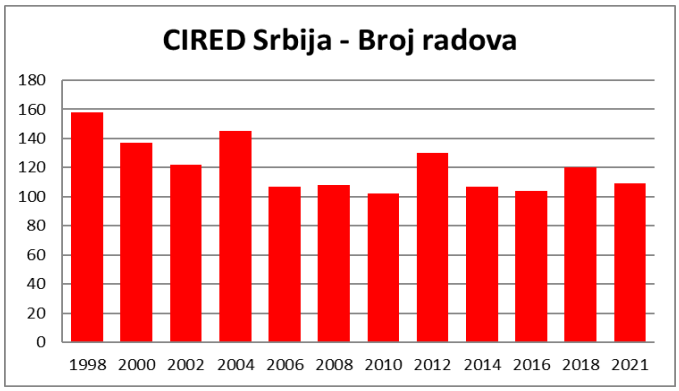
STK 4:

- PFT 4.1 - Integracija i upravljanje distribuiranih izvora električne energije (DER) u distributivnim mrežama (Aktivno upravljanje sa distribuiranim izvorima električne energije, Upravljački algoritmi i filozofije, Prognoza proizvodnje iz obnovljivih izvora, Analiza mogućnosti priključenja distribuiranih izvora, Mikro-mreže, Električna vozila);
- PFT 4.2 - Uloga DER u poslovnim procesima u distributivnim sistemima (Koordinacija i upravljanje DER, Dobiti od skladišta električne energije i različitih strategija upravljanja, aktivno upravljanje DER u cilju optimizacije rada, uloga u unapređenju otpornosti distributivnih mreža, upravljanje opterećenjem);
- PFT 4.3 - Efikasno korišćenje električne energije (Smanjenje gubitaka, unapređenje efikasnosti distributivnih sistema, isporuka održive energije sa niskom emisijom gasova staklene bašte);
- PFT 4.4 - Pametna brojila i sistemi za daljinsko očitavanje i upravljanje brojilima (Korišćenje informacija sa pametnih brojila, analitika i studije slučaja, analiza troškova i dobiti).

STK 5:

- PFT 5.1 - Predviđanje potrošnje i proizvodnje distribuiranih izvora;
- PFT 5.2 - Pokazatelji kvaliteta mreža: zahtevi, rezultati i poređenje;
- PFT 5.3 - Strukture mreža i kriterijumi za planiranje mreža;
- PFT 5.4 - Metode za planiranje;
- PFT 5.5 - Strategije za investiranje.

STK 6:



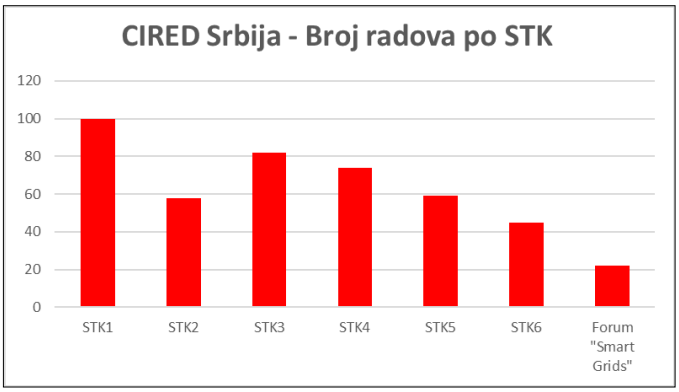
- PFT 6.1 - Otvaranje tržišta električne energije i restrukturiranje elektroprivrede u regionu, praksa i iskustva;
- PFT 6.2 - Regulacija, modeli regulacije, uloga regulatora, izmene i unapređenja;
- PFT 6.3 - Učesnici tržišta električne energije, modeli

 ISBN 978-86-7466-930-3

snabdevanja i modeli tržišta;
PFT 6.4 - Distribuirani izvori energije u konkurentnim uslovima otvorenog tržišta.

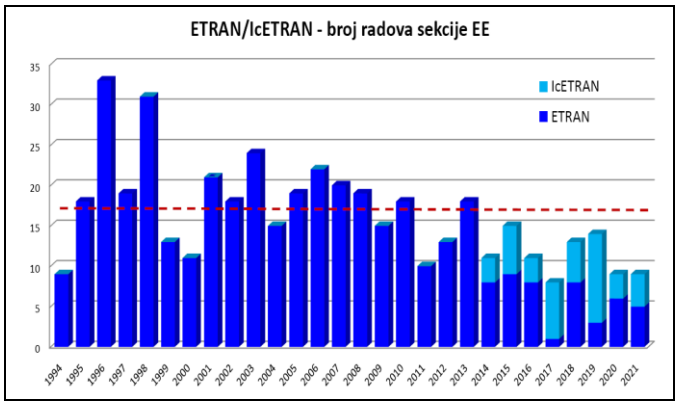
B. Tematska struktura naučnih radova

CIRED savetovanja održavaju se od 1998. god., a ove 2022. god. se proslavlja 25 godina. U tom periodu održano je 12 savetovanja i predstavljeno 1449 radova u formi referata i stručnih informacija, odnosno u proseku po 121 rad po savetovanju [1, 3]. Na slici 1 prikazan je pregled prikazanih radova po godinama u kojima su održana savetovanja. Može se videti da broj radova se polako menja (opada), ali da se na poslednjih nekoliko savetovanja ustalio na oko 110 radova, što ukazuje na promenu aktivnosti istraživača u ovoj oblasti. Interesantno je uočiti da pandemija Korona-19 virusa nije ostavila posledice na broj radova, ali da je usled nje 12. savetovanje iz 2020. god. pomereno u 2021. god.



Sl. 1. Pregled broja radova na savetovanjima CIRED Srbija (ranije JUKO CIRED) od 1998. – 2021. god.

Međutim, da bi se dobila adekvatna slika tematske orijentacije istraživača u Srbiji kroz prezentovane radove na savetovanju CIRED Srbija, koja bi pravilno odslikavala postojeće stanje istraživanja u Srbiji, sužen je obim posmatranja. U obzir je uzet period poslednjih sedam godina (2014. god. – 2021. god.) u kom su održana četiri savetovanja na kojima je ukupno referisano 440 radova, informacija i referata na forumu „Smart grids“. U tom periodu su predstavljeni radovi razvrstani po studijskim komitetima, da bi se uočili dominantni pravci istraživanja. Na slici dva prikazan je broj radova po studijskom komitetu na poslednja četiri savetovanja. Može se uočiti da su najviše bile zastupljeni radovi iz tematike STK 1 (ukupno 100 rada), pa onda STK 3 (82 rada) i STK 4 (74 rada), dok su manje zastupljeni radovi iz oblasti STK 5 (59 radova), STK 2 (58 radova) i STK 6 (45 radova), dok je forum „Smart grids“ okupio još 22 rada.



III. KONFERENCIJE ETRAN/ICETRAN

Društvo za ETRAN se sastoji od 16 tematskih sekcija, koje pokrivaju kompletnu oblast elektrotehnike i to: Akustika (AK), Antene i prostiranja (AP), Automatika (AU), Biomedicinska tehnika (BT), Električna kola, električni sistemi i obrada signala (EK), Elektroenergetika (EE), Elektronika (EL), Metrologija (ML), Mikroelektronika i optoelektronika (MO), Mikrotalasna tehnika, tehnologije i sistemi (MT), Novi materijali (NM), Nuklearna tehnika (NT), Računarstvo (RA), Robotika i fleksibilna automatizacija (RO), Telekomunikacije (TE), Veštačka inteligencija (VI). Društvo svake godine organizuje dve paralelne konferencije (nacionalnu ETRAN i međunarodnu IcETRAN), a prosečan broj radova je oko 200. Na ovim konferencijama autori uglavnom dolaze sa naučno-obrazovnih (univerziteta, fakulteta) i naučno-istraživačkih (instituta) institucija, odnosno iz akademskog okruženja, dok je prisustvo i doprinosi učesnika iz privrede znatno ređe.

Sl. 2. Pregled ukupnog broja radova po studijskim komitetima (tematskim celinama) u periodu 2014.-2021. god.

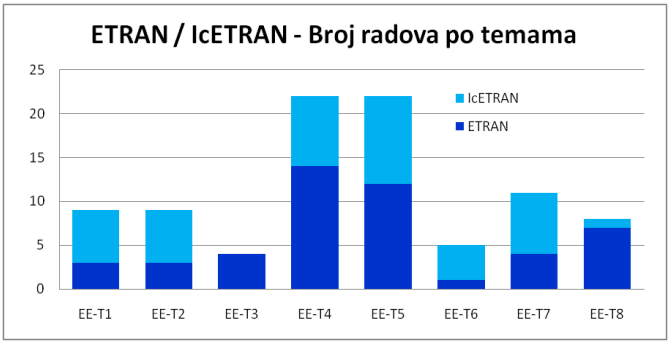
Dok su savetovanja CIRED Srbija u celosti posvećena elektroenergetici, konferencije ETRAN/IcETRAN tek u jednom segmentu, kroz aktivnost sekcije Elektroenergetika pokrivaju ovu oblast. Međutim, konferencije se odvijaju svake godine, pa se u poređenju sa savetovanjima CIRED Srbija mogu predstaviti nešto aktuelniji radovi. Do sada je na sekciji prezentovano 456 radova, s tim da je na konferencijama ETRAN bilo 414 radova, a na IcETRAN 42 rada. Na slici 3 prikazan je pregled broja radova u periodu od formiranja sekcije 1994. god. do 2021. god. [2, 4]. Može se uočiti sličan opadajući trend, kao i kod CIRED Srbija savetovanja, s tim da se ovde prosečan broj radova 16,3, ali se poslednjih godina ustalio (spustio) na oko 10.

Sl. 3. Pregled broja radova na sekciji Elektroenergetika na konferencijama ETRAN i IcETRAN od 1994. – 2021. god.

 ISBN 978-86-7466-930-3

Iz razloga aktuelnosti i ovde će se posebno analizirati period 2014. – 2021. god. Karakteristika tog perioda je da se u njemu javlja IcETRAN konferencija (počinje od 2014. god.), kao međunarodna konferencija i ETRAN, kao nacionalna. To daje mogućnost autorima da svoje radove predstave na jednoj od ove dve paralelne konferencije u zavisnosti kom auditorijumu žele da predstave svoje rezultate. Na slici 3 se može videti odnos radova na ove dve konferencije, koji se kreće u proseku 1,14:1 (53,3% i 46,7%).

Radovi na sekciji EE konferencija ETRAN/IcETRAN uglavnom su deljeni u dve oblasti: elektroenergetski sistemi i industrijska elektroenergetika. Međutim, da bi se bolje sagledala njihova tematska orijentacija i uskladila sa onom sa savetovanja CIRED Srbija, urađena je detaljnija klasifikacija. Kriterijum je bila uža tematika rada utvrđena kroz naslov, ključne reči i abstrakt. Sad su radovi svrstani su u osam tematskih oblasti:



EE-T1: Električne mreže (prenosne i distributivne), mikromreže i pametne mreže (smart grids);
EE-T2: Kvalitet električne energije, prenaponi i kompenzacija;
EE-T3: Elektroenergetska oprema, zaštita i informacioni sistemi;
EE-T4: Generatori, obnovljivi izvori energije (DER), električna vozila, te upravljanje proizvodnjom i merenje;
EE-T5: Električne mašine i transformatori (modelovanje, kvarovi, gubici, održavanje i sl.);
EE-T6: Elektromotorni pogoni (modelovanje, regulacija brzine, dinamika i sl.);
EE-T7: Energetska elektronika (energetski elektronski pretvarači, filteri, upravljački sklopovi i sl.);
EE-T8: Edukacija i ostalo.

Može se uočiti da se prve četiri oblasti (EE-T1 – EE-T4) više-manje poklapaju sa oblastima delovanja studijskih komiteta STK 1 – STK 4, dok su ostale van toga. Isto tako, radovi iz oblasti preostalih studijskih komiteta (STK 5 i STK 6) generalno nisu zastupljeni na konferencijama ETRAN/IcETRAN, pa su u slučaju eventualnog pojavljivanja svrstani pod ostalo, odnosno u EE-T8.

Na slici 4 prikazan je pregled broja radova na konferencijama ETRAN/IcETRAN svrstanih u skladu sa gornjom listom tematskih oblasti. Može se primetiti da su po broju radova tematske oblasti EE-T4 i EE-T5 dominantne, da su izražene teme iz oblasti EE-T7, EE-T1 i EE-T2, dok su oblasti EE-T6 i EE-T3 manje zastupljene. Dakle, na ovim konferencijama najčešće su bili izlagani radovi vezani za električne generatore, obnovljive izvore energije (DER), električna vozila, upravljanje proizvodnjom i merenjem, kao i vezane za električne mašine i transformatore, pa i energetsku elektroniku (energetske elektronske pretvarače) i filtere.

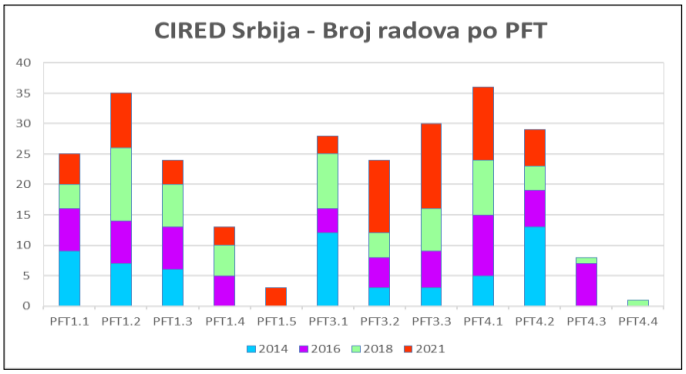
IV. Pravci istraživanja u Srbiji

Na osnovu podataka sa slika 2 i 4 može se videti da su istraživači u Srbiji najviše bili zaokupljeni temama iz oblasti STK 1 (Komponente mreža), STK 3 (Zaštita i upravljanje elektroenergetskim mrežama) i STK 4 (Distribuirana proizvodnja i efikasno korišćenje električne energije), odnosno EE-T4 (Generatori, obnovljivi izvori energije (DER), električna vozila, te upravljanje proizvodnjom i merenje), EE-T5 (Električne mašine i transformatori) i EE-T7 (Energetska elektronika, energetski elektronski pretvarači i filteri). U tim oblastima, ukupno je prikazano 58,2% radova savetovanja CIRED Srbija, odnosno 62,1% radova sa konferencija ETRAN/IcETRAN. S obzirom na datu tematiku i pomenuto preklapanje tema, može se zaključiti da je fokus autora na obe konferencije u periodu 2014. god. – 2021. god. bio usmeren na različite teme, osim u slučaju problematike izučavane u STK 4, odnosno EE-T4. To opravdava organizaciju oba skupa, ali i ukazuje na zone daljeg profilisanja.

Sl. 4. Pregled broja radova sekcije Elektroenergetika na ETRAN/IcETRAN konferencijama u periodu 2014.-2021. god. svrstanih po oblastima

Dublja analiza radova iz tih oblasti može ukazati na specifičnu tematiku, kao i njenu moguću tehnološku vrednost i aplikativnost u srpskoj industriji.

A. Pravci istraživanja i broj radova



U skladu sa gornjim zaključkom, dublje je analizirana produkcija po preferencijalnim temama pojedinih STK sa savetovanja CIRED Srbija, odnosno subtemama tematskih oblasti na konferencijama ETRAN/IcETRAN.

U studijskim komitetima STK 1, STK3 i STK4 na savetovanjima CIRED Srbija ponuđeno je ukupno 12 preferencijalnih tema (STK1=5, STK3=3 i STK4=4), s tim što je kod STK3 za savetovanje 2022. god. njihov broj znatno uvećan, pa su ovde one agregirane pod tri glavne. Na slici 5 prikazano je ukupno učešće radova po PFT za pomenuta tri STK u periodu 2014.-2021. god. Može se videti da su najistaknutije preferencijalne teme PFT 4.1, PFT 1.2 i PFT 3.3. Pored toga, istaknute su (sa više od 25 radova) teme PFT 4.2 i PFT 3.1.

Na osnovu toga može se zaključiti da su savetovanjima CIRED Srbija najčešće prezentovani rezultati istraživanja po temama Integracija i upravljanje distribuiranih izvora električne energije (DER) u distributivnim mrežama, Testiranje, monitoring, dijagnostika i strategija održavanja komponenti elektrodistributivnih mreža, Upravljanje i komunikacije u distributivnim mrežama, kao i teme Uloga DER u poslovnim procesima u distributivnim sistemima i Ekploatacija distributivnih mreža.

 ISBN 978-86-7466-930-3

Što se tiče istaknutih tema iz elektroenergetike na konferencijama ETRAN/IcETRAN, sa slike 4 vidi se da se radi o temama EE-T4, EE-T5 i EE-T7, čiji sadržaj je naveden ranije. Po broju radova, konferencije ETRAN/IcETRAN nešto su skromnije od savetovanja CIRED Srbija, pa dalja parcelizacija ne bi bila svrsishodna.

Sl. 5. Pregled broja radova sa savetovanje CIRED Srbija sortiranih po preferencijalnim temama za STK1, STK3 i STK4 u periodu 2014.-2021. god.

B. Pravci istraživanja i nagrađeni radovi

Oba skupa nagrađuju najistaknutije radove po STK-ovima, odnosno po sekcijama. Nagrade se dodeljuju i mladim autorima, kao podsticaj u njihovom razvoju. Uglavnom se radi o radovima koji su ostavili najbolji utisak, prikazuju rezultate naprednih istraživanja ili neka istaknuta tehnička rešenja. U skladu sa prethodnim posmatrane su teme nagrađenih radova iz STK1, STK3 i STK4, odnosno sa sekcije EE.

Kod savetovanja CIRED Srbija u posmatranom periodu STK1 je dodelio dve nagrade za radove u sklopu PFT1.2, a dve za PFT1.3, kod STK3 dve nagrade su bile u PFT 3.2, a po jedna PFT3.1 i PFT3.3, dok su kod STK4 tri nagrađena rada bila iz PFT4.1, a jedan iz PFT4.2. Ovo u potpunosti odgovara prethodnom zaključku o glavnim pravcima istraživanja za STK1 i STK4, dok delimično za STK3.

Kod konferencija ETRAN/IcETRAN nagrađeni radovi su bili iz tematskih oblasti EE-T5 sa pet radova, EE-T4 sa tri rada, EE-T1 i EE-T2 sa po dva rada i iz EE-T6 i EE-T7 sa po jednim nagrađenim radom. Vidi se da se ovo poklapa sa ranijim zaključkom o najpopularnijim temama.

C. Ključni pravci istraživanja

Poređenjem rezultata o najčešćim temama radova sa skupova CIRED Srbija i ETRAN/IcETRAN u periodu 2014.-2021. god., može se uočiti skoro potpuno poklapanje najpopularnije PFT 4.1 od STK4 i najzastupljenije teme EE-T4. To ukazuje da je i interesovanje akademske i stručne javnosti usmereno na istraživanja iz oblasti generisanja električne energije, distribuirane proizvodnje, primene obnovljivih izvora energije, priključenja električnih vozila, te upravljanja takvom proizvodnjom i pridruženim merenjima.

V. ZAKLJUČAK

Posmatranjem tematike radova sa dva skupa, koja prezentuju rezultate istraživanja iz oblasti elektroenergetike, savetovanje CIRED Srbija i konferencije ETRAN/IcETRAN, razmatrani su glavni pravci istraživanja u Srbiji.

Po prirodi, prvi skup je nacionalnog karaktera sa međunarodnim učešćem (radovi su na srpskom jeziku sa dodatim naslovom i abstraktom na engleskom ili kompletno na engleskom jeziku, ako se radi o nekim stranim učesnicima), konferencija ETRAN je takođe nacionalnog tipa (radovi su na srpskom jeziku sa dodatim naslovom i abstraktom na engleskom jeziku), dok je konferencija IcETRAN čisto međunarodna (radovi su na engleskom jeziju u IEEE formatu).

Po svojoj naučno-stručnoj orijentaciji, koncepciji i strukturi, prvi skup je u potpunosti orijentisan na oblasti elektroenergetike, odnosno preciznije na oblast elektrodistributivnih sistema, dok se na druga dva razmatraju rezultati iz kompletne elektrotehnike, pa je tek u jednom segmentu posvećen elektroenergetici, u sklopu istoimene sekcije.

Po svojoj nameni i učesnicima, prvi je generalno namenjen stručnoj i akademskoj javnosti, dok je druga dva u najvećem broju okuplja učesnike sa univerziteta i naučnih instituta. Pored toga, gro autora je iz Srbije, ali je značajno i učešće autora iz inostranstva.

Na bazi ove komparacije, može se zaključiti da su ova dva skupa kompatibilna i da mogu poslužiti za dobijanje predstave o glavnim pravcima istraživanja.

U posmatranom periodu od 2014. god. do 2021. god. u kom su održana četiri savetovanja i osam konferencija uočeno je da postoji odgovarajuća bliža tematika, koja je najzastupljenija na oba skupa i koja ukazuje na glavni pravac istraživanja u Srbiji. Ona se odnosi, odnosno upravljena je na istraživanja iz oblasti generisanja električne energije, distribuirane proizvodnje, primene obnovljivih izvora energije, priključenja električnih vozila, te upravljanja takvom proizvodnjom i pridruženim merenjima.

Autori su uvereni da bi se slični zaključci mogli doneti i za druge (slične) konferencije u Srbiji i svetu. Ovo ukazuje da istraživači u Srbiji tretiraju najnovije prodore u nauci i struci, te da razmatrani skupovi mogu da posluže za dobijanje dobrog uvida o najnovijim dostignućima iz oblasti elektroenergetike u svetu.

ABSTRACT

The paper discusses the directions of research through papers at two important scientific and professional gatherings, which are held in Serbia, the CIRED Serbia conference and the ETRAN/IcETRAN conferences. The structures of the both are presented in more detail, as well as the key topics discussed in them. At the CIRED Serbia

conference, topics are related to the issue of electricity distribution, through standing study committees and their preferential topics, while at the ETRAN / IcETRAN conferences, they are related to and cover the entire field of electricity. Based on that, the interest of the participants in these gatherings was discussed through the number of presented scientific and professional papers for the relevant thematic areas. It was concluded that the most common topics are in the field of electricity generation, distributed generation, application of renewable energy sources, a connection of electric vehicles, and control of such generation and associated measurements. This indicates that researchers in Serbia are treating the latest breakthroughs in science and profession, and that the considered conferences give an adequate overview of the latest achievements in this fields.

Directions of research in electrical power engineering through thematic orientation of papers from CIRED Serbia and ETRAN/IcETRAN conferences

(ЕКІ/ЕК)

A method for laser rangefinder reticle position calibration in a multi-sensor imaging system

Saša Vujić, *Member, IEEE,* Miloš Radisavljević, *Member, IEEE,* Dragana Perić, *Senior Member, IEEE* and Branko Livada, *Senior Member, IEEE*

***Abstract*— A method for laser rangefinder reticle position calibration in a multi-sensor imaging system is presented. This method was developed to provide system control software with proper parameters used for LRF reticle position, for all imagers and for different field of view configurations of those imagers in a typical multi-sensor imaging system. The importance of reticle position calibration and accuracy is explained, and error calculated. A prerequisite for laser rangefinder reticle position calibration is to perform each imager calibration and the multi-sensor imaging system optical axes rectification. The method is straight forward, fast and reliable. Details of the method are described and experimental verification of results obtained after the calibration are given.**

***Index Terms*—laser rangefinder; LRF; reticle calibration; multi-sensor imaging system; electro-optical system; long-range surveillance.**

I. Introduction

Multi-sensor imaging systems (MSIS) with zoom lenses are used for surveillance with number of technical, technological and application challenges [1], and also for other applications where observed object of interest (target) distance is important, e.g. target geolocation. These MSIS' functionalities are related with the use of laser rangefinders (LRF) and their proper integration within the MSIS [2], [3]. A control station – operator's console, which provides a user interface to MSIS sensors data, is another important part of MSIS [4]. In order to create a usable system it is necessary to provide a system operator with possibility to accurately point with LRF beam to desired object of interest. For this purpose it is necessary to determine control software parameters used for LRF reticle positioning. With properly determined parameters control software displays the LRF reticle at the right place and operator is able to direct the MSIS, i.e. the LRF beam to target, for any selected field of view (FOV).

Miloš Radisavljević is with the Vlatacom Institute of High Technologies, 5 Milutina Milankovića Blvd., 11070 Belgrade, Serbia (e-mail: milos.radisavljevic@vlatacom.com), and with the Belgrade Metropolitan University, Tadeuša Košćuška 63, 11000 Beograd, Serbia

DraganaPerić is with the Vlatacom Institute of High Technologies, 5 Milutina Milankovića Blvd., 11070 Belgrade, Serbia (e-mail: dragana.peric@vlatacom.com).

Branko Livada is with the Vlatacom Institute of High Technologies, 5 Milutina Milankovića Blvd., 11070 Belgrade, Serbia (e-mail: branko.livada@vlatacom.com).

This work is continuation of work published in [2] and [3], where LRF integration, LRF reticle integration and camera calibration are described. In available literature there are also other articles related to these topics [5-12], however, the details and methods about how to determine control software parameters used for LRF reticle positioning are not readily available, and therefore we are not able to make any comparison with other calibration methods in the sense of complexity and accuracy.

In this work the main research issue was to establish the correlation between LRF beam, images from different imagers and for any FOV, and reticle which is shown on display. Furthermore, the particular goal was to define a method for determining control software parameters used for LRF reticle position.

In this paper in section II we describe a typical electro-optical MSIS architecture and basic functionalities, in section III some zoom lens properties, in section IV we explain the importance of LRF reticle position calibration and its accuracy, in section V we list prerequisites for LRF reticle calibration, in section VI we present a method for LRF reticle position calibration in a multi-sensor imaging system, in section VII we summarize results of the method experimental verification, and in section VIII we give the conclusion.

II. Electro-optical multi-sensor system architecture and basic functionalities

Multi-sensor imaging systems (MSIS) are used for surveillance, observed object geolocation and other applications [13], [14]. Each of those systems comprises an electro-optical head with integrated sensors mounted on a gimbal, and remote operator's console with application software for monitoring and control [4].

A typical MSIS with MWIR thermal imager, visible light imager and a LRF mounted on a gimbal is shown in Fig. 1.

Fig. 1. Multi-sensor imaging systems with laser rangefinder.

The sensors that those systems usually comprise [1] are

 ISBN 978-86-7466-930-3

midwave infrared (MWIR) or longwave infrared (LWIR) thermal imagers with continuous zoom optics, visible light imagers with continuous zoom optics, short-wave infrared (SWIR) imagers with continuous zoom optics, laser rangefinders (LRF), positioning sensors and orientation sensors. Such systems are capable of measuring the line of sight distance from the electro-optical head with sensors to some object of interest, by using a LRF, and are also capable to accomplish many other more advanced tasks, e.g. calculating observed object of interest geolocation, based on known data about MSIS position, orientation and observed object distance [15-17].

A MSIS operator uses such a system through an operator's console with input and output devices, via a graphical user interface (GUI) which is a part of a software application for monitoring and control installed on the operator's console [4]. The operator's console can be in different forms, with one or more displays as output device, and with joystick, touchpad, trackball, touchscreen, keyboard or mouse as input device. An example of operator's console is shown in Fig. 2.

Fig. 2. Multi-sensor imaging system operator's console with three displays.

The GUI provides video streams for each of the integrated imagers, as well as other data, statuses and controls for MSIS functionalities. Depending on the selected operator's console for the particular application, the GUI is usually optimized to provide the best possible usability in a given scenario. An example of GUI with two video streams, map, statuses and controls is shown in Fig. 3.

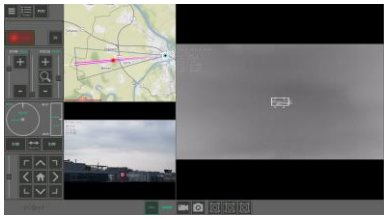

Fig. 3. Graphical user interface (GUI) of an operator's console, with two video streams, map, statuses and controls.

For each of the video streams there is an option to display a LRF reticle which shows the operator where the LRF beam is aiming. A video stream with reticle is shown in Fig. 4.

In order to bring such a system into the function there is a need to perform calibrations on different levels, including the continuous zoom imagers' calibration. One of the calibration tasks is to perform a calibration of LRF reticle position coordinates, for each imager, for different zoom levels. Before performing this reticle position calibration it is necessary to perform optical axes alignment to set up the axes of all imagers and LRF to be parallel to each other (a process called optical axes rectification, or boresighting).

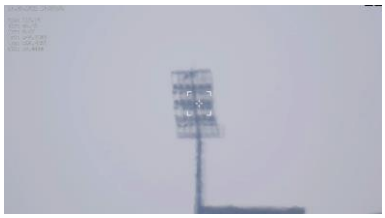

Fig. 4. Video stream with LRF reticle (object distance 4320m).

The optical axes rectification process is performed by means of precise mechanical positioning of structures holding optical elements. The optical axis rectification process is performed with zoom optics set in high end position, which gives a narrow field of view (NFOV), in order to achieve better accuracy. However, other fields of view (FOV) are also of interest and in order to provide a proper alignment of reticle for different zoom levels (different FOVs) there is a need to calibrate reticle position for different zoom levels due to an inherent characteristic of zoom lens to have deviation of optical axis from the ideal one when changing the zoom level. Therefore, the process of optical axis rectification does not have to be perfect and several pixels displacement can be allowed. Those displacements can be compensated by means of precision positioning of reticle in the image, i.e. in each frame of the video streams. The size of the reticle corresponds to the solid angle of the LRF beam. A typical LRF reticle, as drawn on visible light imager is show in Fig. 5.

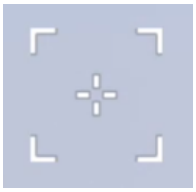

Fig. 5. LRF reticle as shown on screen

The process of reticle position coordinates calculation for all imagers and for different FOVs is time consuming and requires highly skilled operators and their high concentration, with high risk of making mistakes during the process. Therefore, in Vlatacom Institute we developed a method for LRF reticle position calibration such that the whole process is straight forward, fast and not prone to random errors.

III. ZOOM LENS PROPERTIES

Zoom lenses are very popular in modern multi-sensor imaging systems used in long-range surveillance and related applications. They provide flexibility and controllability for different missions and use cases. Zoom lenses provide users with a functionality to observe areas with any FOV angle, from a wide field of view (WFOV) to NFOV, and also to focus objects on different distances from minimal object distance (MOD), to infinite distance, for any FOV. Some of

 ISBN 978-86-7466-930-3

the basic properties of each zoom lens are minimal and maximal focal length - f_{min} and f_{max}, f-number - N, WFOV, NFOV and MOD. There are also many others which define lens optical characteristics and electro-mechanical interfacing.

WFOV and NFOV of imager depend on imaging sensor size and minimal/maximal lens focal lengths. WFOV, NFOV of two MSIS, C330 and C1000, are given in Table I.

TABLE I
CONTINUOUS ZOOM LENS PARAMETERS OF TWO THERMAL AND TWO VISIBLE LIGHT IMAGERS

Lens\Par.	WFOV [°]	NFOV [°]	f_{min} [mm]	f_{max} [mm]
C330-VIS	36	3.5	16	160
C330-TH	35.4	1.67	16	330
C1000-VIS	21	0.55	20	800
C1000-TH	18	0.75	40	1000

The thermal imager resolution is 640 x 480 with pixel size of 15 μm for C330-TH, and 1280 x 1024 with pixel size of 10 μm for C1000-TH.

One of the important properties is back focal length (BFL), also known as flange focal distance (FFD), flange focal depth (FFD), flange back distance (FBD), flange focal length (FFL). BFL defines the position of the zoom lens focal plane distance, where the imaging sensor plane should be placed, and the lens mounting reference plane. The adequate distance of the imaging sensor will result in the a possibility to focus objects from MOD to infinite distance, for any FOV from WFOV to NFOV. A typical test target used for back focus calibration, USAF 1951, is show in Fig. 6.

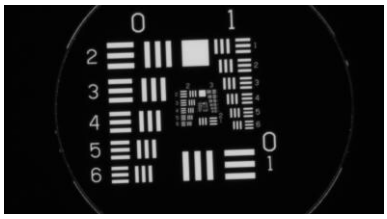

Fig. 6. USAF 1951 test target used for back focus calibration.

The zoom lens functionality is based on moving mechanisms which inherently involve lens elements displacements relatively to their ideal positions. For this reason it is necessary to perform additional zoom lens calibration for proper alignment of LRF reticle with LRF beam [17-21].

All these calibrations are necessary for successful LRF integration in any MSIS [2], [3].

Instantaneous field of view or (IFOV) is an important parameter which determines how much a single pixel can see in terms of FOV, depends on pixel size and focal length and equals IFOV = Pixel Size / Focal Length. With zoom lenses IFOV changes with FOV from wide IFOV(f_{min}) to narrow IFOV(f_{max}) angle.

IV. THE IMPORTANCE OF RETICLE CALIBRATION AND ITS ACCURACY

The LRF beam is quite narrow with Gaussian distribution [2] and in tested systems it is circular in shape with divergence angle of 700 μrad in case of MSIS C330, and 250 μrad in case of MSIS C1000. Both are eye safe with 1,54 μm wavelength. The maximal measurement ranges are 20 km and 39 km, with range measurement accuracy of ±5 m, and ±1 m respectively. The minimal IFOV (at NFOV) in tested systems is 32 μrad in case of MSIS C330, and 5 μrad in case of MSIS C1000. For these cases the LRF beam divergence is 22 to 50 pixels.

If the LRF reticle was not well aligned with the LRF beam the LRF functionality would be lost, due to the fact that LRF beam would miss the target, i.e. it would not hit the area where the MSIS operator is targeting with the reticle, resulting in a wrong measured data, or no measurement at all. If the reticle was quite well aligned with the beam, but not perfectly, it would be possible to measure the object distance, but for any mistake or deviation in misalignment between the reticle and LRF beam an added error in geolocation calculation [16] would be made. With MSIS C330, at 10 km distance, the error introduced with reticle misalignment is 0,32 m for each pixel of reticle displacement. Therefore, the accuracy of reticle positioning is important for such systems. In a simplified model of MSIS, the LRF beam is an ideal line corresponding to the center of the reticle shown on the screen. However, in real case the center of LRF beam will not match ideally to the reticle center, as shown in Fig. 7.

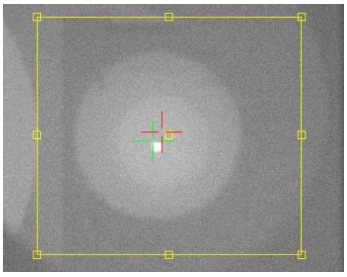

Fig. 7 Displacement of reticle and LRF

For some real MSIS and long distances at which these systems are used, the error that is made due to the reticle displacement can be significant. The error in geolocation calculation for one pixel of reticle displacement on real systems for four different imagers given in Table I, at distances of 1, 2, 5, 8 and 10 km, are given in Table II.

TABLE II
ERROR IN GEOLOCATION CALCULATION FOR ONE PIXEL OF RETICLE DISPLACEMENT AT DISTANCES OF 1, 2, 5, 8 AND 10 KM, IN MM

Error in mm	Distance				
Imager	1km	2km	5km	8km	10km
C330-VIS	32	64	159	255	318
C330-TH	46	91	228	364	455
C1000-VIS	5	10	25	40	50
C1000-TH	10	20	51	82	102

 ISBN 978-86-7466-930-3

The error in geolocation calculation at object distance of 10 km, for 1, 2, 5, 8 and 10 pixels of reticle displacement on real systems for four different imagers given in Table I, are given in Table III.

TABLE III
ERROR IN GEOLOCATION CALCULATION AT 10KM DISTANCE FOR RETICLE DISPLACEMENTS OF 1, 2, 5, 8 AND 10 PIXELS, IN M

Error in m	Displacement				
Imager	1 px	2 px	5 px	8 px	10 px
C330-VIS	0,32	0,64	1,59	2,54	3,18
C330-TH	0,46	0,91	2,28	3,64	4,55
C1000-VIS	0,05	0,10	0,25	0,40	0,50
C1000-TH	0,10	0,20	0,51	0,82	1,02

V. THE PREREQUISITES FOR LRF RETICLE CALIBRATION

A prerequisite for LRF reticle calibration is to perform each imager "zoom to FOV" calibration [2]. Depending on non-linearity of imager lens characteristic it is necessary to decide the number and value of discrete zoom lens positions for which the reticle will be calibrated. For all other zoom lens positions, in between the selected discrete positions, the reticle position will be calculated during the run time in the software application, using piecewise-linear approximation.

Furthermore, it is necessary to perform MSIS optical axes rectification, by means of precise mechanical positioning of structures holding optical elements, which is usually performed in NFOV setup for each imager. This way we will ensure that the calibrated MSIS will have the full correspondence of each imager reticle presenting the area where the LRF beam is aiming. In the ideal case the beam central line will correspond to each reticle central point. When the optical axes are nearly parallel, which can be observed and confirmed with use of collimator (few pixels displacement can be tolerated), a procedure of LRF reticle position calibration can be started.

It is necessary to perform the described procedure for each of the imagers contained in the MSIS. The sequence of the imagers' reticle calibration is irrelevant. Therefore the procedure can be started with any of the imagers that are contained in the MSIS. A MSIS set up in front of the collimator for rectification of visible light imager with LRF is presented in Fig. 8.

Fig. 8 A MSIS set up for rectification of visible light imager in front of the collimator

If the LRF is equipped with properly aligned visible light boresighting LED source, it can be used to make LRF reticle calibration, instead of LRF emitter. In that case instead of capturing videos a single image can be captured for each FOV. The same method can be used for LRF devices that can operate in continuous measurement mode (CMM). A single image will be sufficient for determining of LRF beam central point.

VI. A METHOD FOR LRF RETICLE POSITION CALIBRATION IN A MULTI-SENSOR IMAGING SYSTEM

Within this method there are four stages to be completed. In the first stage the raw data should be captured, then in the second stage the position of LRF beam in the target should be determined, for each FOV. In the third stage the reticle calibration parameters should be calculated, and finally in the fourth stage the calibration parameters should be entered into software application that draws the reticle in the video stream.

For the first stage we need a device under test (DUT), in this case a selected imager, and an appropriate collimator for the selected imager's maximal focal length. In Fig. 9 an image taken with visible light imager of LRF firing in a target is shown.

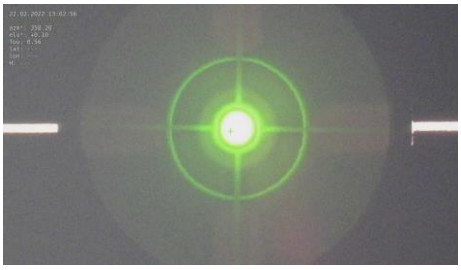

Fig. 9. Image taken with visible light imager of LRF firing in a target

All steps of the first stage are shown in block diagram in Fig. 10.

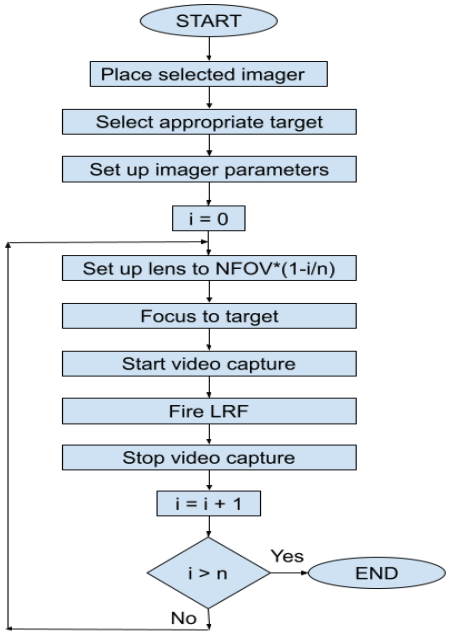

Fig. 10. Block diagram for first stage of the LRF calibration

 ISBN 978-86-7466-930-3

The procedure is then repeated for each of the imagers contained in the MSIS.

When all videos are captured, for all imagers, then the first stage of this process is finished and the second stage can start. In the second stage for each captured video from the first stage we extract a frame in which the LRF beam is clearly visible. From that frame we determine the central coordinates of the LRF beam relatively to the image center.

In Fig. 11 an image taken with visible light imager of LRF firing in a target is shown.

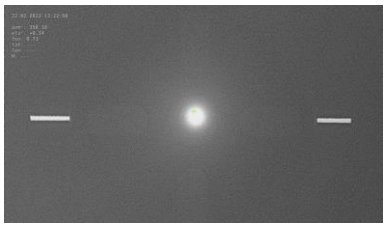

Fig. 11. Image taken with thermal imager of LRF firing in a target

For small angles close to NFOV the displacement from the image central coordinates to the LRF beam central coordinates depend on precision of optical axes rectification performed in previous stage. For wider angles closer to WFOV the displacement of LRF beam central coordinates depend on lens' construction. That can be seen also on the Fig. 12 where the reticle displacement in pixels for visible light and thermal imager are shown, for x and y axes. In case of visible imager the displacements are in range from 0 to 29 pixels in x axis, and from -6 to 29 pixels in y axis. In case of thermal imager the displacements are in range from -7 to 4 pixels in x axis, and from -1 to -12 pixels in y axis. In this case the displacements are higher for visible light imager due to the fact that its IFOV is twice smaller then in thermal imager.

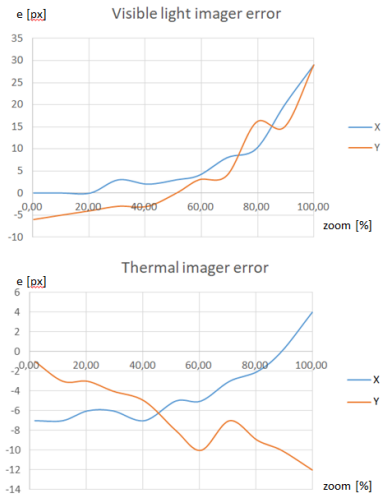

Fig. 12. Reticle displacement in pixels for visible light and thermal imager

When we have central coordinates for all imagers for each selected FOV, then in stage three we calculate reticle positioning parameters. As a result we have x and y reticle positioning parameters for each imager.

Finally, in stage four, the reticle positioning parameters can be entered into the software application that draws the reticle in the video stream.

By default, without the calibration, the reticle is drawn in the center of the video stream for any FOV. Only after the calibration parameters are entered the reticle will be drawn displaced to the image center, corresponding to the relative displacement of the LRF beam for any selected FOV.

VII. Results of Experimental Verification

The proposed method for LRF reticle position calibration has been verified in real conditions using available MSIS. The MSIS has been placed on the rooftop of the building from where there is a good view on existing remote objects.

Fig. 13. A heating plant chimney at 8km distance used to verify the x-axis deviations of the reticle, in thermal and visible imager

The most appropriate objects for verification of LRF beam correspondence with reticle position on the screen are those objects which have large and sharp edges. It is important to use remote objects on relatively long distances, in order to minimize error due to non-coaxial quasi parallel axes of

 ISBN 978-86-7466-930-3

imagers and LRF.

In this particular case a heating plant chimney at 8km distance was used to verify the x-axis deviations of the reticle from the ideal case in NFOV. Images taken with thermal and visible light imagers are shown in Fig. 13.

For verification of y-axis a rooftop heliport structure with upper and lower limits, at the distance of 620m was used as shown in Fig. 14.

Fig. 14. A rooftop heliport structure with upper and lower limits, at the 620m distance, used to verify the y-axis

Several LRF measurements have been accomplished in order to confirm where the LRF beam is really aiming and to verify the good correspondence with the LRF reticle on the screen. It has been shown that deviation is equal to 2 pixels in thermal imager, which in this case corresponds to 0.1 mrad, and 3 pixels in color imager, which in this case corresponds to 0.15 mrad.

Furthermore, it has been shown that for other FOVs reticle deviation from the ideal one is similar in pixel size, but is lower in angle, due to larger FOV angles.

VIII. Conclusion

The described method was implemented to provide straight forward, fast and reliable process of reticle position calibration. The calibration process is complex but with this method it is straight forward, and can be performed by trained personnel. It is fast allowing efficient use of expensive equipment. Furthermore, it is reliable resulting in high process efficiency. However, there is a need for further work on additional improvements in process of reticle calibration. The further work will focus on automatic extraction of LRF spot central coordinates based on image processing techniques which can be applied on the same images taken during the reticle calibration process.

Acknowledgment

Authors would like to thank Vlatacom Institute for equipment and support which enabled continuous work and improvements in the field of electro-optics. This work was undertaken within the Vlatacom Institute project P157.

Linear regression in RR-RT domain for cardiac cycle evaluation

Milan S. Milivojević, *Student Member, IEEE*, Ana Gavrovska, *Member, IEEE* and Dragi Dujković, *Member, IEEE*

***Abstract*—Analysis of cardiac variability is of great importance for numerous applications. Among them are the ones based on electrocardiograms where detection of distorted signals during the acquisition process can be performed as well as discrimination of pathological records due to various diseases. ne way of presenting the cardiac variability relates to parameters derived from the time duration of the respective segments within the electrocardiogram cycle as well as their relationships. In this paper, cardiac cycle evaluation is performed in the domain of time features for the assessment of cardiac variability using the linear regression procedure. The calculated quotient shows the possibility to be useful in terms of error polarity.**

***Index Terms*— lectrocardiogram (CG), cardiac cycle, pea , T wave, quotient, linear regression.**

I. INTRODUCTION

The cardiac cycle is a series of pressure changes that take place within the heart. These pressure changes result in the movement of blood through different chambers of the heart and the body as a whole. They originate as conductive electrochemical changes within the myocardium that result in the concentric contraction of cardiac muscle [1]. The cardiac cycle can be divided into two phases: the systole phase and the diastole phase. During the systole phase heart muscle contracts and blood is pumped into the arteries. For electrocardiogram (ECG) this phase is manifested in the form of QRS complex appearance (associated with ventricular depolarization) and T waves (ventricular re-polarization). Diastole phase follows systole and represents relaxation of the heart muscle where the heart is filled with blood. Diastole can be identified on the electrocardiogram through the appearance of the P wave, which is further related to atrial depolarization [2].

Besides standard analysis of RR intervals (time intervals between successive R peaks), cardiac variability can be observed through intervals that describe the phase of diastole or systole. The characteristic points that divide the cardiac cycle into two phases are the R peak and the end of the T wave. There are different variants of interval definitions in the literature that are specific for these phases, which also include Q or S wave [3]. Since detection of the maximum within a cycle (R peak) is the basic procedure in ECG signal processing, R peak is taken as the point that defines the boundary between systole and diastole. Therefore, RT and corresponding difference between RR and RT intervals are considered to be suitable for the ventricular systole and ventricular diastole phases. Appropriate relationships derived from these intervals are the basis for the evaluation of cardiac cycles in electrocardiogram signal.

The golden ratio or cross-section represents a constant ϕ with an approximate value of 1,6180339887… This relationship has been known since ancient times as a principle in art from antiquity through the Renaissance to the present day. However, it is interesting that this relationship can be found in nature in organic and inorganic structures. Mathematical definition of the golden ratio ranges from the inherent geometric definition to the definition that includes extended fractions and series [4].

In this paper, a linear regression is performed in the domain of ECG time intervals (RR and RT intervals) in order to differentiate cases, like male and female individuals. Signals are taken from publically available Physionet data which includes healthy volunteers. A comparison of calculated direction coefficients obtained by the regression procedure with the reference representing the golden ratio constant is performed.

The work is organized into five sections. Section II presents the materials and methods applied in the paper. In Section III the experimental analysis is described. The results of the analysis are given in Section IV. Finally, Section V presents a conclusion with a note on further work.

II. MATERIAL AND METHODS

A. Golden atio efinition

Fibonacci array can be defined as a collection of elements where each array element value equals to the sum of the previous two elements of the array. Initial values of the first two members of the sequence are equal to 1. If limit value of the quotient of two consecutive members of the Fibonacci sequence is observed, a constant, here noted as ϕ, can be defined. This is illustrated in Fig. 1.

This constant describes the golden ratio [5]:

$$\lim_{n\to\infty}\frac{[n+1]}{[n]}=\phi=1.61803399... \quad (1)$$

 ISBN 978-86-7466-930-3

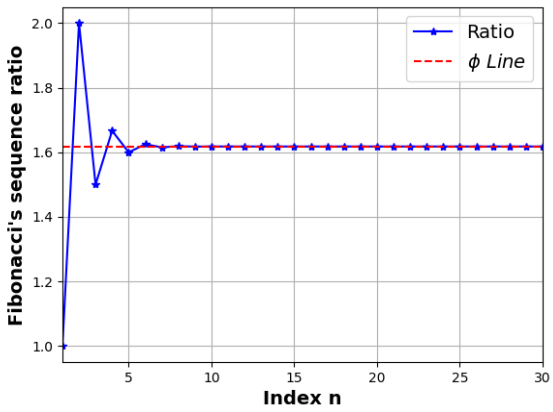

Fig. 1. Fibonacci sequences convergences.

The constant value ϕ can also be reached geometrically by dividing a segment into two parts. Let the lengths of the first and the second segment be noted as *a* and *b*, respectively. The segments are said to make a golden ratio if the ratio is as:

$$\frac{a+b}{a} = \frac{a}{b} = \phi . \tag{2}$$

The previous equation can be written in the form of the golden ratio characteristic equation:

$$\phi^2 - \phi - 1 = 0 \tag{3}$$

where solution leads to the exact value of the constant ϕ which is also equal to the positive solution of the quadratic equation:

$$\phi = \frac{1+\sqrt{5}}{2} . \tag{4}$$

B. *ataset*

PhysioBank is a large and growing archive of digital recordings of physiological signals and corresponding data for biomedical and similar research. In this paper ECG-ID Database from Physionet is used for the analysis [6].

The database contains 310 ECG recordings, obtained from 90 individuals. Each record contains one electrocardiogram channel of twenty seconds duration and 12-bit resolution with 500Hz sampling frequency. The signal amplitude is within interval from -10mV to +10mV. The records were obtained from volunteers (44 men and 46 women aged from 13 to 75 years). The number of records per each person varies from two (collected during one day) to twenty (collected periodically over 6 months). The raw ECG signals are rather noisy and contain both high and low frequency noise components. Each record includes both raw and filtered signals. In the simulation presented in this paper only raw ECG signal are used [7].

C. *Software Tools*

For the purposes of this work, Python 3 programming language is used, as well as the corresponding libraries, among which the Neurokit2 library stands out. NeuroKit2 is an open-source, community-driven, and user-centered Python package for neurophysiological signal processing. It provides a comprehensive suite of processing routines for a variety of bodily signals like ECGs [8].

III. Experimental Analysis

Within electrocardiogram (ECG) signal, three basic parts can be distinguished: P wave, QRS complex and T wave. Sometimes U wave is also visible. These waves are result of non-homogeneities of action potentials throughout the heart. They are directly related to the start time of depolarization and the time course of the action potential. The waves Q, R and S are manifestation of the depolarization in the two ventricles, while the waves T and U are consequence of the repolarization process in the ventricles [9].

Depending on the application, appropriate features can be extracted from the signal itself. In this paper, the focus is on finding the appropriate relations of the golden section, where temporal features are found [10].

Here, electrocardiogram signals from different volunteers are analyzed. Each signal is preprocessed, and this is followed by the detection of characteristic points. Based on the detected points, the corresponding time intervals (timestamps) are found as valuable features expressed in seconds. Based on two time intervals that are selected for each cardiac cycle, quotient value is estimated using the appropriate definition as well as in the form of direction coefficient obtained using the linear regression procedure. The values of this quotient are compared with the value given by the golden ratio constant.

A. *Preprocessing*

As a first step, pre-processing of the original ECG signal was performed to remove unwanted signal components. These components primarily include muscle noise, 50 Hz network noise, and baseline deviation [11]. Noisy raw signals are chosen to observe practical importance of the ratio base relations between the waves. In order to suppress the interferences, a band-pass filter with a finite impulse response and a zero phase has been applied. The lower and upper bandwidth limits have been set to 0.3 Hz and 45 Hz, respectively. In Fig. 2 examples of raw signal from ECG-ID database and preprocessed signal are presented.

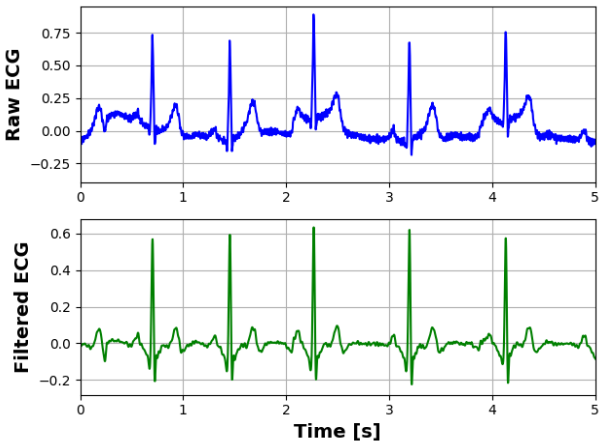

Fig. 2. Raw and preprocessed ECG signal.

B. *ECG based inter al determination by characteristic point detection*

After the preprocessing step, characteristic points in time domain are found. Namely, for the experimental analysis

 ISBN 978-86-7466-930-3

two characteristic points are detected: R peaks and the moment corresponding to the end of the T wave (T wave offsets). The detection of these points is based on the wavelet method using functions from the Neurokit2 library [12]. The time intervals between two consecutive R maxima define the sequence of RR intervals.

For each RR interval, an additional time interval RT is found. It corresponds to the difference between the time moments of the end of the T wave and the corresponding R maximum. Since R peaks are relatively easy to detect T wave offsets can be considered also as fiducial points for further analysis. Figure 3 illustrates the detection of characteristic points in Fig.3 (a) as well as the determination of RR and RT time intervals based on detected characteristic points in Fig.3 (b).

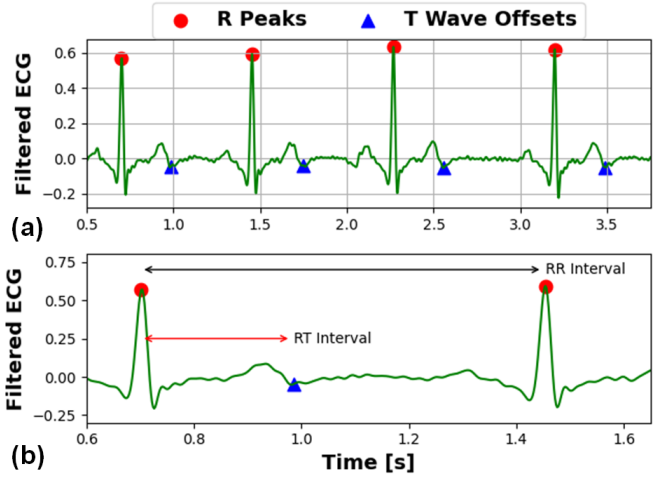

Fig. 3. (a) Detected ECG fiducial points (R peaks and T Wave offsets) and (b) corresponding time intervals (RR and RT intervals).

C. *uotient based cardiac cycle description*

Having in mind available characteristic fiducial points a cardiac cycle can be described using a quotient based on RR and RT intervals. In this paper, quotient noted as r can be defined as:

$$r = \frac{- \quad T}{T} \sim \phi \,. \tag{5}$$

This quotient can be find in the literature as the ratio of the diastolic and systolic phases of a cardiac cycle, where it is further averaged at the level of the cardiac cycle [13]. Moreover, RR interval can be expressed as a function of RT interval by applying the quotient:

$$= \quad T \cdot \left(1 + r\right). \tag{6}$$

In that case the slope is equal to the value of the ratio increased by one, and can be used as a mathematical model of cardiac behavior.

. *Statistical e aluation of the uotient based cardiac cycle description*

For each set of points a well known linear regression is performed and the direction coefficient, noted as k, is estimated. Also, for each coefficient calculated in this way, the relative error is estimated, and the value $1 + \phi$ is taken as the correct value. The error value is calculated based on the formula:

$$\delta = \frac{r - \phi}{\phi} \cdot 100\% = \frac{k - 1 - \phi}{\phi} \cdot 100\% \tag{7}$$

where constant in the proportion of the golden section is taken as the reference value ϕ [14]. In this case, the modified relative error stores information about the sign of deviation from the golden ratio. The value of the quotient r and the line direction coefficient obtained by linear regression are connected by a unique connection. Since there are several signals per each volunteer, in the second step averaging of the quotient values for a volunteer from the ECG ID database is performed.

IV. Results

Analysis was performed for signals from ECG ID database. After the described preprocessing, the detection of characteristic points and determination of RR and RT intervals for each cardiac cycle was performed. For each volunteer, ECG signals were recorded in several iterations meaning data was collected for a patient several times independently. Each calculated duration of RR and RT interval within a cycle make an ordered pair (RT, RR) representing a point in the RT-RR diagram. Figure 4 shows a set of all points for one volunteer from the ECG ID database, with all values observed for heart cycles from all iterations of signal recording as a single set. A linear regression procedure was performed on the set while forcing the passage of the regression line through zero (fit intercept is zero). As a result of linear regression, the direction coefficient k was obtained, which is equal to $1 + r$ on the basis of (6). This value is compared to a value of $1 + \phi$ where the constant ϕ corresponds to the golden ratio. The relative error in this case of the golden ratio is 1.14%.

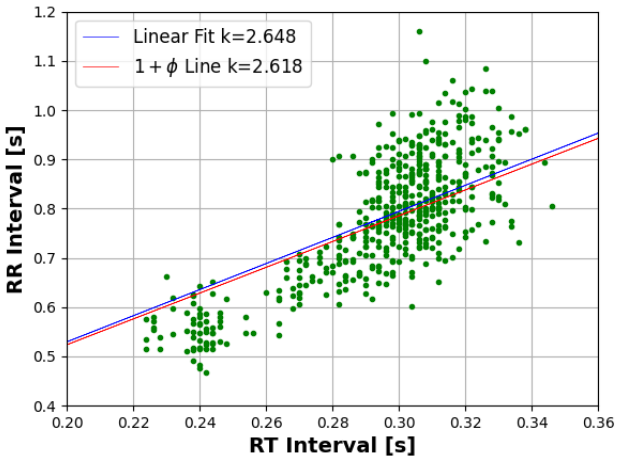

Fig. 4. Linear regression over points whose coordinates represent RR and RT values of cardiac cycles corresponding to a patient from ECG ID dataset.

In the second step, the quotient r is averaged after iteration for the same volunteer. In this way, each iteration corresponds to one ratio of the averaged quotient. Figure 5 shows histogram of the averaged values of the quotient r. The histogram was fitted according to the Gaussian distribution, and the parameters and σ were determined, which correspond to mean value and standard deviation, respectively. By comparing the mean value with respect to the value of ϕ, a relative error value of 2.35% was obtained.

The procedure that involves determining the set in the RT-RR plane was repeated for volunteers. In Fig. 6 several

 ISBN 978-86-7466-930-3

individuals from the ECG ID database (two males and two females) are shown through corresponding sets.

After the calculation of error values, it can be noted that for males negative values are obtained, while for females this value is positive. There has also been some separation in terms of points belonging to different volunteers, which means that it is possible to differentiate individuals of different sex to some extent on the basis of quotient calculation. In the experimental analysis this is obtained for around 80% cases of samples that belong to female volunteers and around 70% cases belonging to male individuals. This can be considered to be a good starting point for further research.

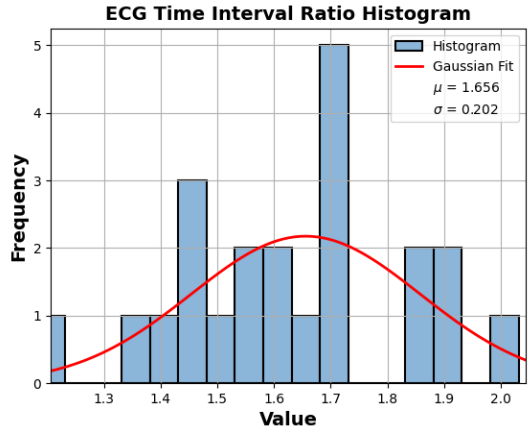

Fig. 5. Histogram representation and fitted normal distribution for averaged ratio values for a volunteer from the ECG ID database.

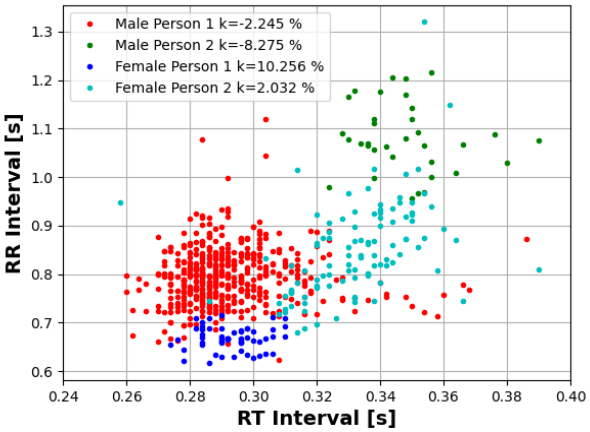

Fig. 6. Calculated RT and RR values in RT-RR domain for several volunteers.

V. Conclusion

In this paper, the analysis of cardiac cycles is performed through the consideration of a relationship that exists between RR and RT intervals. The linear regression procedure used to estimate the direction coefficient, describes the proportionality between two quantities quite well. The estimated direction coefficients are related to the corresponding quotient of the diastolic and systolic portions in ECG signal. Errors of the coefficient deviation from the reference constant are calculated and here, for healthy individuals, the results showed minimal deviations. Also, signals belonging to volunteers of different sex are observed in order to analyze the usefullness of the quotient. It is noticed in the experimental analysis that the error values between the calculated quotient and the "golden ratio" have common case of different signs depending on the gender.

This paper is an initial study to test the hypothesis of whether the corresponding relationships within the ECG signal follow the "golden ratio" for further use and experiments. In the next steps, it is necessary to analyze the bases on a wider scale, where we would also analyze the signals that are pathologically altered due to cardiovascular diseases.

Application of Bayes and knn classifiers in tumor detection from brain MRI images

Marta Mirkov and Ana Gavrovska, *Member, IEEE*

***Abstract*— Automatic detection of regions of interest is of great importance in computer-aided diagnosis systems. Magnetic Resonance Imaging (MRI) of head due to good soft-tissue contrast is widely used for brain tumor detection showing potential anomalies that indicate the need for further treatment. Current algorithms for processing and classification of medical images often involve complex designs of deep learning that require significant hardware resources and considerable execution time in order to assist doctors in detecting diseases. This may lead to labeling more complex cases in brain tumor detection. In this paper, statistical features are considered with application of Bayes and kNN classifiers showing comparable results having in mind publicly available brain tumor detection database.**

***Index Terms*— Magnetic Resonance Imaging, brain tumor detection, segmentation, feature extraction, machine learning.**

I. Introduction

Today, depending on the need, various medical imaging modalities are used: X-ray, fluoroscopes, mammography, computer tomography (CT) devices as well as devices based on nuclear medicine techniques – Positron Emission Tomography (PET) and Single Photon Emission Tomography (SPECT). However, equipment that does not require ionizing radiation can be used for computer-aided diagnosis systems. Magnetic Resonance Imaging (MRI) scanners employ strong magnetic fields and magnetic field gradients to generate images of the organs or the whole body, and are found very useful in diagnostics. For example, according to the World Health Organization (WHO), cancer is the second leading cause of death [1]. Cancer detection from biopsy procedures is a painful process for patients, and therefore appropriate medical imaging modalities can facilitate this procedure [2].

Images obtained from MRI scanners show satisfying soft-tissue contrast, which is suitable for brain imaging. They provide a good visualization of the posterior cranial fossa, which contains the brain stem and cerebellum. The contrast between gray and white matter makes MRI the best choice for diagnosing many central nervous system conditions, including demyelinating diseases, dementia, cerebrovascular disease, infectious disease, Alzheimer's disease, and epilepsy [3]. Since many images are taken in milliseconds, it shows how the brain reacts to different stimuli, thus enabling doctors to study the brain's functional and structural abnormalities.

In this paper, statistical feature extraction and application of two classifiers will be observed, where the aim is to create a simple algorithm for brain tumor detection [4]-[9]. One of the motivations is usefulness of texture related features in MRI images [10]. Also, one of the famous examples of hypothesis testing is the Bayes test [5], which will be implemented here, and compared to knn (k-nearest neighbors) approach [7] based on revising hand-crafted statistical features.

The paper is organized as follows. After the introduction, in Section II related work is presented. It considers traditional statistical feature extraction and machine learning usage in brain tumor detection. Steps in the experimental analysis performed in this paper are explained in Section III, where further details for feature extraction are given in Section IV. Section V is dedicated to classifiers design and performance evaluation. Obtained results and conclusion are given in Section VI and Section VII, respectively.

II. Related work

The brain tumor is an abnormal growth of cancer cells in the brain which disrupts the work of functional cells. Early detection and rapid diagnosis of tumors can help save the patient's life. Mathematical and software tools can be very successful in detecting brain abnormalities. Thus, related work is oriented towards statistical feature extraction and machine learning methods used in brain tumor detection.

Statistical features are found useful in machine learning and medical image segmentation and classification [10]-[12]. Particularly, in brain tumor detection texture is one of the most valuable features in designating the image appearance [10], [13]. It can be described statistically for the purpose of distinguishing image characteristics by the spatial allotment of gray levels. The most popular mathematical representation of image texture is co-occurrence matrix. For example, in the Gray Level Co-occurrence Matrix (GLCM), the spatial relationship of pixels is considered to examine the texture by using statistical methods. Four features can be extracted and found useful as in [10], [13]-[14]: energy, correlation, contrast, homogeneity. Namely, these features are used for extracting features and forwarding it to neuro-fuzzy models and, generally, machine and deep learning methods [15]-[18]. In [13] support vector machines are applied as classifier, where in [18] authors implemented deep convolutional neural network, and one of the publicly available datasets for brain tumor detection [19]. Using hand-crafted features are still valuable for obtaining satisfying results in brain tumor detection and more parameters may give better results. On the other hand, smaller dimension of the feature vector is important for algorithm execution, especially in the cases

 ISBN 978-86-7466-930-3

where there is no need for higher complexity according to tested dataset. In this paper, Bayes and knn classifier are analyzed for classification model implementation using [19].

III. Experimental analysis

The cancer tissue is expected to stand out from the normal part of image, but the question of choice of MRI features still remains. The experimental analysis performed here consists of:

- tumor segmentation based on labeled regions in images,
- hand-crafted feature extraction,
- classification and evaluation of results on available dataset.

The proposed work is tested with Brain MRI Images for Brain Tumor Detection dataset [19], containing 98 brain MRI images with healthy tissue and 155 brain MRI images with cancer tissue. Among features for segmentation task solidity of labeled regions is applied. Having in mind traditional hand-crafted features for classification: energy, correlation, contrast and homogeneity, two classifiers are tested in initial phase. Based on preliminary segmentation analysis, two additional statistical features are added for the binary classification. Both tested classifiers, Bayes and knn, are evaluated on the test set, which is made from 30 % of the whole dataset selected in a random manner, where the rest was used for the training set. For performance evaluation true positive rate (TPR), true negative rate (TNR) and balanced accuracy (BACC) are calculated as in (1)-(3), respectively:

1) *True Positive Rate- TPR*

$$Sensitivity = \frac{TP}{P}, \quad (1)$$

where TP represents true positive, the number of samples that were positive and detected as positive, and P represents the whole set of positive samples;

2) *True Negative Rate- TNR*

$$Specificity = \frac{TN}{N}, \quad (2)$$

where TN represents true negative, the number of samples that were negative and detected as negative, and N represents the whole set of negative samples;

3) *Balanced Accuracy- BACC*

$$BACC = \frac{TPR + TNR}{2}. \quad (3)$$

IV. Proposed tumor segmentation

Proposed brain tumor segmentation is consisted of several steps. Firstly, MRI image is preprocessed using: high-pass filtering and image intensity adjustment, and then, after image binarization, connected regions are labeled. Finally, solidity is implemented for tumor segmentation.

A. MRI image preprocessing and labeling

High-frequency filtering highlights sudden changes in the image by passing high-frequency components [4]. A fifth order Gaussian HP filter with cutoff frequency of 55 Hz was used. Although MRI images provide good tissue contrast, adjusting image intensity is important for tumor segmentation. By saturating the bottom 2% and the top 1% of all pixel values the grayscale range of image is shortened and the contrast is enhanced, and therefore it highlights tumor areas.

Because the image contrast is adjusted, the histogram of the image has a bimodal distribution with a deep and sharp valley between the two peaks, which enabled using Otsu's method for automatic thresholding [4]. Finally, binary image has different white regions where some of them might represent tumor tissue. Pixels are connected and are part of one region if their edges touch. Two adjacent pixels are part of the same object if they are both of the same intensity and are connected along all directions.

B. Solidity characterization

For each labeled region, solidity can be calculated. Solidity is a measurement of the overall concavity of a particle. It is defined as the image area divided by the convex hull area. As the object form digresses from a closed circle, the convex hull area increases, and the calculated solidity decreases. Images with high solidity are more likely to contain tumor regions [13, 23]. A tumor can successfully be detected by comparing the calculated solidity of the labeled image with a higher value (closer to 1). In this case, the tumor is detected if solidity is higher than 0.6. When this area represents a tumor, it is the region or candidate with more white pixels, and when there is no tumor tissue on the image, some small regions can still be extracted. It may be assumed that differences between healthy and tumor tissue can be provided using features that describe the area and shape of this extracted region.

V. Statistical hand-crafted features

GLCM is created by calculating how often a pixel with grayscale intensity value i occurs horizontally adjacent to a pixel with the value j. Offset isn't used for defining pixel spatial relationships. The number of gray levels in the image determines the size of the GLCM. Scaling to 8 gray levels is used to reduce the number of intensity values in an image, so the size of GLCM is 8x8 pixels. The traditional statistical hand-crafted features extracted from GLCM are: energy, correlation value, contrast and homogeneity.

Energy estimates the sum of squared elements from GLCM and represents feature 1:

$$Energy = \sum_{i,j=0}^{N-1} p^2(i,j), \quad (4)$$

where N represents the number of pixels in image, i and j the location of pixel, and $p\,(i,j)$ the intensity of the pixel at the location (i,j).

The mentioned pixel pairs are then estimated using joint probabilities. It gives linear dependency of the gray levels of neighboring pixels. In general, it ranges from [-1,1]:

$$Correlation = \sum_{i,j=0}^{N-1} \frac{(i-\mu x)(j-\mu y)p(i,j)}{\sigma_x \sigma_y}, \quad (5)$$

where μ_x, μ_y, are the means and σ_x and σ_y are the standard deviations of P_x and P_y, respectively. Note that $P_x(i)$ is the ith entry in the marginal-probability matrix obtained by summing the rows of $P(i, j)$ and $P_y(i)$ is the ith entry in the marginal-probability matrix obtained by summing the rows of $P(i, j)$.

Contrast value (feature 3) estimates the local variations, i.e. sum of square variance, as in (6):

$$Contrast = \sum_{i,j=0}^{N-1} |i-j|^2\, p(i,j). \quad (6)$$

The fourth feature, homogeneity, estimates the closeness of distributed pixels.

 ISBN 978-86-7466-930-3

$$Homogenity = \sum_{i,j=0}^{N-1} \frac{p(i,j)}{1+|i-j|}. \quad (7)$$

These four features are applied in brain tumor detection, but having in mind the segmentation task, in combination with two more features like the number of white pixels (feature 5) and skewness (feature 6), one may assume further improvements can be obtained. The number of white pixels in the segmented images are expected to increase the accuracy results. Also, some additional statistical parameters can be great indicators of tissue condition. Skewness represents a measure of the asymmetry of the probability distribution [20]. It can be expected that umor tissue has much higher skewness than healthy tissue, thus it is also a reliable feature for classification.

VI. Bayes and knn Classifiers and Evaluation of the Results

A. Bayes classifier

For implementing Bayes classifier, it is necessary to define the posterior probabilities $q_i(X)$ which represent the conditional probability that the sample X comes from the class ω_1 if its exact realization is known. Using the Bayes theorem, these probabilities can be calculated if priori probabilities of occurrence of class p_i and posterior density probability functions of measured vectors $q_i(X)$ are known [5], [11]. In this case, the first class represents images with tumor tissue, and the second represents healthy tissue. A simple decision rule can be made based on conditional probabilities:

$$q_1(X) > q_2(X) \Rightarrow X \in \omega_1 \quad (8)$$

$$q_2(X) > q_1(X) \Rightarrow X \in \omega_2 \quad (9)$$

Although the probability density functions of the classes are not known, it can be assumed that, if there is a large number of samples, they can be taken as Gaussian (according to the central limit theorem) [6]:

$$f(x) = \frac{1}{|\Sigma|^{1/2}(2\pi)^{n/2}} e^{-(X-M)^T \Sigma^{-1}(X-M)} \quad (10)$$

where n represents the dimension of the vector X, M the mathematical expectation of the vector X, and Σ the covariance matrix of the feature vector. These values for both classes are obtained from the training set. For both classes, feature vectors are formed for classification.

B. k nearest neighbors Classifier

The most common issue in practice is information missing needed for classification based on hypothesis testing, so one may resort to non-parametric classification. One of the most popular methods is k nearest neighbors or knn. The algorithm classifies the observation point in relation to how the neighbors are classified. In the knn algorithm, k is a parameter that indicates the number of nearest samples involved in the classification [7], [21].

In Fig. 1, a new green sample that needs to be classified can be observed. The full circle in the figure represents the case when k=3: the neighbors are one blue square and two red triangles. Since there are more triangles, the green circle sample is assigned to the same class as the triangles.

However, if four is taken for k, the green circle will be classified into the blue squares class because there are more of them in the region. In conclusion, k is an essential parameter for successful classification [21]. Also, the success of the classification depends on which methods are used for defining what the nearest neighbors are. Some of the methods that are going to be considered in this paper are Euclidean, Chebyshev, Mahalanobis distance, and cosine similarity [22].

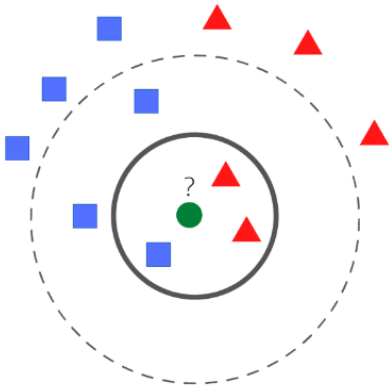

Fig. 1. Graphical representation of knn method, where green circle sample needs to be assigned to blue rectangle or red triangle class.

C. Evaluation

On proposed tumor segmentation steps and feature extraction, results of Bayes and knn classifiers will be shown, as well as the influence of feature vector dimension on results. The performance will be evaluated using confusion matrices and metrics described by (1)-(3).

The confusion matrix for this classification consists of two columns and two rows. Each row of the matrix represents the instances in an actual class, while each column represents the instances in a predicted class. Images with tumor tissue are labeled as ‘positive’, and healthy tissues are labeled as ‘negative’. Four and six features are tested to observe the effects on the results using Bayes and knn classifiers. The effect of the distance type and different values of k (1 to 40) on accuracy have been also analyzed.

VII. Experimental Results

A. Preliminary segmentation and feature inspection results

Preliminary segmentation results are show in Fig. 2 and Fig. 3. It can be observed that tumor is correctly detected in Fig. 2 for cancer tissue example. In the image with healthy tissue in Fig.3, small regions which are not tumor are segmented as one (false) candidate. Segmented image that contains a tumor has larger white area extracted, as it can be seen in Fig. 2 and Fig. 3, so this can be also used as an effective feature that provides good separability.

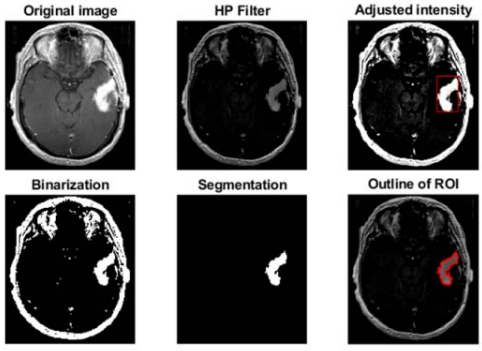

Fig.2. Results of segmentation for cancer tissue

 ISBN 978-86-7466-930-3

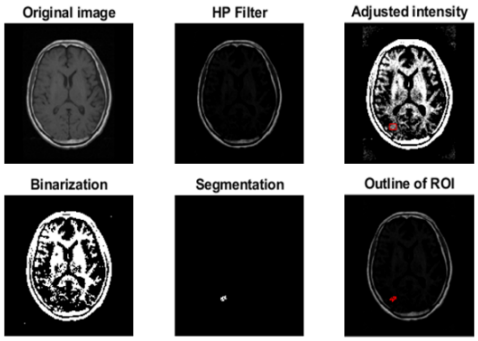

Fig. 3. Results of segmentation for normal tissue

Using the first four hand-crafted features may not be enough for high accuracy results. Adding two more features (feature 5 and feature 6) can improve results. From Fig.3 some of the separability inspection results can be seen.

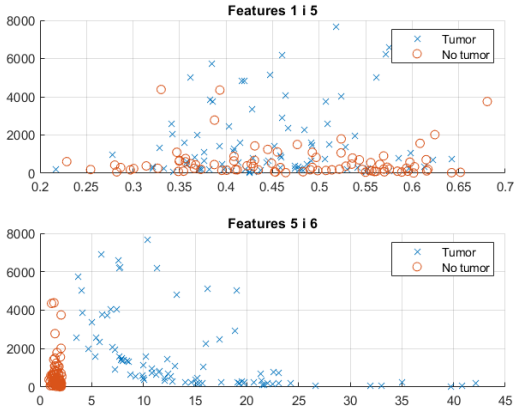

Fig. 4. Some of the separability inspection results of the selected features.

B. *Classification results using proposed method*

Classification results with only traditional or texture related features using Bayes classifier did not give expected results, as presented in Table I. Similarly is obtained for knn classifier and it is presented in Table II. For higher accuracy results, these classifiers require more information obtained through using additional features.

TABLE I
RESULTS OBTAINED WITH BAYES CLASSIFIER

Metric	TPR	TNR	BACC
Traditional four feature approach	71.4 %	82.6 %	75.8 %
The proposed method	96.6 %	100 %	98.3 %

TABLE II
RESULTS OBTAINED WITH KNN CLASSIFIER

Metric	TPR	TNR	BACC
Traditional four feature approach	89.6 %	65.5 %	77.6 %
The proposed method	100 %	96.5%	98.2 %

In the case of knn and four feature selection, the accuracy is highest for the Chebyshev distance, which is achieved for k = 39. This is illustrated in Fig. 5. These results are not suitable for practice and two additional features are applied to feature vector. The accuracy in the case with more features is highest for the cosine similarity and the best case is secured with lower number of neighbours (k = 3), which can be seen in Fig. 6, where smaller number of neighbours is a better choice.

For medical image classification, sensitivity is aimed to be high because of the need for all positives to be recognized correctly. Specificity should not be low because many false alarms are undesirable.

It is proven that only four texture related features cannot provide expected results, and adding two more features improves results. Feature vector still contains relatively small number of elements. In further experiments it is shown that the kNN algorithm with more features provides reliable results for all parameters, and compared to the Bayes classifier, it provides better sensitivity for both cases (with the lower and higher number of features), which can be seen in Table III. Slightly higher results in overall evaluation are obtained for knn for the proposed method.

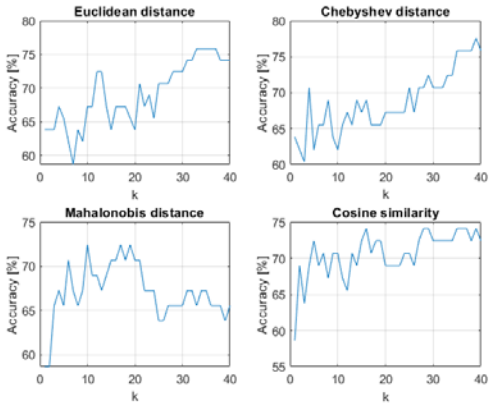

Fig. 5. Accuracy versus parameter k for four types of distances for four feature approach.

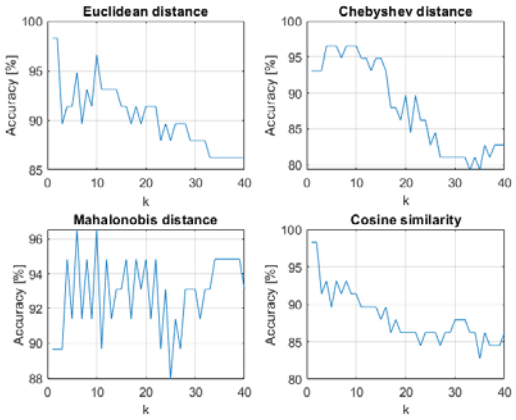

Fig. 6. Accuracy versus parameter k for four types of distances for proposed approach.

VIII. CONCLUSION

The proposed tumor segmentation in MRI head images provided an excellent base for analyzing the tumor classification methods. The proposed classification method gives surprisingly good results compared to the other methods based on machine learning tested on the same dataset. The advantage of the proposed method lies in less demanding hardware resources where traditional classification methods are used. A more diverse selection of features can further increase accuracy. Since the knn method stood out as a method with high accuracy, it is possible to test other selections and analyze the types of distances by

 ISBN 978-86-7466-930-3

which the classification is performed.

A possible improvement of the model would also be classifying different types of tumors and labeling more complex cases in brain tumor detection. Such data labeling for classification improvements would require help from the experts.

From puppet-master creation to false detection

Ana Pantelić and Ana Gavrovska, *Member, IEEE*

***Abstract*— Nowadays, many issues in society are affected by the misuse of deepfakes. One can say that we came to a point when prior knowledge of image processing is not a requirement for deepfake creation. With different motives, in a short period, and with limited resources, many deepfakes can appear on the internet. That brings us to testing that hypothesis of how easy and how fast someone can make a deepfake. In this paper several puppet-master creations are made for experimental purposes. In the aftermath of deepfake creation, an off-shelf available deepfake detection algorithm is applied for the detection analysis which is expected not to be universal solution for every type of deepfake realization. This brings us to high false detection, where specific cases are considered in this paper, like closed eye and head shape effects.**

***Index Terms*— Deepfake, puppet-master, deep learning, closed eye, head shape, false detection.**

I. INTRODUCTION

Technologies are rapidly evolving, and the challenges due to hardware limitation are becoming obsoleted. On the other side, different associations are trying to solve technical issues through hackathons with solutions in the interest of society. One of those issues is the detection of deepfakes [1]-[3].

DeepFakes are getting easier to produce and harder to detect. DeepFake can be considered as altering approach based on artificial intelligence and deep learning architecture. Moreover, there are different types of deepfakes, where deepfake can be often described as a synthetic switch of identities of two persons, for example in a video sequence. Namely, there are different types of deepfakes like: face-swap, entire face synthesis, puppet-mastery, and lip-syncing [4]. It is highly used in revenge pornography, and based on DEEPTRACE research [5]-[6], in September 2019, 96% of deepfake videos belong to pornographic content, where the victims are widely women. There are also widely used for politicians and public figures. With available software tool almost everyone can generate a deepfake or deepface using recorded video and an image of a taget person.

In this paper a puppet-master creation as a popular method for deepfake creation is applied. Here, performed steps for creating a deepfake is explained. Moreover, one of the methods for deepfake detection is implemented in order to observe false detections. One may have in mind that the algorithm taken for experimental analysis is not selected purposely, but in a random manner from available recent solutions, in order to observe expected false detections. It is to expect that the detection method is not prepared for dealing with each type of deepfakes and scenarios. Thus, the motivation of this work is to perform popular deepfake generation and observe what would happen if a deepfake creation approach is not directly connected to some of the state-of-the art solutions focusing on specific details like edges around important face parts like: mouth, eye and similar.

The paper is organized as follows. After introduction, in Section II we give a brief description of popular deepfake creation and detection. Section III is dedicated to simulations for puppet-master creation and for neural network based detection without taking into account the type of creation. This is followed by the experimental results and discussion related to observed detection results in Section IV. Final conclusions are given in Section V.

Ana Gavrovska is with the University of Belgrade - School of Electrical Engineering, Bulevar kralja Aleksandra 73, 11120 Belgrade, Serbia (e-mails: anaga777@gmail.com; anaga777@etf.rs).

II. DEEPFAKE CREATION AND DETECTION

One of the most popular ways of creating deepfake is GAN (Generative Adversarial Network) [7]-[8]. GAN is an algorithm with two opposed neural networks that generate new, synthetic data that can pass as regular data. Neural networks and, generally, machine learning tools show the ability to mimic the human brain by learning, memorising and making the data they acquire in general. Typical deepfake algorithms for generating data are X2Face and First order motion model [2]-[3], [9].

In this paper, the neural network starts with the Monkey-Net neural network [10], and advance it to the First order motion model for image animation [9]. The First order motion model presents a fast and effective way of creating a deepfake with better results than advanced animation processing software.

Puppet-master deepfake creation is one of the modest and popular methods for making a deepfake. It shows how realistic the results can be, where the artefacts are still seen by human eye especially in video material. So, this method for creating a deepfake has its positive and negative sides. Artefacts are observable and this can be negative experience for the creater. This is also a positive information since we can still believe that we can distinguish true or false video story.

For deepfake detection, one has to be aware of the algorithm used for deepfake creation. Taking into consideration that the person who published a deepfake won't leave a piece of information related to origin or source or used tools for deepfake design, the common decision is that the detection from practial point of view will be applied to images cropped/grabbed from the video.

The main focus of detection of a deepfake are face parts like eyes and mouth, and head movement. Deepfake may be recognized on irregular pixel weight at the edges of the mentioned regions after training the neural network that detects them. One of the state-of-the art models based on such detection is Meso-4 model [11]-[12]. It is based on convolutional neural network and represents an efficient tool for dealing with particular types of visual modifications.

 ISBN 978-86-7466-930-3

Here, it is used as only one of the solutions for observing how can some deepfake examples created by the First order motion model be detectable as deepfakes and what are the cases when one may get high number of false detections, when deepfake frames are passed as regular images.

III. SIMULATION

A. *Steps for creating a deepfake*

Here, preparations for the deepfake creating is filming a video of 256×256 px, that is frontal with simple backround. Next to that, an image of a person we want to switch the identity with is chosen. The selected image is also frontal with simple backround and with the lack of face-covering details. In this paper Google Colaboratory with python script are used for experimental purposes [13]-[14].

First order motion model for image animation is upgraded convolutional neural network based on Monkey-Net-u [9], [11]. Monkey-Net codes information of movement through keypoints that are pretrained and self-observed. Down side of this neural network is possibly that, while following the trajectory of keypoints in faster movements, missing spots in image can appear. To solve that missing spot, affine transformation is used to perserve the propotion of the line and collinearity between dots. While it perserves propositions between lines and dots, affine transformation doesn't perserves all the angles. To have a clear overview, the improved parts of Monkey-Net are: keypoints aren't just detected but they are self-controled, which will add the adaptability on the targeted image; the generator of occlusion is added that gives a mask based on the parts that are not initially visible; it improved the visual domain of the puppet in general. In Fig. 1 simulation steps for creating a puppet deepfake are shown. If we follow from the video of the puppet, the keypoints are generated and local affine transformation is applied and collected. Until it comes to dense motion, from the source image we encode all the needed features and by warp operation the parts of process are connected. This is followed by occlusion map and decoder that brings the final creation result.

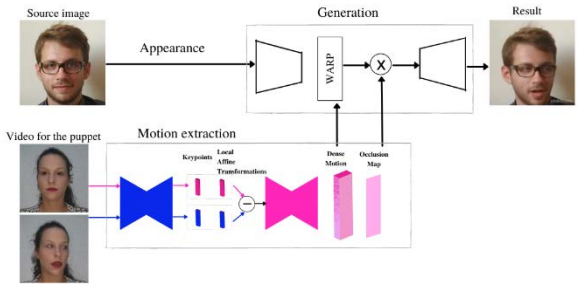

Fig. 1. Simulation steps for creating a puppet deepfake.

B. *A deepfake detection model*

For the need of deepfake detection, a pretrained convolutional neural metwork MESO-4 model is used [12]. The architecture of the model is shown in Fig. 2. It is constructed of four convolutional blocks and one hidden layer. It recognizes the vertical and horizontal lines; applies batch normalization; uses the convolutional matrix with a task to bring all the important edges like edge of the lips, shape of the head or edges of the eyes; it employs pooling layer that will pick the pixel with dominating characteristics. Based on the pixel the reducing of spatial size of convolutional operations is possible. To improve the generalization, in the addition to the normalization of the batch, ReLU (Rectified Linear Unit) which introduces nonlinearity is applied.

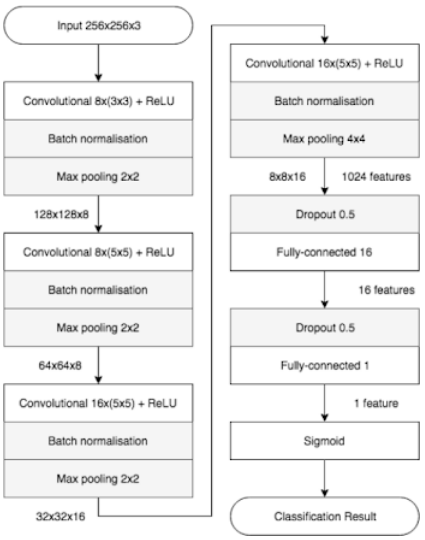

Fig. 2. Meso-4 architecture, where layers and parameters are displayed in rectangles [12].

C. *False detection counting in a puppet related data*

We wanted to see if the head movement and misshapes of the head will be detected by Meso-4 neural network. That is the reason we produced the video with head movement on both sides (left and right), and then abruptly moved to one of the sides. Furthermore, the idea is to make mouth and eyes to seem natural in a deepfake, so the person often blinks. When making mouth movements, the mouth is moved naturally without exaggeration.

IV. EXPERIMENTAL RESULTS

A. *Experimental results for created deepfakes and false detection*

Three deepfake videos are made with source images of university assistant, public figure, and politician. One of the created deepfakes for a public figure is shown in Fig. 3.

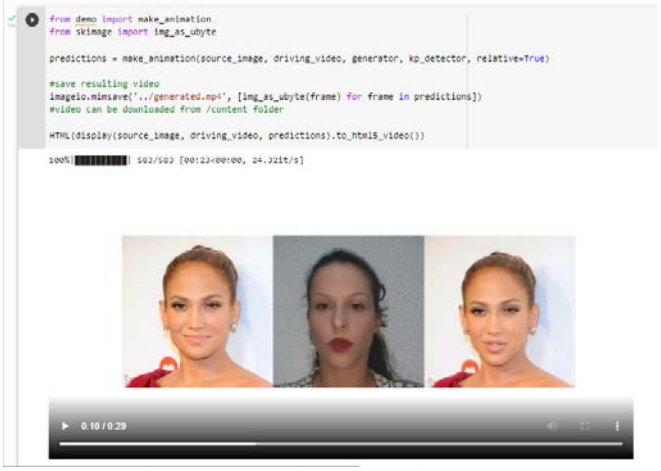

Fig. 3. One of the created deepfakes. From left we have source image, video for the puppet and the end result.

 ISBN 978-86-7466-930-3

The results were satisfying, with expected characteristics of puppet-mastery. The process resulted in a source image that was following all the given movements of head, eyes, and lips.

For the detection task both original and deepfake frames are used. Totally, 461 images are tested whether they are real or not, giving for original examples satisfying results as shown in Fig. 4. Predicted likelihood is close to 1 which means that labeling is performed in adequate manner. Correct prediction can be noticed and it proves that the result is true.

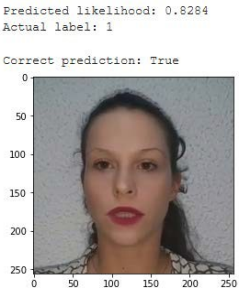

Fig. 4. The result of the detection. If the predicition is closer to one it means it sees it as real, and next to that it proves it predicition as True or False.

At first glance, a lot of images that are real are also detected as real, but unsatisfactory results are shown for deepfakes. The summary of obtained results is given in Fig.5. Out of 110 real images, 94 real cases are detected. On the other hand, high percentage is found for false detections where deepfake frame is considered real. In the experiment it is found that we have around 82.33% of chances for misinterpreting a deepfake image as real, and around of 14.5% of misinterpreting a real as a deepfake. The high false detection exists as it was expected.

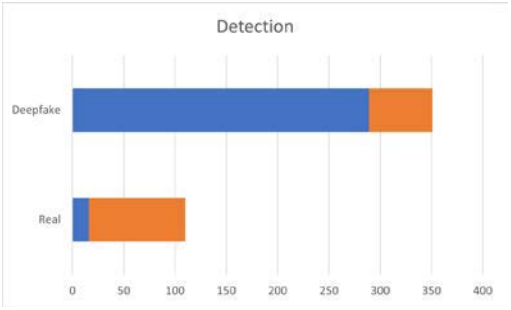

Fig. 5. The summary of detection. The blue colour presents the number of falsely detected images. Out of 351 deepfake images, 289 are detected real.

B. *Further analysis on accurate results*

When observing accurate real results it was noticed that the probability of images with closed eyes, and when the head is curved, is close to 0.5, which means that there is a significant level of doubt. Similarly is noticed with cases where errors occurred, i.e. when real images are detected as deepfakes. The probability of around 50% can be interpreted as random class selection.

In Fig. 6 examples of true predictions are presented, where one of the examples show lower predicted likelihood. This is the case where eyelids and pupils are not visible while blinking. On the other hand, when eyelids and pupils are visible and when there is less blur around the face, there is a higher probability that the detected image is real.

Fig. 6. Examples of True predicitions.

There are frames that are detected as deepfake and similar pattern can be recognized as in Fig. 7.

Fig. 7. Real images detected as deepfake

It can be noted that there are frames in Fig. 7. where pupils and irises are not visible, as well as where there is a greater curvature of the head. In these cases Meso-4 has detected that there is a chance that it is a deepfake. Also, it is important to note that most predictions are around 0.4 and that the probability leans towards deepfake, mostly where the eyes are closed and the head is tilted. The results of the experiment were best shown on the targeted personalities with similar facial symmetry as in the video used for the puppet.

The script for the puppet video had slow head movements to one side and then to the other, and then it abruptly moved to one side to see the artefact mentioned in the works for Monkey-Net and the First Order Motion Model. The appearance of this artefact was expected, and the artefact appeared in the results. For a better solution, photos from other angles should be found for the target person, which would improve the occlusion - in the sense that the focus is placed on the other eye (which should not be visible) or the whole part of the face that should be covered, and a 3D model, which is not obtained here due to the different shape of the person's head in the original. As for the background, the improved occlusion gave favourable results. Also, on several clippings, an artefact was obtained, which was conceptually mitigated, and that is the disappearance of parts of the image/person, as shown in Fig.8.

Fig. 8. Image with the disappeared part of the image

 ISBN 978-86-7466-930-3

Accurate results are obtained in this case, and a significant number of cases, as shown in Fig.9. It can be immediately noticed that the third of the displays are around 0.4 probabilities. All detected images have distorted heads and artefacts due to movement, i.e. tracking the trajectory of key points on the face of different symmetry in the 3D model or they have their eyes closed.

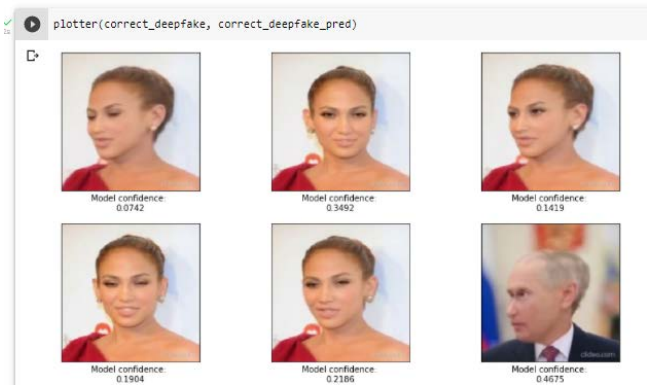

Fig. 9. Examples of images that are deepfakes, and detected as deepfakes

C. *Analysis of false detection results*

Here, of the greatest importance are images that are detected as real, and these are images from deepfake videos.

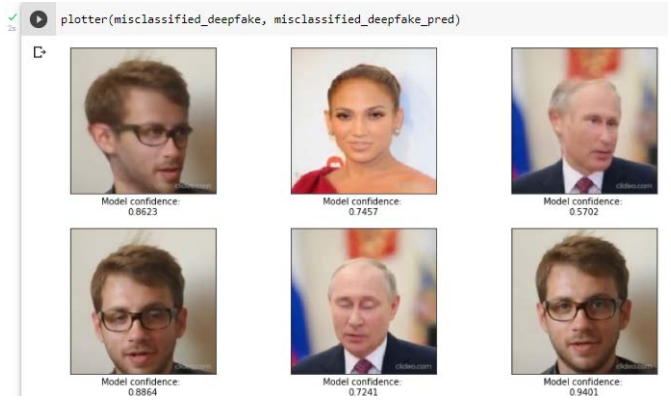

Fig. 10. Examples of images that are deepfakes and detected as real.

Three specific cases can be observed where there is a space for further improvements:
- mouth/lip movements,
- head movements and
- eye movements

Speaking of mouth movements, Fig.11, satisfactory results were obtained in creating a puppet, where the targeted persons followed the movements and had a tooth display at the appropriate moments. All lip movements that were observed in isolation from other movements contributed to the reality of deepfake and false detection. The lips are mostly in motion with teeth or collected. Compared to well-detected lips, every fifth well-detected mouth as a deepfake has a deformity along with the head. So one can say that lips are one of the parts where there is a need for a better detection.

Slow head movements to one side and then the other, and then abruptly movement to one side is a significant process, Fig.12. All the end movements are recognized as real images, in a manner that if the head is still, meaning in one place for more than one second without motion blur, the image will be detected as real. Furthermore, the detector sees even distinguished distortions of the head and face as realistic images. This is noticed in nearly 33% of false detected images. Moreover, it is very likely to have errors in differentiation when real images are frontal with clear head movement, while eyes are visible and lips in motion or collected. Those characteristics are visible in around 97% of all images that are deepfake and marked as real.

Fig. 11. Images with mouth movement

Fig. 12. Examples of frontal, right, left and right side (column-wise).

The most relevant results in terms of authenticity are in creating obtained by tracking eye movements, Fig.13. It can be considered the most difficult case in the creation process. False detection occurred in the eye related situations when the eyes are fully visible or when the iris and pupil are visible. Also, false detection is present when the eyes have a proportional distance between the pupils concerning the position of the face. This is shown in the most majority of images/frames, around 99%.

Fig. 12. Examples of eye movement.

 ISBN 978-86-7466-930-3

V. CONCLUSION

Based on the results of the experiments, it can be concluded that the creation of fast and efficient deepfake still meets the need for additional training of neural networks that map key points and where trajectories needs to be adapted to different head shapes so that the appearance of deepfake is invisible to the human eye. It is important to emphasize that the results completely coincided with the results from the paper [9]. It is believed that further training of such neural networks can lead to even more adaptable results.

On the other hand, the selected detection was not the best example for a given set of images which is shown through a variety of false detection results. This can be attributed to the fact that the detection follows certain edges and looks for dominant characteristics that were not the focus in creating the deepfake, such as eye details. Therefore, it is suggested that the type of detection should be adapted to specific type of deepfake. The importance of focusing on deepfake detection, and particularly eye movement, is emphasized which must be adapted to all new ways of creating deepfake videos.

In future work, we would focus on better detection of the misshaped head, as well as different tools for recognition of lip-syncing and eye tracking.

ACKNOWLEDGMENT

This work is written during the research supported and partially funded by the Ministry of Education, Science and Technological Development, Republic of Serbia. No. 2022/200103.

I. UVOD

Potrebno je imati u vidu da mogućnost projektovanja i realizacije kristalnih filtara prema konkretnom zahtevu korisnika pruža pogodnosti u ispunjenju različitih zahteva u pogledu centralne frekvencije filtra, širine propusnog opsega i selektivnosti, toka amplitudske i fazne karakteristike u propusnom opsegu. Mogući su i mnogi specifični zahtevi vezani za klimomehaničke karakteristike, intermodulaciju i druge karakteristike koje diktira primena filtra u specifičnim uslovima. Mali je broj proizvođača koji pružaju mogućnost realizacije kristalnih filtara na osnovu konkretnih zahteva korisnika. Uglavnom se proizvodnja zasniva na realizaciji kataloških tipova filtara [1-7].

U ovom je radu realizovan novi tip kristalnog filtra na frekvenciji 35.4 MHz. Projektovan je filtar koji obezbeđuje ispunjenje postavljenih zahteva. Proračunom filtra definisani su elementi ekvivalentne električne mreže i zahtevi za kristalne jedinke. Ovde zahtevi za kristalne jedinke obuhvataju: dozvoljeni nivo neželjenih rezonancija; frekvencije kristalnih jedinki; dozvoljeno odstupanje frekvencije kristala na sobnoj temperaturi i u radnom temperaturnom opsegu; vrednosti parametara kristalne jedinke; serijsku i paralelnu kapacitivnost; faktor dobrote kristala.

Postupak proizvodnje primenjen u realizaciji ovih filtara može da se uvede u proces proizvodnje svih tipova kristalnih filtara koji imaju slične zahteve u pogledu strogo definisanih električnih karakteristika.

Mogu se razmatrati sledeći iazazovi: ostvarivanje što većeg slabljenja u nepropusnom opsegu filtra i što manjeg slabljenja u propusnom opsegu filtra. Zajedno sa navedenim razmatranjem odvijao se razvoj kristalnih jedinki koje imaju ostvarene sve parametare koje je odredilo projekatvanje filtra. Posebno je vođeno računa o uslovu da se ostvari što veći - faktor i što veći faktor potiskivanja neželjenih rezonancija.

Q faktor je bezdimenzioni parametar koji opisuje koliko je oscilator ili rezonator nedovoljno prigušen. Približno se definše kao odnos početne energije rezonatora i energije izgubljene u jednom krugu ciklusa oscilovanja. Faktor potiskivanja neželjenih rezonancija je logaritam odnosa amplituda neželjenih signala i signala na centralnoj frekvenciji rezonatora.

Uporedo sa tim je urađena i analiza svih komponenata koji se ugrađuju u filtar i proveren njihov uticaj na osetljivost filtra u pogledu funkcionisanja u radnom temperaturnom opsegu i pri zadatim uslovima rada [10-11].

Rad je organizovan na sledeći način. U drugoj glavi dat je kratak osvrt na potrebe za realizacijom ovakvih filtara. Treća glava je posvećena samom projektovanju filtara. Kristalne jedinke su opisane, kao i njihova realizacija u glavi četiri. Na kraju, u petoj glavi nalazi se zaključak.

II. REALIZACIJA FILTARA TRAŽENIH KARAKTERISTIKA

Zahtevane električne karakteristike filtara su direktno povezane sa namenom samog uređaja, a to određuje oblik amplitudske i fazne karakteristike u propusnom opsegu, centralnu frekvenciju filtra, širinu propusnog opsega i selektivnost.

Pored osnovnih karakteristika postoje i karakteristike koje u zavisnosti od toga u kakvim uslovima rada uređaj funkcioniše imaju zahteve koji se odnose na vibracije, udare, potrese, temperaturu, pritisak, vlagu. To su tzv. klimomehanički uslovi rada, ali postoji i dosta drugih specifičnih zahteva.

Ovi kristalni filtri, koji se prema traženoj specifikaciji ne mogu pronaći u katalozima proizvođača, zahtevaju kompletan razvoj uz odgovarajući projekat filtra prema postavljenim zahtevima.

Važna je potreba da se mogu realizovati kristalni filtri na osnovu specifičnih zahteva korisnika. To zahteva razvoj novih tehnoloških postupaka pri proizvodnji, kao i projektovanje filtara i njihovih komponenata. Zbog toga se većina proizvođača bavi proizvodnjom kataloških tipova filtara sa standardnim karakteristikama i komponentama [4–12].

III. PROJEKTOVANJE FILTARA

Na osnovu liste tehničkih zahteva koja je prikazana u tabeli I, završen je projekat željenog filtra. Takođe, na osnovu zahteva u pogledu oblika amplitudske karakteristike u propusnom i nepropusnom opsegu određuje se red filtra i sama mreža koja ispunjava postavljene zahteve. Na slici 1 prikazana je šema jednog filtra. Prilikom proračuna parametara i projektovanja filtra mora se voditi računa i o tolerancijama komponenata koje se ugrađuju u filtar kako bi bile ispunjene tražene karakteristike.

Na osnovu predviđenih gubitaka u mreži, završen je proračun filtra, određena je električna šema i definisani su zahtevi vezani za kristalne jedinke. Projektovanjem filtra moraju se tačno definisati svi parametri kristalnih jedinki, njihove vrednosti i tolerancije. Proračunavaju se i parametri kao što su frekvencija kristala, serijske i paralelne kapacitivnosti kristala i podešenosti frekvencije na sobnoj temperaturi. Takođe se definišu i maksimalna dozvoljena odstupanja frekvencija kristala u radnom temperaturnom opsegu filtra.

Sl. 1. Električna šema kristalnog filtra.

Prema datim zahtevima urađen je projekat filtra 6-og reda uz Chebyshev aproksimaciju. Razvijene su kristalne jedinke AT-reza sa malim odstupanjem frekvencije (lista tehničkih podataka tačka 8) u širokom temperaturnom opsegu koje ispunjavaju zadate zahteve u vidu položaja i potisnutosti sporednih rezonancija.

Potrebno je napomenuti i da se projektovanjem filtra oodređuju i vrednosti parametara ostalih elemenata, kao što su otpornici, kalemovi i kondenzatori, a takođe i njihov raspored na štampanoj ploči.

Mora se uzeti u obzir da filtri rade na visokim frekvencijama, gde prisustvo parazitnih kapacitivnosti značajno utiče na karakteristike filtara, tako da je raspored elemenata od izuzetnog značaja u podešavanu vrednosti selektivnosti i slabljenja u nepropusnom opsegu filtra [1-5].

IV. PRISTUP ZASNOVAN NA KRISTALNIM JEDINKAMA I REALIZOVANI KRISTALNI FILTAR

Projektovani filtar ima relativno slabljenje u propusnom opsegu od ±4.25 kHz koje je manje od 3dB. Izvan frekvencijskog opsega od ±20 kHz slabljenje je veće od 60 dB . U širem opsegu frekvencija, do ±5 MHz, relativno slabljenje je veće od 60 dB.

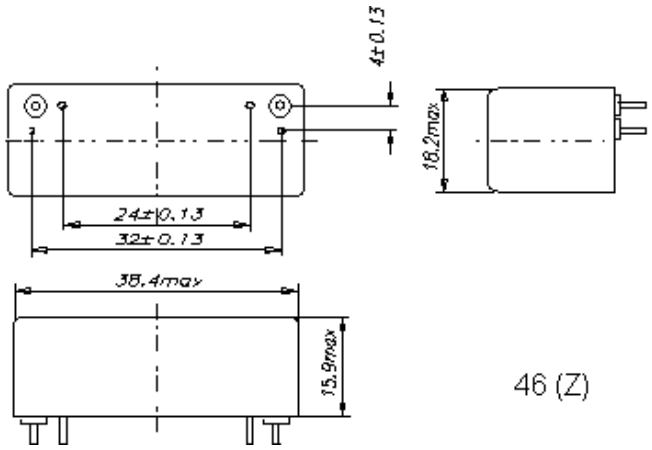
Minimalno pogonsko slabljenje filtra je manje od 6 dB. Ulazna i izlazna otpornost filtra iznose 50 Ω. Radni temperaturni opseg filtra je -10º C do +60 ºC. Temperaturni opseg skladištenja, odnosno opseg temperatura u kojima filtar neće promeniti karakteristike dok se čuva u skladištu je -40 ºC do +85 ºC.

Filtar je smešten u kućište dimenzija (38,4×18.2×15.9) mm. Detalji svih tehničkih karakteristika filtra su dati u Tabeli I.

Nizom eksperimenata ustanovljen je povećan škart usled lomova na mašinama za glačanje i poliranje pri obradi pločica čiji je odnos prečnika i debljine Φ/t>100. S obzirom da kvarcna pločica prečnika Φ=5 mm, frekvencije 35.4 MHz osnovne učestanosti, ima odnos prečnika i debljine Φ/t=106.38 pristupilo se realizaciji kristala trećeg overtona čiji je Φ/t=35.46 čime je, sa druge strane zadovoljen uslov za planparalelni (PP) oblik pločica trećeg overtona (Φ/t>35).

Overton je pojava odziva na rezonatoru koja je na frekvenciji 3, 5 ili 7 puta većoj od osnovne frekvencije rezonatora. Ova pojava se koristi da bi se postigle veće frekvencije rada kristalnog rezonatora.

U projektu mikrominijaturnih kristalnih jedinki trećeg overtona učestanosti 35.4MHz vodilo se računa o prečniku elektrode d=1.63mm i debljini nanetog filma t = 2,9x10-7m zbog zahteva za položaj i potisnutost sporednih rezonancija. S obzirom da se radi o tankim filmovima kao elektrodni materijal korišćen je aluminijum. Podešavanje frekvencije je hemijsko u sodi i anodnom oksidacijom. Sve kristalne jedinke su posle grupnog naparavanja i cementiranja stajale na vazduhu 24h radi formiranja stabilnog prirodnog oksidnog sloja. Kvarcne pločice su planparalelne (PP) prečnika Φ=5 mm i realizovane su od kvarca faktora dobrote Q>1.8 x10^6 bez strukturnih defekata i grešaka pakovanja. Kristalne jedinke montirane su u držač tipa RW-HC45.



Realizovane kristalne jedinke AT-reza zadovoljavaju zahteve za položaj i potisnutost sporednih rezonancija i dozvoljeno odstupanje frekvencije u radnom temperaturnom opsegu.

Na slici 2 prikazan je realizovani filtar. Filtar je smešten u standardno kućište koje je prikazano na slici 3.

Sl. 2. Realizovani kristalni filtar.

 ISBN 978-86-7466-930-3

Sl. 3. Kućište filtra.

Ispitivanje filtara koje je izvršeno na sobnoj temperaturi i u radnom temperaturnom opsegu od -10˚C do +60˚C urađeno je na analizatoru spektra HP 8568A. Merenjima je utvrđeno da filtar zadovoljava tražene električne karakteristike.

Rezultati merenja amplitudske karakteristike filtra na sobnoj temperaturi prikazani su u dijagramima na slici 4.

Lista tehničkih podataka za kristalne jedinke za filtre 35,4 MHz je sledeća:

1. Kućište RW-HC45
2.
3. frekvencija f_1 = 35392.53 kHz
f_2 = 35401.27 kHz
f_1 = 35393.73 kHz
f_2 = 35400.07 kHz
4. -faktor > 120000
5. dinamička kapacitivnost C_1 = 380 apF ± 10%
6. paralelna kapacitivnost C_o = 1 pF ± 5%
7. dinamička otpornost $_1$ < 90 Ω
8. podešenost *df f*=±5 ppm
9. odstupanje *df f*=±15 ppm
10. starenje *df f*=1 ppm/god
11. radni temperaturni opseg -10÷+90˚C
12. neželjene rezonancije A. f_0+70 kHz–bez f_n

V. ZAKLJUČAK

Pored proračuna i realizacije kristalnog filtra, razvijena je i nova kristalna jedinka. Ovakvi kristalni filtri predstavljaju novi proizvod, jer su u njemu korišćene nove tehnologije i nove komponente. Ovi proizvodi imaju širok dijapazon primena i veliku upotrebnu vrednost i ističu se svojom cenom i svojim kvalitetom, tako da se mogu smatrati konkurentnim na tržištu. Navedene karakteristike i konkurentnost na tržištu daju perspektivu razvoju novih elektronskih sklopova i proizvoda zasnovanih na kristalnim jedinkama.

U daljem razvoju ovih i sličnih uređaja treba ići na usvajanje novih tehnologija izrade kristalnih jedinki i upotrebe novih i kvalitetnijih komponenti u kolu elektronskih sklopova novih uređaja.

ZAHVALNICA

ABSTRACT

In modern telecommunications, especially digital, it is very important to use quality components for receiving, sending and transmitting signals. Among the most valuable components are crystal filters, which are also commonly used components. The paper describes a 35.4 MHz crystal filter based on crystalline units of the third overtone and applied technical characteristics.

Primena vremensko-frekvencijskih metoda kod analize spektra u kognitivnom radiju

Nenad Stojanović, Milenko Andrić, Dimitrije Bujaković, Boban Bondžulić i Vladimir Ristić

***Apstrakt*—U radu je izvršena analiza primene tri metode vremensko-frekvencijske analize signala za potrebe analize spektra kod kognitivnog radija. Analiza je sprovedena modelovanim i realnim signalima za aditivni beli Gausov šum različitog odnosa signal/šum. Performanse metoda su analizirane kroz promene odnosa signal/šum i praga detekcije, određivanjem verovatnoće lažnog alarma, verovatnoće propuštene detekcije i verovatnoće ispravne detekcije. Pokazano je da se metode vremensko-frekvencijske analize signala mogu efikasno koristiti za potrebe analize spektra uz odgovarajuću optimizaciju parametara.**

***Ključne reči*—Frekvencijsko skakanje, kognitivni radio, vremensko-frekvencijska analiza spektra.**

I. Uvod

EKSPONENCIJALNI rast broja bežičnih uređaja i sistema prenosa, kao i zahtevi korisnika za većim brzinama prenosa i boljem kvalitetu usluge, uticali su na sve izraženije probleme kod dodele spektra i uopšte pristupu radio spektru. Jedno od rešenja predstavlja kognitivna radio tehnologija, čiji je cilj da poveća spektralnu efikasnost koristeći delove sprektra koje ne koristi primarni korisnik za prenos signala sekundarnih korisnika [1]. Sekundarni korisnici određenog spektralnog opsega ni u kom slučaju ne smeju ometati primarne korisnike. U tom cilju, ovako koncipiran pristup radio spektru, odnosno upravljanju spektrom (eng. *Spectrum Management*) se sastoji iz četiri koraka [2]:

- analiza spektra (eng. *Spectrum Sensing*),
- donošenje odluka (eng. *Spectrum Decision*),
- deljenje spektra (eng. *Spectrum Sharing*) i
- mobilnost spektra (eng. *Spectrum Mobility*).

Kognitivni radio se može definisati kao unapređeni softverski definisani radio, sa ostvarenom sposobnosti učenja i zaključivanja, odnosno kognitivnost [3]. Jednu od definicija dao je i američki FCC (*Federal Communication Commision*) po kojem kognitivni radio predstavlja bežični uređaj koji dinamički detektuje neiskorišćene delove spektra i koristi ih tako da ni na koji način ne ometa primarne korisnike u tom opsegu [4].

Najvažnija funkcija kognitivnog radija je analiza spektra, pri čemu je osnovni izazov analize spektra detekcija signala male snage sa malom verovatnoćom propuštene detekcije u uslovima niskog odnosa signal/šum (eng. *Signal to Noise Ratio*, SNR). Postoji više različitih klasifikacija tehnika za analizu spektra [5, 6, 7]. Jedna od najčešće korišćenih je podela na: tehnike analize spektra za detekciju primarnih predajnika, tehnike analize spektra za detekciju primarnih prijemnika i tehnike analize spektra zasnovane na temperaturi interferencije.

Vremensko-frekvencijske metode analize signala se koriste za analizu spektra kognitivnog radija [8]. U [9] je izvršena analiza spektra kada je primarni signal digitalna televizija, odnosno OFDM (*Orthogonal Frequency Division Multiplexing*) signal. Autori u [10] predlažu modifikaciju vremensko-frekvencijskih metoda za analizu spektra u prisustvu OFDM signala. U [11] su autori pored OFDM signala, razmatrali i signal sa frekvencijskim skakanjem. Analiza spektra radio sistema TETRA (*Terrestial Trunked Radio*) je predložena u [12]. Karakteristika svih navedenih radova je korišćenje modelovanih signala za analizu spektra kognitivnog radija.

Slična analiza spektra vrši se tokom elektronskog rata u cilju prikupljanja informacija, ali bez potrebe za iskorišćenjem spektralnih šupljina. Kod ovakvih sistema neke od osnovnih funkcija su detekcija izvora zračenja, klasifikacija i identifikacija emitera, određivanje lokacije emitera i njegovo praćenje. Sve ove funkcije potrebno je obavljati u veoma kompleksnom okruženju u realnom vremenu.

U ovom radu su analizirane metode vremensko-frekvencijske analize signala za potrebe analize spektra kognitivnog radija. Razmatran je signal sa frekvencijskim skakanjem koji se često koristi u vojnim radio sistemima. Frekvencijsko skakanje predstavlja tehniku prenosa koja se zasniva na skokovitoj promeni frekvencije nosioca u širem opsegu nego što je to neophodno [13]. Za potrebe analize razvijen je simulacioni model, a takođe su korišćeni i snimljeni realni signali iz baze signala [14].

Ostatak rada je organizovan na sledeći način. U drugom delu rada ukratko su opisane korišćene metode za vremensko-frekvencijsku analizu signala. U trećem delu rada opisana je

metodologija analize spektra. Analiza modelovanih signala sa frekvencijskim skakanjem je data u četvrtom poglavlju, dok je u petom izvršena analiza realnih, akviziranih signala sa frekvencijskim skakanjem. U poslednjem odeljku dati su najvažniji zaključci i budući pravci istraživanja.

II. METODE VREMENSKO-FREKVENCIJSKE ANALIZE SIGNALA

Najčešće korišćena vremensko-frekvencijska predstava signala je spektrogram. Spektrogram predstavlja energetsku verziju vremenski zavisne Furijeove transformacije (eng. *Short-time Fourier Transform*, STFT). STFT je definisana kao [15]:

$$STFT(n,k)=\sum_{m=-N/2}^{N/2} w(m)x(n+m)e^{-j(2\pi/N)mk}, \quad (1)$$

gde su $x(n+m)$ signal koji se analizira, $w(m)$ prozorska funkcija, dok je broj tačaka za izračunavanje Furijeove transformacije $N+1$. Spektrogram je definisan kao:

$$SPEC(n,k)=\left|STFT(n,k)\right|^2. \quad (2)$$

Vremenska i frekvencijska rezolucija određene su dužinom prozorske funkcije. Smanjenjem dužine prozora dobija se bolja vremenska rezolucija čime se negativno utiče na frekvencijsku rezoluciju. Povećanjem dužine prozora, smanjuje se vremenska rezolucija, ali se poboljšava predstava signala u frekvencijskom domenu. Prozori se međusobno mogu preklapati ili ne. Povećanjem preklapanja prozora poboljšava se vremenska rezolucija [16].

Vignerova vremensko-frekvencijska distribucija (eng. *Wigner Distribution*) je razvijena kao optimalna za predstavu jednokomponentnih linearno frekvencijski modulisanih signala u vremensko-frekvencijskom domenu. Pri analizi višekomponentnih signala, pojavljuju se komponente koje se ne nalaze u originalnom signalu, što predstavlja jedan od nedostataka ove transformacije. Kompleksnost izračunavanja ove distribucije je veoma velika, što je još jedan nedostatak. Pseudo Vigner-Vilova vremensko-frekvencijska distribucija signala (eng. *Pseudo Wigner-Ville Distribution,* PWV) predstavlja Vignerovu raspodelu analitičkog signala i može se predstaviti primenom STFT kao [17]:

$$\begin{aligned} WD(n,k)&=\sum_{i=-N/2}^{N/2} STFT(n,k+i)STFT^*(n,k-i)= \\ &=\left|STFT(n,k)\right|^2+2\,\mathrm{Re}\left\{\sum_{i=1}^{N/2} STFT(n,k+i)STFT^*(n,k-i)\right\} \end{aligned}, \quad (3)$$

gde je sa * označena konjugovano kompleksna vrednost. Poređenjem (2) i (3) uočava se da kod Vignerove raspodele postoji dodatni član koji povećava broj računskih operacija i time povećava složenost ovog algoritma u odnosu na spektrogram.

U cilju postizanja kompromisa između Vignerove raspodele i spektrograma, uz iskorišćenje prednosti koje daje Vignerova raspodela u smislu predstave signala i smanjenja računarske složenosti što je karakteristika spektrograma, predložen je S-metod, koji se definiše kao [18]:

$$SM_L(n,k)=\sum_{i=-L}^{L} STFT(n,k+i)STFT^*(n,k-i), \quad (4)$$

gde je L frekvencijska dužina prozora. Za slučaj kada je $L=0$, S-metod predstavlja spektrogram, dok je za slučaj kada je $L=N/2$, S-metod zapravo pseudo Vignerova raspodela [17].

III. ANALIZA SPEKTRA KORIŠĆENJEM VREMENSKO-FREKVENCIJSKIH METODA

U ovom istraživanju predložena je analiza spektra kognitivnog radija. Analiza spektra izvršena je na osnovu dve hipoteze:

$$\begin{aligned} H_0&: y[n]=z[n], n=1,...,N \\ H_1&: y[n]=x[n]+z[n], n=1,...,N \end{aligned}, \quad (5)$$

gde je $y[n]$ signal čiji se spektar analizira, $x[n]$ je signal primarnog korisnika, dok je $z[n]$ aditivni beli Gausov šum. Hipoteza H_0 je tačna kada u analiziranom spektru nema prisustva signala primarnog korisnika, dok je hipoteza H_1 tačna kada postoji primarni signal.

Analiza spektra se sprovodi kroz sledeće korake:

1. realizacija vremensko-frekvencijske analize spektra korišćenjem neke od opisanih metoda (spektrogram, S-metod za $L=2$ i pseudo Vigner-Vilova raspodela),
2. poređenje amplituda spektralnih komponenti sa pragom detekcije u svakom vremenskom binu i
3. donošenje odluke da li postoji primarni signal u određenom vremenskom intervalu i ako postoji koji deo spektra zauzima.

Analiza efikasnosti rada kognitivnog radija realizovana je kroz verovatnoće ispravne detekcije (P_d), lažnog alarma (P_{fa}) i propuštene detekcije (P_{miss}). Određivanje da li je signal primarnog korisnika ispravno detektovan vršeno je po vremenskim binovima, koji su određeni brojem odbiraka korišćenim za izračunavanje spektra nekom od opisanih vremensko-frekvencijskih metoda. Analiza je sprovedena za slučaj kada se u radio spektru javlja emisija samo jednog primarnog korisnika.

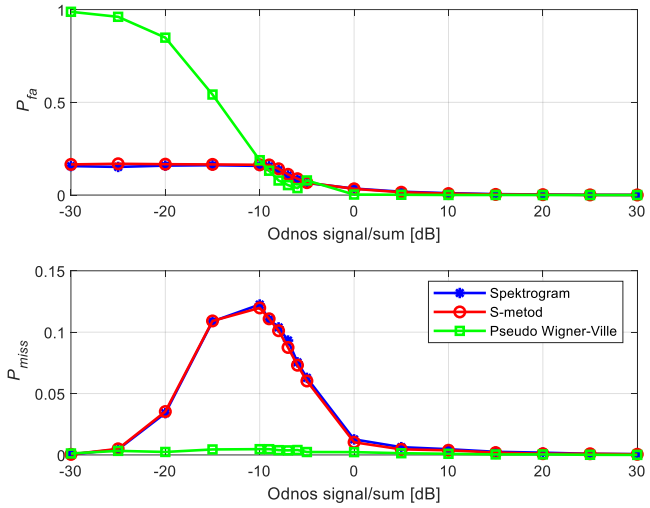
Određivanje definisanih verovatnoća vršena je po vremenskim binovima prema sledećem:

- ukoliko je detektovan signal u frekvencijskom opsegu u kojem je i emitovan, izvršena je uspešna detekcija,
- ukoliko nije detektovan signal kada nije ni bilo emisije, izvršena je uspešna detekcija,
- ukoliko je detektovan signal u nekom frekvencijskom opsegu u kome primarni korisnik nije vršio emisiju, došlo je do pojave lažnog alarma,
- ukoliko primarni signal nije detektovan u opsegu u kome je postajala emisija došlo je do propuštene detekcije,

 ISBN 978-86-7466-930-3

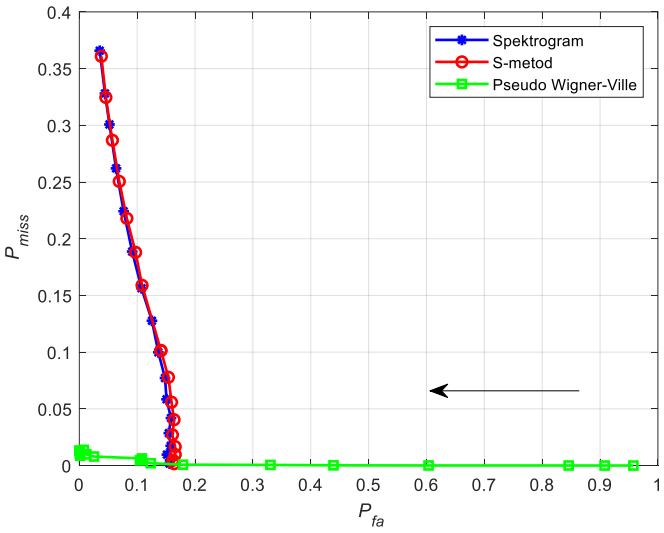
– ukoliko je detektovano više signala, od kojih je jedan signal primarnog korisnika, izvršena je uspešna detekcija,
– ukoliko je detektovano više signala, ali nijedan od njih nije u opsegu gde je emitovan primarni signal, došlo je do propuštene detekcije,
– ukoliko je detektovano više signala, a primarni korisnik nije vršio emisiju, došlo je do pojave lažnog alarma,

Testiranja su vršena Monte-Karlo simulacijama, pri čemu je zbog slučajnog procesa u kanalu izazvanog aditivnim belim Gausovim šumom, postupak ponavljan 100 puta, nakon čega je vršeno usrednjavanje rezultata. Izabran broj ponavljanja testova je u skladu sa [11]. Analizirani su spektri modelovanog signala i spektri realnog signala sa sporim frekvencijskim skakanjem primenom spektrograma, S-metoda za L=2 i pseudo Vigner-Vilove distribucije.



IV. Analiza spektra modelovanog signala

Za potrebe analize razvijen je simulacioni model radio sistema prenosa sa frekvencijskim skakanjem koji predstavlja signal primarnog korisnika. Modelovani sistem koristi opseg od 30-80 MHz sa sporim frekvencijskim skakanjem, tako da se tokom jednog skoka prenosi 50 informacionih simbola. Korišćen je BFSK (*Binary Frequency Shift Keying*) modulacioni postupak. Generisani signal je trajanja nešto više od dve sekunde. Snaga aditivnog belog Gausovog šuma menjana je promenom njegove varijanse.



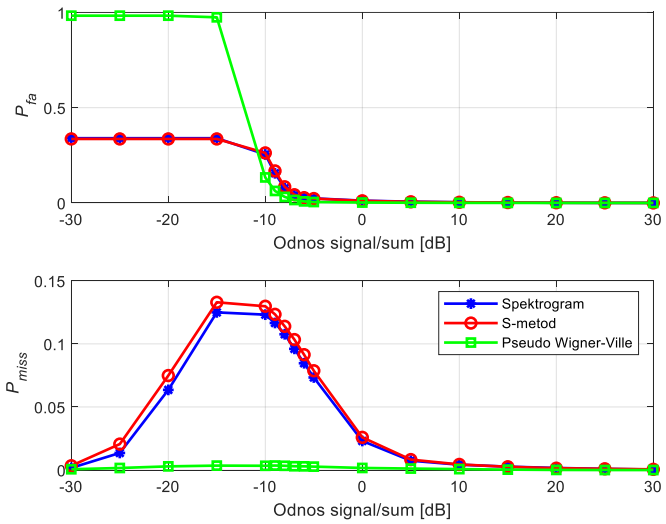
Na Sl. 1 prikazane su verovatnoće lažnog alarma i propuštene detekcije u odnosu na SNR za tri analizirane metode vremensko-frekvencijske analize signala (spektrogram, S-metod za L=2 i pseudo Vigner-Vilova distribucija). Tokom analize, korišćeno je 128 odbiraka (N=128) za potrebe analize spektra sa preklapanjem 50%. Hamingov (*Hamming*) prozor je korišćen. Prag detekcije je postavljen na 50% maksimalne vrednosti snage simuliranog signala primarnog korisnika.

Analizom Sl. 1 se može uočiti da za pozitivne vrednosti SNR gotovo da nema slučajeva propuštene detekcije i lažnog alarma. Smanjenjem SNR, dolazi do porasta verovatnoća lažnog alarma i propuštene detekcije u intervalu od -10 do 0 dB. Kod verovatnoća propuštene detekcije, spektrogram i S-metod imaju rast, a nakon toga, za još niže vrednosti SNR, ponovo pad i vraćanje na vrednosti približno jednake nuli. Kod PWV takođe postoji ovaj rast verovatnoće propuštene detekcije, ali je on zanemarljiv u odnosu na vrednosti dobijene korišćenjem druge dve metode. Pad ovih vrednosti se javlja zbog povećane snage šuma pa je detekcija signala češća, te stoga raste verovatnoća ispravne detekcije. Korišćenjem spektrograma i S-metoda, verovatnoće lažnog alarma za vrednosti SNR niže od -10 dB daju konstantnu vrednost, od oko 0.2. Verovatnoća lažnog alarma kod PWV raste postepeno dok ne dostigne vrednost približno jedinici. Kod PWV, zbog velike rezolucije detektovan je veliki broj spektralnih komponenti šuma, kao i međukomponenti signala primarnog korisnika, pa je verovatnoća lažnog alarma veća nego što je to slučaj kod druge dve metode.

Kako je u otežanim uslovima rada teško svesti verovatnoće lažnog alarma i propuštene detekcije na nulu, sa stanovišta realizacije kognitivnog radija povoljnije je obezbediti veću verovatnoću lažnog alarma u odnosu na verovatnoću propuštene detekcije. Smanjivanjem verovatnoće propuštene detekcije mogućnost ometanja primarnog korisnika svodi se na minimum.

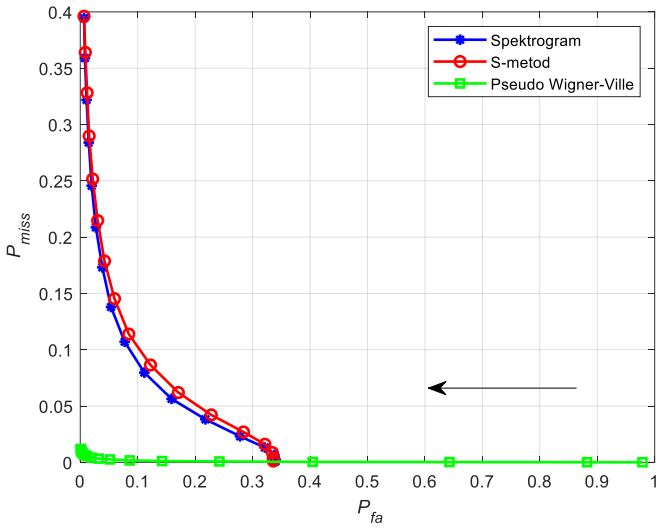
Sl. 1. Verovatnoća lažnog alarma i verovatnoća propuštene detekcije u zavisnosti od odnosa signal/šum kod simuliranog primarnog signala.

Sl. 2. Odnos verovatnoće propuštene detekcije i verovatnoće lažnog alarma za različite vrednosti praga detekcije kod simuliranog primarnog signala.



Na Sl. 2 prikazan je odnos verovatnoće propuštene detekcije u odnosu na verovatnoću lažnog alarma za sve tri analizirane metode vremensko-frekvencijske analize signala. Krive na Sl. 2 dobijene su za konstantnu vrednost SNR od -8 dB i dužinu prozora od 128 odbiraka, sa preklapanjem 50%. Promenom praga detekcije od 10% do 90% maksimalne vrednosti snage primarnog signala menjaju se odnosi verovatnoće lažnog alarma i verovatnoće propuštene detekcije. Vrednost SNR od -8 dB je uzeta jer se u tom

 ISBN 978-86-7466-930-3



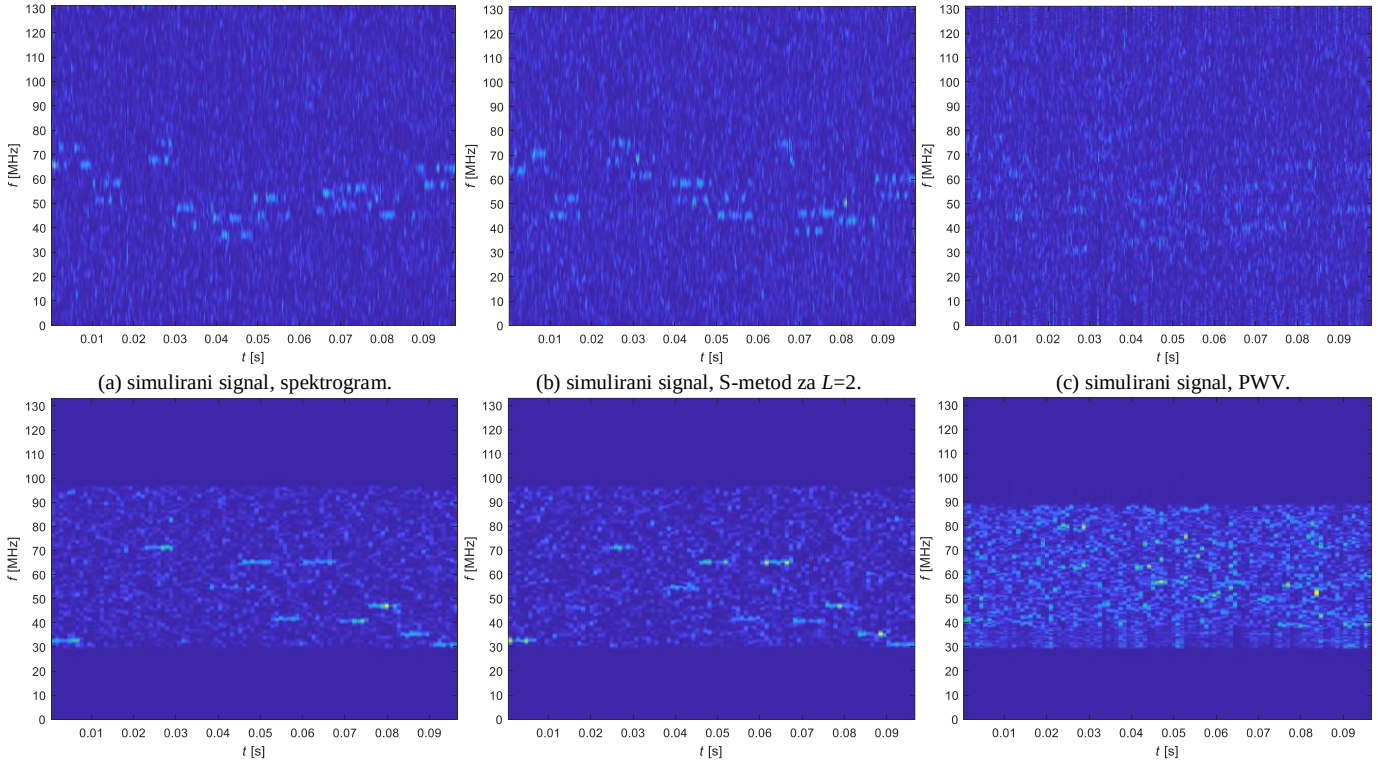
intervalu vrednosti SNR narušava primarni signal dovoljno da se može testirati efikasnost metoda pri radu u otežanim uslovima. Za niske vrednosti praga detekcije, povećava se verovatnoća lažnog alarma, a smanjuje verovatnoća propuštene detekcije i obrnuto. Spektrogram i S-metod su pokazali približno slične rezultate, dok je primenom PWV ostvarena mala verovatnoća propuštene detekcije za različite vrednosti praga detekcije. Ipak, iako PWV ima malo propuštenih detekcija, veliki broj detekcija lažnog alarma onemogućava korišćenje spektra od strane sekundarnih korisnika. Strelica na slici pokazuje smer povećanja praga detekcije.

V. Analiza spektra realnog signala

Testiranje mogućnosti primene vremensko-frekvencijskih metoda analize signala u kognitivnom radiju izvršeno je na realnim signalima iz dostupne baze prikupljenih telekomunikacionih signala [14]. Navedena baza je, prema saznanjima autora, jedina dostupna baza telekomunikacionih signala u razmatranom opsegu učestanosti, a da je pogodna za vremensko-frekvencijsku analizu signala, s obzirom da je primarna namena korišćene baze klasifikacija različitih modulacionih postupaka i tehnika prenosa. Signali su prikupljani pomoću analizatora spektra koji je bio kablom direktno povezan sa radio uređajem kao generatorom signala, čime je pojava šuma prilikom snimanja signala bila smanjena u najvećoj mogućoj meri. U bazi signala postoji nekoliko različitih tipova modulisanih signala, a za potrebe analize u ovom radu korišćeni su samo signali sa frekvencijskim skakanjem. Snimljeni signali su trajanja nešto dužeg od dve sekunde. Radio uređaj je podešen tako da koristi opseg od 30 do 80 MHz za potrebe prenosa frekvencijskim skakanjem. Uređaj koristi 8-CPFSK (*Continuous Phase FSK*) modulaciju. U skladu sa brzinom promene frekvencije nosioca, uređaj podržava samo sporo frekvencijsko skakanje.

Sl. 3. Verovatnoća lažnog alarma i verovatnoća propuštene detekcije u zavisnosti od odnosa signal/šum kod realnog primarnog signala.

Sl. 4. Odnos verovatnoće propuštene detekcije i verovatnoće lažnog alarma za različite vrednosti praga detekcije kod realnog primarnog signala.



Na Sl. 3 su prikazane verovatnoće lažnog alarma i propuštene detekcije u zavisnosti od SNR, gde su korišćeni isti parametri za vremensko-frekvencijske metode kao i kod modelovanih signala. Dobijeni rezultati su veoma slični u odnosu na slučaj analize modelovanih signala prikazanih na Sl. 1. Dobijene vrednosti za verovatnoću propuštene detekcije su gotovo identične u slučaju modelovanih i realnih signala. Kod verovatnoće pojave lažnog alarma, korišćenjem PWV, za više vrednosti SNR u odnosu na modelovani signal, dostiže se verovatnoća bliska jedinici. Spektrogram i S-metod za niske vrednosti SNR dostižu vrednosti verovatnoće lažnog alarma oko 0.4, što je nešto više nego kod modelovanog signala. Na ovu razliku utiče i šum koji se javio tokom snimanja signala.

Sl. 4 ilustruje odnos verovatnoće propuštene detekcije u odnosu na verovatnoću lažnog alarma, za prozor dužine 128 odbiraka uz 50% preklapanja, SNR=-8 dB i za različite vrednosti praga detekcije u istom opsegu kao i kod modelovanih signala. Dobijene krive su veoma slične kao pri analizi modelovanih signala, uz neznatno više vrednosti verovatnoća lažnog alarma i propuštene detekcije u slučajevima primene spektrograma i S-metoda. Primenom PWV ostvarena je mala verovatnoća propuštene detekcije, čime će se postići neometan rad primarnog korisnika. I na ovoj slici strelica pokazuje smer povećanja praga detekcije.

Na Sl. 5 dat je uporedni prikaz vremensko-frekvencijskih distribucija realnih i simuliranih signala. Slike su prikazane za slučaj kada je SNR=-8 dB, prag detekcije postavljen na 50% amplitude primarnog signala, a broj odbiraka za analizu spektra je 128 uz polovinu odbiraka koji se preklapaju u sledećem intervalu analize. Na slikama je prikazan samo deo vremena signala, u trajanju od oko 100 ms, zbog preglednosti. Sa slika se jasnije uočavaju promene frekvencija nakon određenog vremena korišćenjem spektrograma i S-metode, bilo da su u pitanju modelovani ili realni signali, uprkos niskoj vrednosti SNR. Korišćenjem PWV, uprkos većoj rezoluciji, zbog pojave međuspektralnih komponenti, energija signala je rasuta i ne mogu se uočiti tačne frekvencije signala

 ISBN 978-86-7466-930-3

tokom određenih vremenskih perioda. Iz tog razloga je češća pojava lažnih alarma kod PWV nego kod spektrograma i S-metode. Nešto kvalitetnija rezolucija za isti period prikaza signala dobijen je kod modelovanog signala zbog veće frekvencije odabiranja prilikom generisanja signala u odnosu na frekvenciju odabiranja prilikom snimanja realnih signala. Kod modelovanih signala, uočavaju se dve noseće frekvencije u zavisnosti od poslatog simbola, u toku jednog skoka zbog korišćenja BFSK modulacije.

(a) simulirani signal, spektrogram. (b) simulirani signal, S-metod za L=2. (c) simulirani signal, PWV.

(d) realni signal, spektrogram. (e) realni signal, S-metod za L=2. (f) realni signal, PWV.

Sl. 5. Vremensko-frekvencijski prikaz simuliranog i realnog signala za SNR = -8 dB.

VI. Zaključak

U radu je izvršena analiza mogućnosti upotrebe tri metode vremensko-frekvencijske analize signala kognitivnog radija prilikom analize spektra. Za potrebe analize, metode su testirane na modelovanom signalu i snimljenom realnom signalu frekvencijskog skakanja.

Utvrđeno je da dobre performanse za potrebe analize spektra kod kognitivnog radija pokazuje pseudo Vigner-Vil zbog veoma male verovatnoće propuštene detekcije. Ipak, zbog svoje računarske složenosti nije pogodan za implementaciju u sistemima koji za cilj imaju rad u realnom vremenu. Spektrogram je pokazao performanse koje bi bile zadovoljavajuće uz određenu optimizaciju pre svega u broju odbiraka korišćenih za analizu spektra, jer je moguće postići male verovatnoće propuštene detekcije uz male verovatnoće lažnog alarma, čime bi se pored efikasne analize spektra uspešno mogla odvijati i emisija kognitivnog radija. S-metod je metoda koja bi mogla biti dodatno istražena i testirana, radi optimalnog izbora parametra L u cilju dostizanja male verovatnoće propuštene detekcije i male verovatnoće lažnog alarma kod nepovoljnog odnosa signal/šum, čime bi se postigla visoka verovatnoća ispravne detekcije kao kod pseudo Vigner-Vila i što niža računarska efikasnost kao kod spektrograma, što su i ciljevi daljeg istraživanja. Pokazano je da se adekvatnim modelovanjem može realizovati pogodno testno okruženje radi utvrđivanja performansi vremensko-frekvencijskih metoda analize signala.

U budućem radu planirana je implementacija predložene metode analize spektra na hardversku platformu softverski definisanog radija sa akcentom na optimalan izbor parametra L kod S-metode. Dalje unapređenje analize spektra je moguće tako što će se nakon detekcije vršiti analiza karakteristika detektovanog signala sa karakteristikama očekivanog signala u cilju klasifikacije.

Zahvalnica

Ovo istraživanje je deo projekta VA-TT/3/20-22, podržanog od strane Ministarstva odbrane Republike Srbije.

ABSTRACT

The paper analyzes the application of three time-frequency signal analysis methods for spectrum sensing in cognitive radio. The analysis was performed based on simulated and real signals for additive white Gaussian noise of different signal-to-noise ratios. The performance of the methods is analyzed through changes in the signal to noise ratio and the detection threshold, determining the probability of false alarm, the probability of missed detection and the probability of correct detection. It is shown that the methods of time-frequency signal analysis can be efficiently used for spectrum sensing with appropriate parameter optimization.

A Gigabit Ethernet Media Access Controller for TCP/UDP Radar Data Streaming and Visualization

Vukan D. Damnjanović, *Student Member, IEEE*, and Vladimir M. Milovanović, *Senior Member, IEEE*

***Abstract*—A design of a gigabit Ethernet media access controller implemented using Verilog hardware description language is depicted in this paper. The proposed digital hardware module can be utilized for establishing client-server connections over a computer network with a PC, an FPGA-based board or some other separate piece of hardware. It allows users to perform network data transfers using either TCP or UDP communication protocols, in both directions. Data is transmitted to or received from a predefined Internet Protocol address utilizing packets of predefined size, in a format suitable for the corresponding protocol, with a packet header providing the receiving end with the information about the packet itself. The described design is able to achieve network throughput rates that exceed 110 MB/s making it suitable for systems and applications that require high-speed data streaming, such as the system for radar data streaming and PC visualization depicted in the latter part of the paper. Besides that, it can be used in a wide range of applications developed on systems containing boards and devices with the Ethernet 8P8C port as an integral part. The implemented design has been thoroughly tested using a combination of a commercial FPGA development kit and the PC-run Python applications. It was verified and confirmed that the design meets the expectations regarding both the specified functionality and performance.**

***Index Terms*—Gigabit Ethernet MAC, data streaming, UDP and TCP protocols, PC data visualization, Verilog hardware description language.**

I. Introduction

During the last couple of decades, there is a growing trend for the amount of different devices used in the systems and applications in practically all the spheres of the IT industry. The same also applies for the systems used for collecting data, such as some sensor-based systems or radar systems. They are becoming more complex, consisting of more devices with more information needed to be carried. Whether it is because of the insufficient available resources, some environmental limitations, inappropriate system topology or something else, the data-collecting devices are often unable to perform the complete cycle of information extraction, processing and utilization relying only on themselves. Therefore, at some point of the cycle, it is necessary that the data is transferred to another device (or devices) so the system can work properly and fulfill its purpose. In most cases, those devices are PCs, due to their abilities and versatility.

Vukan D. Damnjanović is with the School of Electrical Engineering, University of Belgrade, Bulevar kralja Aleksandra 73, 11120 Belgrade, Serbia and also with NOVELIC d.o.o., Veljka Dugoševića 54/B5, 11060 Belgrade, Serbia (e-mail: vukan.damnjanovic@novelic.com).

Vladimir M. Milovanović is with the Department of Electrical Engineering, Faculty of Engineering, University of Kragujevac, Sestre Janjić 6, 34000 Kragujevac, Serbia (e-mail: vlada@kg.ac.rs).

The need for these data transfers is especially emphasized on the distinguished group of systems - real-time systems, where the information acquirement, extraction and/or presentation is performed constantly at relatively high rate [1]. That implies that the data transfers from one platform to the other needs to be performed in the same manner. The amount of data that needs to be transferred and the transfer rate differ from system to system and can vary significantly, which includes some large numbers as well.

In order to achieve the ability of performing these transfers, a vast number of mechanisms have been developed during the years. They can rely on different technologies and all of them have their advantages and disadvantages. Among the most common and popular ones is definitely Ethernet [2].

Ethernet is, technically speaking, a family of wired computer networking technologies, but it usually refers to the most common type of Local Area Networks (LANs) - a connected network of computers (or, to be more precise, devices) in a small area[1]. Devices possessing the Ethernet port and connected through it to the network are able to perform data transfers with other connected devices by following the series of standardized protocols and rules [3]. Ethernet has been developing and improving during the years. It is currently one of the fastest communication technologies.

Computer networks using Ethernet consists of several abstraction layers [4]. In order for the whole mechanism to work correctly, rules for each one of them have to be applied. Following those rules is often managed by some kind of the processing unit, in devices that poses one, but in ones that do not, such as an FPGA-based board, it might be challenging to achieve the flawless operation of the system. The gigabit Ethernet media access controller from this paper's topic is created so that the Ethernet ports can be utilized for preforming data transfers without engaging any kind of processing unit.

This paper, in its first part, gives the quick overview of the data streaming protocols used in the gigabit Ethernet media access controller module, as well as the detailed description of the module's design, along with the description of its implementation using Verilog Hardware Description Language (HDL). In the second part of the paper, obtained testing results and performances are provided with the example of one of the systems which the module was tailored for in the first place.

[1]Computer networks is a large field in network sciences and a lot could be written about it, but the information provided is sufficient for the comprehension of the content of this paper.

 ISBN 978-86-7466-930-3

II. A Gigabit Ethernet Media Access Controller and Data Transfer Protocols

A gigabit Ethernet media access controller is a digital component which allows the user to perform data transfers between itself and some other module or device. Basically, the implemented module allows the user to send and receive the data to and from the specified address on the network belonging to some other device. In order for it to work properly, the module requires that the Ethernet port along with the gigabit Ethernet transceiver exist on the device. It is used to set up the transceiver for working in the appropriate mode at the beginning of the application and then to send (or receive) data through the Gigabit Media-independent interface (GMII) to the transceiver [5] and through the port to the network and the rest of the system. Data is fragmented and transferred in packets, where every packet is of the same length and consists of a header and data itself.

A. Ethernet Abstraction Layers

Currently, two different versions of this module exist: one that supports transfers (receive and transmit) using Transmission Control Protocol (TCP) [6] and another that supports transfers using User Datagram Protocol (UDP) [7]. Those two protocols are parts of the Ethernet transport layer, one of the abstraction layers mentioned in the previous section. This layer provides the end-to-end communication services for applications. This module also secures that the device is working in accordance with two other abstraction layers: link layer, which provides the link to a physical connection of the host, and internet layer, which serves as a bridge between link and transport layer [4]. The fourth and final layer - application layer, can be implemented on the PC or on some other device.

The controller module implements the network link layer by applying the Address Resolution Protocol (ARP) [8]. It sends a message in the appropriate format that provides the physical MAC address of the Ethernet port when another device on the network asks for it.

The internet layer regulates that every message or packet in the network end up at the appropriate destination. The primary protocols for the internet layer are the Internet Protocol (IP). This protocol assigns an IP address to every device on the network, which allows a packet to find its way to the destination. The implemented module utilizes the IP protocol version 4 (IPv4).

The Ethernet transport layer, as mentioned before, is implemented using either TCP or UDP protocol. This layer provides services to the network, such as connection-oriented communication, reliability, flow control etc.

B. TCP and UDP Protocols

TCP is a more complex protocol than UDP. It is connection-oriented with built-in systems checking for errors and guaranteeing that data will be delivered in the order it was sent. The connection firstly needs to be established, then maintained, and finally terminated, making it a more reliable protocol. All of this, however, requires larger overheads in data packets, which reduces its speed and efficiency. On the other hand, UDP is a simpler, connectionless protocol, faster and more efficient, but it does not provide any recovery options when a data error occurs or when a packet is lost [1].

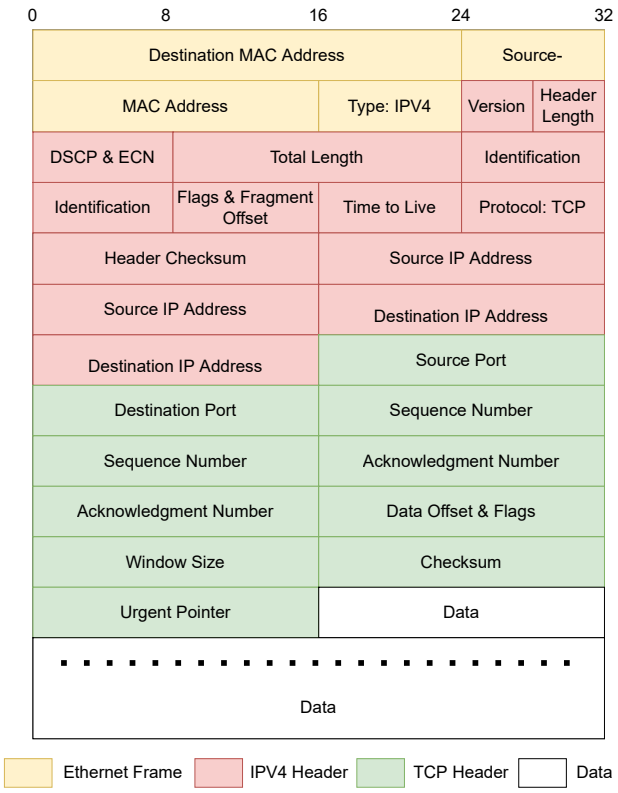

Fig. 1. A structure of data packets of the TCP protocol used in the design.

A structure of data packets of the TCP protocol used in the design is shown in Fig. 1. This type of format allows three network layers to be implemented: the link layer implementation is marked in yellow, the IPv4 header representing the internet layer is marked in red and the TCP header, as a part of the transport layer is marked in green [9]. The link layer carries the information about MAC addresses and the used IP protocol. The IPv4 header has the fields for various information, such as the IP addresses, packet identification number, packet length, header length, used transport layer protocol, the IPv4 header checksum value etc. The TCP header, besides the port numbers, holds the information necessary for establishing, maintaining and terminating the TCP connections, detecting and recovering from errors, flow controlling etc.

The main fields for enabling the TCP to have the connection-oriented communication are sequence number, acknowledgment number, flags and checksum. The sequence number is a 32-bit wide field that carries the number that identifies the first data octet in the packet. The acknowledgment number is also a 32-bit wide field, and it represents a response from the receiving end. It has the value of the next expected sequence number. If the first packet that has

 ISBN 978-86-7466-930-3

arrived had the sequence number of 1 and the N bytes of data have arrived, then the acknowledgment number in the response would be $1 + N$. This mechanism ensures that the order of the received packets is preserved and that there is no packet or data missing. The flag fields have the purpose to indicate that some functionality is being used. There are six flags in total indicating different things: URG - the urgent pointer field is significant, ACK - the acknowledgment number field is significant, PSH - push functionality, RST - reset the connection, SYN - synchronize sequence numbers, FIN - no more data from sender. Basically, to run a TCP connection, only three flags are needed: SYN flag for establishing it, FIN flag for terminating it and ACK flag for acknowledging every received data packet during the connection's life. The checksum field is used for detecting if there is an error in the received data. It has a width of 16 bits, and it is the 16 bit one's complement of the one's complement sum of all 16 bit words in the header and text (only the TCP header and some field of the IPv4 header are included).

In Fig. 2, a diagram that depicts establishing, maintaining and terminating a TCP connection between a client and a server is shown. A client is called a device that initiates the connection and a server is a device that accepts it. Even though it is more usual for the server to send data and for the client to accepts it, it is the other way around in the example shown in Fig. 2. The client initiates the connection by sending a packet with the SYN flag active. The server responds with SYN and ACK flag, which the client acknowledges. At that point, the connection is established. The client then sends N bytes of data in each one of X sent packets, and the server responds for every packet received. Note that it is not necessary for the server to respond to every packet individually. It could also wait for all the packets to arrive and then to acknowledge the reception of them by sending the final acknowledgment number along with the ACK flag. After all the packets are sent, the client expresses the wish to end the communication, which the server accepts and the connection is then terminated.

The UDP data packet structure used in the design is similar to the one used for the TCP protocol. In fact, the only thing that differs is the transport layer protocol header. As mentioned before, the UDP does not provide the possibility of connection-oriented communication, flow control etc. so the UDP header has fewer fields than the TCP header. It only carries the information on the port numbers, packet length and the checksum value. The UDP protocol does not support or require the acknowledgement of the received packets. It straight-forwardly goes to the formation of the following packet, after the previous one has been sent.

III. The Implementation of the Controller

Previously depicted gigabit Ethernet media access controller have been implemented using Verilog HDL. Its design has been thoroughly tested using standard verification and implementation paths for FPGA design flow. The design is made available [10] by the authors for public use as a free and open-source hardware library.

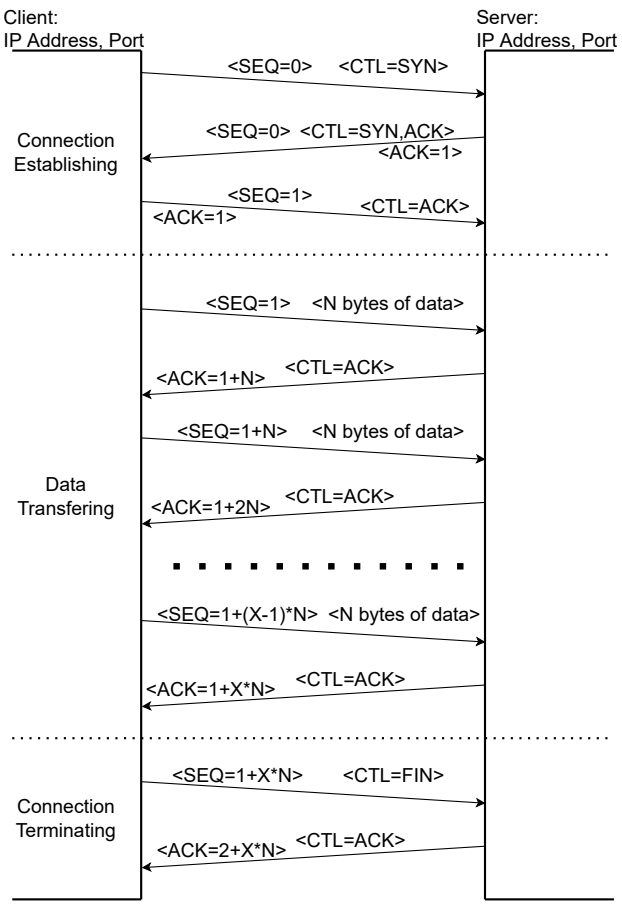

Fig. 2. A diagram that depicts establishing, maintaining and terminating a TCP connection between a client and a server.

The implemented design of the gigabit Ethernet media access controller is relatively complex. It can be divided into several mutually connected submodules, with some of them communicating with the outer world as well, through one of the module interfaces. A block diagram of the module with its submodules and interfaces is depicted in Fig. 3. In this section, descriptions of every individual submodule, implemented interfaces to the outer world and the way the module communicates with other devices will be provided.

A. Design Interfaces

As it can be seen from Fig. 3, the implemented gigabit Ethernet media access controller has four interfaces. The first one is the AXI Stream interface. The purpose of this interface is to continuously collect data needed to be sent between the devices on the network. The direction of the interface can be both input and output, depending on the fact whether the module is receiving data from some other device, or sending it to the network. The second interface of the implemented module is the AXI4 memory-mapped interface. This interface is used to write values to the memory-mapped configuration registers of the controller, as well as to read status values from it. The next interface is the Reduced

 ISBN 978-86-7466-930-3

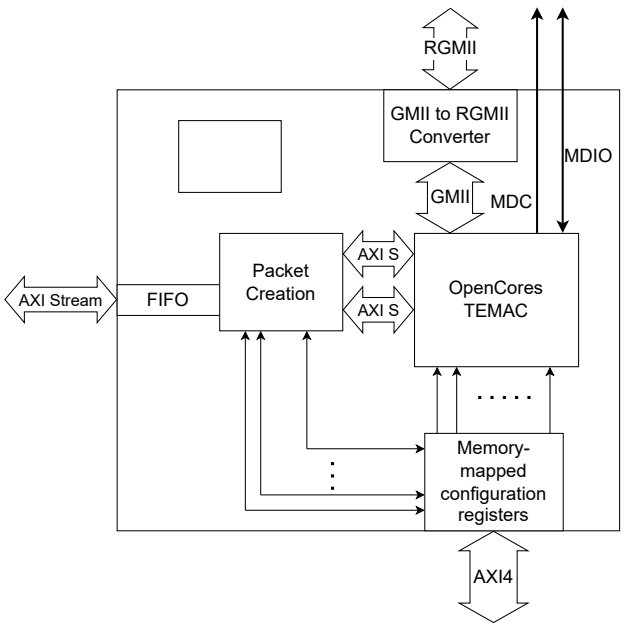

Fig. 3. A block diagram of the implemented module with its submodules and interfaces.

Gigabit Media-independent interface (RGMII), a version of the already mentioned GMII interface. Its role is to communicate with the Ethernet physical layer transceiver that controls the Ethernet port. The last interface is the Serial Management Interface (SMI), also known as Media-Independent Interface Management (MIIM). It is a serial interface used for configuration of the Ethernet physical layer transceivers. In the following paragraphs, the functionality and implementation of every submodule of the controller design will be described.

B. Design Clock Domains

The whole design can be divided into four clock domains. The frequency of the input clock equals 100 MHz, and it drives the clock generator block that creates all other clocks in the module. These four clock domains are the user clock domain, the RGMII physical layer clock domain, the MIIM management interface clock domain and the AXI4 memory-mapped clock domain. The RGMII physical layer clock domain operates at the frequency of 125 MHz, and it is the only mandatory value for all the clock frequencies in the design. The frequency of the MIIM clock domain clock is run-time configurable. Its value depends on the value stored in one of the memory-mapped registers, and it equals the value of the AXI4 memory-mapped clock frequency divided by the register value. The MIIM clock frequency must not exceed 2.5 MHz. The AXI4 memory-mapped clock frequency is the frequency on which the memory-mapped configuration registers and the AXI4 bus operate. It has to be equal to the frequencies of the other memory-mapped devices connected to the bus, and in this version of the design it equals 10 MHz.

C. Design Submodules

The OpenCores Tri-mode Ethernet Media Access Controller (TEMAC) is one of the most important submodules in the design. It is a modified version of an open-source controller downloaded from the OpenCores website [11]. The module has a ”Tri-mode” phrase in its name because, apart from being a gigabit controller, it can also operate as a 100-megabit or 10-megabit. However, in the proposed design, it is utilized solely as a gigabit version. The TEMAC module has several functionalities and five interfaces: an output and an input AXI Stream interfaces, a GMII interface, a MIIM interface and an input interface that provides the module with the memory-mapped register data. Its main function is to convert streaming data-to-be-sent from the input streaming native interface to the output GMII interface and data-to-be-accepted from the input GMII interface to the output streaming native interface. These two native interfaces are converted to the AXI Stream interfaces using the submodule wrapper. For these GMII-to-Stream conversion processes, the module instantiates two dual port block RAMs to serve as asynchronous FIFOs for getting the data from both sides. The finite-state machines (FSMs) control the flow for both directions, from 32-bit streaming data synchronized on the user clock, to 8-bit GMII data synchronized on the GMII clock (or vice versa). The submodule and the exact way it will operate can be set up by reading the input values from the memory-mapped configuration registers. Depending on some of those values, it also generates the MIIM signals for the Ethernet physical layer transceiver configuration.

The GMII to RGMII converter adapts the GMII interface signal to the needed RGMII interface signal. Basically, the RGMII signals are used instead of the GMII signals in order to reduce the number of the occupied output pins. Total number of utilized output pins is halved (12 instead of 24). It is achieved by running half as many data lines at a double speed, time multiplexing the signals and by eliminating non-essential signals. Output pins operate with double data rate (DDR) instead of single data rate (SDR), with the same clocking frequency of 125 MHz. Receiving pins are synchronized to the external clock provided by the Ethernet physical layer transceiver, while transmitting pins are synchronized to the internally generated clock. The clock generating block creates two different 125 MHz clocks with the 90 degrees phase difference, one for the output clock pin itself and the other for the synchronizing of the data and control lines, so that the setup and hold times of the output DDR pins are as large as possible.

The memory-mapped configuration registers module is a submodule whose function is to be accessible from the AXI4 interconnect bus and the rest of the system through the AXI4 memory-mapped interface and to provide the rest of the submodules inside the controller with the written values. It also has a task to inform the OpenCores TEMAC submodule to generate the signals in the MIIM interface. It has numerous registers and here are the most important ones:

 ISBN 978-86-7466-930-3

- `Physical address` - Value of the address of the Ethernet physical layer transceiver.
- `No preamble` - Indicator whether the transmitting packets will have the preamble to precede them.
- `Clock divider` - Value used to calculate the frequency of the MIIM interface clock.
- `Packet size` - Number of bytes in one data packet, can be up to 1500.
- `PHY data` - Data value to be written to one of the Ethernet transceiver registers.
- `PHY register address` - Register address inside the Ethernet transceiver to which data will be written.
- `PHY write enable` - Indicator that a write operation should be performed through the MIIM interface.

The packet creation submodule is responsible for implementing all the network abstraction layers and protocols in the design. This submodule has several tasks in its jurisdiction. It wraps the data arrived from the streaming interfaces with the appropriate header and calculates all the values for the header fields. It also accepts data packages arrived from the network and checks if they are addressed to this module and creates and sends the response if it is needed. IP addresses, MAC addresses and port numbers for both the client and the server side in this design are hard-coded. For both TCP and UDP versions of the module, this submodule always checks if there is an ARP request sent to the network. If the asked IP address is the one belonging to this module and the ARP format of the message is correct, an ARP response packet is created and sent providing the information about this module's MAC address. Creation of the UDP packets is not too complicated, considering that every field of the header except the identification field is a constant value. The packet creation submodule receives the streaming data and forwards it to the OpenCores TEMAC submodule, except for the occasions when the previous packet has ended and when the header fields are needed to be sent. The end of packet is indicated by sending the active high value for the AXI Stream data last signal.

The situation for the TCP version of the design is a bit more complex. The creation of the header is not as straight-forward as in the UDP version, and the communication between the devices on the network is more complicated. The packet creation submodule calculates the value for several fields for every sent packet, such as the sequence and acknowledgment number, checksum value, flags etc. When the application starts, it sends the synchronization request packet, as depicted in Fig. 2. Then it waits for the response and acknowledges it if the response has the appropriate form and values, and starts creating data packets and streaming data. At the end of the application, it waits for the data acknowledgment message, and then it terminates the connection as described in the previous section.

IV. Testing Results and Streaming Radar Data Visualization Example

In this section, the design testing flow will be presented. During these tests, the functionality of the design was verified,

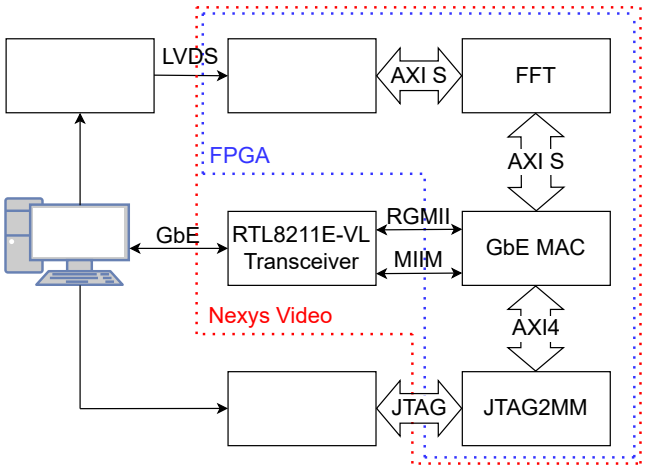

Fig. 4. A simplified block diagram of the complete radar data PC visualization system.

performances and resource utilization were measured, and the design validity is shown as it is used in the example system for radar data visualization. The first step in the design testing flow were the software simulations in the form of the testbench files written in Verilog and VHDL languages.

The next step is the implementation and verification of the design on an FPGA-based development board. A Digilent's Nexys Video board with Xilinx Artix-7 FPGA family is used for it. Nexys Video development board has the Realtek RTL8211E-VL Gigabit Ethernet Transceiver [5] as an integral part of it, making it suitable for the depicted design. For the design testing, some additional features were needed. An open-source JTAG-to-memory-mapped bus master bridge [12] for accessing the memory-mapped register space was used. An alternative for it can be Xilinx's JTAG-to-AXI4 Master module [13]. Write data transactions through AXI4 memory-mapped interface are initiated from the PC using the Python PyFTDI library and the FTDI's cable containing the FT232H chip [14]. Also, a server was run on the PC in order to generate responses for the arrived packets and to send data to the board. For running the server, Socket Python library was used. The arrived packets can be verified by utilizing software for the network packet monitoring, such as Wireshark [15]. Moreover, packets with previously defined data were sent from the board and checked on the PC using Pyhton scripts, therefore proving the correctness of the proposed design. All the examples and testing systems presented in this paper use 1066-byte long packets (52 bytes for the header and 1024 data bytes).

During the hardware implementation testing, data throughput measurements were done. It was proven that the design meets the performance expectations with the maximal data throughput of around 110 MB/s for both TCP and UDP design versions, making it around 90% of theoretically ideal value of 125 MB/s or 1 Gb/s. The resource utilization is moderate, but with less than 10% utilization for all the resource types and with the possibility to reduce it even more.

 ISBN 978-86-7466-930-3

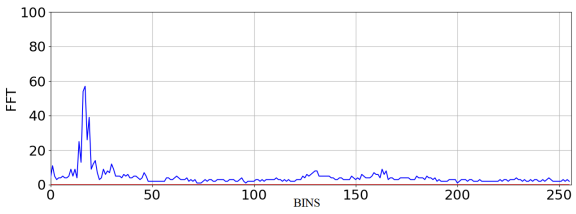

Fig. 5. An example of the radar data plot using Python libraries.

A. Streaming Radar Data Visualization Example

The implemented design of the gigabit Ethernet media access controller, due to the extensive usage of computer networks and its functionality, could find its way into a wide range of different systems. In this subsection, a system for the TCP radar data streaming and PC visualization, one of the mentioned example systems, will be presented.

A simplified block diagram of the radar data visualization system is given in Fig. 4. The system is used to continuously collect data from the radar board, have the incoming streaming data processed (fast Fourier transformation) on the FPGA-based development board, and send it using the gigabit Ethernet to the PC, where the arrived data is plotted. The PC is showing the live display of the distance between the radar board and the detected targets. An example of such a display can be seen in Fig. 5. It should be emphasized that all the processing and data transferring is realized completely in hardware, without involving any kind of processing unit.

For the radar board, Texas Instruments' AWR2243 BOOST [16], along with the MMWAVE-DEVPACK and FMC-ADC-ADAPTER, is chosen. The output is in the form of the Low-Voltage Differential Signaling (LVDS) lines [17] containing radar data, clock and frame clock. Those LVDS lines are connected to the FPGA pins on the Nexys Video board, and they are received and converted to the 32-bit AXI Stream interface. The logic behind this conversion is not relevant for the matter and therefore not elaborated. The AXI Stream data is then driven to the input of the open-source fast Fourier Transformation processor module [18] available to simultaneously perform the processing and stream the output data to the gigabit Ethernet media access controller from the topic of this paper. The TCP packets are created there and sent to the PC through the gigabit Ethernet, where there is a Python script running the server and receiving and plotting data acquired from the Ethernet port using the Python's Matplotlib library. The radar board is previously configured using the MMWAVE Studio software [17] for the PC and the USB interface, as is the gigabit Ethernet MAC module using the JTAG-to-memory-mapped bus master bridge, depicted in the previous section.

V. Conclusion

In this paper, a design of the gigabit Ethernet media access controller for the UDP and TCP data streaming implemented using Verilog HDL is proposed. This module can be used in a wide range of different systems, due to the nowadays' constant presence of the computer networks in many industrial spheres. One of those systems, or the system for the processed radar data PC visualization to be more precise, is depicted in this paper as well.

The generated instances of the JTAG to memory-mapped bus master bridge were tested and verified by both using software simulations and mapping onto a commercial FPGA development board, proving the correct functionality of the design. The hardware implementation also proved the competitiveness of the design in terms of performances, having the data throughput of over 110 MB/s.

It should be noted that this is only the first version of the design, and there is still a lot of space for improvement and for broadening the functionality of the module. Making it more parameterizable, completely run-time configurable, having better mechanisms to recover from data loss or error etc. are just some of the things that could be and hopefully will be improved in some future versions.

ANN model for one day ahead Covid-19 prediction

Jelena Milojković, Miljana Milić, and Vančo Litovski

Abstract— **One-day-ahead prediction of number of COVID-19 infected patients is presented in this paper. The study is relying on the data available in [1]. A model of artificial neural network (ANN) was developed and used with only the most recent data taken into account. We believe that only a few data from the near past is important for this type of prediction. ANNs have been proven as a very reliable method for the real time prediction systems. In our previous work in prediction electricity consumption [2] and traffic prediction [3], we obtained small prediction error. That encouraged us to conduct the research described in this work. The absence of the trend and the seasonal component in the given time series, made the prediction task more difficult. However, we have obtained good results, which could encourage the application of the model in health management to make better decision in control and prevention of the occurrence of a pandemic.**

***Index Terms*—Covid-19, number of infected, artificial neural network, short-term prediction.**

I. Introduction

Global pandemic, named COVID-19, created his first wave of infection in China in the Wuhan province [4]. It has started in December 19 and continued to the present days. By the World Health Organization (WHO), the virus has affected populations worldwide, and its rapid spread is a universal concern. The high rate of spread as well as the high chance of transmission is still not effective, even with engaging all recommended prevention and implemented control strategies (isolation, detection tests and prophylactic measures). They still have limited effect in preventing or stopping the spread of the virus worldwide [5]. Since its first reporting at the end of December 2019. until 28.04.2022, over 508 million people have been infected, around 500 million people recovered, and 6 227 291 people died due to pandemic [6]. Basic and most important fact of COVID-19 is that it is spreading rapidly by a human-to-human transmission; where about 20% infected subjects are without symptom. The main characteristics of COVID-19 pandemics are high infection rate, incubation period, patients to be contagious during the incubation period, and symptomatic infection [7]. The elderly people and those who have weakened immune systems as well as people with special health conditions such as cancer, hypertension, severe asthma, cardiovascular disease, lung conditions, heart disease, diabetes, neurological conditions, HIV/AIDS infection, pregnancy and high weight are more vulnerable to the serious effects of this pandemic [8]. Based on this we can conclude that a global pandemic like Covid-19 has a high negative impact on the population health, social–cultural activities and global economy [9]. For this reason, it is necessary to develop models to predict the course of events during a pandemic outbreak. In our paper, we used ANN adapted to predict the number of infected on a daily basis. The developed model will help decision-makers, doctors and medical assistants to prepare and understand the magnitude of the risk and take appropriate measures to prevent major leaps. Forecasting tools can also help to assess the extent of risk in a timely manner and make the necessary preparations.

According to the research in the field of Covid-19 prediction by statistical methods, in order to achieve a satisfactory prediction, a basic prediction period of several hundred samples must be used [10, 11]. In the case when we have a set of data of several dozen samples, then time series is presented as a set of trends, random and seasonal components; these models also have a very limited number of parameters. In some cases, even some time series with a striking trend and seasonal component can be predicted with a smaller base period [12]. Actually, the amount of data available in this case is large enough to apply any other prediction method [13, 14, 15], but looking at a diagram curve representing the number of infected patients in one year, we easily recognize that past values of the infected patients are not very helpful when prediction is considered. Accordingly, we propose the problem of prediction of the infected case number in the next day to be performed as a deterministic prediction based on very short time series.

II. Previous related work

The research in Covid -19 pandemic related with infected case number we describe here is based on our previous results in development and the application of ANN.

In our paper [16] we can see the evaluation of the idea about ANN structures dedicated to short term prediction. First, we will here briefly illustrate the development of two complex ANN structures, which started with a simple one-input-one-output feed-forward ANN.

We first got involved in the ANN based prediction when solving a problem of electronic waste management in Serbia [17]. It came out that there was no systematic way of forecasting the amount of electronic waste to be found in the literature. The main reason for that was the lack of data for a longer period in the past. That inspired us to start with the

Jelena Milojković, Miljana Milić and Vančo Litovski are with the Faculty of Electronic Engineering, University of Niš, Aleksandra Medvedeva 14, 18000 Niš, Serbia (e-mail: jelena.milojkovic@elfak.ni.ac.rs, miljana.milic@elfak.ni.ac.rs, vanco.litovski@elfak.ni.ac.rs).

 ISBN 978-86-7466-930-3

implementation of ANNs that are known as universal approximators. Namely, by using the ANN for approximation of a function represented by a set of equidistantly taken samples one automatically solves one of the biggest problems in approximation: the choice of the approximating function. Furthermore, ANNs are known as very successful interpolators which is frequently defined as a generalization property of ANNs. One had to investigate if ANNs could also extrapolate.

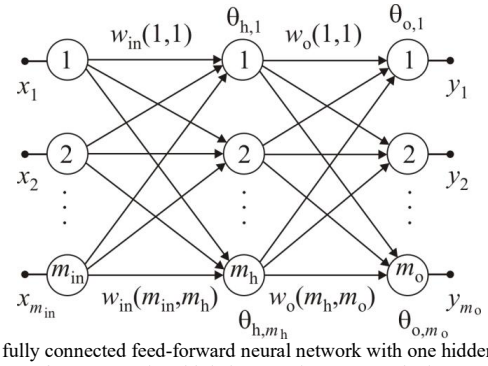

Fig.1. A fully connected feed-forward neural network with one hidden layer of neurons and multiple input and output terminals

This research was conducted in [18]. One fully connected feed-forward neural network is depicted in Fig. 1. To predict the amounts of electronic waste we have implemented a feed-forward ANN, named feed-forward accommodated for prediction - FFAP. The efficiency and good accuracy of the FFAP network inspired us to enter the problem of prediction for consumption of electrical power. There we were confronted with two types of periodicity (daily and weekly) where we have created new structure named Extended FFAP - EFFAP [19].

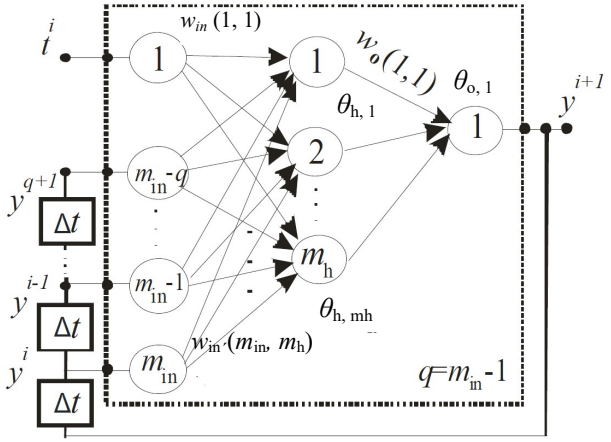

Fig. 2. Time controlled recurrent ANN - TCR

To improve the performance of the ordinary feed-forward ANN, in [20], we examined the capacities of time delayed ANN and evolved to a time controlled recurrent – (TCR) neural network depicted in Fig. 2. The prediction results obtained by the TCR ANN were equally good as those obtained by the FFAP ANN. That was confirmed in its application of prediction in microelectronics [21]. Using similar procedure to FFAP, we have formed a new structure named ETCR (Fig. 3). Two such ANN models we have also applied for prediction of electric power consumption and traffic [2, 3, 22].

III The Method

The basic neural network structure is shown in Fig. 1. It was proven that only one hidden can be sufficient for prediction problem [23] that is the subject of this research. In this figure input layer is denoted with "in", hidden layer with "h", and output layer with "o". The set of weights, $w(k, l)$, connects the input and the hidden layer, where we have: k=1,2,..., m_{in}, l=1,2,..., m_h, while for the set that connects the hidden and output layer we have: k=1,2,...m_h, l=1,2,..., m_o. The threshold levels θ, are here designated with $\theta_{x,r}$, (r= 1, 2, …, m_h or r= 1, 2, …, m_o), with x standing for "h" for hidden or "o" for the output layer. The input layer neurons are only delivering the signals, and the hidden layer neurons are activated by a sigmoidal activation (logistic) function. At the end, the output layer neurons have a linear activation function. A variant of the steepest-descent minimization algorithm is applied during the ANN training [24].

To obtain the number of hidden neurons, m_h, a procedure based on proceedings given in [25] is applied. In prediction of time series, in that case, a samples dataset is available (acquired in every two hours) which means that only one input signal is enough, and that is the discretized time. According to equation (1) only one output value is predicted at a time, which means that only one output is required, too. Network's output signals are consumed average power for a period of two hours.

For the implementation of the architecture in Fig. 1, (one input and one output terminal), the following time series would have to be learned: $(t_i, f(t_i))$, i=1,..., m.

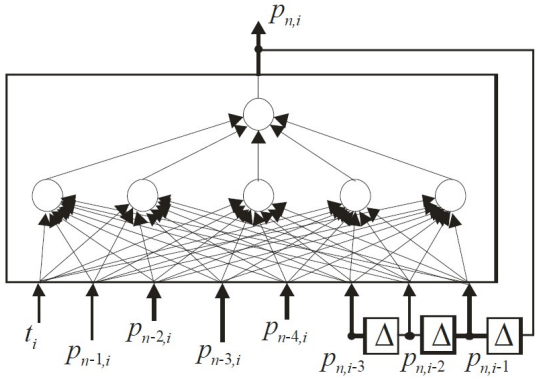

Fig. 3. ETCR. Extended time controlled recurrent ANN

To solve this problem, two new architectures were suggested as the possible solutions. They appeared to be the most convenient for the forecasting problem that is based on the short prediction base period [20]. However, these architectures had to be properly accommodated, due to the availability of data related to previous weeks.

The first network, referred to as a *time controlled recurrent* - TCR, Fig. 2 was derived from the basic time delayed recurrent ANN [26]. The structure has a recurrent architecture

 ISBN 978-86-7466-930-3

where time is the input variable, and it controls the predicted value. This structure is then extended, in order to allow that the values for the power consumption at a given time per day, and the values for the same days in three previous weeks, control the output. Consequently, the word *extended* had to be appended. The final architecture is depicted in Fig. 3, and is referred to as the Extended Time Controlled Recurrent (ETCR) architecture. It would be very useful to use the advantages of the ANNs' generalization property and the efficiency of the recurrent structure. This network learns a set in which the output value is controlled by the present time and its own previous instances of the average power consumption for a two hour period in a given day of the week:

$$p_{n,i}=f(t_i,\ p_{n,i-1},\ p_{n,i-2},\ p_{n,i-3},\ p_{n-1,i},\ p_{n-2,i},\ p_{n-3,i}),\quad i=3,\ \ldots,\ m. \qquad (1)$$

where n stand for the number of the week (in the month or in the year). In that way the values designated with n are from the current week, while the values indexed n-j, j=1,2,3, are from the previous weeks. The designation "i" stands for the i-th sample in the selected day. The actual value $p_{n,i}$ is unknown and should be predicted.

The second architecture is referred to as a *feed forward accommodated for prediction* (FFAP) and is shown in Fig. 4. The idea here was to push the neural network to learning the same data window several times simultaneously but shifted in time. It is expected that the previous responses of the function will have larger impact to the $f(t)$ mapping. The architecture has one input terminal - t_i. The approximation y_{i+1} is obtained at the *future* terminal *Output*3. For multiple-step ahead predictions the future terminal can be considered as a vector. The *present* value y_i is represented at the terminal *Output*2. *Output*1 has to learn the *past* value i.e. y_{i-1}. *Output*1 may also be considered as a vector if we need to control the mapping using a *set* of previous values. The functionality of the network could be expressed as

$$\{y_{i+1},\ y_i,\ y_{i-1},\ y_{i-2}\} = \mathbf{f}\,(t_i)\,, \qquad i=3,\ \ldots,m, \qquad (2)$$

where *Output*1={ y_{i-1}, y_{i-2}}. This indicates that one future, one present and two previous responses are to be learned.

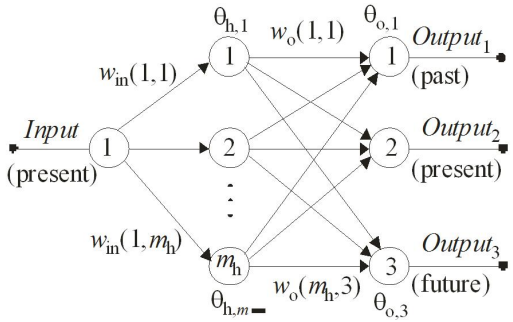

Fig. 4. FFAP. Feed forward ANN structure accommodated for prediction

According to our experience, the FFAP architectures produce more accurate forecasts than the TCR. However, it is a common practice to implement both of them for each forecasting problem and use the results obtained as a reference to each other when choosing the forecast that makes most sense. In this way, we could easily detect and avoid those solutions that represent local minima in the optimization process during the training of the ANN.

In the case of power consumption we have extended the FFAP architecture exactly in the same way as for the TCR architecture. The approximation function could then be written as

$$\{p_{n,i+1},\ p_{n,i},\ p_{n,i-1},\ p_{n,i-2},\ p_{n,i-3}\} = f(t_i,\ p_{n-1,i},\ p_{n-2,i},\ p_{n-3,i},p_{n-4,i})\,,\quad i=4,\ \ldots,m. \qquad (3)$$

The obtained network can estimate the future (unknown) values $p_{n,i+1}$, using the data for:

- the actual time t_i,
- the actual consumption $p_{n,i}$,
- the past consumption values for the given day in n–th week ($p_{n,i-k}$, k=1,2,3),
- and the past consumption values for the same day and actual time of the previous weeks ($p_{n-j,i}$, j=1,2,3,4).

The new architecture is referred to as an *extended feed forward accommodated for prediction* (EFFAP), and is shown Fig. 5.

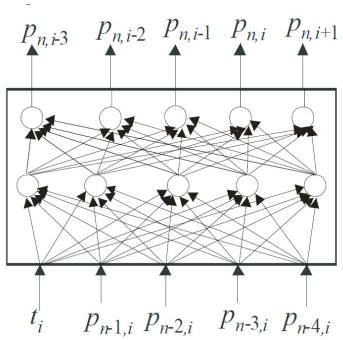

Fig. 5. EFFAP. Extended feed-forward accommodated for prediction ANN

IV. Main Results

Having in mind the nature of the available data we have decided to implement the ETCR structure. A network with 6 hidden neurons was used while 8 previous samples were exploited for prediction.

The procedure could be described with the following steps. Having in mind the random choice of the initial values of the ANN's parameter for training, and the fact that for every such a choice local minima are reached after convergence, we have decided to repeat the prediction for every new day ten times. In that way 10 potential predictions were produced. Then, in order to make a better choice, those with a value above 80% and below 20% of the average were discarded. The final accepted prediction was the average of the rest.

Fig. 6 depicts the prediction results for a 50 day period in the summer of 2021. As can be seen errors not larger than 5% were obtained. This is in accordance with our previous results and, of course, with our expectations.

 ISBN 978-86-7466-930-3

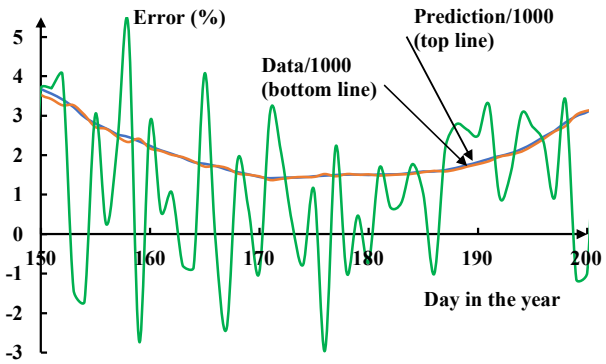

Fig. 6. Prediction results for a 50 day period in the summer of 2021.

V. Conclusion

Based on our 30 years long experience in implementation of ANN in various aspects of technological and social life, we have implemented ANNs for prediction of COVID-19. The results obtained are, in our opinion satisfactory and encouraging for further improvement. That means implementation of other structures as described in the bulk of the paper.

Equivalent Electromechanical Model of a Composite Ultrasonic Transducer

Igor Jovanović and Dragan Mančić

Abstract— **This paper presents an original one-dimensional model of a high-power composite ultrasonic transducer with a new structure. The equivalent circuit method is used for a model that can accurately depict the characteristics of the composite ultrasonic transducer and enable its efficient performance evaluation. The proposed model is verified by comparing the modeled dependencies of input electrical impedance vs. frequency with the experimental results. The equivalent circuit developed in this work can facilitate the design and analysis of complex composite transducer structures.**

Index Terms— **High-power ultrasound, Composite ultrasonic transducer, One-dimensional modeling.**

I. Introduction

The piezoelectric ultrasonic transducer is a device that converts desired electrical signals to ultrasonic waves. The applications of high-intensity ultrasonic waves are based on the adequate exploitation of the non-linear effects associated with high amplitudes, such as the radiation pressure, streaming, cavitation, dislocation in solids, etc. [1].

An ultrasonic transducer is a widely used high-power electromechanical transducer for ultrasonic cleaning, ultrasonic liquid processing, and ultrasonic sonochemistry. There are increasingly needed high-power ultrasonic radiators with large amounts of power radiating surfaces. The development of various power ultrasound applications requires ultrasonic transducers with more significant maximum vibration velocity, energy efficiency, and lower temperature rise [2]. Ultrasonic transducer, which consists of piezoceramic and metal rings, has a low resonant frequency (considering the size of the transducer) and a high-quality factor.

Recent research in the field of powerful ultrasound aims to optimize the design of ultrasonic transducers by numerical and analytical modeling methods and the use of precise devices for measuring vibration, mechanical displacement, and stress [3].

The finite element method (FEM) has been a commonly used numerical modeling method to analyze acoustic characteristics of ultrasonic transducers. As a representative work on the use of the FEM, Kagawa and Yambuchi used this method to assess the effect of dimension and material on the resonance frequency of an ultrasonic transducer [4]. In [5], the finite element technique is used for polymer characterization. Wang et al. used FEM to evaluate the output displacement directions of a composite transducer [6]. In addition, FEM is used to evaluate the effect of structural parameters on the output displacement of an ultrasonic transducer [7]. Lin et al. used FEM to evaluate the composite transducer's radial radiation acoustic field distribution [8].

The need for extensive computing resources and long analysis time constitutes the main disadvantage of the FEM [9]. The FEM typically requires a long analysis time and considerable computational resources despite its widespread usage. Therefore, there is a strong need for a more efficient method for analyzing the performance characteristics of the ultrasonic transducer with high accuracy.

The most widely used analytical modeling approach for ultrasonic transducers found in literature is an application of one-dimensional theory using equivalent electromechanical circuits [10]. The equivalent circuit is a method that can analyze the acoustic characteristics of transducers more simply and efficiently than the FEM [9]. It has been utilized to design and analyze various transducers [11].

In their simplest form, ultrasonic transducers are represented by one-dimensional models that represent networks with one electrical and two mechanical approaches. However, when the modeling considers the influence of other parameters (influence of bolt, electrodes, insulators, various electrical connections, prestress, loads, power, etc.) of the transducer, there is an increase in the number of electrical and mechanical approaches in the electromechanical equivalent circuit [10]. Additionally, in the [12], it has been confirmed that using equivalent electromechanical circuits is still possible to model more complex transducer constructions with reasonable accuracy.

Therefore, the composite transducer with a new structure, analyzed in this paper, is presented in the simplest form as a network with two electrical and two mechanical approaches.

II. Analytical One-Dimensional Modelling of Composite Transducer

A new structure of the composite transducer is shown in Fig. 1(a). The composite transducer contains a central mass (2) placed between the two active layers of the transducer ($PZT_{1,2}$ and $PZT_{3,4}$) and two metal endings (1 and 3) connected to the central mass by two central bolts.

 ISBN 978-86-7466-930-3

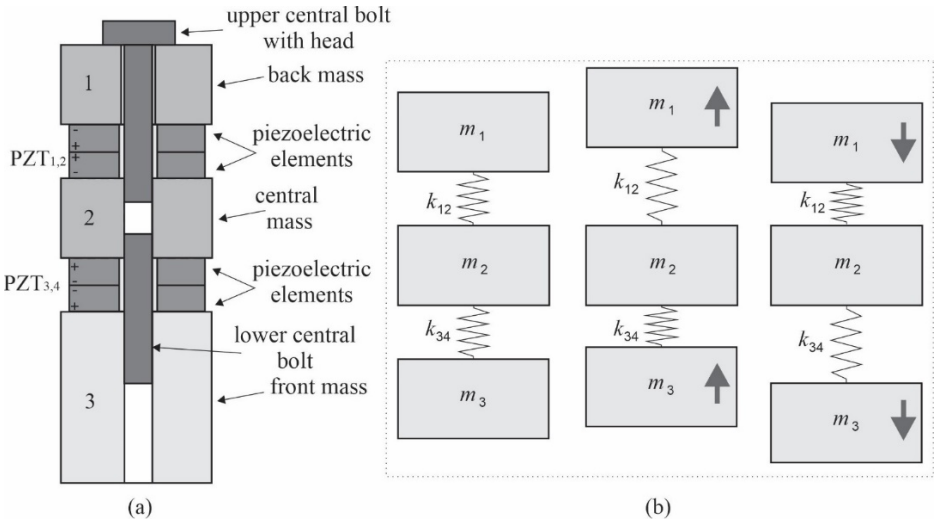

Fig. 1. The composite transducer with a new structure (a), represents of the simplest oscillatory structure of composite transducer (b).

Due to the mutually opposite polarization of the active piezoelectric elements connected to the same power supply, the masses in such a construction oscillates in the manner shown in Fig. 1(b). The three masses constituting this system are m_1, m_2, and m_3 (it is assumed in Fig. 1(b) that the masses are equal to each other), while k_{12} and k_{13} are the stiffness constant.

In its simplest form, the proposed composite transducer is a simple mechanical combination of two half-wave ultrasonic transducers with a sandwich structure that oscillates in the thickness direction (two Langevin-type transducers) [13].

Since the metal endings in the proposed structure are not of the same material, the composite transducer is not bidirectional. The proposed composite transducer has greater flexibility in operation than conventional transducers, which is reflected, among other things, in the possibility of independent excitation of the upper and lower active layer with different signals.

In this paper, modelling of the realized composite transducer with new structure, which represents a special unidirectional composite ultrasonic transducer, is performed. Prestressing the structure is achieved using two central bolts that are in contact with the central mass. The proposed model was adapted based on the structures of the composite transducer and shown as an equivalent electromechanical circuit shown in Fig. 2.

Elements of electromechanical circuits corresponding to isotropic and asymmetric metal parts made of different materials are calculated as:

$$Z_{i1} = jZ_{ci}tg\frac{k_i l_i}{2} \tag{1}$$

$$Z_{i2} = \frac{-jZ_{ci}}{\sin(k_i l_i)} \tag{2}$$

wherein $Z_{ci}=\rho_i v_i P_i$ and $k_i=\omega/v_i$ (for i=1, 2, and 3) are characteristic impedances and the corresponding wave numbers. ρ_i are densities, l_i and P_i are lengths and surface areas of the cross-sections, and v_i are the velocities of longitudinal ultrasonic waves propagation through the corresponding elements.

Elements of the circuit shown in Fig. 2 correspond to the piezoceramic rings in the upper active layer (PZT_{12}), and the piezoceramic rings in the lower active layer (PZT_{34}). These elements are determined as:

$$Z_{p1} = jZ_{cp}tg\frac{nk_p l_p}{2} \tag{3}$$

$$Z_{p2} = \frac{-jZ_{cp}}{\sin(nk_p l_p)} \tag{4}$$

wherein $Z_{cp}=\rho_p v_p P_p$ and $k_p=\omega/v_p$ are characteristic impedances and corresponding wave numbers, respectively. ρ_p, l_p, P_p are densities, lengths, and surface areas of the piezoceramic cross-sections, v_p are velocities of longitudinal ultrasonic waves propagation, respectively. The input electric voltages and currents are marked as V, I_{12}, and I_{34}.

The piezoceramic models consist of capacitance $C_0=n\varepsilon_{33}{}^S P_p/l_p$, and ideal transformers with transmission ratios $N=h_{33}C_0/n$, wherein n is the number of piezoceramic rings per active layer (n=2). The piezoelectric properties of the transducer active layers are represented by the piezoelectric constant h_{33} and the relative dielectric constant of the pressed ceramic $\varepsilon_{33}{}^S$.

Piezoceramic rings are mechanically connected in series with central mass, back and front endings. Back and front endings are closed with acoustic impedances Z_R and Z_E, which are in this case negligible because experimental measurements were conducted with unloaded transducers oscillating in the air.

 ISBN 978-86-7466-930-3

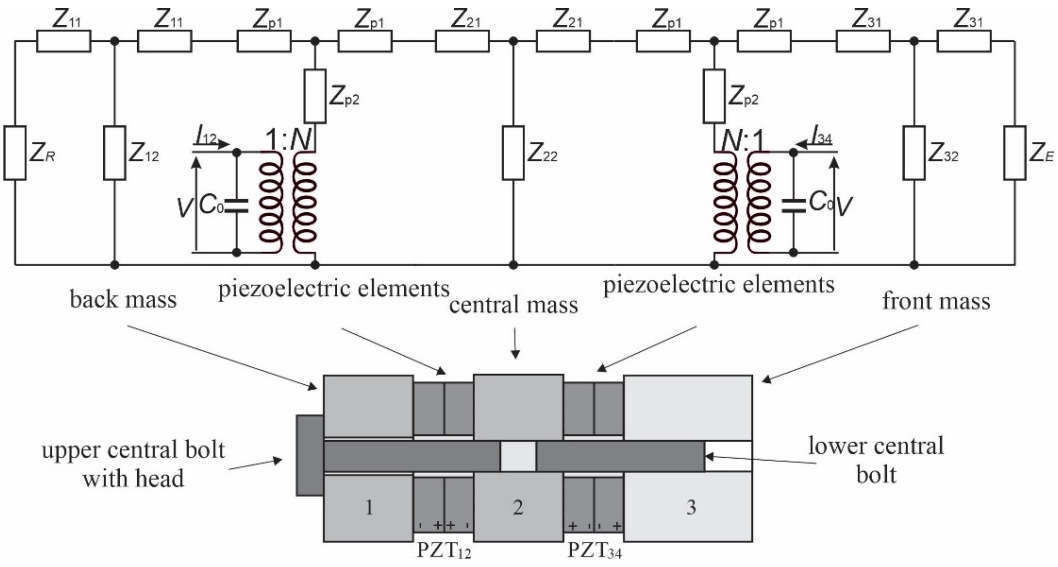

Fig. 2. One-dimensional model of the composite transducer.

Based on Eqs. (1-4) it is obvious that the transducer frequency response depends on the material characteristics of its constituting parts and their geometric dimensions.

In the proposed transducer model, it is assumed that the circuit elements are ideal, i.e. they do not have losses. Losses can be included if piezoelectric constants and constants of elasticity of the transducer metal parts are in the form of complex numbers, in which the imaginary parts represent losses.

III. Simulation and Experimental Results

Table 1 shows the dimensions of the individual composite transducer. Dimensions of the exciting piezoceramic rings are Ø38/Ø13/6.35 mm, and rings are made of PZT8 piezoceramic equivalent material [14]. L_i is the length, a_i and b_i are the outer and inner diameters of the corresponding i-th element. The front ending is made of a dural, while the back ending and the central mass are made of steel with the standard material properties. The electrical impedance measurements are conducted using a Microtest 6366 Precision LCR Meter.

TABLE I
DIMENSIONS OF COMPOSITE TRANSDUCER USED IN EXPERIMENTAL ANALYSIS

Dimension [mm]	Composite transducer
L_1=L_2	11
L_3	37
a_1=a_2=a_3	40
b_1=b_3	9
b_2	8

There is a similarity between the modeled and experimental dependences, as shown in Fig. 2. Since it is a composite transducer with a larger ratio of length and transverse dimensions, the proposed one-dimensional model gives satisfactory results during transducer analysis in the first resonant mode.

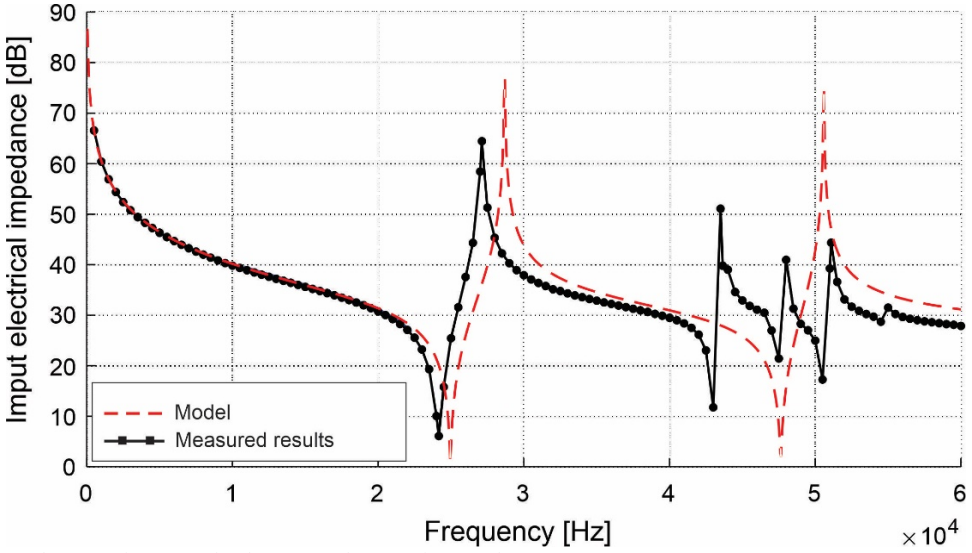

Fig. 3. Input electrical impedance vs. frequency for the proposed composite transducer

 ISBN 978-86-7466-930-3

The measured resonant frequency of the fundamental resonant mode is 24.16 kHz. The calculated resonant frequency using the proposed model is 24.95 kHz, where the error made by the one-dimensional model in determining this resonant frequency is 3.27%. When it comes to the antiresonant frequency, the measured value is 27.12 kHz, while the model calculated 28.7 kHz, i.e., the error made by the model is 5.83%. The proposed model can predict the general shape of the second resonant mode but with significant error. The measured resonant frequency of the second resonant mode is 43 kHz, while the resonant frequency obtained by the model is 47.65 kHz (the error is 10.81%).

This model allows only the thickness resonant modes to be predicted and, therefore, does not consider the inevitable radial resonant modes. One-dimensional models are generally not suitable for determining resonant frequencies of thickness oscillations that are close to resonant frequencies of radial oscillations. In the case shown, when the model does not predict the third and fourth modes, the calculated resonant frequencies for the first two modes are always higher than the measured ones. If a model that considers both the third and fourth modes were used, the first two modes would be moved to lower frequencies.

IV. Conclusion

In this study, an equivalent circuit was developed for accurate analysis of the acoustic characteristics of an ultrasonic transducer over a wide frequency range.

Eqs. (1-4) confirm that the frequency characteristics of transducers in one-dimensional theory depend on the material characteristics of the components of composite transducers and their geometric dimensions.

In practice, one-dimensional modeling is most often used due to the great flexibility and efficient implementation of the model. The flexibility and efficiency of one-dimensional models come to the fore in the analysis of transducers operation, which includes a large number of parameters.

The proposed one-dimensional model of composite transducer does not include mechanical and electrical losses in the material. However, losses can be analyzed if the piezoelectric constants and the elastic constants of the metal parts of the converter are represented in complex numbers, where their imaginary parts represent losses.

Hardware Realization of Nearest Neighbour Search Algorithm over an In-Memory Pre-Stored k-d Tree

Aleksandar Z. Kondić, *Student Member, IEEE*, and Vladimir M. Milovanović, *Senior Member, IEEE*

***Abstract*—Nearest neighbour search is a fundamental statistical classification algorithm with widespread use in artificial intelligence (AI) sub-fields such as machine learning, computer vision, and robotics. Considering the shift in host platforms running AI algorithms from general-purpose computers to specialized hardware implementations, a parameterizable design generator of special purpose hardware instances that perform nearest neighbour search is proposed, captured inside Chisel hardware construction language, and validated on an FPGA platform. Based on an algorithm of nearest neighbour search that traverses a k-dimensional tree pre-stored inside read-only memory (ROM), the generator provides parameters for configuring the structure and volume of the tree and the points stored within it.**

***Index Terms*—Nearest neighbour search, hardware implementation, Chisel hardware construction language, k-dimensional tree.**

I. Introduction

Nearest neighbour search is an algorithm which, for a given input point, finds a point closest to it among a set of points. It is useful for solving classification problems, which are especially prevalent in artificial intelligence (AI) subfields such as machine learning, computer vision [1], and robotics [2].

With artificial intelligence algorithms being increasingly shifted from general-purpose computers to dedicated hardware instances as a consequence of the need for increased computational power [3], various hardware implementations of classic AI algorithms targeting different platforms have appeared. The Nearest Neighbour Search (NNS), along with its variants, the Approximate Nearest Neighbour (ANN) and k-Nearest Neighbours (k-NN) algorithms, are no exceptions.

Considering field programmable gate arrays (FPGAs) as a hardware implementation platform of choice, there are various incarnations of the above mentioned algorithms. They are usually described and implemented either in the form of pure register-transfer level (RTL) [4], [5], high-level synthesis (HLS) [6], [7], or Open Computing Language (OpenCL) [8], [9] code. An alternative to these approaches is to write the behavioral code in an RTL-like form but utilizing a higher level hardware design language instead. One such language is Chisel [10], which is embedded in the Scala programming language, enabling its users to write RTL instance generators while providing benefits of both functional and object-oriented programming paradigms. This paper proposes an implementation of the nearest neighbour search algorithm in Chisel using an agile [11] digital design methodology.

An effective implementation of the nearest neighbour search algorithm should presumably work for a large number of pre-defined points as potential output points for a given input point. For such an implementation to be efficient in terms of resource utilization for a target hardware platform such as FPGA, the points need to be stored inside a memory module. This naturally implies that the digital logic may have access only to a limited number of pre-stored points per clock cycle. Therefore, it is desirable to minimize the number of memory accesses for a given input point while obtaining the correct solution.

This is the same problem that a purely software implementation of a nearest neighbour search algorithm on a processor would have. To minimize the amount of time needed to process an input point, an efficient algorithm with a desirable run-time complexity needs to be chosen. While the simplest solution would be to run an exhaustive search of the entire memory containing pre-defined points to find a point with the minimal distance from the input point—yielding a linear run-time complexity—more efficient algorithms exist.

Similar problems were encountered in the field of computer graphics. In order to ensure the rendering of a scene in a timely manner, it was necessary to retrieve relevant spatial data of the scene efficiently. A technique named *binary space partitioning* (BSP) was developed to solve this problem, mainly implemented through a tree data structure [12]. The technique entails recursively subdividing space into two parts along a hyperplane. When a given point or polygon is queried, the search is performed only in the sub-spaces where it could possibly be located, thus reducing the search domain.

Space partitioning is a general method of subdividing space in a defined manner until a certain condition is satisfied. There are multiple implementations of this method in the form of different tree structures with specific criteria on how a space is divided into sub-spaces and under which conditions. Examples of some tree structures that perform space partitioning are k-d trees, quadtrees, and octrees. Concerning the nearest neighbour search problem, some of the appropriate data structures that can be used are R-trees and k-dimensional trees.

The principal data structure driving this particular implementation of the nearest neighbour search algorithm is the k-dimensional tree, or k-d tree for short. A k-d tree is essentially a binary search tree that contains multi-dimensional points and is traversed based on the value of one of the coordinates of the input point at each node in the tree.

 ISBN 978-86-7466-930-3

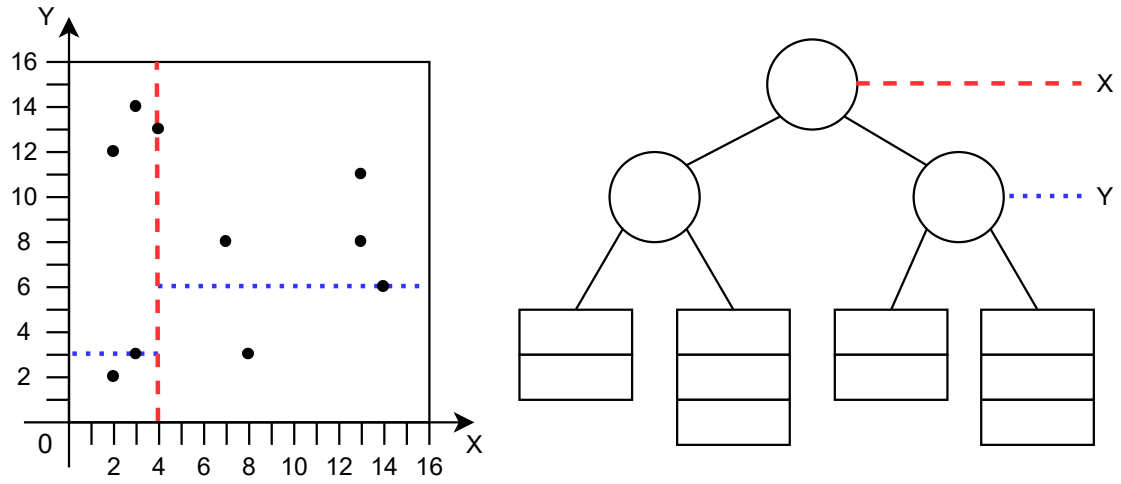

Fig. 1. An illustrative example of a k-dimensional tree (with $k = 2$ to simplify the drawing) and the two-dimensional space partitioning it performs.

Each node of the k-d tree contains a value by which the hyperspace it belongs to is split into two. The dimension in which the split is performed corresponds to the node's depth in the tree, which repetitively cycles from the last dimension to the first when the depth of the node becomes greater than the dimensionality of the points stored inside the tree. All child points that have the value of the coordinate in the corresponding dimension less than the node's stored value are part of the left sub-tree, while the child points with the corresponding coordinate's value greater than the value in the node are part of the right sub-tree. In the case of a child point having an equal corresponding coordinate value to the value of the node—due to the nature of the nearest neighbour search algorithm—it may belong to either of the sub-trees.

The average run-time complexity of the nearest neighbour search algorithm over a k-dimensional tree is $\mathcal{O}(m + \log_2 n)$, where n is the number of nodes in the tree and m is the average number of points contained in a leaf node.

II. A k-D Tree-Based Hardware Implementation

The primary purpose and the use scenario of the proposed implementation is to execute the nearest neighbour search algorithm over a k-dimensional tree. The tree structure, along with the points it contains is assumed to be constructed and stored beforehand inside some form of a read-only memory (ROM). In the case of an FPGA platform the ROM is in the form of a single-port block RAM and mimics the static RAM.

This implementation uses a variant of the k-dimensional tree in which the number of nodes in the tree is not necessarily equal to the number of points. The points are, after a proper traversal through the k-d tree, stored in the leaf nodes. A leaf node may contain more than one point. An example k-dimensional tree of this kind is shown in Fig. 1, along with an illustration of how the tree partitions a two-dimensional space (but in general it can be an arbitrary k-dimensional hyperspace).

The nearest neighbour search algorithm finds the closest point to the query point by first performing a traversal of the k-d tree until reaching a leaf node. When visiting a node, the value of the query point's coordinate in the dimension corresponding to the node's depth is checked against the value in the node. If the value is smaller, traversal proceeds to the left sub-tree. Otherwise, traversal proceeds to the right sub-tree. When reaching a leaf node, all of the points in the leaf node are checked, calculating the distances between them and the query point. The current closest point, along with its distance to the query point, are stored inside dedicated registers which are updated when a closer point is found.

After exhausting all of the points in a leaf node, the search algorithm traverses backwards, that is up the tree and checks if the hypersphere around the current closest point with the radius equal to its distance from the query point intersects the node's splitting hyperplane. If so, a closer point to the query point may exist on the other side of the splitting hyperplane, so the search algorithm proceeds by traversing down the sub-tree contained in the node's unvisited child, until reaching a leaf node again. This process is repeated until the algorithm terminates when it is guaranteed to yield a point stored within the k-dimensional tree with the minimal distance from the query point.

For the purposes of this work, the structure of the k-dimensional tree and the points it contains are stored in two separate memories (or two non-overlapping memory segments). The memory used to store information about the points contains coordinates of each point. The points inside this particular memory (segment) are arranged in such a way that the points belonging to the same leaf node of the k-dimensional tree occupy consecutive memory locations.

Memory containing the tree structure stores the properties of each node. The following properties are stored: an indicator bit of whether the node is a leaf node, the discriminating value stored inside the node for tree traversal (valid only for non-leaf nodes), the starting address in the points ROM and the

 ISBN 978-86-7466-930-3

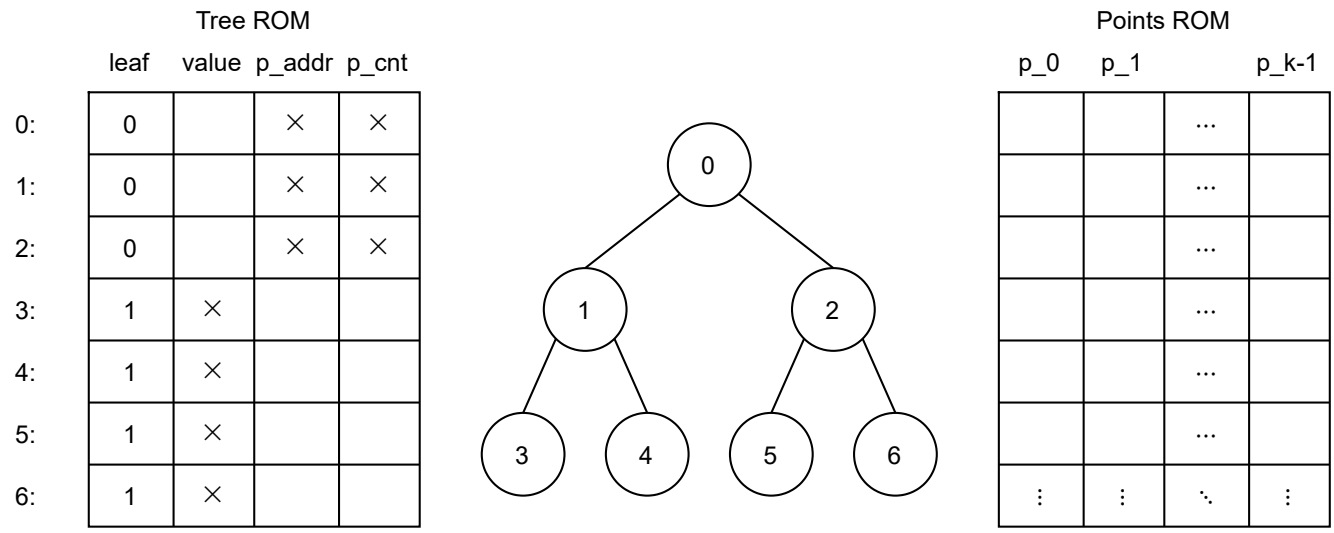

Fig. 2. Memory layout of a k-dimensional tree showing the associated Tree ROM and Points ROM structures over which the NNS realization operates.

number of points contained in the node (valid only for leaf nodes). A node at location n in the tree ROM has its left and right children at locations $2n + 1$ and $2n + 2$, respectively. With this it is assumed that the stored k-d tree is balanced. It is possible to construct a balanced k-d tree from an arbitrary set of points as long as the points with the same coordinate value as the discriminating value in the node may be stored in either of the node's child sub-trees. In particular use cases of interest this discriminating value is actually the median value of relevant coordinates of the points being considered during k-d tree construction. The described memory layout is illustrated in Fig. 2.

The tree traversal algorithm is recursive. Traversal is performed in a depth-first manner, that is similar to the depth-first search algorithm (DFS), which is also recursive. The DFS algorithm, starting at the root of the tree, visits its child nodes in a pre-defined order. When visiting one of the child nodes, another instance of the DFS algorithm is started on the node, running more instances of the DFS algorithm on its children if it has any. Once an instance of the DFS algorithm for one child node terminates, the same process is repeated for the other. Therefore, by the time DFS starts visiting the root node's second child, the entirety of the sub-tree rooted in its first child will have already been explored.

An example of the order of traversal of binary tree nodes in the depth-first search algorithm is shown in Fig. 3. Non-leaf tree nodes are each visited a total of three times in order to visit the subtree rooted in their second child after visiting the first, and to potentially traverse back up to the parent node.

Each non-leaf node's left child is first explored, followed by the right child. The primary characteristic of DFS is that after visiting the leaves, it traverses back up the tree in order to traverse down unvisited sub-trees, repeating this process until the entire tree is explored.

A k-d tree traversal is essentially a variation on DFS tree traversal. The difference with k-d tree traversal is that the order of the children visited depends on the query point for which the closest point is to be found. The left child is first visited if the query point is on the "left" side of the splitting hyperplane represented by the node, otherwise the right child is first visited. Also, if the first child node's closest point is at a distance shorter than or equal to the distance of the query point from the splitting hyperplane, the second child is not explored. Unlike depth-first search, with k-d tree search the entire tree may not necessarily be explored.

A tree traversal over an example k-d tree is illustrated in Fig. 4. The query point for which to find the closest point is $(5, 3)$. In this example, during the traversal three out of the four leaf nodes were visited. The metric used to calculate the distance between two points (or between the query point and a splitting hyperplane) is the squared Euclidean distance.

Software implementations of recursive algorithms may make use of recursive function calls, which are realized on a call stack, or allocate a stack structure specifically to store their data and implement the algorithm as a non-recursive function. In this case only the second option is viable, so the stack data structure is actually implemented as an array of registers. A separate dedicated register is used to store a pointer that keeps track of the position of the top of the stack in the array.

III. Design Generator of the k-d Tree-Based NNS

The previously described accelerator has been implemented as a parameterized RTL design generator in Chisel 3 hardware construction language. The generator has been extensively tested by following standard Chisel verification and implementation paths for FPGA design workflows. As a hardware library it is freely available for public use [13]. The next few paragraphs are elaborating on different generator parameters, as well as modes of operation of the module.

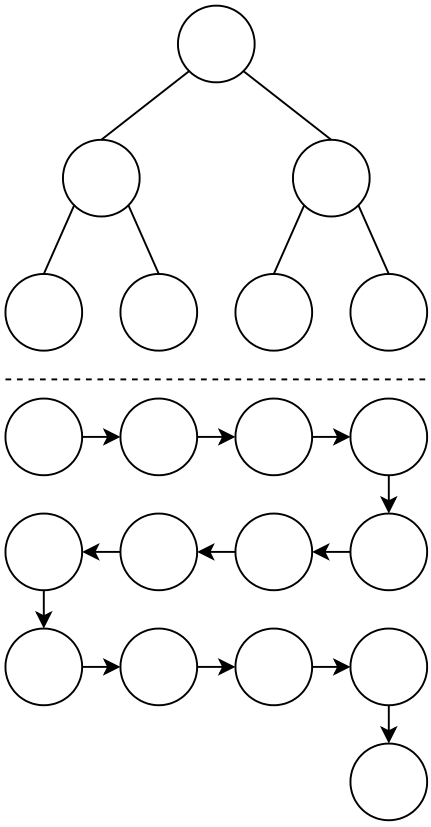

Fig. 3. An example of the order of nodes traversed in a binary tree using depth-first search.

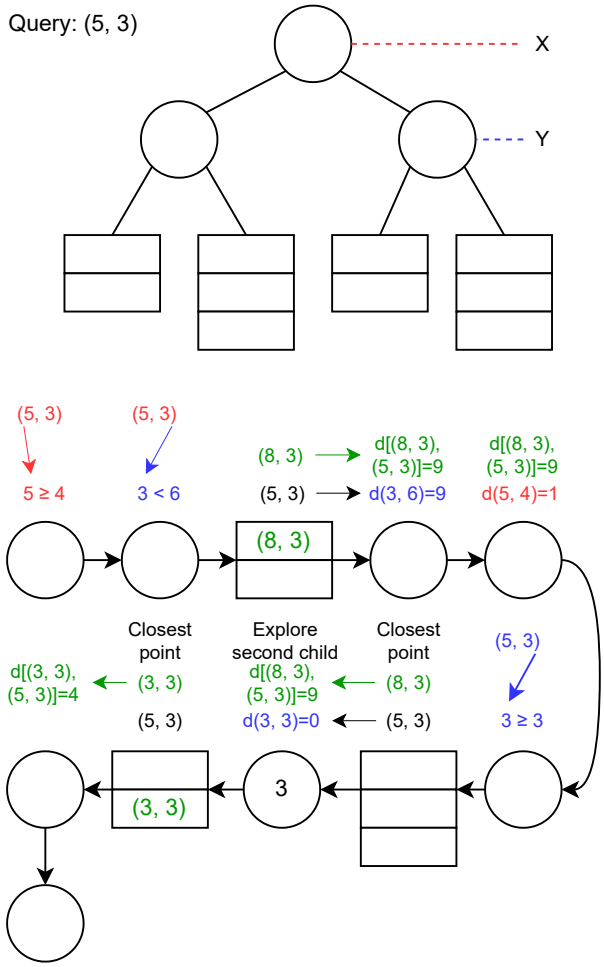

Fig. 4. An example of the order of nodes traversed in a k-d tree when finding the closest point to the query point $(5, 3)$.

A. Generator Parameters

Parameterizable properties of the design pertain mainly to the structure of the k-dimensional tree itself and its points.

The values of point coordinates are signed integers with a specified bit width, which is one of the parameters of the design generator. Another generator parameter is the number of dimensions of each point. The total size of the points ROM is inferred from the bit width of its unsigned integer addresses, which is specified as a yet another generator parameter. These three parameters make up the structure of the points ROM.

Concerning the structure of the tree ROM, each location contains one bit indicating whether the node is a leaf, a signed integer representing the discriminator value of a node (in our use cases referred to as the *median*), and two unsigned integers representing the location and count of points inside the points ROM. The bit width of the discriminator is the same as the bit width of the points' individual coordinates, while the bit width of the location and count of points is the same as the bit width of the addresses in the points ROM. The size of the tree ROM, along with the bit width of its addresses is inferred from a generator parameter specifying the maximum depth of the tree. The number of nodes in the tree may be arbitrary though, as the nearest neighbour search algorithm assumes that nodes marked as leaves in the tree ROM do not have children.

B. Modes of Operation

To keep track of the nodes visited for the purposes of traversing back up the tree after visiting a leaf node, a stack structure is implemented as an array of registers. Three distinct values are pushed onto the top of the stack to aid with the execution of k-d tree search:

- *Address of the node in tree ROM* – this is the main piece of data used to keep track which tree node to visit next.
- *The child of the node to visit next* – a single bit that determines whether to visit the first or the second child of the node during tree traversal. A value of 0 corresponds to visiting the first child, while a value of 1 corresponds to visiting the second child. When the value is 1, first the distance of the current closest point to the query point is compared to the distance of the query point to the splitting hyperplane of the node (the median value of the node in this case). If the distance of the closest point to the query point is not greater, the second child is not visited.
  Since after visiting the second child of a node there is nothing left to process, the current node visited is popped from the stack before the second child node is pushed

 ISBN 978-86-7466-930-3

onto the stack. More precisely, the value at the top of the stack, which currently contains data about the current node being visited, is simply replaced with the data of its second child. In case the second child node is not to be visited, the current node is popped from the stack.

- *The depth of the node in the tree* – This information is used for calculating the distance of the current closest point from the splitting hyperplane. The value of the depth directly maps to which coordinate of the current closest point to compare to the stored node median and is also used to determine the coordinate of the query point to compare to the median value during tree traversal.
  While the depth of the node can be calculated from its index (memory address) in the tree ROM, it is simpler to just push onto the stack the current depth value of the node incremented by one when pushing child nodes. The depth value does not exceed the dimensionality of the points in the tree as it cycles between 0 and $k-1$.

Since the first node to process when a new query point is given is always the root of the tree (address 0 in tree ROM), whose depth is 0, and the next node to process is always its first child, the stack is always initialized to contain these values as the sole element of the stack before processing a new point.

At each clock cycle, the values at the top of the stack are retrieved, which mostly determine the mode of operation of the module. The relevant modes of operation are as follows:

- *Leaf processing* – this mode is active when the indicator for whether the current node is a leaf has the value 1. The values at the top of the stack are not used in this case. At each clock cycle, a counter indicating how many points were visited in the points ROM is incremented until reaching the value in tree ROM that indicates how many points a leaf node has. After that, the counter is reset to 0 and the current node is popped off the stack.
  The value of the counter is added to the starting address of the node's points in the points ROM, yielding an address of each point to be retrieved from the points ROM. The distance of each point is compared to the current minimal distance from the query point. In case it is smaller, both registers containing the closest point and its distance from the query point are updated accordingly.
  Since there is a delay of a few clock cycles due to memory access in the points ROM and distance calculations using registers to decrease the length of logic paths, once the points counter is set to 0, a "delay" counter is also initialized to 2. Each clock cycle the value of this counter is decremented until it reaches 0, regardless of the mode of operation. The module may not produce a valid result on its output while the value of this counter is greater than 0, even if there are no remaining nodes left in the tree to process for a given query point.
- *Tree traversal, first child node being next* – This mode is active when the current node is not a leaf (explained above) and the value of the child indicator at the top of the stack is 0. The appropriate query point coordinate is compared to the median value of the node to determine which of the left and right children is the first child to be visited. After that, the corresponding first child node is pushed onto the stack.
- *Tree traversal, second child node potentially being next* – This mode is active when the current node is not a leaf and the value of the child indicator is 1. The stored current minimal distance from the query point is compared to the distance of the query point's appropriate coordinate from the median value of the node. If the current minimal distance is not greater, the second child of the node will not be visited, and the current node is popped off the stack. Otherwise, values at the top of the stack are replaced with the values corresponding to the second child node.
  Since the median distance calculation also uses a register in order to decrease the length of logic paths, the result of this calculation is available in the next clock cycle. Therefore, a special one-bit register is set to signify that this mode of operation is still in progress. In the next clock cycle this register is reset, and the rest of the operations are performed as described.
- *Final phase of the algorithm* – active when the node stack is empty. While the value of the previously described "delay" counter is greater than 0, no additional operations are performed. Once the value of the counter reaches 0, the output valid signal of the module is set to 1, while the output point is simply a set of wires connected to the register storing the current closest point to the input point. The initial values of the stack are pushed onto the empty stack to prepare the processing of the next input point.

The block diagram in Fig. 5 depicts the generator's design. The inputs and outputs of this design adhere to the Ready/Valid handshaking protocol. Apart from the *ready* and *valid* signals, both the input and the output consist of a single k-dimensional point represented as a series of k signed integers depicting their respective coordinate values. The dimensionality of these points, along with the structure of the point and tree ROMs, depend on the generator's parameters.

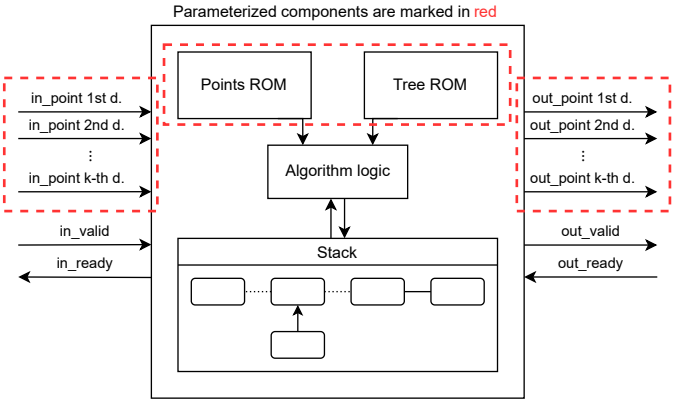

Fig. 5. Interface of the implemented Chisel design showing its input, output, and internals.

 ISBN 978-86-7466-930-3

IV. Implementation and Testing Results

Testing of the generator is also performed using testing facilities provided by Chisel, i.e. *ChiselTest*. All generator parameters are randomized during testing, and the ROMs are also populated by appropriate randomly generated k-dimensional trees. The output of generated instances for random inputs is compared against the output of a k-d tree golden model written in Scala. The distances of the outputs of Chisel instances are compared with the distances of the outputs produced by the respective Scala golden model class instances.

The Scala golden model of the k-dimensional tree has also undergone rigorous testing. A list of random points is generated after selecting a random number of dimensions for the points. From the list of points and the desired number of tree nodes an instance of the golden model class is created.

This "golden model" instance is then supplied with random points as input. The output point's distance from the input point is compared to the distance of the closest point to the input point from the list of points in the tree, which is obtained by applying a simple brute-force exhaustive search algorithm. Due to the order of nodes and points traversed not being the same for the k-d tree model and the brute-force algorithm, only distances of the respective closest points to the input point are compared.

For additional testing and real in-hardware validation, various instances obtained from the design generator have been synthesized and implemented onto a commercially available FPGA development board. The board in question is Digilent's Arty A7 with Xilinx's Artix-7 FPGA family. All instances have been synthesized for a 100 MHz target clock frequency.

Resource utilization for the different generated instances is shown in Table I. Slice LUT utilization is most influenced by the bit width of the coordinates and k, the dimensionality of the points. A more minor effect on slice LUT utilization is exerted by the sizes of the point and tree ROMs. The number of slice registers seems to be mostly influenced by the bit width of the coordinates, followed by the dimensinoality of the points. Number of dimensions k has an influence on both Block RAM Tile and DSP multiplier counts, although the greatest influence on the number of DSP multipliers is exerted by point coordinate data bit width.

TABLE I
FPGA Resource Utilization for Generated Design Instances

Generator Instance Parameters				FPGA Resources			
Data Width	Nodes	Points	k	Slice LUTs	Slice Regs	BRAM Tiles	DSP muls
8 bits	31	100	3	728	272	1	3
16 bits	31	100	3	383	288	1.5	7

16 bits	31	100	4	381	337	1.5	8
16 bits	31	100	5	453	393	2	9

V. Conclusion

An approach to implementing a nearest neighbour search algorithm on an FPGA hardware platform has been explored. One of the key characteristics in this approach is in using a pre-stored k-dimensional tree to perform nearest neighbour search operations. Another is in using the Chisel hardware design language to create a generator of instances that can accommodate k-d trees with different structure parameters.

A variety of instances have undergone testing and additional verification by implementing them on a commercial FPGA development board. Apart from testing and verification, some consideration has also been given to their utilization of resources. This paper proves on an example case of the nearest neighbour search algorithm that parameterizable design generators can be used to produce instances of AI and machine learning hardware modules as an alternative to using CPU-based implementations.

An Intercomparison of the Broadband Electrical Field Meter NARDA NBM 550

Nenad Munić, Aleksandar M. Kovačević, Nenko Brkljač, Ljubiša Tomić

***Abstract*— This paper presents the intercomparison of five broadband electric field meters from the three laboratories. The Intercomparison was performed in broadband frequency range at different level of the electric field meter. The measurement results were compared using the z-score criteria. The intercomparison was performed with the aim of confirming the accuracy of broadband electric field meters, until the realization of calibration in an accredited metrology laboratory.**

***Index Terms* — Intercomparison, Broadband Electric Field Meter, z-score, Calibration.**

I. Introduction

DIFFERENT measuring equipment can be used during the tests. Their accuracy can significantly affect the reliability of the measurements. Therefore, the measuring equipment must be calibrated before use [1]. In doing so, each laboratory must establish a program and procedure for calibrating its measuring equipment. Due to all the above, the Technical Testing Center (TTC) [2], a specialized military scientific research institution, in accordance with the requirements of the quality management system [3], developed a Procedure [4] for periodic calibration of measuring equipment.

One of the ways to determine and review the deadline for periodic calibration of measuring equipment are intermediate checks [1, 4]. In that case, the method of checking certain metrological characteristics of measuring equipment between two calibrations is used, in one of the following ways: a) using a references instrument; b) using a specially designed test device; c) participation in interlaboratory comparisons; e) participation in intercomparison.

Participation in intercomparison is one of the requirements for laboratories that are entering the accreditation process or have already been accredited [5]. Positive results of intercomparison are confirmation of the accuracy of measurements performed in the laboratory and the competence of that laboratory.

Intercomparison of meters is performed at the request of the user of the meter. In doing so, the intercomparison is performed by the laboratory user of the meter, and if necessary, other laboratories and the competent metrological laboratory can also participate [4]. Measurement intercomparison means the comparison of metrological characteristics of meters of the same type and approximately the same measurement uncertainty under established conditions.

Due to the complicated procedure of calibration in foreign accredited metrological laboratories, and for the needs of measuring in the field of electromagnetic compatibility (EMC), the Department of Electromagnetic Compatibility and Environmental Impacts in TTC initiated and organized intercomparison of broadband EM field meter NBM-550 with other broadband electric field S.A 43, manufactured by CHAUVIN ARNOUX [6].

In the meantime, the number of intercomparison participants increased, at the request of laboratories dealing with risk assessments at workplaces and in the work environment, (non-ionizing radiation), the Institute of Occupational Medicine of the Military Medical Academy (MMA) [7] and the Military Hospital in Nis [8]. A total of five meters from three laboratories were used in this intercomparison.

Intercomparison was performed for two cases: in the first case when setting defining value of electric field from the frequency range of meter and in the second case by measuring several different values of electric field at a certain frequency. Measurement results were compared using the z-score criterion.

The goal of the intercomparison is to extend the use of the broadband EM field meter NBM-550, manufactured by NARDA, until the realization of calibration in an accredited metrological laboratory. Namely, the aim of processing the results of intercomparison of these measures is to analyze the results according to the criteria for measures of the same type and approximately the same measurement uncertainty, under established conditions, then to determine the acceptability of results, and thus confirm their applicability to measure electric field strength.

II. Intercomparison Conditions

The intercomparison was performed in the Faraday cage of the Technical Experimental Center, as shown in Fig. 1.

The subject of intercomparison are broadband EM field meters, as follows:

– Narda NBM-550, s/n: B-0503, with antenna (sensor) EF0391, s/n: A-0610 (Sen 1);
– Narda NBM-550, s/n: B-0594 with antennas (sensors):

Nenad Munić, , Nenko Brkljač, Ljubiša Tomić– Tehnički opitni centar, Generalštab Vojske Srbije, Vojvode Stepe 445, 11000 Beograd, Srbija (email: nenadmunic@yahoo.com).

Aleksandar M. Kovačević– Fakultet tehničkih nauka Čačak, Univerzitet u Kragujevcu (email: aleksandarkovacevic1962@yahoo.com).

- EF0391, s/n: A-0700 (Sen 2);
- EF6091, s/n: 01084 (Sen 3);

– Narda NBM-550, s/n: H-0386 with antennas (sensors):
- EF0691, s/n: H-0550 (Sen 4);
- EF5091, s/n: 01606 (Sen 5);

Fig. 1. Electric field strength measurement with electric field meter, transmitting Ultra log antenna.

Fig. 2. NBM-550, „NARDA“ [6].

Intercomparison was performed by comparing the measured values of the electric field of different antennas (sensors) of EM field meters for the case when changing:
- transmission signal frequency (constant transmission power level),
- transmission signal strength (fixed transmission frequency).

EM field meters NBM-550, with its corresponding antenna (EF0391, EF6091 or EF5091), are mounted on a non-conductive styrofoam bracket mounted on a conductive table in a Faraday cage at a distance of 1.45 m from the transmitting antennas: Ultra log antennas (Fig. 1) or double-crest antennas (Fig. 3). The height of the transmitting antennas of 1.385 m corresponds to the height at which the antenna of the EM field meter is located.

Fig. 3. Electric field strength measurement with electric field meter, double-ridge transmitting antenna.

The NBM-550 meter is controlled by an application installed on a PC, NBM-TS PS Transfer software V 2.1.1. EM field meters are connected via a suitable optical cable and converter to a PC to monitor the value of the electric field.

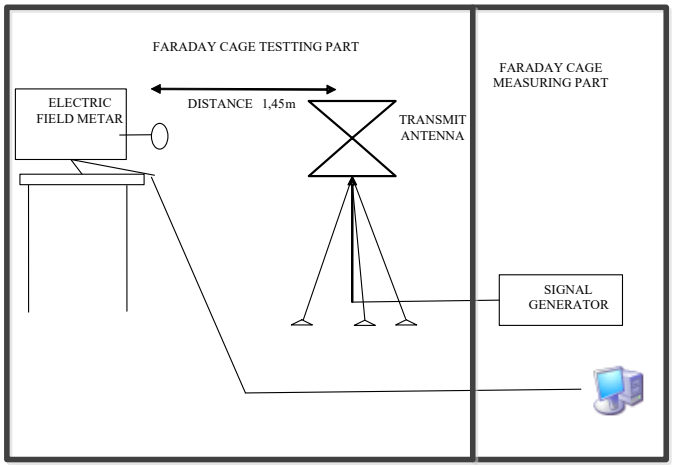

Fig. 4. Block diagram of measuring the strength of electric field, for different frequencies and fixed power level of signal generator.

The measurement is first performed when the excitation frequency is variable, by setting the transmit power level to the maximum value allowed by the signal generator. The block diagram of measuring the value of the electric field strength with the NBM-550 "NARDA" meter, in case when

 ISBN 978-86-7466-930-3

the frequency of the excitation signal was being changing is shown in Fig. 4.

For fixed frequency measuring, a signal amplifier was used while the excitation power level changed. The operating frequency is determined in the previous measurement by selecting the frequency from the middle of the measuring range at which the highest values of the electric field were achieved. In this case, the frequency of 600 MHz is selected. The block diagram of this measurement is shown in Fig. 5.

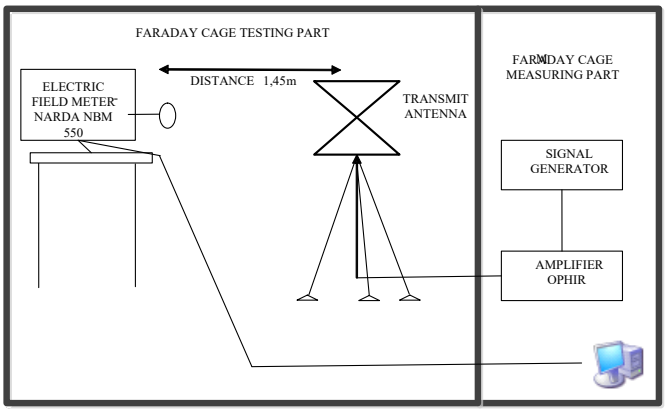

Fig. 5. Block diagram of measuring the strength of electric field, for different values of power levels and at a fixed frequency of signal generator.

The following measuring instruments and equipment were used for testing purposes:

- Broadband EM field meters NBM-550, "NARDA", listed in Chapter II,
- Signal generator SMB100, R&S, s/n. 1406.6000K03-178572-eW,
- RF amplifier 5126, „OPHIR“, from 20 MHz to 1000 MHz, s/n. 1020,
- ULTRALOG antenna HL562, R&S, ser. num. 1000324
- double-ridge antenna 960001, AILTECH, ser. br. 2097,
- Optical cable, 115200 Bd, length of 20 m,
- Cables RG-214/U (N-N), length of 10 m and 1,5 m,
- Wooden stand (tripod).
- Laptop with NBM-TS PS Transfer software V 2.1.1

At the same time, the characteristics of the measuring equipment meet the prescribed standards [9, 10].

Environmental conditions:

- temperature: 24 °C ± 2 °C,
- relative humidity:50 % ± 15 %.

III. Intercomparison Criteria

As a criterion for evaluating the results of intercomparison, taking into account all the specifics of the measurement, the z-score was adopted, in accordance with the standard ISO 13528: 2005 [9, 10]. As five test samples participated in the comparison, the mean value of the test results for all samples was taken as the assigned (reference) value X_{ref}. The z-score should indicate whether the measured value deviates significantly from the assigned value, in our case from the mean value of the test results, taking into account the standard deviation σ.

The z-score is calculated as follows [10]:

$$z_i = \frac{x_{\text{lab}i} - X_{\text{ref}}}{\sigma}, i = 1, 2, \ldots, 5. \quad (1)$$

where:

x_{lab_i} test results for each sample (i = 1, 2, ... , 5);

X_{ref} the assigned (reference) value is the mean value of the test results of all samples,

$$x_{\text{ref}} = \frac{\sum_{i=1}^{n} x_{lab_i}}{n}, \text{ n = 5 ;} \quad (2)$$

σ standard deviation for non-repeat testing,

$$\sigma = \sqrt{\frac{\sum_{i=1}^{n} (x_{lab_i} - x_{\text{ref}})^2}{n}}, \text{ n = 5.} \quad (3)$$

The z-score coefficient can be positive or negative and determines the number of standard deviations of the data set from the arithmetic mean. A negative result indicates a value less than the mean, and a positive result indicates a value greater than the mean, with the average of each z-score weighing to zero.

The value of z-score is interpreted as follows:

- A result that gives $|z| \leq 2{,}0$ is considered to be acceptable;
- A result that gives $2{,}0 < |z| < 3{,}0$ is considered to give a warning signal;
- A result that gives $|z| \geq 3, 0$ is considered to be unacceptable (or action signal) and the participants should be advised to check their measurement procedures following warning signals in case they indicate an emerging or recurrent problem [10].

IV. Results of Intercomparison

The results of intercomparison at a given maximum signal level of the signal generator and different frequency values are shown in Table I. Based on the results obtained from Table I and the calculation of mean and standard deviation, and using formula (1) obtained values of z-score coefficient, shown in Table II.

The results of the intercomparison of the measurement of the electric field value with the NARDA NBM-550 meter, for different values of the power level at a fixed frequency of the signal generator, are shown in Table III. Based on the results obtained from Table III and the calculation of the mean and standard deviation, and using formula (1), the values of the z-score coefficient were obtained, which are shown in Table IV.

TABLE III

V. CONCLUSION

Due to the complicated procedure of calibration in foreign metrological laboratories, and due to the need to confirm the accuracy of five EM field meters NBM-550, the Department of Electromagnetic Compatibility and Environmental Impacts in TTC, initiated and organized intercomparison. The intercomparison was also attended by laboratories that deal with risk assessments at workplaces and in the work environment, from the point of view of non-ionizing radiation, the Institute of Occupational Medicine of the Military Medical Academy and the Military Hospital in Nis.

The result of intercomparison according to frequencies and electric fields strength is represented by the numerical value of the z-score model in Tables 3 and Table 5. Based on the presented results, we conclude that the values of z-score, $|z| \leq 2$ and that the results are satisfactory (acceptable), and no corrective measures are needed. This shows that the deviations in the measurements, the values of the electric field between the five meters are acceptable in the entire frequency range of the meters.

The goal of the intercomparison, which was to extend the use of the broadband EM field meter "NARDA" NBM-550, until the realization of calibration in the accredited metrology laboratory is fulfilled. NBM-550 "NARDA" meters can be used to measure the strength of the electric field, until the realization of calibration in an accredited metrological laboratory.

Based on the above and the analysis of the conducted procedure and the results of the comparison of meters, it can be concluded that the conducted intercomparison procedure is currently sufficient to consider the metrological characteristics of NBM-550 "NARDA", but not metrological confirmation in terms of SRPS ISO / IEC 17025: 2006.

LiDAR measurements in Maritime transport safety and navigation of the deep seafloor

Dijana Džever, Marjan Urekar, *Member, IEEE*

***Abstract*— This paper provides an insight into how LiDAR can be applied for the benefit of shipping, sea and ocean traffic, as well as for navigation and detection of the deep seafloor. The current measuring and control methods of this sensor are presented along with the used equipment. The principles of sensor operation are described. The aim of this paper is to emphasize the future applications of LiDAR in ocean transport and its safety, as well as the detection and visualization of the underwater world and its hidden objects.**

***Index Terms*—**LiDAR; maritime; safety; seafloor; sensor; airborne; shipping; bathymetry; laser.

I. INTRODUCTION

Nowadays, LiDAR (*Light Detection and Ranging*) is widely used in order to examine various properties of the atmosphere, in autonomous driving and many other aspects such as mapping and topography. LiDAR's possibilities in autonomous driving are highly evolving these days but, if we think about the other types of traffic such as oceanic transport, or transportation and navigation in general, we can see that it is not developed and utilized enough to fulfill the needs for a safer transport. This topic is possibly disregarded because of the limitations in the underwater use, which seem to cause more issues regarding its development, in comparison to LiDAR's use in the atmosphere and earth's surface. In this paper, the discussion on how LiDAR can be used to benefit shipping, navigation, autonomous navigation, present weather measurements and detection, is made and some proposals are given. The scope of this work is to present the multiple usages that LiDAR can offer in shipping together with a total proposed solution for the deep seafloor and underwater world detection. New and unfamiliar usages of LiDAR that could change the future in many ways are given some thought. I would like to emphasize the possibility of LiDAR's role in coastline protection, biological analysis of deep seafloor species, animals, algae's and other water plants and sea sponges. Also, one of the interesting applications are detection of water salinity levels and the analysis of chemical properties of underwater minerals. Later, we will mention a few more applications of LiDAR with their advantages, that could bring humanity more knowledge regarding the underwater world.

II. WORKING PRINCIPLE OF LIDAR SENSOR

LiDAR represents a digital optical measuring device for the detection and range of light. It is a remote sensing method that uses light in the form of a pulsed laser beam to measure the range, more precisely the variable distance to Earth. This sensor emits laser output pulses that have variable frequencies and intensity, while pulsed rays pass through the project area. Outgoing impulses are reflected from the surface objects and from the ground, and later, they are detected and captured by the sensor itself. The time delay between transmission and detection of each feedback pulse provides the distance from the sensor to the surface object, producing its 3D model [8].

In general, when we speak about the working principle of LiDAR, it is similar to EDMI devices [17], where a pulse, continuous wave or laser is fired from a transmitter, and later the reflected energy is captured.

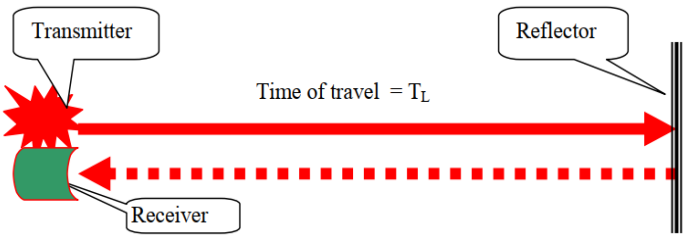

Fig. 1. Range measurement using laser principle [8]

The measuring distance from the transmitter and the reflector is determined by calculating the time of travel (T_L / ToT). In some specific cases, the role of the reflector can be some natural object or an artificial reflector such as a prism. A laser pulse is emitted from an aircraft, to measure the terrain elevation from the time between emission and reception of reflected pulses. Measuring distance provides the coordinates (x, y, z) of the reflector.

 ISBN 978-86-7466-930-3

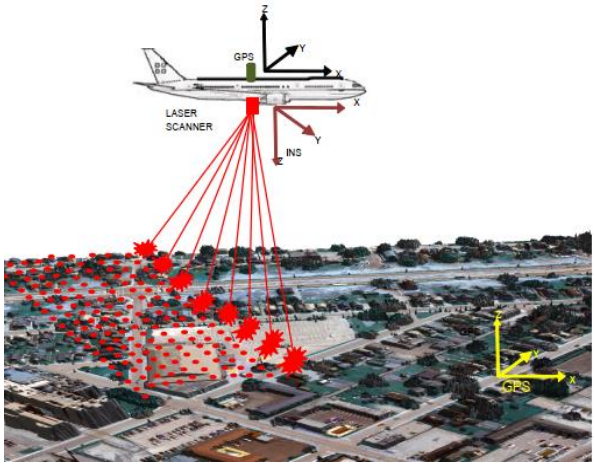

Fig. 2. LiDAR topographic system [8]

Flow diagram below indicates implemented sensors of various kinds in a LiDAR instrument, as well as the computation steps which form the ground and underwater coordinates.

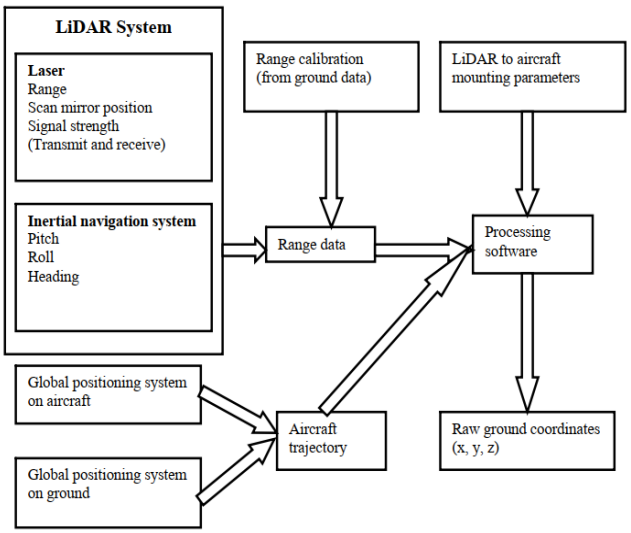

Fig. 3. An illustration of flow diagram used for computation of the ground coordinates [8]

III. AIRBORNE TOPOGRAPHIC LIDAR

Airborne LiDAR System or ALS which stands for Airborne Laser Scanning represent a remote sensing technique used to measure the distance to an object. The basic principle of measuring distance to an object using this type of LiDAR is by determining the time of flight for an emitted laser beam. Basically, a laser pulse is emitted from an aircraft in order to measure the terrain elevation, which is derived from the time between emission and reception of reflected pulses. Then, the x, y, and z coordinates are registered through laser altimetry. Technologies on which LiDAR relies for its operation on are Global Positioning System (GPS) and Inertial Measurement Unit (IMU). The importance of these technologies plays the crucial part in airborne LiDAR scanning because it provides LiDAR with the location and orientation of the remote sensor which is located on the airborne platform. This technique has a special application in shallow waters.

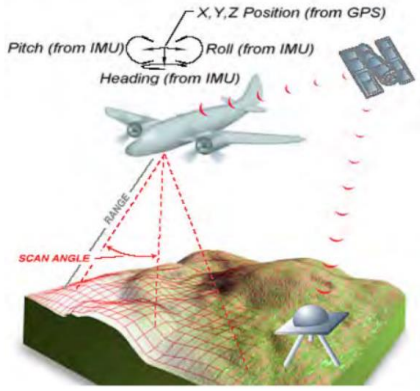

Fig. 4. Airborne LiDAR technology in the process of providing the location of the airborn platform, using a laser beam, GPS and IMU systems [7]

A. Bathymetric LiDAR

When there is a need for scanning water bodies or even some ocean traffic points such as bridges, piers, dams and other infrastructure, topographic LiDAR does not complete this task. In order to accomplish sensing of these areas and objects, bathymetric LiDAR is commonly used. The main difference between these two types of LiDAR sensors is that a bathymetric LiDAR has the ability to shoot green laser pulses, while every other component of the bathymetric LiDAR is the same as the topographic one.

The basic principle implies the action of the pulses penetrating the water surface and then returning back to the sensor which is attached to the airborne vehicle. Estimated depth of the water and water bodies is attained by processing the collected data. As it is mentioned already, a laser pulse is transmitted to the water surface, where a portion of the energy is recaptured back to the optical receiver. The remainder of the pulse continues to penetrate to the water bottom through the water column and later, is reflected back to the receiver. Two main factors that defines the maximum depth penetration for a laser are water clarity and bottom reflection. LiDAR can measure various depths from 0.9 m to 40 m with a vertical accuracy of ±15 cm and horizontal accuracy of ±2.5 m, depending on the water clarity. It is important to mention that the elapsed time between the bottom pulses and the received surface allows determination of the water depth.

 ISBN 978-86-7466-930-3

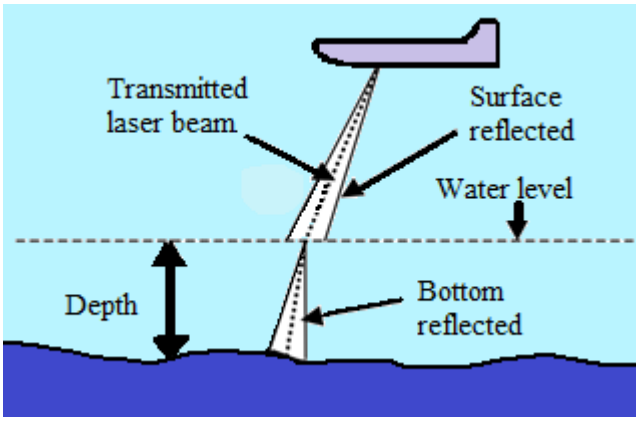

Fig. 5. Basic principle of bathymetric LiDAR [8]

Among all of those parameters mentioned before, water turbidity [18] is the most important one. It is defined as a factor caused by suspended or dissolved particles in water. Those particles scatter light in the water, making it appear cloudy. As far as water penetration is concerned, it is equal to two to three times the Secchi depth [19], which means three times the penetration depth of natural sunlight in a given water column. To be able to compute the water depth, the bottom and surface signals should be clearly distinctive, but in case of shallow depths, these signals overlap. This situation makes determination of the water depth unavailable.

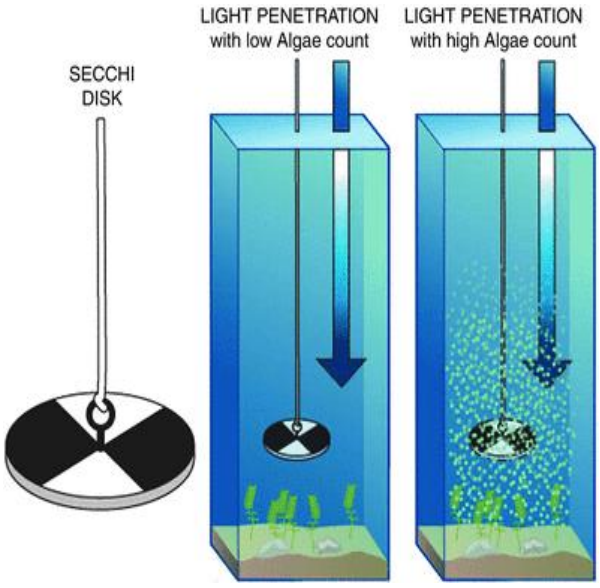

Fig. 7. Display of Secchi disk which is used to measure water clarity [19]

B. Bathymetric LiDAR Sensor Characteristics

When we discuss modern bathymetric LiDAR sensors, it should be noted that it can measure topography in addition to bathymetry, which is a double feature and a great advantage over a traditional topographic LiDAR sensor. It can measure both shallow and deep water systems.

The limit for shallow water is < 10 m and the lower limit for deep water systems is > 10 m. Characteristics of the shallow water systems are a higher measurement frequency, they have a higher resolution, and they have less laser power per pulse and smaller laser footprint diameter. A smaller receiver FOV (field of view) is also characteristic for them and they can only measure water depths within the visible water column. Opposite to this, the deep-water bathymetric LiDAR systems have a lower measurement frequency, low resolution, and they use more laser power per pulse. Also, a larger receiver field of view and a larger laser footprint is used within deep water LiDAR systems.

Depth penetration capability of the laser varies in between 2.0 to 3.0 times the Secchi depth measurement, as it was mentioned before. It is common for survey operators to utilize both sensors for shallow and deep water systems simultaneously, in order to achieve maximal coverage and detail. It is managed by combining those sensors in twin optical port survey aircraft.

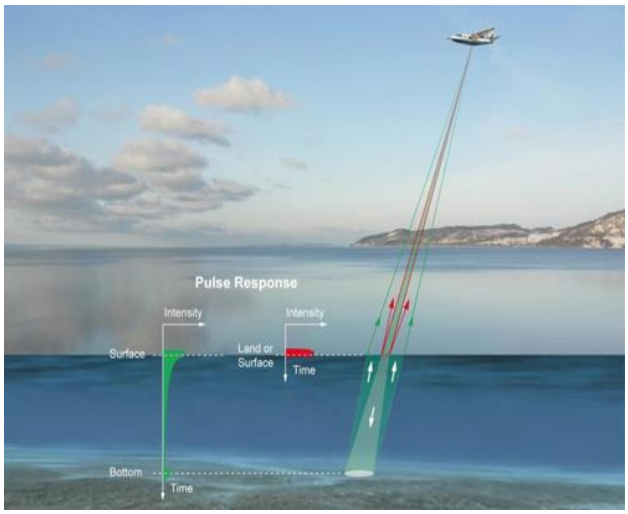

Fig. 6. Illustration of bathymetric LiDAR measurement [17]

We can see that the most important factor when bathymetric LiDAR systems are employed, is its laser energy per pulse, because the laser power represents the strongest influence on depth penetration, when it's combined with the pulse duration. This is important because the combination of high laser power and pulse duration, can provide us with a result even in deeper water column penetration. All of this mentioned influences a full insonification of the seabed, besides the fact that a high resolution laser's energy per pulse and low measurement frequency will result in a lower point density.

 ISBN 978-86-7466-930-3

C. *Advantages and disadvantages of bathymetry*

In comparison to methods of topographic data collection such as land surveying, GPS, interferometry, and photogrammetry, LiDAR technology has some great advantages. Over time, LiDAR technology is rapidly improving, as well as its sensors characteristics. Some of them are listed below:

- Higher accuracy and data density
- Fast acquisition and processing
- Minimum human dependence
- Weather/Light independence (not dependent on the sea state)
- Canopy penetration possibilities
- Additional data storage
- High costs
- Fast method (up to 70 km^2 per hour over large linear areas)
- Reflectivity gives information on seafloor characteristics

Also, like every other sensor or detector used nowadays, these sensors have some disadvantages likewise. With that being said, some disadvantages of the LiDAR sensor are:

- Aircraft usage is weather dependent
- Applicable in clear shallow water only
- Less resolution than multibeam unless resolution survey is very high
- Limited penetration in high turbidity areas such as sandy shores
- Hard to use in shallow water depths (< 0.5 m)

IV. ENVIRONMENTAL CONSIDERATIONS

All of the external environmental effects can impact the water column in bathymetric LiDAR measurements. It makes them more sensitive and can lead to data errors, gaps, bad measurement quality and reduced data coverage. It can produce problems and increase cost. Preparations for a successful bathymetric LiDAR survey and measurements, imply numerous factors that needs to be considered in order to minimize unfavorable impacts. These include tides, turbidity, vegetation condition, sea state, ground control accessibility, traffic controls and last but not least weather conditions for flying the aircraft. Important conditions which impact shallow-water laser penetration from bathymetric LiDAR sensors, need to be properly understood and managed before measurement and processing of data. One major hindrance for this process is water clarity, which can either be satisfactory or insufficient. The lack of water clarity can cause great problems for the bathymetric LiDAR sensor. Furthermore, there are other factors that can disrupt the sensor, such as sea grass, low-reflectance and high turbidity.

Considerations of environmental factors and individual characteristics of the system are very important when selection and employment of LiDAR is in focus. Some important attributes and points of a best system for a survey are environment, survey area, sensor availability and project requirements. Point density, coverage, maximum depth, final product requirements and intended purpose for the data are some of the most important aspects that determine the choice of sensor. Even when the choice is the right one, the knowledge and experience of the operator is the key to a successful survey.

V. AUTONOMOUS SHIPPING

Since LiDAR is not very widespread and investigated around the world, so it had recently paved a path towards a better understanding and greater investigation as well as exploration. We are surrounded by deep waters and oceans that are considered as mysterious areas in the manner of exploration, even in the 21st century with all of technological opportunities and achievements.

Exploration of deep oceans is a complex process. Maritime transport requires knowledge of terrestrial parameters, climate change and accurate weather forecasts in order to ensure safe trips. In addition, all of these conditions need to be fulfilled to achieve accurate LiDAR measurements. Protecting marine and coastal environment, bridges and various objects, is considered as one of the more important tasks of this sensor. However, it can serve for the purpose of updating nautical charts, cable landing sites which are connected to undersea fiber communication projects and off-shore wind farms.

Fig. 8. EchoBoat-240 seafloor system [13]

EchoBoat-240 Unmanned Surface Vessel dockside will eventually be demonstrated by Seafloor Systems. It excels in mapping shallow bodies of water. EchoBoat-240 has navigation abilities that led it into the real of fully-autonomous vehicles. A portable multibeam survey vessel will be displayed by the Seafloor System as a new platform which combines heightened portability and high-resolution data quality of a multibeam sonar.

 ISBN 978-86-7466-930-3

Predictions assume that LiDAR will be crucial in mapping and monitoring of coastlines which could bring us many new improvements in safety transport, investigation of the seafloor and even in ecology.

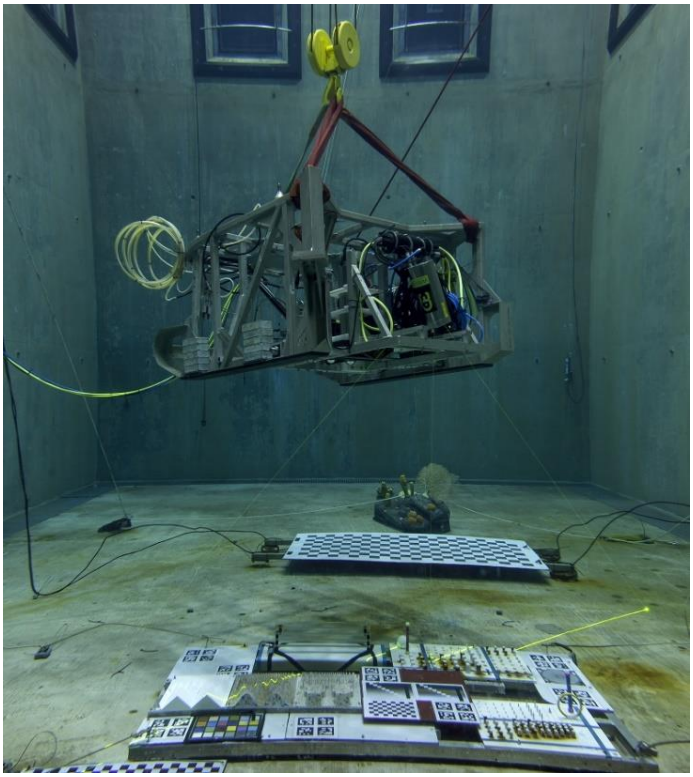

Fig. 9. Wide Swath Subsea LiDAR system in a test tank flown at a low altitude to achieve much higher resolutions than systems imaging from further off the bottom [2]

The Wide Swath Subsea LiDAR sensor, called WiSSL is able of mapping large areas at a 1 cm resolution. Its lasers are capable of pulsing 40,000 times per second in order to produce discrete surroundings. 90 degree vide field of view is made possible due to the WiSSL being equipped with two optical heads. With that being said, it is possible to achieve full bottom coverage at a maximum velocity of 1 m/s. Therefore, it is concluded that WiSSL is the first subsea LiDAR optimized for efficient mapping in the deep ocean [2].

Automated guided vehicles that are capable of providing real-time position data on port infrastructure, people, and objects, have one of the important roles in LiDAR application. The role of LiDAR sensors is to provide and enhance predictability and reliability, being a valuable component to port equipment. It can also improve efficiency and reduce risks and costs in marine transport and seafloor exploration processes.

Fig. 10. This photo shows launching the ROV Ventana into the ocean [2]

VI. CURRENT APPLICATIONS IN MARITIME TRANSPORT

One of the newest applications regarding maritime transport and safety is helicopter-mounted laser that scans and detects underwater mine targets. The US Navy is the first user of this system which brings faster detection and a wider FOV to countermine investigating missions.

LiDAR type that enables high-speed shallow water mine detection and efficient results and data processing, is called Airborne Laser Mine Detection System. When echo is returned to the sensor, the data is collected, and next step is choosing the method of destroying the mine. For example, a detected mine can be either destroyed or brought out and transported to another place safety. Cameras underneath an aircraft are receiving reflections of emitted laser beams, from the water and later, processed reflections produce images that are displayed on an airborne console.

This system can work either in day or at night, regardless of light conditions, and without worrying about submerged equipment. This action can provide identification of objects on the bottom of the ocean and pursue attack with a much lower risk of mine-attack and mine explosion.

 ISBN 978-86-7466-930-3

Fig. 11. An illustration of Stanford's photoacoustic airborne sonar system [3]

VII. CONCLUSION

LiDAR is currently experiencing an expansion. The contribution and value of this technology can change the future in which we will live. Changes in humanity are inevitable if we want to live longer and healthier, as well as save the planet. This sensor can help us succeed in that with its techniques that could provide us with data on inaccessible parts of the planet. Opportunities for research and protection of nature and humankind, transportation development among other things are growing as LiDAR becomes more effective, widespread and autonomous.

In this paper, the emphasis was put on safer maritime traffic and transport, as well as on the research of sea floor and hidden or buried objects. Airborne LiDAR can help improve coastal operations, along with signalling other ships at sea of a potential hazard detected by the sensor. That hazard could be a natural obstacle or perhaps an underwater mine, even a bridge that is not visible at night under some circumstances. Given that climate change is beginning to seriously threathen the planet, contributing towards the battle against climate change is necessary, and this could be achieved with the benefits of Industry 4.0 and novel measurement techniques and analysis.

A future application of this sensor, could be to help in the removal of carbon dioxide from the oceans. Using this technology, we can direct laser beams to determine where heavy seaweed is cultivated and enrich the water with alkaline compounds that would equalize the pH levels. By doing this, we can accelerate the restoration of underwater ecosystems, and remove excess carbon dioxide from water via electrochemical purification. In addition, another potential use can be found in analysis of seafloor and underwater rocks, minerals and various underwater species. One more idea worth mentioning is submarine and hazardous liquid detection, such as oil spills.It would be delightful to see the industry reap the benefits of this development, as that would provide additional valuable information to the end user. It is certain that LiDAR technology is already benefiting from open data, artificial intelligence and machine learning. These advantages should be utilized as much as possible as an overture to the solution for the near future.

Dvokoračna segmentna linearizacija kao deo mernog lanca termopara

Dragan Živanović, Milan Simić, Milica Stojanović i Dragan Denić

***A stra t*— ad pri azuje implementaciju dvokoračne segmentne metode linearizacije za smanjenje greške apro simacije termoparova. prvom delu je opisana softvers a obrada mernog signala pretvarača sa termoparom. valuaciju linearizacionih funkcija i analizu aproksimacionih grešaka vrši softvers i pa et virtuelne instrumentacije ab I W. snovni princip ove metode je da se apscisa prenosne fun cije prvo transformiše pomoću tabela za segmentnu linearizaciju na takav način da se opseg ulaznih vrednosti proširuje na opsezima na kojima je nelinearnost karakteristike značajna, a zatim se vrši standardna linearizacija po segmentima. a ovaj način, primena dvokoračne metode linearizacije na jedna im segmentima ima isti efe at ao i primena linearizacije na nejedna im segmentima. a date primere prenosnih fun cija termoparova, predložena metoda daje značajno manju grešku aproksimacije, uz jednaku potrošnju memorije za linearizacione tabele. Jednostavna softverska implementacija ovog dvokoračnog metoda linearizacije omogućava da se primenjuje u mernim pretvaračima mikrokontrolera male procesors e snage, umesto standardne segmentne linearizacije.**

***Ključne reči*— Dvokoračna linearna aproksimacija, prenosna funkcija termopara, smanjenje aproksimacione greške, virtuelna instrumentacija.**

I. UVOD

Nelinearna prenosna karakteristika senzora u inteligentnim mernim pretvaračima može se kompenzovati brojnim metodama zasnovanim na hardveru i softveru. Polinomna aproksimacija je standardni metod koji se koristi za linearizaciju prenosne funkcije termoparova. Jednačine pogodne za linearizaciju prenosne karakteristike svakog tipa termopara definiše NIST i BIPM u obliku polinomne aproksimacije osmog ili većeg reda, za više (do 5) segmenta linearizacije, sa veoma malom greškom aproksimacije [1, 2]. Ako je dozvoljena greška linearizacije manja od 1%, a prenosna funkcija izrazito nelinearna, potreban je veći broj segmenata kako bi se prenosna karakteristika linearizovala, pa samim tim i polinom većeg stepena, ukoliko se koristi polinomna aproksimacija [4]. Dozvoljena greška termopara, dobijena u procesu proizvodnje i prouzrokovana starenjem pri upotrebi, je značajno veća [3], preko 1 °C. To znači da je za linearizaciju karakteristike moguće uspešno koristiti i polinomne funkcije [4], ili splajn funkcije [5] nižeg reda.

U radu [6] predložena je metoda progresivne polinomne kalibracije, gde se polinom određuje direktno, na osnovu mernih kalibracionih tačaka, što je posebno pogodno ukoliko prenosna karakteristika nije poznata. Sve nesavršenosti mernog sistema se zatim kompenzuju u istoj proceduri.

U nekoliko radova [7, 8] su, kao metode za linearizaciju, predložene veštačke neuronske mreže (Artificial Neural Networks - ANN). ANN metode su pogodne jer je moguće uzeti u obzir nesavršenost mernog sistema, kao i veličine koje utiču na merenje, poput temperature hladnog kraja [9].

Ukupni troškovi memorije i procesorske snage su veoma važni aspekti pri izboru optimalne metode linearizacije za određene primene. Za izračunavanje optimalnih koeficijenata linearizacije na osnovu poznatih funkcija ili kalibracionih tačaka, može se koristiti personalni računar (PC). Ako se za izračunavanje koriste resursi PC - a, kompleksnost algoritma ne predstavlja ograničenje. S druge strane, merni pretvarači obično imaju značajno male resurse u vidu memorije i procesorske snage, pa je veoma važno izabrati metodu za linearizaciju koja ne zahteva veliku memoriju i procesorsku snagu [10-12]. Kada mikroprocesor ima mogućnost povezivanja više ulaza ili direktnog multipleksiranja većeg broja senzora na ulazu, još je važnije odabrati metodu linearizacije koja zahteva mali broj mikroprocesorskih ciklusa za izračunavanja.

U mnogim aplikacijama može biti korisno da se izračunavanja vrše u celobrojnoj matematici, što je kompatibilno sa linearnom segmentnom aproksimacijom. Implementacijom aritmetike sa podacima koji se pamte u formatu sa pokretnim zarezom, može se zauzeti i do 1 KB memorije, što je dovoljno memorije da se zapamti do 500 segmenata u linearizacionoj tabeli sa celobrojnim tipom podataka [12]. Kako je proračun brži ukoliko se koristi celobrojni tip podataka, segmentna linearizacija koja koristi cele brojeve je efikasnija za korišćenje u odnosu na polinomnu aproksimaciju, i pogodna za implementaciju u mikrokontroleru za različite tipove senzora. Takođe je pogodna i za dvodimenzionalnu segmentnu linearizaciju (površinska), kada konačni rezultat zavisi od dve promenljive.

Linearizaciona metoda se u mnogim radovima kombinuje sa praktičnim implementacijama mernog sistema pretvarača

Sl. 1. Protok signala unutar mernog pretvarača sa termoparom

[6, 7, 9, 11, 14].

Radovi [11, 15] daju dobru komparativu analizu primena većeg broja metoda linearizacije. U radovima [15, 16, 17] prikazana je hardverska implementacija segmentne linearizacije.

Pri poređenju metoda, pored tačnosti aproksimacije, treba uporediti potrošnju memorijskog prostora i brzinu odziva, a sve ovo dosta zavisi i od posmatrane prenosne karakteristike.

II. Ulazni stepen termopara

Termoparovi se često koriste kao temperaturni senzori, zbog brzog odziva, robusne konstrukcije i temperaturnog opsega od -270 °C do 2500 °C, značajno šireg nego kod otpornih i poluprovodničih senzora [18, 19]. Nedostatak primene termoparova jeste nelinearnost prenosne karakteristike, kao i uticaj temperature hladnog kraja termopara na merenje.

Dve metalne žice, različitih termoelektričnih karakteristika su spojene na jednom kraju, koji je izložen visokim temperaturama, obično mnogo višim od drugog, otvorenog, kraja. Naponska razlika između žica na otvorenom kraju će zavisiti od materijala od kojeg su napravljene žice, kao i od temperature na oba kraja termopara. Tabela sa termoelektričnim naponima standardnih termoparova se daje pod pretpostavkom da se otvoreni kraj termoparova nalazi na temperaturi od 0 °C. Izvan oblasti sa visokim temperaturama, krajevi termopara mogu se produžiti korišćenjem jeftinijih kompenzacionih kablova, koji će omogućiti da se termopar poveže sa elektronikom. Kako bi se merila temperatura na vrućem kraju, temperatura na otvorenom ("hladnom") kraju mora biti poznata. [9, 20]. Za rešavanje problema kompenzacije hladnog kraja, u praktičnim realizacijama se dodaje temperaturni senzor sa boljom tačnošću, ali sa mnogo manjim temperaturnim opsegom, na primer, otporni senzori PT100, ili poluprovodnički senzor TMP275, povezan pomoću I2C digitalnog interfejsa.

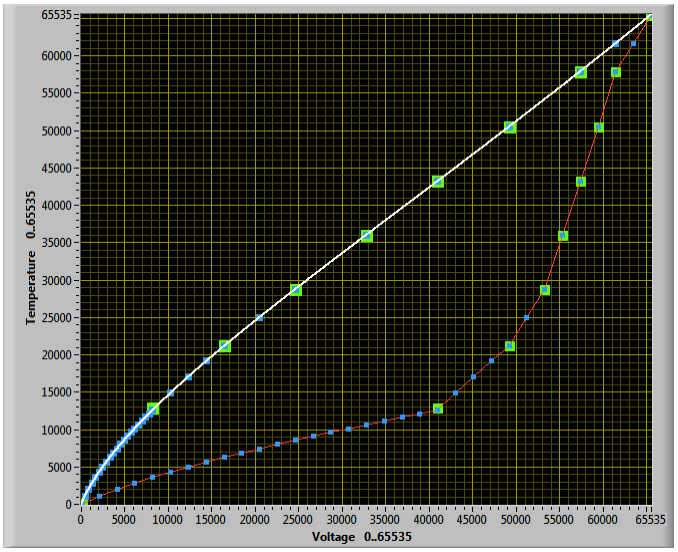
Dodatni senzor temperature mora biti smešten veoma blizu hladnog kraja termopara, po mogućstvu u termoizolovanoj komori sa konektorom. Tipičan postupak linearizacije prenosne karakteristike termopara uključuje konverziju temperature hladnog spoja T_0, na napon U_0, korišćenjem funkcije $U_o = f(T_0)$. U sledećem koraku, napon U_0 treba dodati izlaznom naponu termopara U_T, zatim se inverznom funkcijom dobijeni napon konvertuje u temperaturu pomoću funkcije $T = f^{-1}(U_T + U_0)$ [9, 20]. Zbog nelinearnosti karakteristike termopara, direktno dodavanje temperature hladnog kraja inverznoj funkciji napona termopara nije tačno, jer traženo $T = f^{-1}(U_T + f(T_0))$ nije isto što i $T = f^{-1}(U_T) + T_0$.

Blok dijagram na Sl. 1. prikazuje algoritam softverske obrade signala u mernom pretvaraču, pogodnom za merenje sa različitim tipovima termopara. Odnos između rezultata ADC konverzije i ulaznog napona je isti za sve tipove termopara. Uobičajeno, u toku procesa proizvodnje pretvarača, neophodno je podesiti koeficijente a_d i b_d kako bi se izvršila kalibracija. Nakon toga, vrednost napona termopara treba uvećati za vrednost napona hladnog kraja senzora. Kako bi se pojednostavio postupak linearizacije za različite tipove termoparova i smanjila greška u celobrojnim proračunima, signal se zatim skalira tako da pokrije maksimalan opseg korišćenjem neoznačenih int16 promenljivih, od 0 do 65535, za opseg napona za izabrani tip termopara i temperaturni opseg.

Sledeći korak je primena inverzne funkcije za određeni tip termopara. U datom blok dijagramu, ova inverzna funkcija je podeljena na funkcije f_1 i f_2, prema predloženoj dvokoračnoj metodi linearizacije. Konačno, izračunata celobrojna vrednost temperature u opsegu od 0 do 65535 se konvertuje u konačni rezultat u formatu sa fiksnom decimalnom tačkom, a koeficijenti a_y i b_y (različiti za svaki tip termopara) obezbeđuju da rezultat bude predstavljen u obliku yyyy.y[°C].

III. Metod dvokoračne linearne aproksimacije primenjen na standardne tipove termoparova

Glavni cilj korišćenja metode dvokoračne segmentne linearne aproksimacije, koja je prvi put predstavljena u ranije objavljenim radovima [12, 13, 21,], jeste izvođenje svih izračunavanja pomoću celobrojne aritmetike, kao i da se izbegne određivanje kom segmentu pripada ulazna vrednost, koja je obavezna kod metoda koje koriste podelu na nejednake segmente.



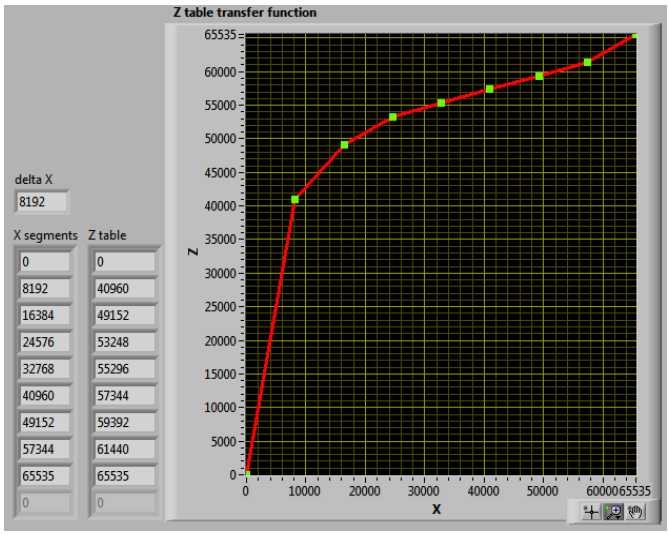
Nelinearna prenosna karakteristika se može aproksimirati pomoću više linearnih segmenata, pri čemu se zahteva da su linearni segmenti povezani, kako bi se obezbedilo da dobijena linearizovana karakteristika bude kontinualna.

Kod segmentne linearizacije, apscisa se deli na jednake segmente. Kako bi se smanjila greška aproksimacije, potrebno je povećati broj segmenata u delu u kome je prenosna karakteristika jako nelinearna. To dovodi do nejednakih veličina segmenata. Razlika u veličini segmenata dovodi do usporavanja metode linearizacije.

 ISBN 978-86-7466-930-3

Jedan od načina da se zadrži mali broj potrebnih segmenata, a da se pri tom ne uspori proces linearizacije korišćenjem segmenata nejednake veličine, je korišćenje dvokoračne metode linearizacije, predložene u radu [12]. Kod ove metode, prvo se određuju delovi prenosne karakteristike u kojima je izražena nelinearnost. Zatim se vrši transformacija X – ose, tako što se segmenti u kojima je nelinearnost izražena razvuku u odnosu na ostatak karakteristike. Za transformaciju X – ose se takođe primenjuje segmentna linearizacija. Zatim se, na tako transformisanu karakteristiku, ponovo primenjuje segmentna linearizacija. Na taj način se smanjuje greška aproksimacije. Transformacija X – ose je ovde izvedena na drugačiji način u odnosu na postupak iz rada [12], korišćenjem iterativnog postupka.

Predloženi metod se može primeniti na različite tipove senzora. Glavni zahtev prilikom vršenja linearizacije jeste da greška aproksimacije bude manja od granične vrednosti greške, definisane NIST i BIPM standardima za termoparove [1, 2]. Konačna greška linearizacije u ovom radu će biti računata kao maksimalna razlika između vrednosti ordinate aproksimirane funkcije i vrednosti ordinate koja se dobija primenom inverzne polinomne funkcije koju definiše NIST, na celom opsegu vrednosti napona, za određeni tip termopara. Cela procedura, sa odgovarajućim grafičkim prikazima, se vrši korišćenjem razvijenih softverskih algoritama u programskom okruženju LabVIEW. Na Sl. 2. dat je Front panel virtuelnog instrumenta LabVIEW na kome je predstavljena normalizovana, inverzna, prenosna karakteristika termopara tipa E.



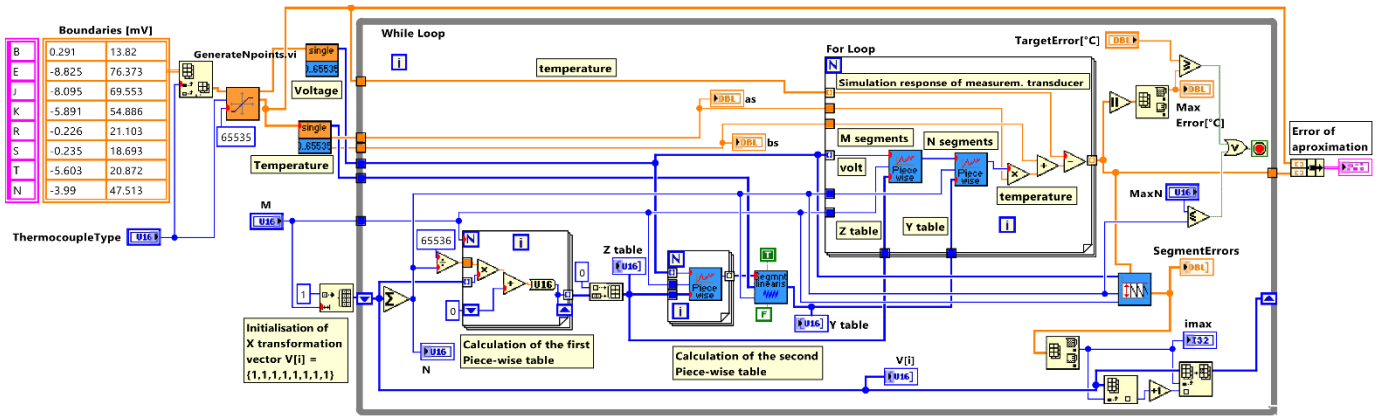
Sl. 2. Front panel LabVIEW – a, prikaz normalizovane, inverzne prenosne karakteristike termopara E tipa (bela linija) i karakteristika sa transformisanom X – osom (crvena linija)

Zelene tačke na graficima odgovaraju početnoj podeli bele (početne) prenosne karakteristike na osam segmenata. Crvena prenosna karakteristika, nakon zamene X – ose sa Z, postaje $Y = f(Z)$. Ova prenosna karakteristika je podeljena na 32 jednaka segmenta, deljenjem apscise, Z – ose (plave tačke). Vraćanjem plavih tačaka sa crvene na belu karakteristiku, može se uočiti da je praktično postignuta segmentna linearizacija sa podelom X – ose na nejednake segmente.

Konačno, linearizacija inverzne prenosne karakteristike termopara i izračunavanje temperature na osnovu normalizovane vrednosti ulaznog napona, vrši se prema relaciji:

$$Y = f_2(Z) = f_2(f_1(X)) = f_T(X) \quad (1)$$

Na Sl. 3. je prikazana funkcija $Z = f_1(X)$ koja transformiše X – osu na osam jednakih segmenata u opsegu od 0 do 65535.



Sl. 3. Transformacija X – ose na 8 jednakih segmenata

Na Sl. 4. je dat prikaz LabVIEW blok dijagrama pomoću koga se vrše izračunavanja potrebna za primenu dvokoračne segmentne metode linearizacije karakteristike termopara, uključujući i računanje greške aproksimacije. U petljama se vrši iterativni postupak kako bi se dobile vrednosti potrebne za formiranje linearizacionih tabela. Ulazni parametri ove petlje su: broj segmenata u prvoj linearizacionoj tabeli, M, maksimalna dozvoljena greška aproksimacije (TargetError[°C] u LabVIEW blok dijagramu) i maksimalni dozvoljeni broj segmenata u drugoj linearizacionoj tabeli (MaxN). Petlja će se zaustaviti u iteraciji u kojoj je ispunjen jedan od dva uslova.

Na levoj strani blok dijagrama se bira jedan tip termopara, i u zavisnosti od izabranog tipa termopara, selektuje se odgovarajući opseg ulaznog napona. Zatim se, korišćenjem funkcije koju definiše NIST za polinomnu aproksimaciju, formira 65535 para tačaka napona i temperatura koje se nalaze u odgovarajućem opsegu, a nakon toga se vrednosti napona i temperature normalizuju na opseg od 0 do 65535.

Nelinearna prenosna karateristika se deli na M jednakih segmenata, deljenjem X – ose, i određuju se segmenti u kojima je karakteristika izrazito nelinearna. Svaka tačka na X – osi se može izračunati kao $X_i = \Delta X \times i$, za i=0, ..., M, pri čemu je veličina segmenata određena kao

 ISBN 978-86-7466-930-3

Sl. 4. LabVIEW blok dijagram koji prikazuje iterativni postupak za određivanje linearizacionih tabela za dvokoračni metod linearizacije i konačne greške aproksimacije

$$\Delta X = \frac{65535}{M} \tag{2}$$

Zatim se vrši transformacija X – ose, tako što se segmentni u kojima je karakteristika izrazito nelinearna, razvuku, tj. formira se Z – osa, $Z_i = f_1(X_i)$.

$$Z_0 = 0, Z_i = Z_{i-1} + \mathrm{V}[i]\Delta Z \tag{3}$$

Veličina segmenata na Z – osi, ΔZ, se izračuna pomoću jednačine:

$$\Delta Z = \frac{65535}{N} \tag{4}$$

U prvoj linearizacionoj tabeli je definisan vektor transformacije X – ose, V[i], tj. niz koeficijenata u (3). Ukoliko se izabere M=8 segmenata za formiranje prve linearizacione tabele, početna vrednost ovog vektora će biti $V[i] = \{1, 1, 1, 1, 1, 1, 1, 1\}$. Ovo znači da će druga linearizaciona tabela imati po jedan segment u svakom od osam naponskih opsega. Tokom iterativnog procesa, vektor V[i] se menja tako što se element vektora, kome odgovara segment sa izrazitom nelinearnošću, povećava.

Vektor transformacije X – ose, koji odgovara termoparu sa Sl. 3., nakon finalne iteracije će biti $V[i] = \{20, 4, 2, 1, 1, 1, 1, 2\}$. Suma svih elemenata vektora V[i] je 32, ukoliko je izabrana vrednost za N=32, tj. ukoliko je izabrano da se za drugu segmentnu linearizaciju apscisa podeli na 32 segmenta.

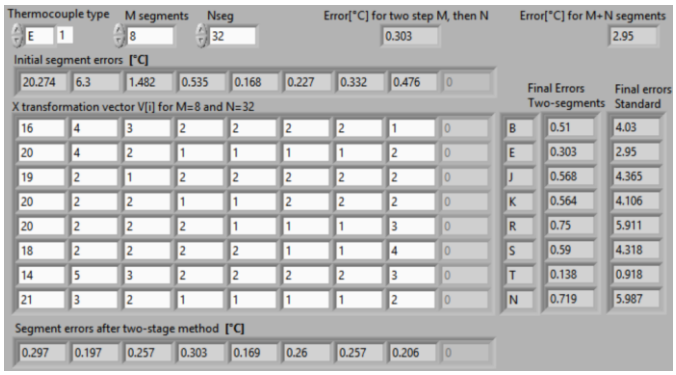
U ovom primeru, koristeći $V[i]$ prema (3), parametri u Z tabeli se računaju na sledeći način:

$$\begin{aligned}
&Z_0 = 0,\\
&Z_1 = Z_0 + 20\Delta Z,\\
&Z_2 = Z_1 + 4\Delta Z = 20\Delta Z + 4\Delta Z = 24\Delta Z,\\
&Z_3 = Z_2 + 2\Delta Z = 24\Delta Z + 2\Delta Z = 26\Delta Z,\\
&Z_4 = Z_3 + \Delta Z = 26\Delta Z + \Delta Z = 27\Delta Z,\\
&Z_5 = Z_4 + \Delta Z = 27\Delta Z + \Delta Z = 28\Delta Z,\\
&Z_6 = Z_5 + \Delta Z = 28\Delta Z + \Delta Z = 29\Delta Z,\\
&Z_7 = Z_6 + \Delta Z = 29\Delta Z + \Delta Z = 30\Delta Z,
\end{aligned} \tag{5}$$

$$Z_8 = Z_7 + 2\Delta Z = 30\Delta Z + 2\Delta Z = 32\Delta Z.$$

Transformisane X vrednosti, odnosno Z vrednosti, su izračunate na celom radnom opsegu, pomoću Z tabele (prve linearizacione tabele). Zatim se analizira inverzna kriva, tj. funkcija koja predstavlja transformisanu X – osu, kako bi se odredila 32 segmenta u drugom koraku linearizacije. Segmentna linearizacija koja se izvodi u drugom koraku je realizovana unutar Sub VI bloka, na isti način kao i određivanje vrednosti na osnovu prve linearizacione tabele, koja je u blok dijagramu nazvana “Segment Linearis” i “Pice_Wise”.

U desnom delu blok dijagrama nalazi se “For Loop” koja daje simulaciju odziva pretvarača, na osnovu linearizacionih tabela Z i Y. Na ulazu Sub VI se dovodi ulazni napon, čija je vrednost normalizovana na opsegu od 0 do 65535, i segmentna linearizacija se izvodi dva puta kako bi se aproksimirala inverzna prenosna karakteristika. Na kraju, dobijena vrednost se skalira na početni opseg temperature. Kako bi se izvršilo poređenje dobijene vrednosti sa vrednošću koju daje polinom koji propisuje NIST, računa se greška aproksimacije. Traženjem maksimalne greške aproksimacije na svakom od osam segmenata, u blok dijagramu se formira vektor “SegmentErrors”.

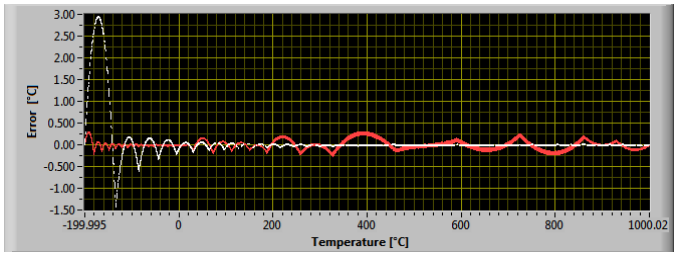


U donjem delu blok dijagrama, nalazi se funkcija čiji je zadatak da odredi u kom od osam segmenata je greška najveća. Kada se odredi segment sa najvećom greškom, “imax”, iterativni postupak povećava za jedan element vektora V[imax]. Petlja, u narednoj iteraciji, koristi izmenjenu vrednost vektora V[i].

U primeru termopara tipa E, početne greške segmenta u stepenima Celzijusovim, za svaki od osam segmenata su 20.274, 6.3, 1.482, 0.535, 0.168, 0.227, 0.332 i 0.476, kao što se može videti na Sl. 5. Može se primetiti da je najveća greška aproksimacije u prvom segmentu, i iznosi 20.274 °C. Dakle, vektor V[i] će u prvoj iteraciji da postane {2,1,1,1,1,1,1,1}. Nastavljajući iterativni postupak, dobija se krajnja vrednost za vektor V[i] = {20,4,2,1,1,1,1,2}.

Primenom dvokoračnog segmentnog metoda linearizacije, dobija se maksimalna greška na celom radnom opsegu od 0.303 °C. Upoređivanjem greške koja se dobija primenom metode dvokoračne segmentne linearizacije, korišćenjem prvo

 ISBN 978-86-7466-930-3



8, a zatim 32 segmenta, i metode segmentne linearizacije koja koristi 40 segmenata, zaključuje se da je greška smanjena 6 do 10 puta. Konačna greška aproksimacije za termopar tipa E je smanjena sa 2.95 °C na 0.303 °C, primenom metode dvokoračne segmentne linearizacije.

Sl. 5. Front panel sa koeficijentima prve linearizacione tabele i konačnim greškama, dobijenim primenom dvokoračne segmentne linearizacione metode koja koristi prvo 8, a zatim 32 segmenta i standardne segmentne aproksimacije sa 40 segmenata, za osam tipova termoparova,

Kako bi se izvršilo bolje poređenje metoda segmentne linearizacije i dvokoračne segmentne linearizacije, u tabeli 1 su date dobijene vrednosti greške aproksimacije za termopar tipa E, koje daju ove metode, za odabrane različite vrednosti broja segmenata M i N. Može se uočiti da povećanje broja segmenata, blago povećava prednost metode dvokoračne segmentne linearizacije, u odnosu na standardnu metodu sa M+N brojem segmenata.

Na Sl. 6. dat je Front panel na kome je prikazana greška aproksimacije dobijena primenom ove dve metode za termopar tipa E. Kriva označena belom bojom predstavlja grešku aproksimacije dobijenu korišćenjem standardne segmentne metode aproksimacije korišćenjem 40 segmenata. Kriva označena crvenom bojom predstavlja grešku aproksimacije koja je dobijena primenom dvokoračne segmentne metode linearizacije, korišćenjem prvo 8, a potom 32 segmenta. Može se primetiti da se primenom dvokoračne

Sl. 6. Greška aproksimacije dobijena primenom standardne metode linearizacije korišćenjem 40 segmenata (bela) i dvokoračne metode linearizacije korišćenjem prvo 8, zatim 32 segmenta (crvena), prikazana na Front panelu u LabVIEW

metode linearizacije značajno smanjuje greška aproksimacije.

Treba još napomenuti da je važno obratiti pažnju prilikom odabira vrednosti za M. Ukoliko je M malo, javlja se velika greška, a ako je suviše veliko, ne ostaje dovoljan broj segmenata za drugi korak linearizacije. Vrednost M je najbolje uzeti kao $M = (N + M)/4$, jer će u tom slučaju vrednost M biti u obliku 2^k. U svakom slučaju, dobijena greška je manja nego u slučaju primene standardne liearizacione metode.

Još jedna prednost ove metode jeste u tome što, ukoliko se ne koristi ceo temperaturni opseg termopara, već uži radni deo opsega, princip dvokoračne segmentne linearizacije je isti. Zadati opseg se na početku normalizuje na opseg od 0 do 65535, i primenjuje se linearizacija na prethodno opisan način. Smanjenje opsega će olakšati linearizaciju, jer se do željene tačnosti dolazi sa manjim brojem segmenata.

Uzimajući u obzir i druge izvore grešaka u mernom sistemu, vrednost greške od 0.2 °C se može opravdano uzeti za cilj za dati dvokoračni segmentni linearizacioni metod. U tabeli 2 je prikazan potreban broj segmenata za sve tipove termoparova kako bi se postigla greška aproksimacije od 0.2 °C, primenom standardne metode segmentne linearizacije i metode dvokoračne segmentne linearizacije.

IV. ZAKLJUČAK

Linearizacioni metod predstavljen u ovom radu, implementiran je na osnovu dvokoračne segmentne linearizacione metode predložene u radu [12]. Opisani metod je pogodan za primenu kod termoparova, s obzirom na nelinearnost njihove prenosne karakteristike.

Predloženi dvokoračni segmentni linearizacioni metod, u poređenju sa standardnom segmentnom linearizacionom metodom, za dat primer nelinearne prenosne karakteristike termopara, daje manju grešku aproksimacije 6 do 13 puta, sa sličnim vremenom izvršenja i jednakom potrošnjom memorije za čuvanje linearizacionih tabela.

Prikazana linearizaciona metoda se lako može primeniti korišćenjem celobrojne aritmetike, što smanjuje broj procesorskih ciklusa potrebnih za izvođenje proračuna, kao i memorijskog prostora potrebnog za pamćenje linearizacionih tabela, za razliku od polinomne aproksimacije. Primena dvokoračnog segmentnog linearizacionog metoda je prikazana na primeru termopara, ali se može primeniti za linearizaciju nelinearne prenosne karakteristike i drugih senzora.

ABSTRACT

The paper presents the implementation of a two - stage piece - wise linearization method to reduce the thermocouple approximation error. The first part describes the software processing of the measuring signal of the transducer with a thermocouple. Evaluation of linearization functions and analysis of approximation errors is performed by the LabVIEW virtual instrumentation software package. The basic principle of this method is to first transform the abscissa of the transfer function using a linear segment look - up table in such a way that the range of input values expands to the ranges where the nonlinearity of the characteristic is significant, and then standard piece - wise linearization is performed. In this way, the application of the two-stage linearization method on equal segments has the same effect as the application of linearization on unequal segments. For the given examples of transfer functions of thermocouples, the proposed method gives a significantly smaller approximation error, with equal memory consumption for look - up tables. The simple software implementation of this two-stage linearization method allows it to be used in low calculation power microcontroller measurement transducers, instead of standard piece - wise linearization.

Two-stage segment linearization as part of the thermocouple measurement chain

Poređenje merenja brzine vetra anemometrom sa šoljicama i ultrasoničnim anemometrom na vetroturbini

Robert Fajhner, Marjan Urekar, *Member*, IEEE

***A stra t* – Ovaj rad se bavi poređenjem performansi anemometra sa šoljicama i ultrasoničnog anemometra, instrumenata za merenje brzine vetra na jednoj od vetroturbina u vetropar u Alibunar. Podaci korišteni u analizi pribavljeni su putem CADA sistema vetropar a Alibunar.**

***Ključne reči* vetar; brzina vetra; anemometar; vetroturbina**

I UVOD

U današnje vreme, potreba za merenjem brzine vetra je prisutna u mnogim sferama privrede. Prvenstveno za potrebe metereologije, u cilju praćenja vremenskih prilika i ocene zagađenosti vazduha, zatim za sisteme reagovanja u vanrednim situacijama, avionski saobraćaj kao i energetiku. U vetroenergetici, podaci o izmerenoj vrednosti brzine vetra koriste se za planiranje budućih projekata vetroparkova ali i za upravljanje radom postojećih vetroturbina.

Sl. 1. Blok dijagram mernog sistema vetroturbine

Anemometar je uređaj koji se koristi za merenje brzine vetra. Naziv potiče od ’anemos’, što je starogrčka reč za 'vetar'. Iako je reč izvedena iz starogrčkog, nismo bili u mogućnosti izmeriti brzinu vetra sve do 1450. godine kada je Leon Battista Alberti izumeo prvi mehanički anemometar – sa klatnom, koji se sastojao od ravnog diska koji se slobodno okreće oko horizontalne ose u svojoj ravni i iznad svog centra gravitacije, ceo sklop je bio usmeren u pravcu vetra pomoću vetrokaza (kasnije je ovaj izum pripisan Robert Hook-u 1667.godine). Poznatiji anemometar je anemometar sa šoljicama, koji je 1846. izumeo irski astronom Thomas Romney Robinson. Vetar je uzrokovao da se šoljice-lopatice rotiraju vodoravno, što je pomeralo niz točkića-zupčanika koji bi pokazivali brzinu vetra. Originalni anemometar koji je on postavio na opservatoriji (sa 4 lopatice), gde je radio eksperimente, još uvek stoji na tom mestu. Njegov dizajn se i danas koristi , naravno uz moderne materijale i drugačije načine prenosa informacije o samoj brzini vetra. Najnovija tehnologija anemometra je ultrasonični anemometar, koji je izumljen 1994. godine. Ova tehologija se i dalje razvija, i kao rešenje za merenje brzine vetra je najzastupljenija u svetu (pored informacije o brzini vetra, ultrasonični anemometar može još da daje informacije o pravcu vetra, temperaturi).

Kroz ovaj rad, porediće se izmerene vrednosti vetra mehaničkog anemometra (sa šoljicama) i ultrasoničnog anemometra, koji se koriste u mernom sistemu vetroturbina, u vetroparku Alibunar, u različitim temperaturnim uslovima, pri različitim izmerenim brzinama vetra.

II KARAKTERISTIKE MERNIH UREĐAJA

Mehanički anemometar je proizvod kompanije Thies, model 4.3519.00. sa 3 lopatice [1], i služi za merenje

Sl. 2. Anemometar sa šoljicama Thies 4.3519.00. [9]

horizontalne brzine vetra. Uređaj je napravljen od materijala otpornih na koroziju. Kućište je napravljeno od eloksiranog aluminijuma i nerđajućeg čelika, dok su lopatice izrađene od ojačanog fiberglasa. Na izlazu iz anemometra je signal u opsegu 2–630 Hz (optoelektrični princip merenja brzine vetra) koji se pretvara putem integrisanog mernog pretvarača u analogni signal oblika 4-20 mA. Optoelektrični princip zasniva se na slanju LED svetla kroz kodni prsten prema foto prijemniku, na osnovu kojeg se formiraju električni impulsi. Merni opseg je od 0,5 m/s do 50 m/s, sa rezolucijom od 0,1

 ISBN 978-86-7466-930-3

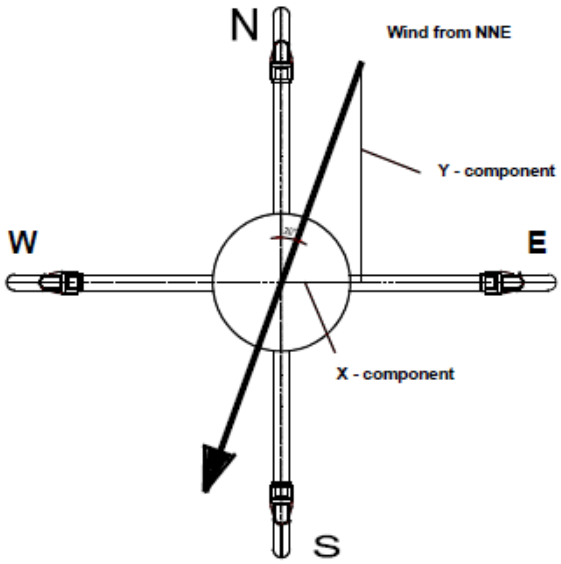
m/s. Tačnost uređaja je definisana na intervalu: za vrednosti vetra 0,5 – 17 m/s, tačnost je +/- 0,5 m/s; za vrednosti 17-50 m/s, tačnost je +/-3% od merene vrednosti.

Ultrasonični anemometar je proizvela, takođe, kompanije Thies, model 2D 4.382x. sa dva para, naspramnih ultrazvučnih pretvarača, na rastojanju od 200 mm [2]. Izlazni signal može biti digitalni i/ili analogni. Anemometar pouzdano radi pri temperaturama od -50°C do +70°C. Merni opseg brzine vetra je 0,01 – 75 m/s (prag detekcije je 0,01 m/s). Što se tiče tačnosti merenja brzine vetra, za brzine do 5 m/s, tačnost je +/- 0,1 m/s, dok za brzine vetra preko 5 m/s, tačnost je +/- 2 % od merene vrednosti [3]. Zbog svoje kontrukcije (otporni materijali, nema pokretnih delova) redovna kalibracija usled starenja nije potrebna.

Sl. 3. Ultrasonični anemometar Thies 2D [2]

Greške u merenju se javljaju usled mehaničkih deformacija nosača pretvarača, odnosno promene dužine mernog puta između ultrasoničnih pretvarača. Uticaji pravca strujanja vazduha i turbulencije su kompenzovani u procesu računanja.

III ODREĐIVANJE VREDNOSTI BRZINE VETRA



Merene vrednosti brzine vetra se šalju u digitalnom obliku upravljačkom sistemu vetroturbine. Operacije izračunavanja brzine vetra se izvršavaju u elektronskom sklopu dnevnika izmerenih vrednosti (data logger).

Kod anemometra sa šoljicama, preko data logger-a, dobijene vrednosti se uzorkuju (u kratkom vremenskom intervalu 10 ms) i tako dobijene vrednosti se dalje koriste u proračunima brzine vetra, u upravljačkom sistemu. Ove vrednosti se usrednjavaju na intervalima 50 ms, 100 ms, 500 ms, 1s, 10s, 30s i 600s, u pokretnom smislu i kao promenljive koriste u drugim operacijama kontrolnog sistema. Proračuni u pokretnom smislu se izvršavaju tako da se ‘najstarija’ merena vrednost zameni najskorijom merenom vrednošću, i ponovo izračuna srednja vrednost. Prilikom produkcije električne energije, u proračunima vrednosti brzine vetra mora da se uključi uticaj turbulencije rotirajućih elisa i vibracija gondole koji utiču na izmerene brzine vetra. Kroz te faktore se linerazuje jednačina po kojoj se vrednost brzine vetra računa i povećava preciznost mernog uređaja:

$$v_v = Af_s + B \tag{1}$$

Merena brzina vetra je v_v u [m/s], f_s je frekvencija generisanog signala na izlazu anemometra [Hz], a A i B koeficijenti dobijeni prilikom kalibracije samog anemometra [4]. Linearna zavisnost izmerene brzine kod anemometra sa lopaticma je i dokazana u laboratorijskim ispitivanjima [5]. Prilikom kalibracije navedenog tipa anemometra sa lopaticama izračunata je merna nesigurnost uređaja σ=2,04% [6].

Kod ultrasoničnog anemometra, proces merenja vrednosti vetra i njeno usrednjavanje je drugačije. Dve putanje na kojima se vrši merenje su međusobno upravne. Pretvarači rade i kao predajnici i kao prijemnici. Elektronski kontrolni sistem anemometra bira pravac i smer merenja, i u jednoj sekvenci merenja (2,5ms pri temperaturi 20°C) izvrše se 4 individualna merenja u sva četiri smera (S-N,W-E,N-S,E-W) mernih putanja. Brzina zvuka značajno zavisi od temperature vazduha, međutim pošto se merenje brzine prostiranja zvuka obavlja duž oba pravca merenja, i u oba smera, time se isključuje uticaj temperature na merenje.

Sl. 4. Princip merenja ultrasoničnog 2D anemometra [3]

 ISBN 978-86-7466-930-3

Merene vrednosti brzine prostiranja daju dve komponente vektora brzine vetra (X i Y), koje DSP anemometra pretvara u polarne koordinate, na osnovu kojih se u potpunosti rekontsruiše vektor brzine vetra. Usrednjavanje merenih vrednosti se odvija svakih 20ms, u pokretnom smislu kao i kod mehaničkog anemometra. Ove srednje vrednosti se ponovo preračunavaju na intervalima 100ms, 500ms, 1s, 10s, 30s i 600s. Pojedinačna horizontalna komponenta brzine vetra u [m/s] može se aritmetički izračunati kao:

$$u = \frac{c^2}{2 f_z d} \tag{2}$$

gde je c – brzina prostiranja zvučnog talasa koji se šalje između ultrasoničnih pretvarača; f_z – frekvencija tog zvučnog talasa; a d – rastojanje između pretvarača. Izračunata vrednost brzine vetra v_v [m/s] je :

$$v_v = \sqrt{{u_x}^2 + {u_y}^2} \tag{3}$$

gde su u_x i u_y komponente vektora brzine vetra. Prilikom testiranja navedenog tipa 2D ultrasoničnog anemometra izračunata je merna nesigurnost uređaja σ=2% [7].

IV POREĐENJE RADA MERNIH UREĐAJA

U svrhu analize rada mernih uređaja, upotrebljeni su podaci iz memorije jedne od vetroturbina iz vetroparka Alibunar, pri čemu se vodilo računa da se uzmu u obzir različiti vremenski uslovi (brzina vetra i spoljna temperatura). Podaci u dalje navedenim tabelama predstavljaju izmerene i usrednjene desetominutne vrednosti brzine vetra, u toku jednog dana (vremena su birana nasumično). Zbog značajno boljih karakteristika i nedostatka referentnog mernog instrumenta na koji ne bi uticali postojeći spoljni faktori, merenja ultrasoničnog anemometra će se smatrati referentnim.Veličine koje se navode u tabelama su: $_1$ – brzina izmerena anemometrom sa lopaticama; $_2$ – brzina izmerena ultrasoničnim anemometrom; Δv – razlika između izmerenih brzina i - relativna greška u odnosu na referentnu vrednost.

U Tabeli I, prikazani su podaci iz 10. januara 2021. Na prvi pogled, lako se uočavaju drastične razlike između merenja mehaničkog i ultrasoničnog anemometra. Promene spoljne temperature su relativno male (manje od 1°C), dok razlike u merenim brzinama variraju od 2,32 m/s do 3,71 m/s (što daje grešku preko 40% u odnosu na referentnu vrednost). Uzrok greške je relativno niska spoljna temperatura (nekoliko dana je bila temperatura konstantno ispod 0°C), što je skoro dovelo do smrzavanja mehaničkog anemometra. Za ova merenja, mehanički anemometar ne ispunjava navedene tačnosti od strane proizvođača.

U Tabeli II, prikazani su izmerene vrednosti vetra od 25.01.2022. Opseg promene spoljne temperature se malo povećao, ali je i dalje na ivici temperature mogućeg smrzavanja anemometra sa lopaticama. Iz izmerenih vrednosti brzine vetra se vidi da se greška mehančkog anemometra smanjila (sad je do 16% merene vrednosti) ali se nalazi u granicama koje navodi proizvođač.

TABELA I MERENJE BRZINE VETRA PRI SPOLJNOJ TEMPERATURI OD -2,8°C DO -3,5°C

VREME	$_1$ [m/s]	$_2$ [m/s]	Δv [m/s]	
20:10	3,720	6,769	3,049	39,25
17:40	3,859	6,960	3,101	44,54

03:40	0	0,280	0,280	100

 ISBN 978-86-7466-930-3

Zanimljivo je primetiti podatak kada mehanički anemometar ne detektuje vetar (brzina 0,28 m/s), što se u potpunosti slaže sa specifikacijom instrumenta.

Tabela IV prikazuje vrednosti izmerene brzine vetra za slučaj iste promene spoljne temperature (od 5,6°C), pri nešto višoj spoljnoj temperaturi u odnosu na Tabelu III. Podaci su od 13.03.2022. U ovom slučaju, izmerene brzine vetra su mnogo veće (preko 5 m/s), i može se zaključiti da se relativna greška merenja mehaničkog anemometra još više smanjila (manje od 2%) u odnosu na referentnu vrednost.

TABELA IV MERENJE BRZINE VETRA PRI SPOLJNOJ TEMPERATURI OD 9,5°C DO 15,1°C

VREME	$_1$ [m/s]	$_2$ [m/s]	Δv [m/s]	
22:40	10,729	10,699	0,030	0,28
20:20	7,597	7,689	0,092	1,19
18:30	10,792	10,890	0,098	0,90
16:00	10,010	10,069	0,059	0,58
14:10	8,810	8,890	0,080	0,90

09:20	5,309	5,400	0,091	1,68
06:10	11,147	11,189	0,042	0,37

U Tabeli V i Tabeli VI prikazane su brzine vetrova izmerene pri spoljnim temperaturama preko 20 °C (Tabela V sadrži podatke od 01.08.2020. a Tabela VI od 03.07.2020.).

TABELA V MERENJE BRZINE VETRA PRI SPOLJNOJ TEMPERATURI OD 26,1°C DO 34,7°C

VREME	$_1$ [m/s]	$_2$ [m/s]	Δv [m/s]	
22:50	8,039	8,060	0,021	0,26
20:50	9,707	9,710	0,003	0,03
18:40	5,059	5,059	0	0
16:20	9,010	9,020	0,010	0,11
13:30	7,789	7,771	0,018	0,23
11:20	7,420	7,409	0,011	0,15
08:00	10,102	10,149	0,047	0,46
05:30	9,770	9,770	0	0

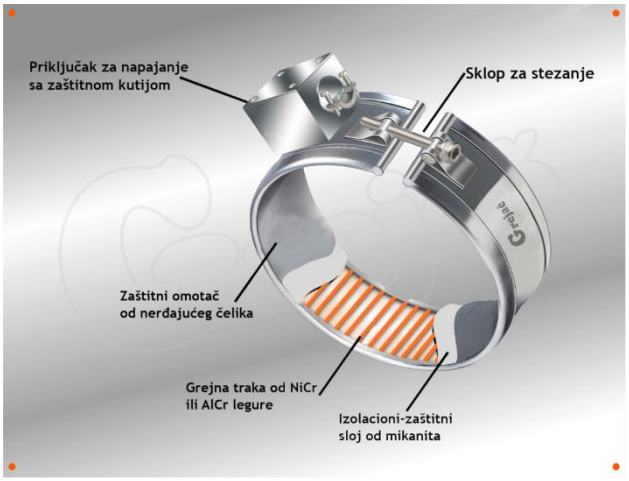

TABELA VI MERENJE BRZINE VETRA PRI SPOLJNOJ TEMPERATURI OD 23,4°C DO 31,1°C

VREME	$_1$ [m/s]	$_2$ [m/s]	Δv [m/s]	
23:20	3,970	4,028	0,058	1,43
21:50	2,700	2,710	0,010	0,37
19:10	3,970	4	0,030	0,75
16:20	2,799	2,838	0,038	1,33
13:00	2,430	2,460	0,030	1,21
10:20	1,379	1,379	0	0
06:00	4,559	4,610	0,051	1,10
02:20	7,050	7,130	0,080	1,12

U ovim tabelama obuhvaćene su vrednosti brzine vetra do 5 m/s i preko 5 m/s. Kao što se iz priloženog vidi, merene vrednosti mehaničkog anemometra se često podudaraju sa merenim vrednostima ultrasoničnog anemometra ili odstupaju manje od 1,5% merene vrednosti brzine vetra.

V ZAKLJUČAK

Kroz analizu prikupljenih podataka o izmerenim brzinama vetra, uočio sam da mehanički anemometar ne ispunjava karakteristike date od strane proizvođača u slučajevima konstantne temperature ispod 0°C (skoro zamrzavanje anemometra). Velike razlike u merenjima predstavljenih uređaja daje indikaciju kontrolnom sistemu vetroturbine o

Sl. 4. Pojasni grejač [10]

mogućnosti stvaranja leda na elisama vetroturbine, koje može

biti veoma opasno po okolinu.Ova pojava inicira aktivaciju drugih podsistema vetroturbina kao što je zagrevanje elisa vetroturbine u cilju prevencije formiranja leda na njima. Takođe, potrebno je izvršiti neke modifikacije u sistemu merenja anemometra sa šoljicama, u cilju pružanja tačnijih izmerenih vrednosti brzine vetra.

Jedan od načina bio mogao biti tretiranje mehaničkih delova anemometra premazom ili sprejem protiv zamrzavanja, da se led ne bi hvatao za njih. Drugi način bi mogao biti dodavanje pojasnih grejača oko samog anemometra, koji bi mogao sprečiti smrzavanje osovine i ležajeva.

Sa druge strane, promenom metode za obradu signala koji generiše anemometar sa šoljicama mogla bi se smanjiti merna nesigurnost instrumenta. Umesto klasične metode uzorkovanja koja se koristi u današnjim mernim instrumentima, primenom stohastičke digitalne merne metode ovo bi bilo izvodljivo [8].

ABSTRACT

This paper compares the performance of a mechanical anemometer with cups and an ultrasonic anemometer, instruments for measuring wind speed on one of the wind turbines in the Alibunar windfarm. The data used in the analysis were obtained through the SCADA system of the Alibunar windfarm.

Comparison wind speed measurements with cup anemometer and ultrasonic anemometer on the wind turbine

Primena linearnog niza fotodetektora kod optičkih pseudoslučajnih pozicionih enkodera

Ivana Ranđelović, Dragan Denić, Goran Miljković i Aleksandar Jocić

***Apstrakt*—Precizno i pouzdano merenje ugaone pozicije je zahtev mnogih savremenim pokretnih sistema u industriji i drugim oblastima. Pseudoslučajni optički apsolutni enkoderi nude dobru rezoluciju, ali i pouzdanost i fleksibilnost u radu. U radu se analizira primena linearnog niza fotodetektora za paralelno očitavanje pseudoslučajnog koda pri čemu se dobija pravi apsolutni enkoder, koji za razliku od klasičnog ima jednu kodnu traku nezavisno od rezolucije. Razmatraju se karakteristike primenjenog senzora kao i ograničenja njegove primene za očitavanje pseudoslučajnog koda. Kako bi se izbegle greške prilikom projektovanja diska enkodera predlaže se metoda njegove provere nakon projektovanja bazirana na obradi slike. Takođe, moguća je i provera kvaliteta diska nakon njegove realizacije.**

***Ključne reči*—Pseudoslučajni pozicioni enkoder, merenje pozicije, paralelno očitavanje pseudoslučajnog koda, integrisani linearni niz fotodetektora.**

I. Uvod

Pseudoslučajni optički enkoderi predstavljaju dobro rešenje za precizno i pouzdano merenje ugaone pozicije u različitim pokretnim sistemima u industriji, računarskim periferijama, antenama, kamerama, itd. Na tržištu se mogu naći kao obrtni i linearni pozicioni enkoderi visokih rezolucija. Pseudoslučajni pozicioni enkoderi, kao poseban tip apsolutnih enkodera, imaju manji broj kodnih traka, manji broj optičkih čitača, bolju pouzdanost i fleksibilnost. Pri samoj realizaciji pseudoslučajnog enkodera, obrtnog ili linearnog, potrebno je naneti pseudoslučajni binarni kod na disk ili traku enkodera i izvršiti odabir optičkog čitača, zatim definisati način očitavanja pseudoslučajnog koda [1], razmotriti metode skeniranja koda [2] kao i metode konverzije pseudoslučajnog u prirodni kod [3]. Dodatni kvalitet pseudoslučajnih enkodera koji im daje i veliku prednost u odnosu na klasične enkodere, jeste detekcija grešaka očitavanja koda. Korisniku se pruža dodatna informacija koja potvrđuje ispravnost informacije o poziciji sistema.

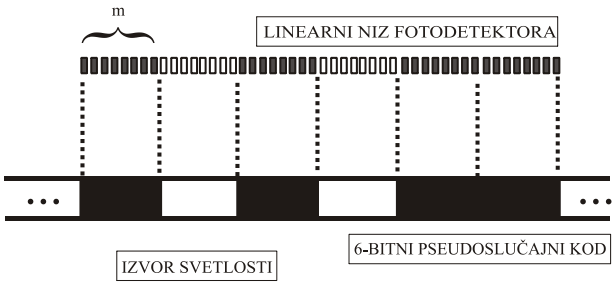
Pseudoslučajni apsolutni enkoderi imaju jednu kodnu traku sa pseudoslučajnom binarnom sekvencom, koja se može očitavati serijski i paralelno. Prilikom određivanja ugaone pozicije kod pseudoslučajnih apsolutnih enkodera se koristi „osobina prozora“ pseudoslučajne sekvence rezolucije n, pri čemu kada se očitaju n susednih bitova; oni predstavjaju jedinstvenu kodnu reč iz koje se može dobiti informacija o poziciji. Kodne reči su raspoređene longitudinalno, pri čemu prvih (n-1) bita tekuće kodne reči su identični sa poslednjih (n-1) bita prethodne kodne reči. Tačnije, dve susedne kodne reči razlikuju se u samo jednom bitu. Pseudoslučajna binarna sekvenca maksimalne dužine 2^n-1 se može generisati primenom pomeračkog registra od n-flip flopova i odgovarajuće povratne sprege. Ovako generisana pseudoslučajna binarna sekvenca sadrži 2^n-1 različitih kodnih reči dužine n. Da bi se očitao pseudoslučajni binarni kod može se koristiti jedan ili dva detektora, a da se kodna reč formira u pomeračkom registru, ili se može koristiti linearni niz n detektora pri čemu se paralelno očitavaju svih n bitova u svakom trenutku [4, 5].

U radu se predlaže očitavanje pseudoslučajnog binarnog koda primenom optičkog modula sa integrisanim nizom fotodetektora. Radi se o metodi paralelnog očitavanja koda primenom senzora TCD1254GFG kompanije Toshiba koja je objašnjena u prvom delu rada. U drugom delu rada su razmatrana ograničenja prilikom primene ovog senzora za očitavanje pseudoslučajnog koda kod optičkog obrtnog pseudoslučajnog enkodera. U trećem delu rada je predstavljen postupak provere ispravnosti projektovanja i iscrtavanja pseudoslučajnih kodnih traka na tehničkom crtežu kao i provera samog diska nakon izrade a pre ugradnje.

II. Metoda paralelnog očitavanja pseudoslučajnog binarnog koda

Kako bi se realizovao apsolutni pseudoslučajni enkoder, koji ne bi zahtevao inicijalno kretanje prilikom startovanja [1], može se primeniti linearni niz fotodetektora za očitavanje pseudoslučajnog koda sa diska enkodera. Inicijalno kretanje pokretnog mernog sistema je potrebno kod pseudoslučajnog enkodera sa serijskim očitavanjem koda kako bi se formirala prva validna kodna reč nakon startovanja mernog sistema. Takođe, ukoliko dođe do prekida napajanja enkodera ili se detektuje greška u merenju pozicije potrebno je inicijalno kretanje radi formiranja pseudoslučajne kodne reči.

Metod paralelnog očitavanja pseudoslučajnog binarnog koda može se postići primenom CCD senzora sa linearnim nizom fotodetektora.



Na slici 1 prikazan je rad pseudoslučajnog apsolutnog enkodera primenom metode paralelnog očitavanja koda [6], pri čemu se jedne strane kodne trake nalazi izvor svetlosti dok je sa druge strane linearni niz fotodetektora. Kodna traka je

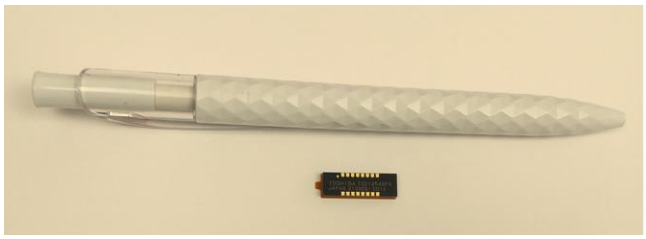
 ISBN 978-86-7466-930-3

sastavljena od prozirnih i neprozirnih polja, širina svakog polja odnosno, pseudoslučajnog bita, veća je od širine fotoelemenata linearnog niza fotodetektora kako bi bilo moguće očitavati bitove pseudoslučajnog koda. Da bi se odredila apsolutna pozicija pseudoslučajnog enkodera neophodno je očitati *n* uzastopnih bitova sa pseudoslučajne kodne trake. Svaki pseudoslučajni bit očitava se sa kodne trake uz pomoć *m* fotodetektora. Primera radi, prikazan je 6-bitni pseudoslučajni binarni kod …101011… i linearni niz fotodetektor gde je broj fotodetektora koji očitava jedan bit *m*=8. Nakon primene linearnog niza fotodetektora, sa pseudoslučajne kodne trake dobija se sledeći niz na izlazu sistema za očitavanje koda



..1111111000000001111111100000000111111111111111...

Sl. 1. Očitavanje pseudoslučajnog koda primenom metode paralelnog očitavanja koda

Rezolucija i tačnost očitavanja pseudoslučajnog koda zavise od karakteristika linearnog niza fotodetektora. Najvažniji parametri senzorskog modula sa lineranim nizom fotodetektora su: razmak između fotodetektora, broj fotodetektora, veličina fotodetektora, tip fotodetektora, napon napajanja, dodatne zaštite na primer u vidu elektronskog zatvarača ("electronic shutter") koji izlazni napon održava konstantnim bez obzira na varijacije intenziteta svetlosti. Kompanije kao što su iC-Haus GmbH [7], Hamamatsu company [8], Sensors Unlimited [9], Taos [10], Toshiba [11] samo su neki od prozvođača komercijalnih linearnih nizova fotodetektora. sa različitim širinama fotoosetljivog elementa koji su reda 400 μm, 100 μm, 50 μm, 25 μm, itd.

U radu se koristi optički modul TCD1254GFG kompanije Toshiba (slika 2), koji sadrži 2500 fotodetektora, dimenzije fotodetektora su 5.25 μm × 64 μm sa razmakom između fotodetektora 5,25 μm. Može se uočiti i da je sama dimenzija optičkog modula svega 13,371 mm.

Sl. 2 Fotografija optičkog modula Toshiba TCD1254GFG

III. ANALIZA PRIPREME LINEARNOG NIZA FOTODETEKTORA KOD PSEUDOSLUČAJNIH ABSOLUTNIH ENKODERA

Optički modul Toshiba TCD1254GFG sa 2500 foto elemenata može raditi na frekvencijama od -4 MHz, vreme jednog očitavanja svih piksela senzora je 10 ms. Vrednost napona napajanja senzorskog modula iznosi 4 V.

Analiziraće se primena prethodno opisanog senzora, linearnog niza fotodetektora, za očitavanje pseudoslučajnog koda različite rezolucije. Najpre se senzor koristi za očitavanje 16-bitnog pseudoslučajnog koda, pri čemu se svaki bit očitava sa 8 fotodetektora (piksela), slika 3a. Za očitavanje ovog koda iz senzora bi se koristio sledeći broj piksela

$$16 \text{ bita x } 8 \text{ piksela} = 128 \text{ piksela}$$

Zatim, ako se koristi za očitavanje 8-bitnog pseudoslučajnog koda, pri čemu se svaki bit očitava sa 64 piksela, broj upotrebljenih piksela iz senzora iznosi, slika 4b:

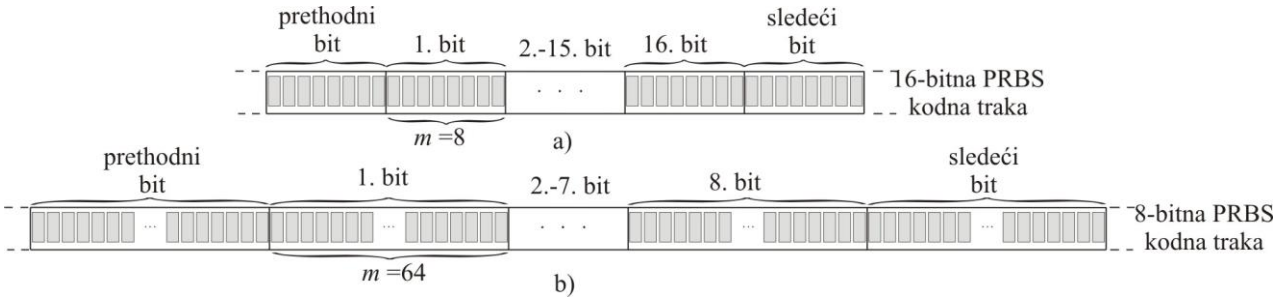
$$8 \text{ bita x } 64 \text{ piksela} = 512 \text{ piksela}$$

Potreban prečnik diska enkodera koji bi bio odgovarajući za očitavanje pseudoslučajnog koda definisane rezolucije prethodno predstavljenim senzorom bi bio:

a) za slučaj 16-bitnog koda dužine $2^{16} - 1 = 65535$ bita

$$5.25 \text{ μm x } 8 \text{ piksela x } 65535 \text{ bita} = 2\, r_{16}\, \pi$$

$$2\, r_{16} = 876.582 \text{ mm}$$



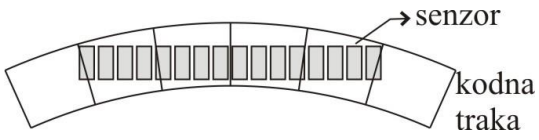
Može se uočiti da je prečnik diska suviše veliki za praktičnu primenu.

b) za slučaj 8-bitnog koda dužine $2^8 - 1 = 255$ bita

$$5.25 \text{ μm x } 64 \text{ piksela x } 255 \text{ bits} = 2\, r_8\, \pi$$

$$2\, r_8 = 27.286 \text{ mm}$$

Sada je prečnik diska enkodera pogodan za praktičnu primenu.



Slika 3. Paralelno očitavanje pseudoslučajnih kodova različite rezolucije

 ISBN 978-86-7466-930-3

Može se zaključiti da je sa povećanjem rezolucije pseudoslučajnog koda potreban veći prečnik diska enkodera, potrebno je naći kompromisno rešenje između broja fotodetektora koji će se koristiti za očitavanje jednog bita i rezolucije pseudoslučajnog koda.

Princip merenja ugaone pozicije kod ovako projektovanih pseudoslučajnih absolutnih enkodera je baziran na određivanju grube pozicije koja ima istu rezoluciju kao pseudoslučajna binarna sekvenca, kao i na povećanju rezolucije merenjem fine pozicije na osnovu očitavanja istog bita pseudoslučajnog koda sa m susednih fotodetektora. Definiše se kodna reč koja predstavlja nultu poziciju enkodera prilikom njegovog montiranja na osovinu motora. Očitava se izlaz senzora, linearnog niza fotodetektora, ukoliko se dobije ista sekvenca nula i jedinica, ponavlja se očitavanje zato što nije bilo kretanja. Zatim se vrši detekcija redoslednih brojeva fotodetektora koji definišu prelaze između nizova nula i jedinica. Broj fotodetektora m lineranog niza fotodetektora kojim se očitava jedan bit pseudoslučajnog koda je definisan prilikom projektovanja enkodera. Broj očitanih uzastopnih nula ili jedinica po jednom bitu koda na izlazu senzora će varirati u industrijskim uslovima rada enkodera od definisanog broja. Analizom sekvence nula i jedinica u izlaznom signalu, na osnovu redoslednih brojeva, definišu se granice bita i određuje se fina pozicija. Ako nema skoka fine pozicije od vrednosti 0 do vrednosti (m-1) i obrnuto, daje se informacija o tekućoj poziciji. Kada se javi skok fine pozicije određuje se smer rotacije i rekonstruiše se kodna reč, a zatim se konvertuje iz pseudoslučajnog u prirodni kod. Očitavanje jednog bita pseudoslučajne binarne sekvence sa m fotodetektora je iskorišćen za povećanje rezolucije merenja ugaone pozicije u odnosu na samu rezoluciju pseudoslučajne binarne sekvence.

Pseudoslučajni absolutni enkoder je složena opto-elektro-mehanička komponenta koja je u industriji pod različitim spoljašnjim negativnim uticajima. Neki od izvora grešaka su ekscentricitet i eliptičnost diska enkodera, zaprljanje kodne trake, neprecizno odštampana kodna traka, vibracije, temperatura, itd. Zakrivljenje kodne trake i nejednako osvetljenje fotodetektora na ivicama kodnih bitova može takođe doprineti greškama očitavanja koda, slika 4.

Sl. 4. Izvor greške očitavanja koda

IV. PROVERA ISPRAVNOSTI PSEUDOSLUČAJNOG KODA DISKA POZICIONOG ENKODERA

Fizička realizacija diska pozicionog enkodera podrazumeva niz postupaka pri kojima je moguće uneti greške, koje dalje mogu dovesti do nefunkcionalnosti krajnjeg uređaja. Greške mogu biti unete u fazi iscrtavanja pseudoslučajnih traka u softveru za generisanje grafičkih prikaza, ali i u fazama fizičke izrade diska.

Prilikom izrade crteža, pseudoslučajna sekvenca bitova se interpretira tamnim (neprozirnim) (logička nula) i svetlim (prozirnim) (logička jedinica) poljima. S obzirom na to da pseudoslučajna sekvenca može imati veliku dužinu (npr. 1024, što odgovara rezoluciji od 10 bita), i da operater manuelno popunjava predviđena polja, postoji velika mogućnost pogrešnog unosa vrednosti bita. Ne postoji mogućnost automatskog (programiranog) iscrtavanja pseudoslučajnih sekvenci "nula" i "jedinica" u *vector graphics* formatu. Eventualna greška u ovoj fazi, koja bi bez provere bila otkrivena tek nakon ugradnje diska u uređaj, dovela bi do nepotrebnih troškova izrade diska kao i gubitka vremena. Kako postoji velika verovatnoća pojave greške u ovoj fazi izrade diska, neophodno je izvršiti pouzdanu proveru njegove ispravnosti.

Faza fizičke izrade diska podrazumeva niz aktivnosti kao što su izrada filma, fotolitografiju i ecovanje. Izrada filma se vrši tehnologijom koja poržava rezoluciju od 60 μm. U fotolitografskom postupku nejasne konture tamnih i svetlih polja, mogu nastati u slučaju nepravilnog postavljanja folije filma sa crtežom kodnih traka na pločicu diska (potrebno je da strana filma na kojoj je štampa bude uz površinu pločice pri osvetljavanju UV zracima kako ne bi došlo do rasipanja UV zraka na ivicama tamnih polja i pojave nejasnih kontura na samom disku). Nakon fotolitografije vrši se ecovanje. Usled nepreciznosti ovih postupaka može doći do promene dimenzija tamnih i svetlih polja, gubitka oštrine ivica polja, kao i njihovog pomeranja, usled čega kasnije pri korišćenju diska može doći do očitavanja pogrešne informacije. Zato se predlaže pouzdana provera ispravnosti diska i nakon ove faze.

Disk 10-bitnog (n = 10) pseudoslučajnog enkodera sadrži 3 koncentrične trake, slika 5. Spoljna traka je inkrementalna traka dužine 2^{n+1} = 2048 bita (naizmenično poređanih "nula" i "jedinica"). Dve unutrašnje trake su pseudoslučajne trake dužine 2^n = 1024 bita.

Sl. 5. Izgled dela diska pseudoslučajnog pozicionog enkodera

Za pouzdanu proveru ispravnosti iscrtanih pseudoslučajnih traka iskorišćena je mogućnost da se slika tj. fajl u *bitmap* formatu, u programu MATLAB [12] može jednoznačno predstaviti matricom čiji elementi nose informaciju o

 ISBN 978-86-7466-930-3

pikselima slike. Dimenzije matrice odgovaraju dimenzijama slike izražene u broju piksela. *Bitmap* fajl mora biti pripremljen u *grayscale* modu, što za posledicu ima predstavljanje piksela, tj. elemenata matrice, celim brojevima u opsegu [0, 255]. Elementi matrice (slike) mogu biti predstavljeni samo vrednostima 0 i 1, ali zbog vizuelizacije potreban je i "sivi" piksel, odnosno, zadržan je dati opseg. Vrednošću 0 predstavlja se potpuno crni piksel, vrednošću 255 predstavlja se potpuno beli piksel, dok se vrednošću 128 predstavlja sivi piksel.

Potrebno je poznavati koordinate centra diska enkodera (X_0,Y_0), kao i poluprečnike koncentričnih kružnica kojima su ograničene kodne trake. Predviđeno je inicijalno softversko određivanje ovih parametara.

Analiza *bitmap* fajla crteža kodnih traka, predstavljenih matricom na prethodno opisani način, vrši se očitavanjem vrednosti piksela po kružnoj putanji određenog poluprečnika sa centrom u (X_0,Y_0). S tim u vezi, analiza se svodi na ispitivanje elemenata matrice primenom polarnih koordinata (r, φ). Ceo krug (360˚) se deli na $P=100\cdot 2^{n+1}$ ravnomerno raspoređenih tačaka sa polarnim koordinatama (r, φ_i) $i=1, ..., P$. Zatim se polarne koordinate transformišu u Dekartove koordinate (x_i,y_i) u kojima se ispituje vrednost elementa matrice. Može se uočiti da je za rezoluciju uzorkovanja uzet ugao koji je 100 puta manji od ugla koji na disku zauzima „bit" sa najmanjom ugaonom širinom (u ovom slučaju „bit" na inkrementalnoj traci). Ovako određena rezolucija uzorkovanja obezbeđuje pouzdanu detekciju prelaza između bitova na inkrementalnoj traci.

Na slici 5. prikazan je detalj traka enkodera. Pri detektovanom prelazu kod inkrementalne trake, za isti ugao na kome je detektovan prelaz φ_i očitava se piksel - elemenat matrice na polupečnicima koji odgovaraju sredinama pseudoslučajnih traka. Očitani pikseli svih traka su na slici 5. predstavljeni sivom bojom. U zavisnosti od vrednosti elementa matrice ustanovljava se da li bit pseudoslučajne trake nosi informaciju o logičkoj nuli ili logičkoj jedinici. Ove vrednosti se pamte u posebnim nizovima u programu. Nakon očitavanja svih bitova pseudoslučajnih traka, sadržaj ovih nizova se poredi sa tačnim pseudoslučajnim kodom koji se učitava preko ulaznog fajla i određuje da li postoji greška u njenoj poziciji.

IV. Zaključak

U radu se predlaže očitavanje pseudoslučajnog binarnog koda primenom optičkog modula sa integrisanim nizom fotodetektora primenom metode paralelnog očitavanja koda. Razmatrana su ograničenja prilikom primene senzora TCD1254GFG kompanije Toshiba za očitavanje pseudoslučajnog koda kod optičkog obrtnog pseudoslučajnog enkodera. Analizirani su parametri kao što su prečnik diska i rezolucija enkodera u cilju nalaženja kompromisnog rešenja. Istaknuti su i neki od izvora grešaka u samoj realizaciji enkodera. Dat je i postupak provere ispravnosti projektovanja i iscrtavanja pseudoslučajnih kodnih traka na tehničkom crtežu kao i provera samog diska nakon izrade pre same ugradnje. U cilju daljeg razvoja predloženog rešenja potrebno je ispitati mogućnost primene drugih softverskih paketa koji bi doveli do ovakvih rezultata.

Zahvalnica

Abstract

Accurately and reliable measurement of angular position is a requirement of many modern moveable systems in industry and other fields. Pseudorandom optical absolute encoders offer good resolution as well as reliability and flexibility in operation. The paper analyses the application the linear array of photodetectors for parallel pseudorandom code reading to obtain a true absolute encoder, which, unlike the classical one, has one code track regardless of resolution. The characteristics of the applied sensor are considered, as well as the limitations of its application for pseudorandom code reading. In order to avoid errors when designing the encoder disk, a method of its verification after design based on image processing is proposed. Also, it is possible to check the quality of the disk after its realization.

Application of linear array of photodetectors in optical pseudorandom position encoders

Ponovljivost rezultata merenja nivoa električnog polja EM smetnji

Aleksandar M. Kovačević, Nenad Munić

***Apstrakt*—Ponovljivost rezultata merenja nivoa električnog polja EM smetnji, tokom vremena, na jednom uređaju informacione tehnologije, treba da omogući donošenje konačne odluke o usaglašenosti uređaja. Istovremeno, ponovljivost rezultata navedenih merenja treba da omogući akreditovanoj laboratoriji da preispita svoje rezultate ispitivanja radi obezbeđenja njihove validnosti.**

***Ključne reči*—Validnost; ponovljivost; merenje; električno polje smetnji.**

I. Uvod

ELEKTRONSKA oprema se danas smatra kritičnim projektnim elementom sredstava i sistema naoružanja i vojne opreme (NVO). Pri tome, savremene telekomunikacione uređaje karakteriše s jedne strane velika snaga ultraširokopojasnih predajnika, a sa druge strane osetljivost prijemnika [1]. Pored toga, tome doprinosi i veoma brz razvoj informatičke tehnike, tako da postaje sasvim jasno da ispravan rad svakog uređaja ponaosob i svih zajedno nije moguć bez analize međusobnih elektromagnetskih uticaja.

U Tehničkom opitnom centru [2], specijalizovanoj vojnoj naučnoistraživačkoj ustanovi, u okviru Odeljenja za elektromagnetsku kompatibilnost i uticaje okoline, već više decenija se obavljaju ispitivanja elektromagnetske kompatibilnosti (EMC) sredstava i sistema NVO prema standardima posebne namene (Standardi odbrane Republike Srbije – SORS) [3-5]. Takođe, za potrebe ispitivanja se koriste i drugi vojni standardi od kojih je najpoznatiji MIL-STD-461 [6].

Pored toga, Odeljenje za elektromagnetsku kompatibilnost i uticaje okoline je akreditovano u oblasti ispitivanja elektromagnetske kompatibilnosti (u daljem tekstu Odeljenje za EMC i uticaje okoline), pa je u obavezi da u sklopu obezbeđenja validnosti rezultata ispitivanja redovno vrši sledeće aktivnosti: funkcionalnu proveru merne opreme i opreme za ispitivanje, međuprovere ključne merne opreme, ponavljanje ispitivanja korišćenjem istih metoda i sl. [7].

Veliki broj ponavljanja ispitivanja karakteristika EMC nije uvek moguć, ali u nekim situacijama može biti opravdan (npr. kada se izmerena vrednost menja i po frekvenciji i po amplitudi), jer se nakon navedenih ispitivanja treba da donese odluka o usaglašenosti uređaja [8].

U ovom radu je prikazano ponavljanje merenja nivoa električnog polja EM smetnji na jednom sredstvu NVO (uređaj informacione tehnologije), tokom vremena, radi donošenja konačne odluke o usaglašenosti uređaja (usvajanje uređaja u naoružanje Vojske). Istovremeno, navedeno ponavljanje je omogućilo akreditovanoj laboratoriji da preispita rezultate svojih ispitivanja radi njihove validnosti [7]. Merenja nivoa električnog polja EM smetnji su obavljena na jednom uređaju informacione tehnologije (u daljem tekstu IT uređaj) prema standardima SORS 1029/89 i SORS 1762/89 [3, 4].

II. Uslovi ispitivanja

Merenja nivoa električnog polja EM smetnji su obavljena na jednom IT uređaju prema standardima [3, 4]. IT uređaj predstavlja laptop računar i robustan (eng. rugged) AC/DC adapter za napajanje iz izvora naizmenične struje.

Ispitivanje je izvršeno u opsegu od 30 MHz do 300 MHz, sa odgovarajućom prijemnom antenom (bikonusna antena), koja je postavljena na rastojanje 1 m od IT uređaja, na visini 1,2 m od poda Faradejevog kaveza. IT uređaj je postavljen na sto, visine 80 cm, i priključen AC/DC adapterom, preko ekvivalentne mreže i razdvojnog transformatora, na mrežu za napajanje. Pri tome, drveni sto je bio dimenzija: dužina 1 m, širina 1 m i visina 0,8 m, na kome se nalazi referentna provodna ploča (od bakra), dužine 2,6 m i širine 1 m (površina ploče 2,6 m^2), pri čemu je ploča savijena pod pravim uglovima na dva mesta (Sl. 1).

Sl. 1. Ispitivanje nivoa električnog polja EM smetnji.

Aleksandar M. Kovačević – Fakultet tehničkih nauka, Univerzitet u Kragujevcu, Svetog Save 65, 32000 Čačak, Srbija (e-mail: aleksandar.kovacevic@ftn.kg.ac.rs). Nenad Munić – Tehnički opitni centar, Generalštab Vojske Srbije, Vojvode Stepe 445, 11000 Beograd, Srbija (e–mail: nenadmunic@yahoo.com).

 ISBN 978-86-7466-930-3

Robustni adapter i kabl su odvojeni od provodne površine izolacionom podlogom dimenzija 1,8 m x 0,5 m, debljine 3 cm, koja je postavljena iza uređaja na rastojanju od 15 cm. Rastojanje između ekvivalentne mreže i IT uređaja je iznosilo 60 cm. Na uređaju je emitovano više paralelnih multimedijalnih sadržaja.

Pre početka merenja nivoa električnog polja EM smetnji izvršena je kontrola smetnji okoline kada je IT uređaj isključen (nivo smetnji ambijenta).

Merenje električnog polja EM smetnji vrši se tako što se mernim prijemnikom (meračem polja) pretraži zadati frekvencijski opseg, i merenje obavi na najmanje 3 frekvencije po oktavi na kojima je nivo EM smetnji najveći. Pri tome, beleži se najveća vrednost električnog napona. Pored toga, merenja treba obaviti i na kritičnim frekvencijama za ispitivano sredstvo (npr. frekvencija lokalnog oscilatora, međufrekvencija itd.) [4]. U ovom slučaju, korišćen je vršni – Pk (eng. Peak) detektor analizatora spektra.

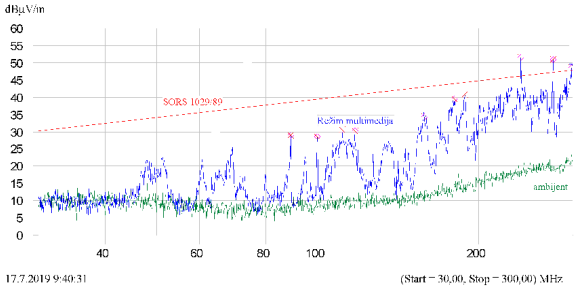
Za navedena merenja korišćena su sledeća merna sredstva i oprema:

- EMC analizator spektra E7402A, Agilent, od 100 Hz do 3 GHz;
- Bikonusna antena SAS-542, A.H. Systems, od 20 MHz do 330 MHz;
- Ekvivalentna V-mreža ENV216, R&S;
- Stoni računar ASUS sa aplikacijom za automatizaciju merenja (EMC Measurement Application E7415A);
- RF limiter 11867A, Agilent;
- Razdvojni transformator MA 4801, ISKRA;
- Kabl RG-214/U.

Pre početka ispitivanja je konstatovano da je navedena merna oprema metrološki ispravna jer ima prihvatljivu metrološku sledivost, koju prate dokumenta o pregledu, odnosno isprave o usaglašenosti merne opreme sa propisanim zahtevima, a u skladu sa Pravilnikom o metrološkoj delatnosti u oblasti odbrane [9].

Uslovi okoline:

- temperatura okoline: 23°C ± 2°C,
- relativna vlažnost vazduha: 50% ± 15%.

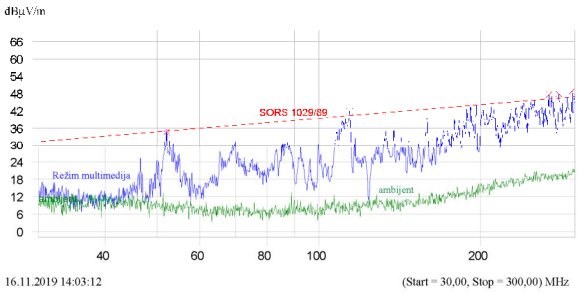


III. KRITERIJUM ZA OCENU REZULTATA MERENJA

Nivo električnog polja EM smetnji u zadatom frekvencijskom opsegu treba da bude manji od graničnih vrednosti [3]. S obzirom da IT uređaj nije ispunio zahteve standarda u frekvencijskom opsegu od 30 MHz do 300 MHz, nakon nekoliko meseci je izvršeno ponavljanje merenja na istom uređaju. Naime, ponavljanje merenja nivoa električnog polja EM smetnji na istom IT uređaju, trebalo je da omogući donošenje konačne odluke o usaglašenosti uređaja (usvajanje uređaja u naoružanje Vojske).

Pri tome, razmatrane su one frekvencije na kojima je nivo električnog polja EM smetnji bio iznad graničnih vrednosti. Kao kriterijum za ocenu rezultata merenja je uzeto da razlika u dobijenim vrednostima između ta dva merenja bude u granicama merne nesigurnosti U_m – proširena merna nesigurnost merenja nivoa električnog polja EM smetnji (za faktor proširenja ili prekrivanja $k = 2$).

IV. REZULTATI MERENJA



Grafički prikaz rezultata merenja nivoa električnog polja EM smetnji (rezultati I) je dat na Sl. 2.

Sl. 2. Grafički prikaz rezultata merenja nivoa električnog polja EM smetnji (rezultati I).

Na osnovu Sl. 2 može se konstatovati da IT uređaj, u režimu multimedija, generiše električno polje EM smetnji iznad dozvoljene granične vrednosti [3], i to na 3 frekvencije: 255 MHz, 272 MHz i 298 MHz. Pri tome, maksimalno premašenje iznosi 5 dB (na frekvenciji od 255 MHz).

Nakon nekoliko meseci, izvršeno je ponavljanje merenja na istom uređaju u frekvencijskom opsegu od 30 MHz do 300 MHz. Grafički prikaz rezultata merenja nivoa električnog polja EM smetnji (rezultati II) je dat na Sl. 3.

Sl. 3. Grafički prikaz rezultata merenja nivoa električnog polja EM smetnji (rezultati II).

Na osnovu Sl. 3 može se konstatovati da IT uređaj, u režimu multimedija, generiše električno polje EM smetnji iznad dozvoljene granične vrednosti [3], i to na 5 frekvencija: 55 MHz, 120 MHz, 260 MHz, 270 MHz i 295 MHz. Pri tome, maksimalno premašenje iznosi 2 dB (na frekvenciji od 295 MHz).

Proširena merna nesigurnost, U_m, za merenje nivoa električnog polja EM smetnji ($k = 2$), kada se za merenje koristi bikonusna antena, iznosi 5,3 dB i u skladu je sa preporukama standarda CISPR 16-4-2:2018 [10]. Pri tome, obračun merne nesigurnosti za električno polje EM smetnji

 ISBN 978-86-7466-930-3

dat je detaljno u internoj Proceduri za određivanje merne nesigurnosti kod ispitivanja EMC [11].

Na osnovu dobijenih rezultata (Sl.2 i Sl.3) i postavljenog kriterijuma, konstatovana je ponovljivost rezultata ispitivanja, odnosno ponovljivost smetnji na približno istim frekvencijama. Razlog manjih odstupanja, može biti razlika u napunjenosti baterije IT uređaja, odnosno struji punjenja u trenutku ispitivanja. Pored toga, utvrđeno je da je razlika u dobijenim vrednostima u granicama merne nesigurnosti, tako da je obezbeđena validnost rezultata merenja.

V. ZAKLJUČAK

U Tehničkom opitnom centru, specijalizovanoj vojnoj naučnoistraživačkoj ustanovi, u okviru Odeljenja za elektromagnetsku kompatibilnost i uticaje okoline, već više decenija se obavljaju ispitivanja elektromagnetske kompatibilnosti (EMC) sredstava i sistema NVO prema standardima posebne namene (SORS).

Kako je Odeljenje za EMC i uticaje okoline akreditovano u oblasti ispitivanja elektromagnetske kompatibilnosti, u obavezi je da u sklopu obezbeđenja validnosti rezultata ispitivanja redovno vrši funkcionalnu proveru merne opreme i opreme za ispitivanje, međuprovere ključne merne opreme, ponavljanje ispitivanja korišćenjem istih metoda i sl.

U ovom radu je prikazano ponavljanje merenja nivoa električnog polja EM smetnji, u frekvencijskom opsegu od 30 MHz do 300 MHz, na jednom IT uređaju (sredstvo vojne opreme), tokom vremena, radi donošenja konačne odluke o usaglašenosti uređaja (usvajanje uređaja u naoružanje Vojske). Pri tome, navedeno ponavljanje je omogućilo akreditovanoj laboratoriji da preispita rezultate svojih ispitivanja radi njihove validnosti.

Na osnovu dobijenih rezultata, konstatovana je ponovljivost rezultata ispitivanja na približno istim frekvencijama. Razlog manjih odstupanja, može biti razlika u napunjenosti baterije IT uređaja, odnosno struji punjenja u trenutku ispitivanja. Pored toga, utvrđeno je da je razlika u dobijenim vrednostima u granicama merne nesigurnosti, tako da je obezbeđena validnost rezultata merenja.

ABSTRACT

The repeatability of EM interference electric field level measurement results, over time, on an information technology device, should enable a final decision on the conformity of the device. At the same time, the repeatability of the results of these measurements should allow the accredited laboratory to review its test results to ensure their validity.

Milan Šaš i Miroljub Pešić

***A stra t* — le trogastrografija (GG) je neinvazivna elektrofiziološka tehni a oja se oristi za snimanje električne a tivnosti želuca pomoću ele troda postavljenih na abdomen. GG se do sada najviše oristio u kliničkim studijama i dijagnostici u gastroenterologiji, ali se sve više javlja interesovanje za naučno istraživanje GG metode u oblasti biomedicine i psihofiziologije. Cilj ovog rada je da se, na osnovu postojeće literature, prikažu osnovne fiziološke ara teristi e EGG signala, kao i mogući načini snimanja i obrade ovih signala.**

***Ključne reči* — le trogastrografija; Gastrični spori talasi; Gastrointestinalni motilitet; Mioelektričnost.**

I. UVOD

ELEKTROGASTROGRAFIJA je neinvazivna tehnika za snimanje mioelektrične aktivnosti želuca pomoću površinskih elektroda postavljenih na abdominalnu kožu u predelu želuca. Signal snimljen elektrogastrografijom naziva se elektrogastrogram (EGG) [1-5]. Tokom prve polovine dvadesetog veka, elektrogastrogram (EGG) su nezavisno otkrila tri naučnika: Valter Alvarez (gastroenterolog, 1922) [6,7], Harison Tumpeer (pedijatar, 1926, 1932) [7-9] i R.C. Davis (psihofiziolog, 1950) [10,11]. Počevši od 1974. godine, kada su istraživači Stevens i Vorrall (1974) prvi primenili tehniku spektralne analize na EGG [12], a potom 1975. istraživači u Engleskoj objavili brojne studije o frekvencijskoj analizi EGG signala, došlo je do velikog napretka u tehnikama analize EGG signala [13-15].

Zbog svoje neinvazivne prirode i sve većeg napretka tehnike snimanja EGG-a, kao i moguće računarske analize snimljenog signala, EGG je postao veoma atraktivan alat za proučavanje elektrofiziologije želuca i patofiziologije poremećaja motiliteta želuca, pa se trenutno koristi i u naučnim i u kliničkim istraživanjima [16-19].

Da bi se procenilo da li je EGG signal koristan kao istraživačko i/ili kliničko sredstvo, najpre treba u potpunosti razumeti šta se može meriti pomoću EGG-a i kako bi EGG trebalo da bude snimljen, interpretiran i analiziran. U tu svrhu, u ovom radu je najpre opisana elektrofiziologija želuca, odnosno mioelektrična aktivnost želuca koja se može meriti korišćenjem površinskih elektroda, a potom su opisani i karakteristični parametri EGG signala. S obzirom da se za snimanje EGG signala koriste površinske elektrode, EGG signal je osetljiv na artefakte pokreta, kao i na električne signale drugih unutrašnjih organa, te su u ovom radu opisani tehnički detalji pravilnog merenja EGG signala u cilju sprečavanja artefakata. Na kraju rada je dat pregled primene EGG-a, uključujući primenu EGG-a za proučavanje elektrofiziologije želuca, upotrebu EGG-a u proceni efekta intervencije i klinički značaj EGG-a kod pacijenata sa simptomima koji ukazuju na želudačnu disfunkciju.

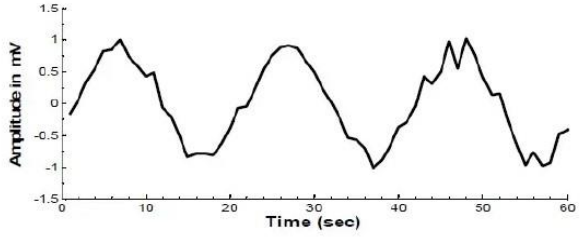
II. ELEKTROFIZIOLOGIJA ŽELUCA

EGG se definiše kao snimanje mioelektrične aktivnosti glatkih mišića želuca pomoću elektroda pričvršćenih na kožu abdomena. EGG predstavlja bezbolan test kojim se određuje električna aktivnost u stomaku, pre, tokom i posle jela.

Radi lakšeg razumevanja rada želuca, na Sl. 1 su prikazani njegovi delovi:

- fundus je rezervoar za hranu,
- korpus - proizvodi se enzim pepsin,
- gastrični pejsmejker se nalazi na velikoj krivini korpusa i generiše električne impulse,
- antrum - proizvodi se hormon gastrin i tu se vrši mešanje i mlevenje hrane,
- pilorus je ventil između želuca i dvanaestopalačnog creva.

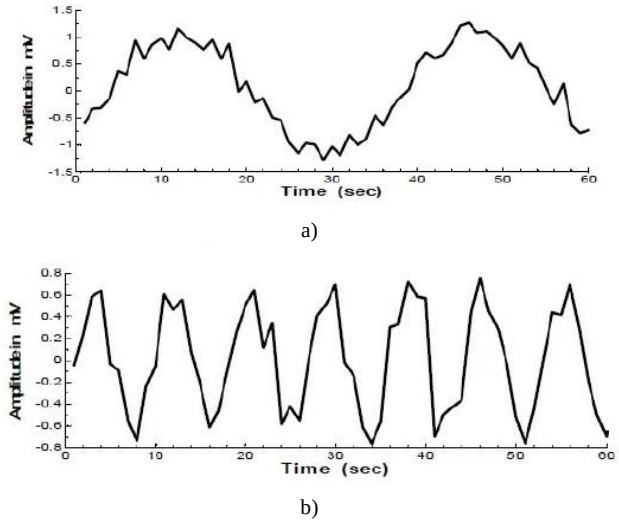


Sl. 1. Delovi želuca.

Gastrični pejsmejker generiše električni signal svakih 20 s, koji se širi ka antrumu, i kao odgovor na kalorijski izazov ili lek, stvara snažne peristaltičke kontrakcije koje guraju antralni sadržaj ka pilorusu i pomažu u mlevenju i mešanju hrane.

 ISBN 978-86-7466-930-3

A. Normalna mioelektrična akti nost želuca



Mioelektrična aktivnost želuca sastoji se od sporih talasa i šiljastih (spajk) potencijala (Sl. 2) [3]. Spori talas se još naziva i aktivnost električne kontrole, dok se šiljasti potencijali nazivaju akcioni potencijali [20,21]. Frekvencija normalnih sporih talasa u želucu iznosi približno 3 ciklusa u minuti (cpm) kod ljudi [22-24] i 5 cpm kod pasa [25,26], dok je amplituda od 50 μV do 500 μV. Gastrični spori talas određuje maksimalnu frekvenciju i propagaciju želudačnih kontrakcija. Šiljasti potencijali se smatraju električnim parom želudačnih kontrakcija, odnosno kontrakcija želuca nastaje kada je spori talas praćen šiljastim potencijalima.

Sl. 2. Normalna mioelektrična aktivnost želuca.

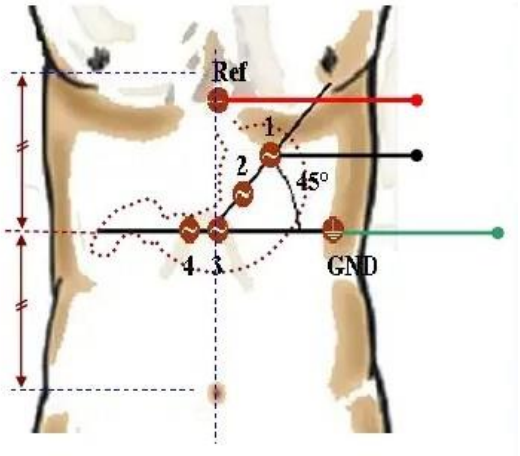
B. Gastrična aritmija i abnormalni spori talasi

Mioelektrična aktivnost želuca može se promeniti ili postati abnormalna u bolesnim stanjima ili nakon operativnih zahvata ili spontano. Abnormalna mioelektrična aktivnost želuca uključuje želudačnu aritmiju, abnormalno sporo širenje talasa (bradigastrija) i abnormalno povećanje brzine električne aktivnosti (tahigastrija). Normalna frekvencija gastričnog sporog talasa kod ljudi je oko 2-4 cpm, dok je bradigastrija u opsegu 0.5-2.0 cpm, a tahigastrija u opsegu 4-9 cpm. Ukoliko se dominantna frekvencija ne može odrediti, u pitanju je želudačna aritmija. Bradigastrija i tahigastrija mogu biti povezani sa mučninom, gastroparezom, sindromom iritabilnog creva.

Sl. 3. Abnormalna mioelektrična aktivnost želuca: a) bradigastrija, b) tahigastrija.

III. MERENJE ELEKTROGASTROGRAMA

Mioelektrična aktivnost želuca se može meriti:



- serozno (elektrode na seroznoj površini želuca se postavljaju hirurški),
- intraluminalno (intubacija katetera sa elektrodama za snimanje želuca), ili
- na površini kože (pomoću površinskih elektroda).

Prve dve metode su invazivne i njihove primene su ograničene uglavnom na životinje i izvode se u laboratorijskim uslovima [1]. EGG metoda (merenje aktivnosti želuca pomoću površinskih elektroda) ima široku primenu kod ljudi i u kliničkim istraživanjima jer je neinvazivna i ne remeti tekuću aktivnost želuca. Brojne studije validacije su dokumentovale tačnost EGG metode upoređujući je sa snimkom dobijenim sa mukoznih i seroznih elektroda [15,1]. Pokazano je da se zapis EGG-a može ponoviti, bez značajnih dnevnih varijacija [27], a utvrđeno je i da kod odraslih, starost i pol nemaju nikakav uticaj na EGG [28,29].

Zbog prirode merenja, EGG je osetljiv na artefakte pokreta. Shodno tome, pažljiva i pravilna priprema pre snimanja je ključna za dobijanje pouzdanih podataka.

Priprema kože - S obzirom da su EGG signali veoma slabi, vrlo je važno minimizirati impedansu između kože i elektroda, pa je neophodno dobro očistiti abdominalnu površinu na koju će se postaviti elektrode. EGG može sadržati ozbiljne artefakte pokreta ako koža nije dobro pripremljena.

Posta ljanje elektroda - Standardne elektrokardiografske elektrode se obično koriste za snimanje EGG. Iako ne postoji utvrđen standard, opšte je prihvaćeno da aktivne elektrode za snimanje treba da budu postavljene što bliže antrumu da bi se postigao visok odnos signal-šum [30]. EGG signali se mogu snimiti bilo unipolarnim ili bipolarnim elektrodama, ali bipolarno snimanje daje signale sa većim odnosom signal-šum. Jedna najčešće korišćena konfiguracija elektroda za snimanje četvorokanalnih EGG zapisa je prikazana na Sl. 4.

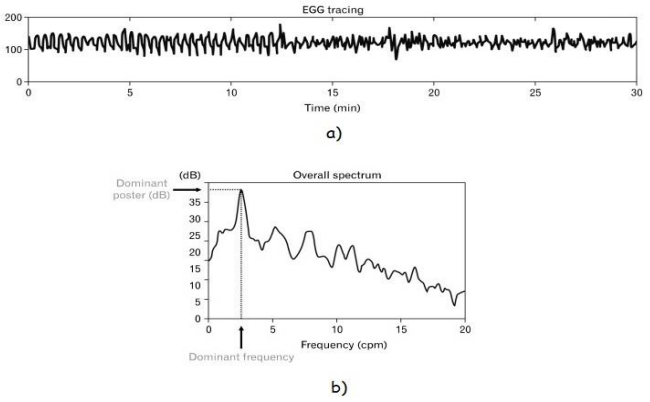
Sl. 4. Primer postavljanja elektroda za merenje EGG signala.

Po icioniranje ispitanika - Ispitanik treba da bude u udobnom ležećem položaju ili da sedi u fotelji, u tihoj prostoriji, tokom čitave procedure snimanja. Kad god je to

 ISBN 978-86-7466-930-3

moguće, preporučuje se ležeći položaj, jer je ispitanik u ovom položaju opušteniji, a samim tim se pojavljuje manje artefakata pokreta. Ispitanik bi trebalo da ostane što je moguće mirniji i da ne učestvuje u razgovorima, kako bi se maksimalno sprečili artefakti pokreta [19,1].

Dužina snimanja i test obrok - Snimanje EGG-a se obično vrši nakon gladovanja od 6 ili više sati. Lekove koji mogu da modifikuju mioelektričnu aktivnost želuca treba prekinuti najmanje 48 sati pre testa [18,19]. EGG treba snimati najmanje 30 minuta (ne <15 min u svakom slučaju) u stanju gladovanja i najmanje 30 minuta u stanju jedenja. Test obrok treba da sadrži najmanje 250 kcal bez mnogo masti [31]. Obično se preporučuju čvrsti obroci, mada se u nekim istraživanjima koristila voda kao test obrok.



IV. PARAMETRI EGG

I pored toga što se eliminacija šuma iz EGG signala može postići pomoću naprednih tehnika obrade signala [1,32], analiza talasnog oblika EGG-a u vremenskom domenu se retko koristi. Talasni oblik EGG-a je povezan sa mnogim faktorima, kao što su debljina trbušnog zida ispitanika, priprema kože, položaj elektroda i karakteristike uređaja za snimanje [33].

Broj specifičnih karakteristika EGG-a je ograničen, pa se kod jednokanalnog snimanja EGG mogu meriti samo frekvencija i amplituda. Nedavne kompjuterske simulacije i eksperimenti pokazali su da se širenje gastričnog sporog talasa može identifikovati uz pomoć višekanalnih snimaka EGG [33], ali je teško dobiti ove informacije iz analize talasnog oblika u vremenskom domenu [32]. Shodno tome, kvantitativne analize podataka EGG-a se uglavnom zasnivaju na metodama spektralne analize.

Frekvencija za koju se veruje da je želudačnog porekla i na kojoj snaga u EGG spektru snage ima vršnu vrednost u opsegu od 0.5–9.0 cpm naziva se *EGG dominantna frek encija*. *ominantna snaga* je snaga na dominantnoj frekvenciji. Snaga EGG može biti predstavljena u linearnim jedinicama ili u decibelima (dB). Dominantna frekvencija i snaga EGG-a se često jednostavnije nazivaju kao EGG frekvencija i snaga EGG-a. Sl. 5 prikazuje definiciju dominantne frekvencije i snage EGG. Simultani kožni i serozni [9,13-15] ili mukozni [7,12] snimci aktivnosti želuca pokazali su da dominantna frekvencija EGG-a predstavlja frekvenciju sporog talasa želuca. Dominantna snaga EGG-a odražava amplitudu i pravilnost želudačnih sporih talasa.

Gastrični spori talas se smatra abnormalnim ako dominantna frekvencija EGG-a nije unutar određenog frekventnog opsega (npr. 2-4 cpm). Iako ne postoji utvrđena definicija normalnog opsega gastričnog sporog talasa, opšte je prihvaćeno da je dominantna frekvencija EGG-a kod asimptomatskih normalnih subjekata između 2 cpm i 4 cpm [17,18,22,34]. EGG, ili segment EGG-a, definiše se kao tahigastrija ako je njegova frekvencija > 4 cpm, ali < 9 cpm, bradigastrija ako je frekvencija < 2 cpm i aritmija ako postoji nedostatak dominantne frekvencije (videti Tabelu I).

Sl. 5. Analiza spectra EGG: a) Zapis EGG u trajanju od 30 minuta, b) Spektar snage 30-minutnih EGG podataka. Dominantna frekvencija EGG-a (DF) i snaga na DF se mogu odrediti iz spectra [3].

TABELA I
PARAMETRI EGG-A

	omponenta	re vencija (cpm)
ignal	Normalni spori talas	2–4
	Bradigastrija	0.5–2
	Tahigastrija	4–9
Šum	Respiratorni	12–24
	Tanko crevo	9–12
	EKG	60–80
	Artefakti pokreta	Ceo interval merenja

V. PRIMENA EGG

EGG ima značajnu primenu u sledećim oblastima:

(1) elektrofiziološke studije,
(2) procena efikasnosti intervencije ili terapije, i
(3) otkrivanje abnormalnosti sporog talasa kod pacijenata sa poremećajem želudačnog motiliteta ili sumnja na poremećaj motiliteta želuca.

Navešćemo neke od primena u pomenutim oblastima.

Elektrofiziološke studije - za proučavanje elektrofiziologije želuca jer je neinvazivna metoda i ne prekida tekući proces u želucu. Jedna od takvih primena je proučavanje razvojnog procesa želudačnih sporih talasa kod novorođenčadi [35]. Progresivno povećanje procenta normalnih gastričnih sporih talasa zabeleženo je tokom prvih 6 meseci nakon rođenja kod 19 nedonoščadi.

Procena efikasnosti inter encije ili terapije - Na spore talase u želucu mogu uticati različite intervencije, stres i farmakološke terapije. EGG se često koristi u proceni efekta stresa i efikasnosti farmakoloških terapija i intervencija.

tkri anje abnormalnosti sporog talasa – EGG se koristi kada se sumnja da pacijent ima poremećaj motiliteta, što se može pokazati kao ponavljajuća mučnina i povraćanje, a to su znaci da želudac ne prazni hranu normalno.

Klinička primena elektrogastrografije najšire je procenjivana kod bolesnika s gastroparezom i funkcionalnom dispepsijom.

 ISBN 978-86-7466-930-3

VI. ZAKLJUČAK

EGG je neinvazivna procedura za pouzdano merenje sporih talasa u želucu i kontraktilne aktivnosti želuca. Iako je dosta osetljiva dijagnostička metoda, EGG predstavlja izuzetan uvid u funkcionisanje čovekovog gastrointestinalnog sistema.

Međutim, EGG pruža klinički, fiziološki i/ili patofiziološki značajne informacije samo kada se pravilno snima, analizira i tumači. Snimanje i analiza EGG-a još uvek nisu u potpunosti standardizovani. Kao što je u radu opisano, snimanje EGG-a treba izvoditi vrlo oprezno da bi se minimizirali mogući artefakti.

Budući razvoj EGG metodologije bi pre svega trebalo da se fokusira na definisanje i postavljanje preciznih standarda za snimanje i analizu karakterističnih parametara EGG-a, kako bi se omogućilo precizno dijagnostikovanje poremećaja motiliteta želuca.

ZAHVALNICA

Ovaj rad je podržan od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

Electrogastrography (EGG) is a non-invasive electrophysiological technique used to record the electrical activity of the stomach using electrodes placed on the abdomen. EGG has been mostly used in clinical studies and diagnostics in gastroenterology, but there is a growing interest in scientific research of EGG methods in the field of biomedicine and psychophysiology. The aim of this paper, based on the existing literature, is to present the basic physiological characteristics of EGG signals, as well as possible ways of recording and processing these signals.

Sistem za merenje pritiska u konceptu Internet of Things

Tomislav Pap, Marjan Urekar, *Member, IEEE*

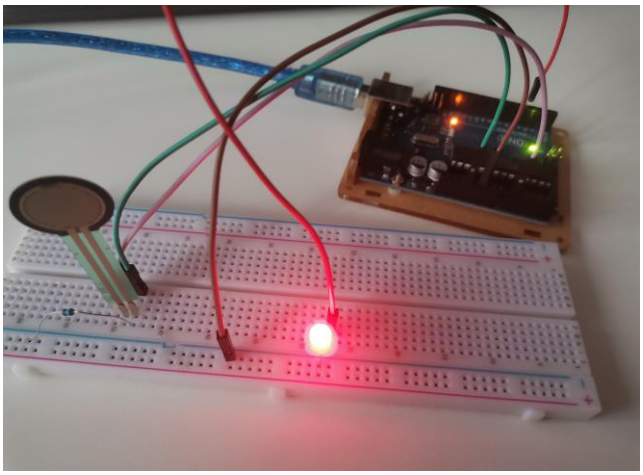
***Apstrakt*—Za potrebe merenja pritiska u konceptu Internet of Things, razvijen je sistem koji se sastoji od komercijalnog mikrokontrolera Arduino UNO, senzora pritiska koji radi na principu otpornika osetljivog na silu, koji je robustan i široko rasprostranjen, čiji je opseg detekcije pritiska do 98 Pa i par LED dioda koji služi za signalizaciju detekcije pritiska. U II poglavlju je dat opis hardvera i detaljan opis senzora. III poglavlje sadrži kratak opis softvera koji se izvršava na mikrokontroleru ovog sistema. Moguće primene sistema su predstavljene u poglavlju IV.**

***Ključne reči*—IoT, Industrija 4.0, metrologija, merenje pritiska, merenje sile, sensor pritiska, otpornik osetljiv na silu, mikrokontroler, merni sistem.**

I. Uvod

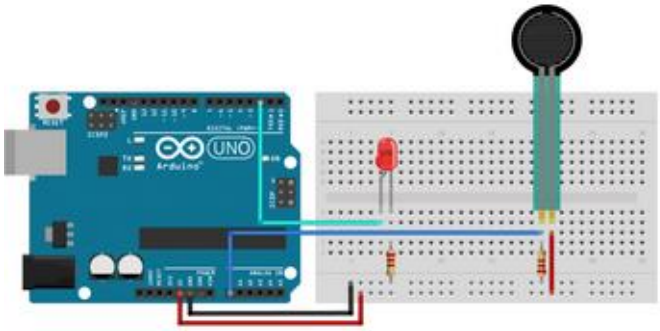
Mi smo sada u četvrtoj industrijskoj revoluciji, poznatijoj kao Industrija 4.0 [1]. Industrija 4.0 je uvela revoluciju u automatizaciji, monitoringu i logistici kroz pametnu tehnologiju. Zasnivajući se na IioT (eng. Industrial Internet of Things) i ugrađene softverske sisteme (CPS, eng. Cyber-Physical systems), koji su dovoljno pametni i autonomni, koji koriste kompjuterske algoritme za monitoring i kontrolu fizičkih stvari kao što su mašine, roboti i prevozna sredstva, transformiše virtualni i stvarni svet u cilju stvaranja mreža gde subjekti i objekti pametno komuniciraju jedni sa drugima.

Temelji Industrije 4.0 su "pametni" računari urađeni u CPS. Ovi računari obrađuju informacije prikupljene preko senzora i oni su sposobni da odrede i mere trenutno stanje opreme i procesa, analiziraju situaciju i pokrenu određene akcije koje poboljšavaju ukupno stanje. Ovo je urađeno kroz povezivanje hardvera i softvera novim digitalnim umrežavanjem. Glavni metrološki zahtevi sa Industrijom 4.0 su: vreme i ekonomičnost, realno vreme izvršenja, automatizacija i velika brzina. Prema tome, razvoj metrologije zasnovan je na aspektima: brzine, preciznosti, pouzdanosti i fleksibilnosti.



Jedan od načina na koji može da se senzor pritiska SEN-09375 priključi na Internet of Things, odnosno da se uvrsti u Industriju 4.0 je koristeći Arduino UNO mikrokontroler.

Tomislav Pap – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail:pap.e125.2020@uns.ac.rs).



Marjan Urekar – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: urekarm@uns.ac.rs).

II. Hardver

Celokupan sistem je spojen na protobordu gde je izlaz senzora doveden na analogni ulaz mikrokontrolera. Kao mikrokontroler, izabran je Arduino UNO zbog njegove široke rasprostranjenosti i jednostavnosti za korišćenje. Arduino UNO je baziran na ATmega328P čipu [2]. Sastoji se od 14 ulazno/izlaznih digitalnih pinova (gde se 6 mogu koristiti kao PWM izlazi), 6 analognih ulaza, 16 MHz rezonatora, USB porta, koji može da služi i kao napajanje, zasebnog porta za napajanje, ICSP (eng. Integrated circut serial peripherial interface) hedera i reset dugmeta. Sistem se može videti na slici 1. Kao napajanje korićen je USB adapter koji pruža napajanje do 5 V.

Sl. 1. Sistem za detekciju pritiska do 98 Pa

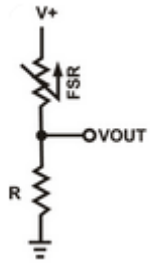
Sl. 2. Šema sistema za detekciju pritiska [3]

FSR (eng. force sensing resistor) su robusni senzori pritiska koji se koriste u raznim industrijama. Izabrali smo FSR [4] jer je jako jeftin i široko je dostupan. Otpornost FSR zavisi od pritiska koji se primeni na aktivnu oblast senzora. FSR menja

 ISBN 978-86-7466-930-3

svoju otpornost u zavisnosti od toga koliki pritisak je primenjen u oblasti detekcije. Što je veći pritisak primeni, manja je otpornost.

Vrednost otpornika osetljivog na silu unutar senzora je veća od 1 MΩ kada nema pritiska, pa do 200 Ω kada senzor trpi najveći pritisak. Ovakvi senzori mogu da detektuju silu od 0.98 N do 98.07 N. Dva pina sa razmakom od 2,54 mm za proširenje nalaze se na dnu senzora i omogućavaju spajanje sa protopločom.



Ovaj senzor je jednostavan za postavljanje i detekciju pritiska ali nema visoku tačnost. Grafik koji je prikazan na slici 3, prikazuje kako se otpornost menja u zavisnosti od primenjene sile. Na početku vidimo priličan pad otpornosti, za malu silu, a kasnije vidimo da je osetljivost manje- više linearna.

Krajnje, za vizuelizaciju detekcije i promene pritiska na aktivnoj oblasti senzora, korišćena je crvena LED dioda. Za detaljniji uvid u merenja senzora pritiska, iskorišćena je serijska komunikacija za prikaz podataka na serijskom monitoru računara.

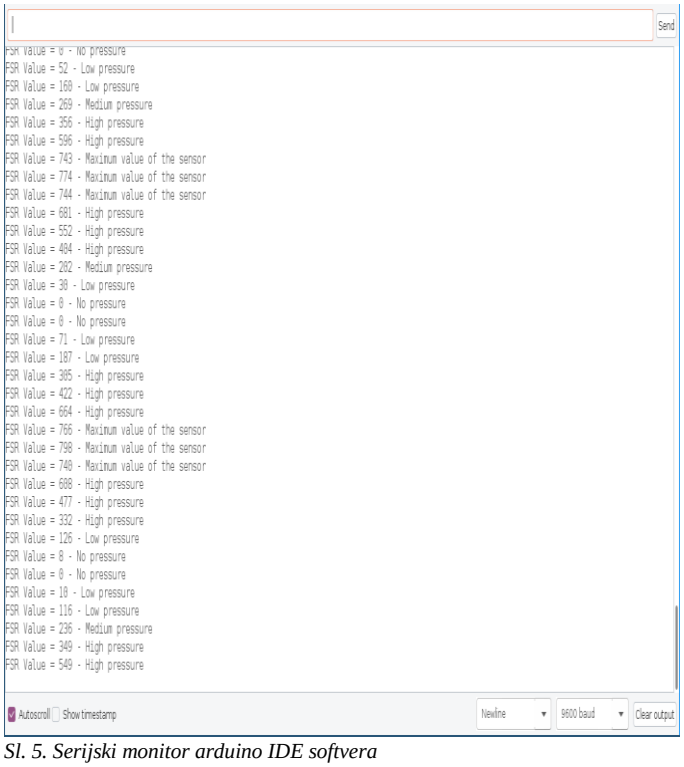
Sl. 3. Osetljivost FSR senzora

Kako bismo detektovali i izmerili vrednost sa FSR senzora za to nam je potreban naponski razdelnik prizan na slici 4. To ćemo uraditi tako što kao prvi otpornik ustvari uzeti FSR senzor, a drugi pulldown otpornik. *V+* je 5 volti(može i 3.3 V), a *Vout* je podatak koji nam dolazi sa FSR senzora. Odabir odgovarajućeg otpornika u naponskom razdelniku određuje osetljivost FSR i direktno utiče na raspon sile koju želimo da merimo.

Sl. 4. Naponski razdelnik

Podatak koji nam daje FSR se preračunava kao:

$$Vout = \frac{Vcc \times R}{R + Rfsr} . \quad (1)$$



Kada sila nije primenjena na senzor, otpornost će biti jako velika, a nasuprot tome, kada baš jako pritisnemo senzor, silom približno 100 N ili jače, otpornost će biti faktički 0 ili jako blizu toga.

III. SOFTVER

Softver sistema za detekciju pritiska je napisan u Arduino IDE okruženju u modifikovanovoj verziji C programskog jezika, podržanog od strane Arduino mikrokontrolera. Arduino IDE podržava C I C++ programske jezike i dolazi sa ugrađenom softverskom bibliotekom koja podržava mnoge funkcionalnosti ulazno/izlaznih pinova.

Koristeći već ugrađene mogućnosti Arduino IDE okruženja, inicijalnom funkcijom, analogni pin na koji je zakačen senzor pritiska je postavljen kao ulazni pin, dok je digitalni pin, koji šalje digitalne signale ka LED diodi postavljen kao izlazni pin. Takođe, setovan je inicijalno baud rate serijske komunikacije na 9600bps, kako bismo mogli ispravno da šaljemo poruke ka serijskom monitoru [5] koji je sastavni deo alata Arduino IDE.

Očitavanje vrednosti analognog pina senzora pritiska se izvršava na svakih pola sekunde u beskonačnoj petlji. Nakon očitane vrednosti senzora, vrši se procena veličine izmerene vrednosti i u zavisnosti u kom opsegu se nalazi očitana vrednost, šalju se poruke ka serijskom monitoru arduinovog sofverskog okruženja. Time dobijamo detaljan uvid u izmerene vrednost senzora pritiska.

Sl. 5. Serijski monitor arduino IDE softvera

 ISBN 978-86-7466-930-3

IV. ZAKLJUČAK

Ovakav sistem bi mogao da se koristi kao detekcija da li je beba/dete i dalje na krevetu, ako bi se ovaj senzor instalirao ispod posteljine što bi dalo mogućnost roditeljima da prate ponašanje svoga deteta u svakom trenutku. Još jedna dobra primena ovog sistema u industriji 4.0 bi bila kada bi se ovaj sistem spregnuo sa frižiderom, tako da se ovakav senzor nalazi ispod slotova sa namirnicama, pa bi se time moglo doći do informacije da li određene namirnice postoje u frižideru i ako da, u kojoj meri. Postojeću šemu moguće je poboljšati dodavanjem još par LED dioda kako bismo mogli ne samo da detektujemo pritisak, nego i preciznije prikažemo trenutno detekciju. Takođe umesto Arduina UNO, moglo bi se koristiti Arduino Nano [6]. Koristeći Arduino Nano, proizvodnja u početku bi bila skuplja jer bi se žice morale lemiti direktno na mikrokontroler, ali dizajn bi bio kompaktniji i jeftiniji jer sam Arduino Nano jeftiniji nego Arduino UNO. Ovakav sistem bi koristio manje električne energije što može da doprinese ekonomičnosti na duži vremenski period. Arduinov radni napon je limitiran do 12 V, tako da neko zaštitno kolo od većeg napona bi bila dobra opcija za razmatranje u budućnosti.

ZAHVALNICA

Ovaj rad je podržan od strane Fakulteta tehničkih nauka u Novom Sadu, Departmana za energetiku elektroniku i telekomunikacije, u okviru realizacije projekta MPNTR 200156 : „Inovativna naučna i umetnička ispitivanja iz domena delatnosti FTN-a“

ABSTRACT

For needs in pressure measurements in concept Internet of Things, it was developed a system which consists of commercial microcontroller Arduino UNO, pressure sensor which works on principal of resistor which is sensitive to force, which is robust and widely spread, which range for pressure detection is up to 98 Pa, and couple of LED diodes which are used for pressure detection visualization. In chapter II is given a description of hardware and description of sensor in detail. Chapter III consists of short description of software which is executed on microcontroller of this presented system. System’s usage possibilities are presented in chapter IV.

Merno-informacioni sistem za automatsko hranjenje kućnih ljubimaca

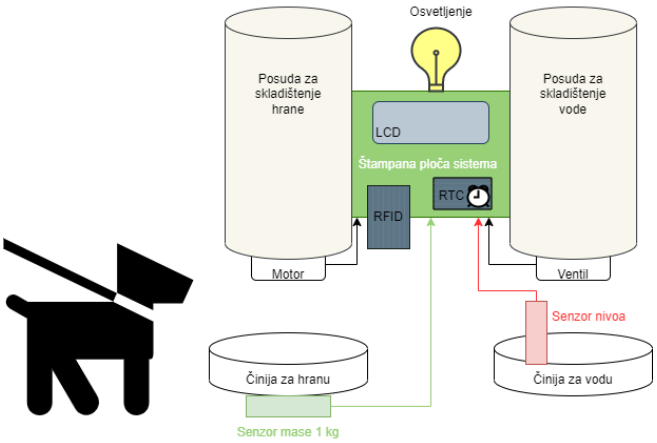
Maja Perić, Marjan Urekar, *Member, IEEE*

***A stra t*— ovom radu je pri azana realizacija sistema za automats o hranjenje ljubimaca u ućnim uslovima korištenjem dostupnih softvers ih alata. le trons a šema sistema je proje tovana u iCad programu, do je deo oda sistema pisan u Arduino ID razvojnom okruženju. Cilj sistema jeste da upotrebom različitih senzora vrši merenje zadatih veličina, ostvari prenos, obradu i pri az podata a do mi ro ontrolera, ao i da automatizuje rad servo motora i magnetnog ventila.**

***Ključne reči*— iCad, Arduino ID , Atmega 2 P, senzori, servo motor, magnetni ventil.**

I. Uvod

Posedovanje kućnih ljubimaca je oduvek bila, i ostaće velika obaveza. Ljubimcima je neophodno posvetiti dovoljno pažnje, što uključuje redovne šetnje, igru, i naravno ispravno i redovno hranjenje. Za mnoge ljude, ispravno hranjenje kućnih ljubimaca može predstavljati problem, koji postaje posebno očigledan ukoliko vlasnici ljubimaca imaju okupiran lični život. Kada vlasnici nemaju vremena da nahrane svoje ljubimce na vreme, obično ostavljaju činije za hranu pune pre odlaska. Nezdrava ishrana, odnosno previše hrane, će skoro uvek izazvati zdravstvene probleme kod ljubimaca, što će uzrokovati kraći životni vek ljubimaca.



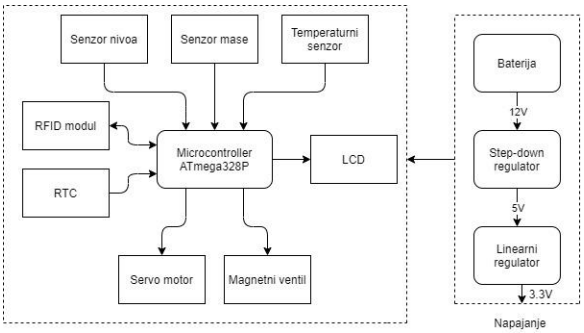
Cilj ovog sistema jeste da obezbedi lakši i efikasniji način za vlasnike da hrane svoje ljubimce, čak i kada nisu kod kuće. Konkretno, cilj je realizacija sistema koji može da detektuje kućne ljubimce, i da im na osnovu informacija koje dobija sa senzora, automatski dosipa vodu i hranu. Vlasnici bi bili u mogućnosti da ovim sistemom hrane različite vrste ljubimaca, ili ljubimce različite starosne dobi. Svaki ljubimac bi imao svoju oznaku, pomoću koje bi se vršila identifikacija. Ovaj sistem nudi personalizovan način hranjenja i brige o ljubimcima, jer je vlasnik u mogućnosti da postavlja oznake ljubimcu ili ljubimcima, kao i da određuje vreme i količinu hrane.

A. Princip rada sistema

Princip rada sistema se zasniva na tome da mikrokontroler dobija informacije sa senzorskih modula, nakon čega te informacije obrađuje i upravlja motorom i ventilom.

Maja Perić – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21120 Novi Sad, Srbija (e-mail: peric.maaja97@gmail.com).

Marjan Urekar – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21120 Novi Sad, Srbija (urekarm@uns.ac.rs)



Slika 1. Ilustracija izgleda sistema u realnosti

Za informacije o količini hrane i vode u činijama iz kojih ljubimac jede, odnosno pije, zaduženi su senzor mase i senzor nivoa. Senzor koji meri nivo vode se nalazi uronjen u vodu. Na osnovu senzora nivoa se dobija informacija da li je nivo vode u činiji nizak ili visok. Ukoliko je nivo vode niži od minimalnog, aktivira se magnetni ventil i dosipa se voda.

Senzor mase se nalazi ispod činije za hranu, i na taj način meri količinu hrane u činiji. Hrana se dosipa više puta dnevno, ali u određeno, unapred postavljeno vreme. Vreme hranjenja se postavlja pomoću RTC (*eal Time Clock*) modula. Ukoliko je činija prazna, i vreme je hranjenja, aktivira se servo motor, i dosipa se hrana.

Modul za identifikaciju je RFID (*adio Fre uency Identification*) modul, i njegova funkcija je da identifikuje ljubimca. Na osnovu podataka sa oznake ljubimca, mikrokontroler dobija informacije o prisustvu ljubimca, kao i o vremenu i potrebnoj količini hrane.

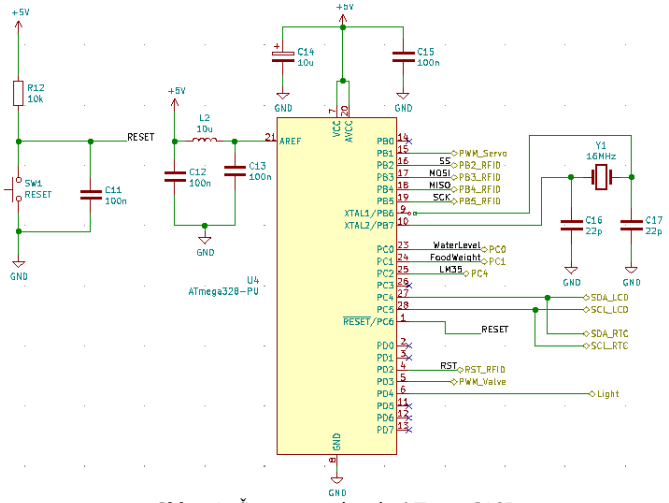
Pored toga, sistem poseduje i temperaturni senzor koji meri temperaturu prostorije, kao i LCD ekran na kom se ispisuju podaci sa senzora.

Slika 2. Blok dijagram sistema

 ISBN 978-86-7466-930-3

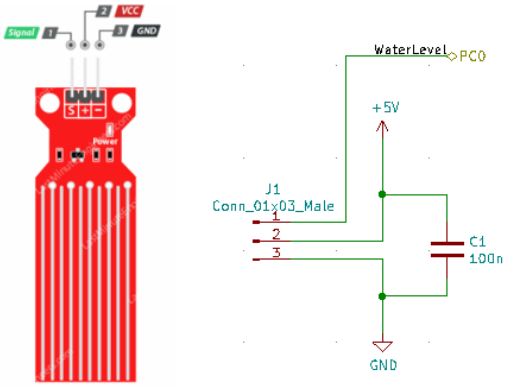
II. ANALIZA DELOVA SISTEMA

A. Elektronska šema sistema



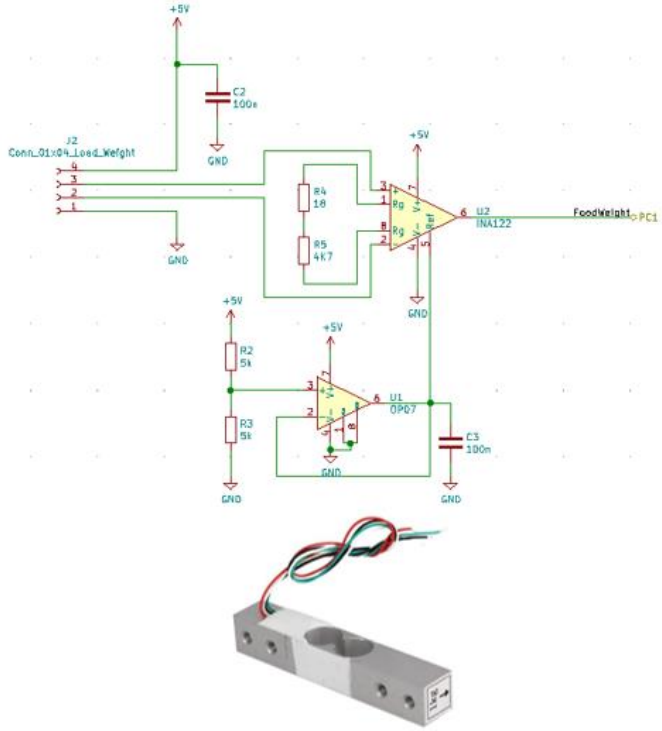
Elektronska šema ovog sistema je projektovana u programu KiCad [1]. KiCad je besplatan softverski program koji se koristi za dizajniranje šema električnih kola, kao i za izradu štampanih ploča (*Printed Circuit Board*).

Za sistem je predviđeno baterijsko napajanje baterijom od 12 V. Pomoću *step-down* regulatora [2] se 12 V pretvara u stabilnih 5 V. Zbog potrebe RFID modula, bilo je neophodno da napajanje sadrži još jedan naponski nivo od 3,3 V. Za dobijanje 3,3 V korišten je čip LM1117 [3], koji je linearni naponski regulator. Prednost baterijskog napajanja je to što je uređaj moguće postaviti na bilo koju željenu poziciju – ne mora da se nalazi blizu utičnice.



Slika 3. Šema napajanja sistema

Komponenta koja je zadužena za upravljanje čitavim sistemom je mikrokontroler ATmega328P [4]. Na slici 4 je prikazana šema povezivanja mikrokontrolera. U levom uglu šeme se nalazi kolo za reset. Kondenzatori C14 i C15 služe kao zaštita od brzih smetnji i kratkotrajnih prekida u napajanju. Komponenta Y1 predstavlja kvarcni kristal, pomoću kog se mikrokontroleru obezbeđuje radni takt, dok kondenzatori C16 i C17 omogućuju oscilovanje kvarcnog kristala.

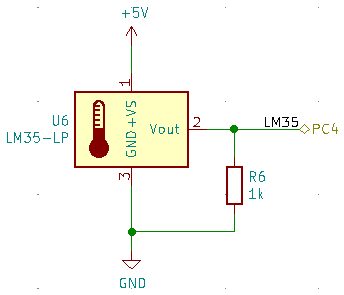


Slika 4. Šema povezivanja ATmega328P

Senzor za merenje nivoa vode [5] se sastoji od deset izloženih bakarnih traka, od kojih je pet za napajanje, a pet za detekciju. Niz izloženih paralelnih provodnika zajedno deluje kao promenljivi otpornik, čiji se otpor menja u zavisnosti od nivoa vode. Promena otpornosti odgovara udaljenosti od vrha senzora do površine vode. Otpornost je inverzno proporcionalna nivou vode – što je senzor više uronjen u vodu, to je bolja provodljivost i manji otpor, i obrnuto.

Slika 5. Izgled senzora nivoa (levo) i šema povezivanja

Za merenje količine hrane korišten je senzor mase od 1 kg [6]. Ovaj senzor radi na principu pretvaranja do 1 kg mase u električni signal. Senzor mase se sastoji od merne trake koja formira Vitstonov most i pretvara masu u električni signal. Pošto je promena napona na dijagonali mosta jako mala, bilo je neophodno da se pojača, i u te svrhe je korišten instrumentacioni pojačavač INA122.

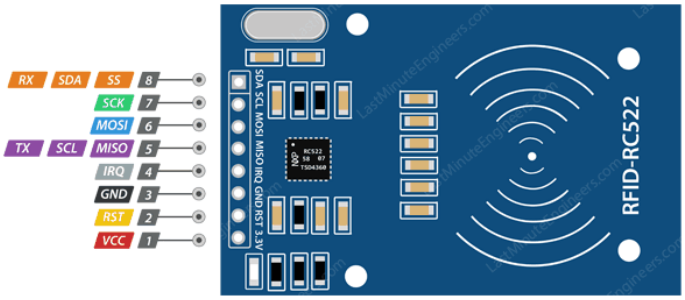


Slika 6. Šema povezivanja sa INA122 (gore) i izgled senzora mase (dole)

Kako bi se merila temperatura prostorije u kojoj ljubimac

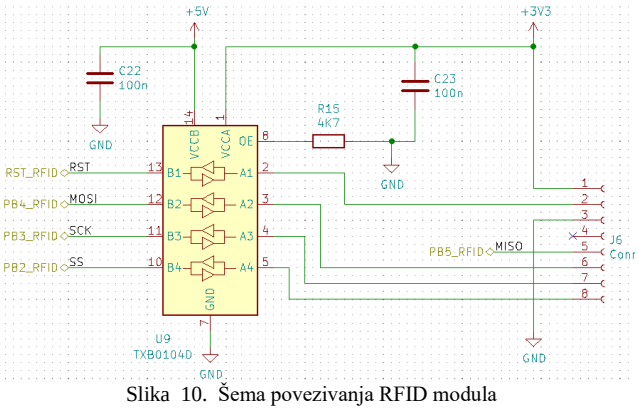
 ISBN 978-86-7466-930-3

boravi, korišten je temperaturni senzor LM35 [7]. LM35 je senzor čiji je izlazni signal proporcionalan trenutnoj temperaturi. Glavna karakteristika ovog senzora jeste ta da ne zahteva dodatnu kalibraciju.



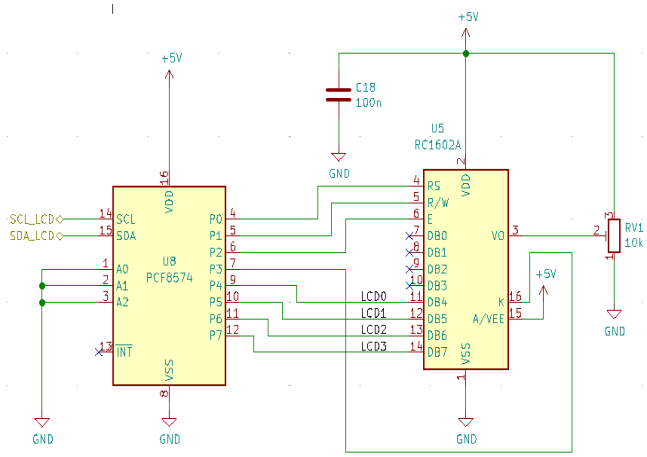
Slika 7. Šema temperaturnog senzora

RTC modul [8] je sat koji sa velikom preciznošću upravlja vremenom i datumom. Modul ima ugrađenu bateriju za rezervno napajanje, i ugrađeni kristalni oscilator. RTC modul radi tako što broji taktove oscilatora, i na taj način se dobijaju informacije o vremenu i datumu.



Slika 8. Izgled RTC modula

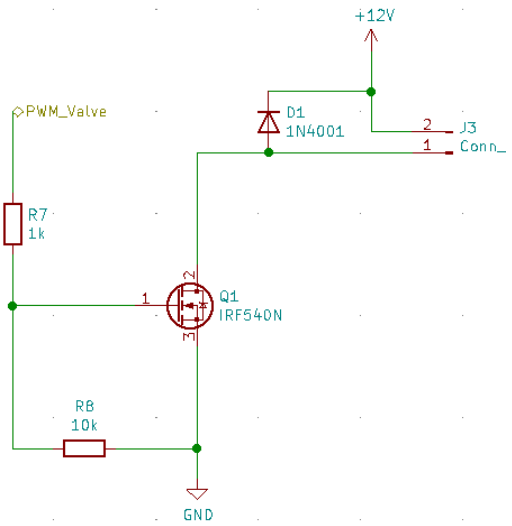
RFID modul [9] je sistem za identifikaciju radio frekvencija, koji se sastoji od dvije glavne komponente. Prva komponenta je *transponder* ili oznaka, koja je prikačena za objekat koji se identifikuje, u ovom slučaju je to ljubimac. Druga komponenta je primopredajnik, odnosno čitač oznake. Čitač se sastoji od radio frekvencijskog modula i antene koja generiše visokofrekventno elektromagnetno polje. Sa druge strane, *transponder* je pasivni uređaj, koji sadrži mikročip koji skladišti informacije, i antenu za prijem i prenos signala. Kako bi se pročitala informacija kodirana na transponderu, ljubimac bi trebalo da se nalazi u neposrednoj blizini čitača, ali ne mora biti u direktnom vidnom polju.



Slika 9. Izgled RFID modula

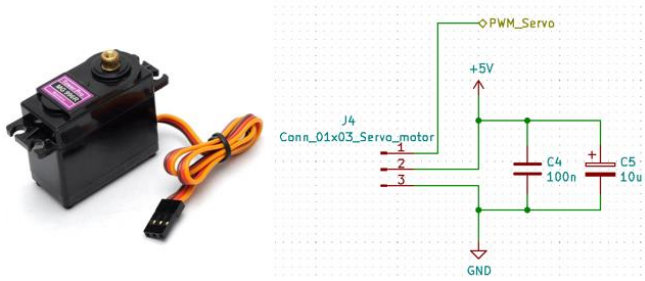
Pošto se RFID modul napaja sa 3,3 V, a mikrokontroler sa 5 V, bilo je neophodno da se modul poveže na bidirekcioni level šifter, pa tek onda na mikrokontroler, kako ne bi došlo do oštećenja modula.

Slika 10. Šema povezivanja RFID modula



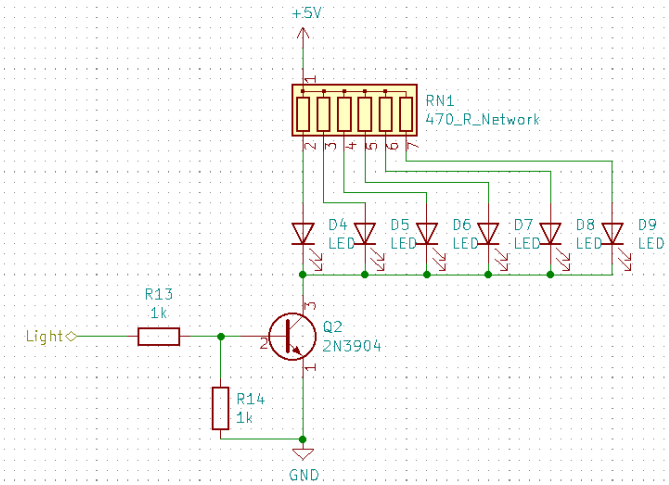
Ekran preko kog se vrši ispis vrednosti sa senzora je LCD RC1602A [10], koji ima 2 × 16 polja u koja stane po jedan karakter. Da bi se izvršila komunikacija sa mikrokontrolerom, i došlo do ispisa podataka na displeju, potrebne su najmanje četiri *data* linije, kao i dvije kontrolne. Pošto na mikrokontroleru ne postoji dovoljan broj odgovarajućih pinova kako bi se povezao LCD i sve ostale komponente sistema, bilo je potrebno da se koristi ulazno/izlazni ekspander [11].

Slika 11. Šema povezivanja LCD ekrana



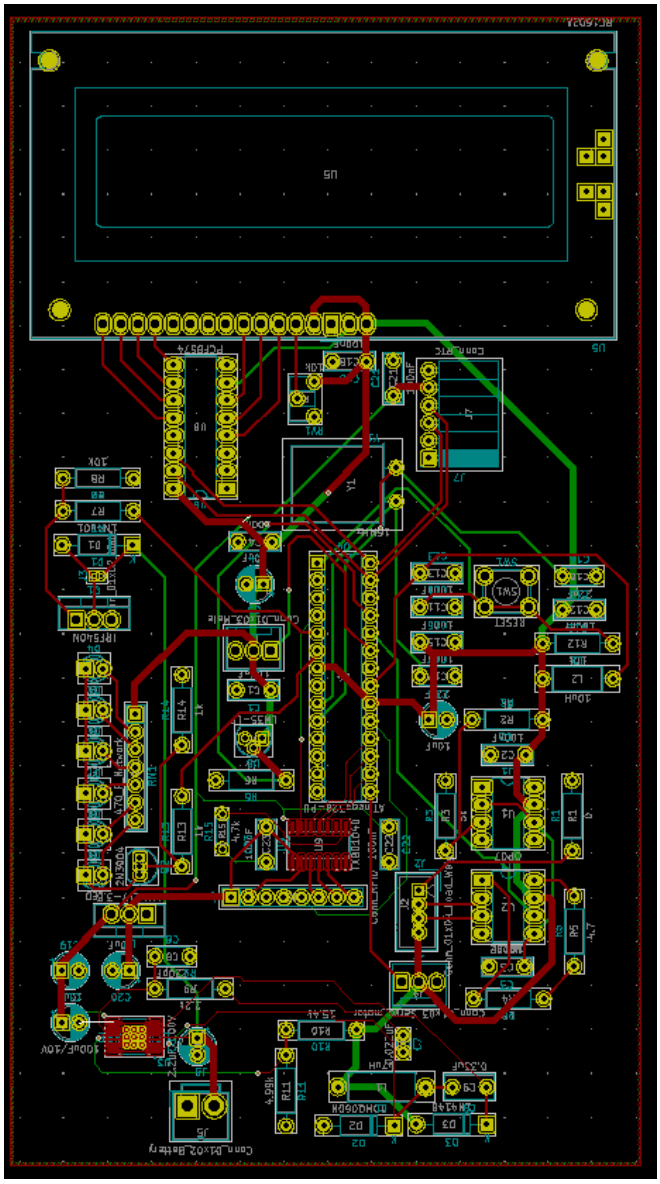
Za dosipanje vode je korišten magnetni ventil [12]. Ventil se uključuje i isključuje pomoću MOSFET-a. Ako se na *gate* pin MOSFET-a dovede napon, ventil će se uključiti. Ukoliko na *gate* pinu nema napona, odnosno povezan je na GND, ventil će se isključiti. Da bi ventil ostao isključen kada nema napona na *gate*-u, *gate* pin je uzemljen pomoću otpornika R8. Pomoću otpornika R7 *gate* pin je povezan na digitalni izlaz mikrokontrolera, odakle dobija ON/OFF signal. Dioda D1 je zamajna dioda, i njena funkcija je da štiti MOSFET od napona kontra elektromagnetne sile, koji se javlja prekidom struje.

 ISBN 978-86-7466-930-3



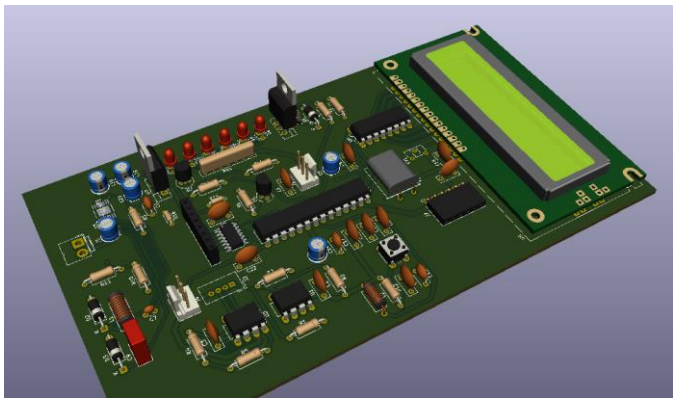
Slika 12. Šema povezivanja magnetnog ventila

Servo motor [13] se koristi za dosipanje hrane, i kontrolisan je pomoću PWM signala sa mikrokontrolera.



Slika 13. Izgled servo motora (levo) i šema povezivanja (desno)

Osvetljenje sistema je realizovano pomoću NPN tranzistora, koji ima ulogu prekidača, LED dioda i otporničke mreže. Svaki put kada RFID modul detektuje prisustvo ljubimca, svetlo će se uključiti.



Slika 14. Šema osvetljenja sistema

PCB sistema je takođe realizovan u programu KiCad. Sve komponente su raspoređene na štampanu ploču dimenzija 165,74 mm × 90,81 mm.

Slika 15. Izgled štampane ploče sistema

Slika 16. 3D prikaz štampane ploče

 ISBN 978-86-7466-930-3

B. Programski kod

Program sistema je pisan u programskom jeziku C, u Arduino IDE (*Integrated e elopment En ironment*) [14] razvojnom okruženju. Arduino IDE je okruženje koje se koristi za razvoj softvera za različite tipove Arduino platformi. Zasniva se na otvorenom kodu (*open-source*), i uključuje veliki broj biblioteka korisnih funkcija.

U program sistema su uključene biblioteke sa funkcijama za upravljanje servo motorom i RTC-om, kao i biblioteka za komunikaciju sa RFID modulom. Napisane su funkcije koje čitaju, i zatim vrše ispis podataka sa senzora temperature, nivoa, mase, kao i podatke o vremenu i datumu. Funkcija za RTC je napisana tako, da se prvo unese vreme hranjenja od strane korisnika, a zatim se ispisuje informacija da li je vreme postavljeno ili ne. U funkciji za RFID se na početku proverava da li je čitaču prinesena nova oznaka, i ako jeste, potom se čitaju informacije koje su kodirane na oznaci. Zatim se ispituje da li je očitani identifikator tačan, tj. da li je ljubimac prepoznat. Ukoliko jeste, uključuje se svetlo, i ispisuju se vrednosti sa senzora. Ukoliko nije, na displeju se ispisuje da ljubimac nije prepoznat.

III. ZAKLJUČAK

Realizovano softversko rešenje sistema za automatsko hranjenje kućnih ljubimaca daje mogućnost korisniku da na vrlo jednostavan način olakša sebi svakodnevnicu pri brizi o kućnim ljubimcima. Kao što je već navedeno, sistem nudi personalizovan način brige o kućnim ljubimcima, što znači da je sistem prilagođen svakom korisniku i njegovom ljubimcu.

Sledeći korak bi bio pravljenje prototipa, i testiranje sistema i programa pisanog za sistem. Na osnovu testiranja bi bilo jasno na koje sve načine bi se hardverski deo sistema mogao unaprediti. Sistem bi se mogao unaprediti i softverski, razvojem aplikacija za različite mobilne i računarske platforme. Potencijalne aplikacije bi u mnogome olakšale upotrebu ovog sistema većini korisnika. U tom slučaju, korisnik bi bio u mogućnosti da u svakom trenutku, preko svog mobilnog telefona ili računara, prati stanje i informacije sa senzora. Unapređena verzija ovakvog sistema bi mogla da se koristi i u druge svrhe, tj. u drugačijim uslovima, kao što su, na primer, azili ili farme.

ZAHVALNICA

Ovaj rad je podržan od trane Fakulteta tehničkih nauka u Novom Sadu, Departmana za energetiku, elektroniku i telekomunikacije, u okviru realizacije projekta MPNTR 200156 : „Inovativna naučna i umetnička ispitivanja iz domena delatnosti FTN-a.“

ABSTRACT

This paper presents the realization of a system for automatic feeding of pets at home, using available software tools. The electronic schematic of the system was designed in the KiCad program, while part of the system code was written in the Arduino IDE development environment. The goal of the system is to measure the set values using different sensors, transmit, process and display data to the microcontroller, as well as to automate the operation of the servo motor and solenoid valve.

Automatic pet feeding system

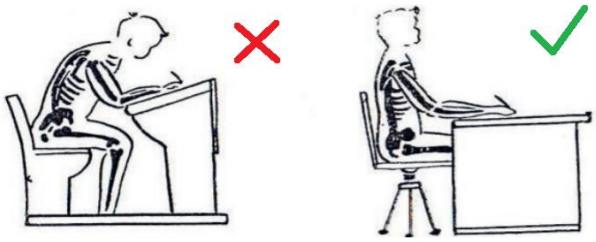
Uređaj za pravilno sedenje baziran na merno–informacionim modulima

Jovana Jović i Marjan Urekar, *Member, IEEE*

***Apstrakt*— U ovom radu predstavljena je ideja za prototip uređaja za pravilno sedenje, koji bi bitno uticao na smanjenje pojave bola u leđima, oboljenje koje je sve prisutnije u svim starosnim grupama. Uređaj se sastoji od *Button load cell* ćelija pomoću kojih se prati da li korisnik sedi pravilno na sedalnom delu stolice. Pored toga postoji i senzor dodira QT100 koji detektuje da li je korisnik naslonjen na naslon stolice. Podaci se UART-om šalju na *web* server, koji se dalje učitavaju na *web* sajtu. Na *web* sajtu korisnik ima uvid u svoj sedeći stav, ali i upozorenje ukoliko ne sedi pravilno. Pored crvenih grafika i iskačućeg prozora na sajtu, kao identifikaciju nepravilnog sedenja imamo i vibro motor koji stvara vibracije i tako korisniku pruža trenutnu haptičku informaciju da popravi svoj stav.**



***Ključne reči*—Uređaj za pravilno sedenje, HX711, QT100, Vibro motor, mikrokontroler, *web* sajt;**

I. Uvod

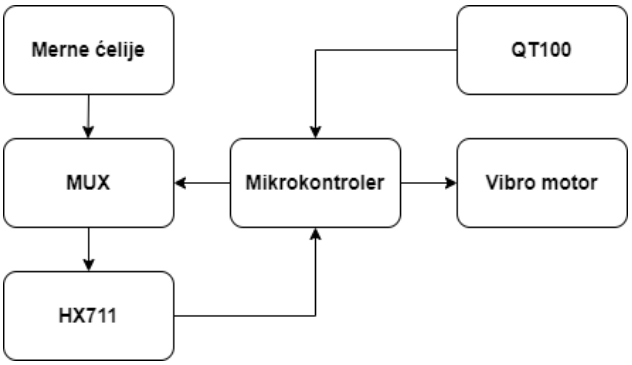
Brzim razvojem nauke, matematike, fizike ali i medicine u poslednjih nekoliko decenija, postignut je veliki razvoj tehnologije koji olakšava život ljudi u svim sferama. U ovom radu opisan je uređaj za pravilno sedenje, koji je osmišljen kao odgovor na pojavu bola kako kod odraslih lica, tako sve češće i kod dece u najranijem dobu. Da bismo shvatili njegov značaj, prvo moramo uvesti osnovne medicinske pojmove vezane za bol u leđima i njegov nastanak, ali i da razumemo definiciju pravilnog sedećeg stava.

Bol u leđima (lumbago, lumbagia) predstavlja bol ili nelagodnost koju osoba oseća u području leđa, između rebarnih lukova i donje glutealne brazde, sa ili bez širenja niz levu ili desnu nogu [1]. Prema definiciji, bol u leđima je simptom, ali oko 85% pacijenata nikada ne dobije tačnu dijagnozu [2]. Razlog tome je što bolovi nastaju ukrštanjem više faktora, kao što su loše držanje, dugotrajno sedenje, genetika, slabost određenih grupa mišića, emocionalni stres, promene uzrokovane starenjem mišićno-koštanog sistema (artritis, degenerativne promene diska …).

Pored saznanja šta je bol u leđima i kako nastaje, potrebno je da razlikujemo i dobar sedeći položaj od onog koji to nije. Dobar sedeći položaj, prema definiciji, podrazumeva položaj kada je telo uspravno ili lagano nagnuto napred, glava pravilno uzdignuta, te na taj način stimuliše lagano i stalno napetost dugih mišića kičme i kratkih mišića vrata. Gornji i donji udovi su u simetričnom položaju, stopala su paralelno postavljena i celom se površinom oslanjaju na pod. Ovakav položaj obezbeđuje najbolju udaljenost očiju od površine čitanja i manji zamor. [3]. Najčešće do pojave lošeg držanja tela dolazi usled slabosti određenih grupa mišića tonostatičke (opružača vrata i trupa, mišića primicača lopatica, opružača natkolenica i potkolenica i mišića stopala) muskulature. Ova pojava se može objasnici sa dva aspekta, dok nam je prvi od velikog značaja za nastanak ovog rada. Prvi aspekt: To je period kada je dete polaskom u školu, izloženo povećanom stato-dinamičkom opterećenju - dugotrajno sedenje u školskoj klupi, pisanje u povijenom položaju. [3].

Sl. 1 - Nepravilan/pravilan sedeći stav

Kako bi se otklonio jedan od čestih razloga zbog kojeg nastaju bolovi u leđima u ovom radu je opisan uređaj za pravilno sedenje. Uređaj se sastoji od 8 mernih ćelija postavljenih na sedalni deo stolice. Pomoću njih može se utvrditi da li korisnik sedi pravilno (približno jednako je oslonjen sa obe noge na sedalni deo) ili to nije slučaj. Pored ovih senzora, na naslon stolice se postavlja elektroda senzora dodira QT100, pomoću koje se detektuje da li je korisnik sada naslonjen na naslon (sedi pravilno) ili ne. Sve ovo je spojeno sa mikrokontrolerom. Mikrokontroler obezbeđuje da kada sedenje nije pravilno (osoba vrši jači pritisak levom ili desnom nogom ili nije naslonjen na naslon stolice) korisnik dobija haptičku informaciju o tome. To je realizovano vibro motorom koji počinje sa radom baš u tom trenutku u kojem položaj tela ne odgovara pravilnom sedenju i tako opominje korisnika da popravi svoj sedeći stav. Mikrokontroler je preko UART-a povezan sa računarom i šalje podatke na internet. Na *web* stranici se u vidu grafika iscrtavaju očitavanja sa mernih ćelija. Tako korisnik ima direktan uvid u podatke o svom sedenju. Kada senzor dodira detektuje da korisnik nije naslonjen, na ekranu se pojavljuje "iskačući" prozor koji opominje korisnika na nepravilno sedenje.



Jovana Jović – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: jovanajovic180@gmail.com)

 ISBN 978-86-7466-930-3

II. TEHNIČKO REŠENJE SISTEMA

Blok dijagram uređaja za pravilno sedenje prikazan je na slici 2. U nastavku biće uopšteno opisano kako uređaj funkcioniše.

Sl. 2 - Blok dijagram uređaja

Kako bismo postigli neometano i normalno funkcionisanje uređaja, potrebno je obezbediti dva napona od +5 VDC i +3.3 VDC. Mrežni napon (230 VAC) se pomoću integrisanog kola LM7805 prilagođava na napon od +5 VDC, koji je neophodan za većinu elemenata u kolu. Za napajanje vibro motora potrebno je obezbediti napon od +3.3 VDC, a to je urađeno korišćenjem podesivog regulatora LM317. Kako bismo dobili željeni napon potrebno je podesiti vrednosti dva otpornika, čije vrednosti dobijamo korišćenjem jednostavne formule:

$$V_{OUT} = 1.25 \times \left(1 + \frac{R_2}{R_1}\right). \quad (1)$$

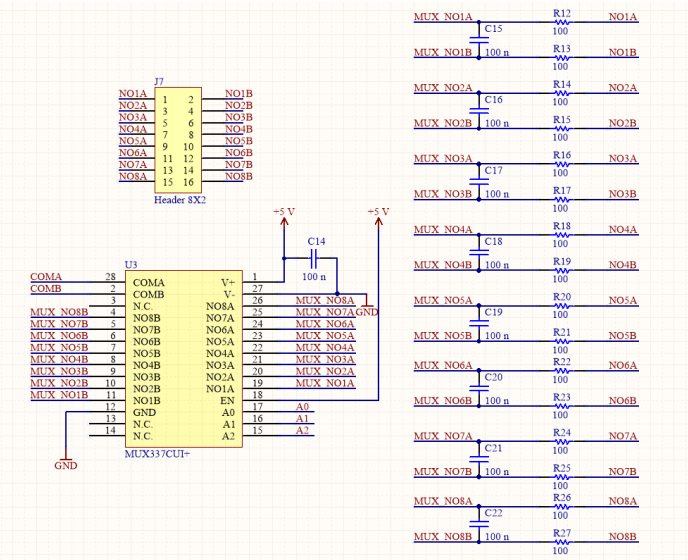
Oba regulatora su obezbeđena blok kondenzatorima koji eliminišu brze promene napona, kao i elektrolitskim kondenzatorima koji dodatno doprinose stabilizaciji napona. Pored kondenzatora, integrisana kola su obezbeđena inverzno polarisanim zaštitnim diodama koje neće provoditi sve dok u kolu ne dođe do pojave inverznog ili negativnog napona. Pomoću dve LED diode na uređaju se može pratiti prisutnost oba napona.

Uređaj za pravilno sedenje poseduje dve vrste senzora pomoću kojih detektuje da li korisnik sedi pravilno. Na sedalni deo stolice postavlja se 8 mernih mostova (*Load cell* senzori koji se nalaze u kućnim vagama). Oni se raspoređuju po celom sedalnom delu, ispod leve i desne noge. Signale sa ovih ćelija dovodimo do analognog diferencijalnog multipleksera koji dovedene signale prosleđuje A/D pretvaraču jedan po jedan. HX711 je A/D konvertor osmišljen specijalno za vage i pomoću njega signal dalje putuje do mikrokontrolera.

Na naslon stolice postavlja se elektroda senzora dodira QT100. Ona ima mogućnost da preko tkanine detektuje da li je korisnik naslonjen na stolicu i sedi pravilno. Takođe, ovaj senzor je spojen sa mikrokontrolerom.

Vibro motor čini poslednji segment ovog uređaja. Zadatak mu je da korisniku pruži haptičku informaciju (informacija koja se može osetiti dodirom) onog trenutka kada korisnik ne sedi pravilno, a to se ostvaruje zahvaljujući mikrokontroleru.

Izgled stolice prikazan je na slici 3.

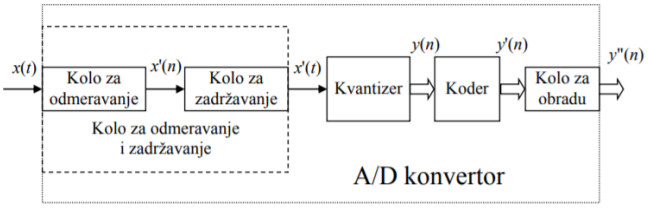


Sl. 3 - Finalni izgled stolice

III. HARDVERSKE KOMPONENTE SISTEMA

A. *Analogni diferencijalni multiplekser*

Kao što je već pomenuto, naš uređaj ima osam mernih mostova. Da bismo imali korisne informacije o svakom njihovom izlazu neopodno je korišćenje multipleksera. Multiplekser (MUX) je kolo koje jedan ulazni signal, koji je izabran od više ulaznih signala može da vodi ka jednom izlazu.



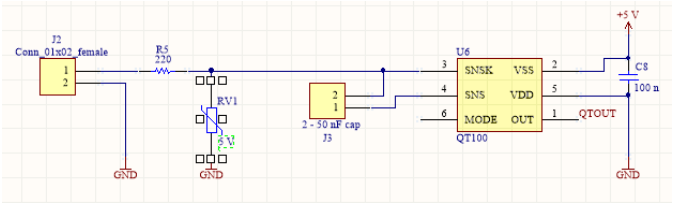
Sl. 4 - MAX337CUI+

Kako imamo osam mernih ćelija koje poseduju po jedan diferencijalni izlaz, koristili smo diferencijalni multiplekser koji na izlaz dovodi i visok i nizak potencijal ulaznog signaa. Signal sa ćelija je filtriran pomoću otpornika od 100 Ω i kondenzatora od 100 nF. MAX 337 je dvostruki, 8-kanalni MUX koji je dizajniran da jedan od osam ulaza prosledi na zajednički izlaz, pomoću trobitne binarne adrese. Njega smo obezbedili *decoupling* kondenzatorom.

 ISBN 978-86-7466-930-3

B. *A/D konvertor HX711*

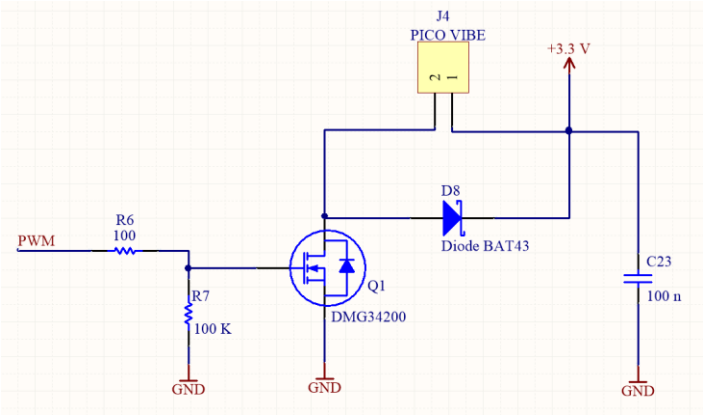
Za pretvaranje analognih signala u digitalne signale prilagođene računarima (mikroprocesorima ili mikrokontrolerima) koriste se analogno – digitalni konvertori. Tipično, proces A/D konverzije obuhvata odmeravanje analogne veličine u vremenu i po amplitudi. Prema tome, A/D konvertori su uređaji koji prevode signale iz domena kontinualno vreme, kontinualna amplituda u domen diskretno vreme, diskretna amplituda. Odmeravanje signala po vremenu znači da se ulazni analogni signal odmerava (eng. *sampling*), tj. da se njegove vrednosti amplitude uzimaju u određenim vremenskim intervalima, a da se između tih intervala pretpostavlja da se signal ne menja ili da se ne menja značajno. Tipična blok šema A/D konvertora prikazana je na slici 5.



Sl. 5 - Blok šema A/D konvertora

Sl. 6 - HX711

Za potrebe ovog rada korišćeno je integrisano kolo HX711. Ono je 24-bitni A/D konvertor koji je dizajniran za kućne vage i industrijske uređaje koji su bazirani na mernim mostovima. Poseduje dva kanala, od kojih kanal A ima opciono pojačanje od 128 ili 64, dok kanal B ima fiksno pojačanje od 32. Rezultati merenja se šalju na serijski interfejs, preko kog se informacije prenose na mikrokontroler. I ovaj segment je obezbeđen *decoupling* kondenzatorima.

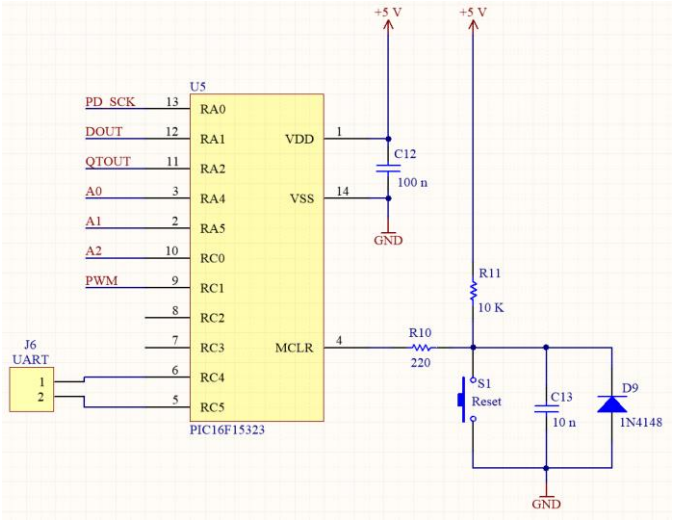


C. *Senzor dodira QT100*

Sl. 7 - QT100

QT100 senzor je samostalno digitalno integralno kolo, koje je sposobno da detektuje blizinu ili dodir. On stvara polje za dodir ili blizinu kroz bilo koji dielektrik, kao što su staklo, plastika, kamen, keramika, pa čak i većina drvenih površina. Takođe, može da pretvori mali metalni objekat u senzor osetljiv na dodir ili blizinu. Ova mogućnost, zajedno sa mogućnošću samokalibracije su u ovom projektu od velikog značaja. Ostavljen je priključak gde se dovodi elektroda pomoću koje se detektuje da li korisnik koristi naslon ili ne. Pored tog priključka, postoji i priključak za kondenzator. Pomoću kondenzatora (čija je vrednost između 2 nF - 50 nF) i otpornika se definiše osetljivost senzora. Vrednost kondenzatora zavisi od debljine naslona i njene dielektrične konstante. Pored kondenzatora, na osetljivost utiče i veličina i oblik electrode. QT100 je obezbeđen *decoupling* kondenzatorom, ali i varistorom koji služi za zaštitu od ESD udara.

D. *Vibro motor*

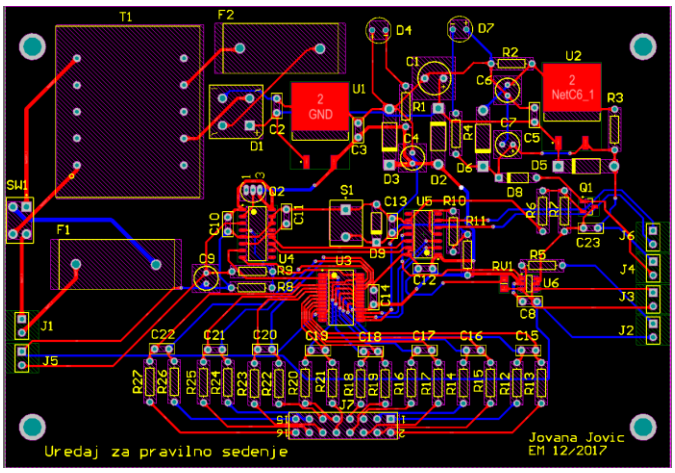


Sl. 8 - Vibro motor

Vibro motor služi kao direktan podsetnik korisniku da ne sedi pravilno. On se uključuje ili kada se ne vrši podjednak pritisak sa obe noge ili kada korisnik ne koristi naslon stolice. Za potrebe ovog projekta koristi se ERM motor sa oznakom C102B002F. Poseduje malu ekscentričnu težinu na svom rotoru koja prilikom rotiranja stvara vibracije. Za pokretanje motora neophodno je koristiti i MOSFET, jer sam mikrokontroler ne može da pruži dovoljnu snagu. PWM signal pokreće motor, tačnije uključuje se gejt MOSFET-a sa impulsima određene širine. Zbog toga struja kroz motor varira u zavisnosti od širine impulse PWM signala, što direktno utiče na brzinu motora i tako određuje jačinu vibracija. Motor predstavlja induktivno opterećenje i njegovim isključenjem može doći do pojave inverznog napona što može oštetiti tranzistor, zbog toga koristimo zaštitnu diodu.

 ISBN 978-86-7466-930-3

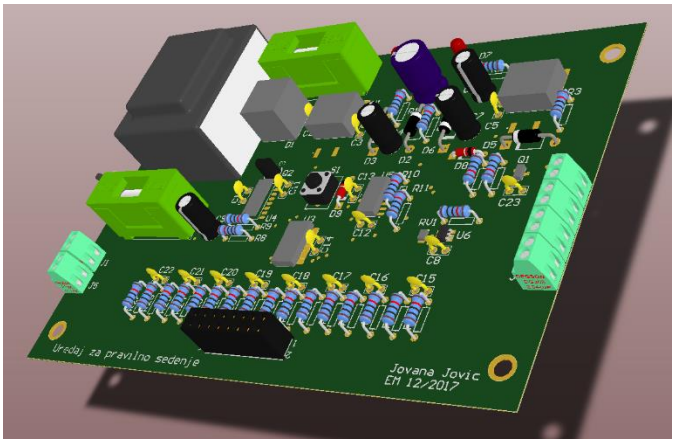
E. Mikrokontroler



Sl. 9 - PIC16F5323

U ovom projektu korišćen je PIC16F5323 mikrokontroler. PIC16F5323 je 8-bitni mikrokontroler, serije PIC16F, sa brzinom od 32MHz. Malih je dimenzija, poseduje 14 pinova što su bili zahtevi uređaja za pravilno sedenje.

MCLR pin pruža dve posebne funkcije, a to su resetovanje uređaja i programiranje uređaja i otklanjanje grešaka. Ukoliko programiranje i otklanjanje grešaka nisu potrebni u nekom projektu, na MCLR pin dovoljno je samo dovesti +5 V. Dodavanjem komponenti povećava se otpornost uređaja na lažna resetovanja (na primer zbog pada napona). *Pull-up* otpornik na MCLR ulazu drži +5 V sve dok taster nije pritisnut. Taster služi upravo za resetovanje mikrokontrolera. Zaštita je obezbeđena *decouping* kondenzatorom i signalnom diodom.

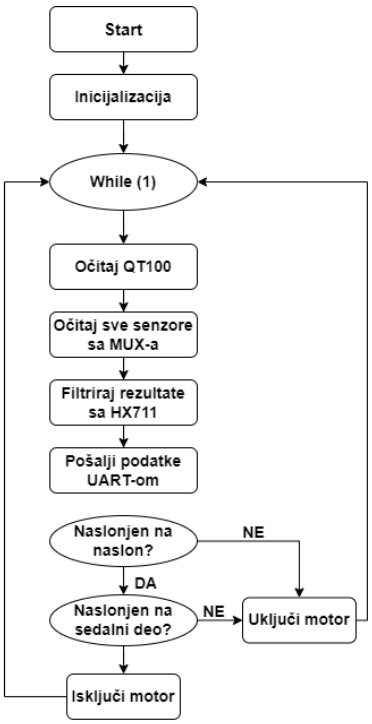


IV. PCB I 3D MODEL UREĐAJA

PCB uređaja za pravilno sedenje je napravljen u programskom paketu Altium Designer. Dizajniran je u dva sloja, jer uređaj poseduje i SMD i THT komponente. Dimenzije PCB ploče su 195 mm x 86 mm. Sve komponente uređaja, ali i designatori i naziv uređaja smeštene su na prednjoj strani. Debljine trekova variraju od 15 mil do 30 mil na ulazu kod napajanja. Korišćena je opcija Polygon Pours-a koja sve komponente koje koriste masu spaja slojem bakra. Na slici 10. prikazan je izgled PCB-a.

Sl. 10 - PCB uređaja za pravilno sedenje

Pored PCB-a u Altium Designer program postoji mogućnost i za dizajniranje 3D modela. Ta opcija je veoma korisna, jer se i pre same izrade može videti izgled ploče i tako uticati na poboljšanje dizajna. Na slici 11. dat je izgled 3D modela.



Sl. 11 - 3D model uređaja za pravilno sedenje

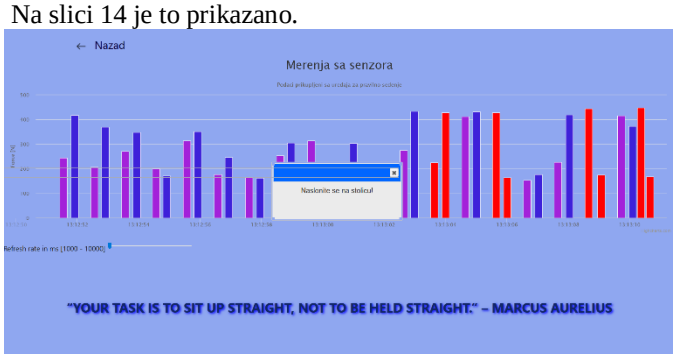
V. FIRMVER I SOFTVER UREĐAJA

Pri pokretanju mikrokontrolera prvi korak predstavlja inicijalizaciju svih potrebnih modula i promenljivih unutar mikrokontrolera. Nakon toga se ulazi u glavnu programsku petlju. Glavna programska petlja je beskonačna petlja koja se izvršava sve dok mikrokontroler radi. U njoj je prvo potrebno očitati podatke sa senzora QT100, kako bi mikrokontroler imao uvid da li je korisnik naslonjen na naslon stolice. Nakon toga sledi očitavanje svih senzora koji se nalaze na sedalnom delu. Mikrokontroler pomoću multipleksera i AD konvertora HX711 pristupa svakom senzoru pojedinačno i očitava ih. Pošto su rezultati sa senzora zašumljeni, njih je potrebno filtrirati i softverski. Svi rezultati se preko UART-a dalje šalju na *Web* server. Kada su prikupljeni podaci sa svih senzora mase i sa senzora dodira, potrebno je odrediti da li korisnik pravilno sedi. Ako to nije slučaj, treba pokrenuti vibro motor. Na slici. 12 prikazan je izgled upravljačke petlje.

 ISBN 978-86-7466-930-3

Sl. 12 - Upravljačka petlja

Internet of Things je koncept koji se sastoji iz mreže uređaja koji međusobno razmenjuju podatke. To su *embedded* sistemi koji imaju jedan ili više senzora. IoT ima sve širu primenu u svim sferama života, kako u *smart home* aplikacijama, tako i u medicini. Zbog tolike primene, IoT se može naći i u ovom radu.



Podaci sa *web* servera se učitavaju na *web* sajt, koji služi kao grafički interfejs za korisnika. Na slici 13. je prikazana naslovna strana sajta.

Sl. 13 - Naslovna strana

Na tom *web* sajtu korisnik može pratiti rezultate svog dosadašnjeg sedenja, kao i da bude upozoren ako njegovo sedenje u datom trenutku nije pravilno. Na grafiku se to identifikuje crvenom bojom kada korisnik ne vrši približno jednak pritisak sa obe noge ili iskačućim prozorom ako nije naslonjen na naslon. *Web* aplikacija bi takođe mogla da pruža i dodatne mogućnosti, kao što su arhiviranje rezultata sedenja, praćenje napredovanja ili ipak nazadovanja u veštini pravilnog sedenja. To bi od velikog značaja bilo roditeljima i vaspitačima koji bi imali uvid o napredovanju deteta pri stvaranju dobrih navika tokom sedenja. Uvid u rezultate sedenja bi mogao poslužiti u i medicinske svrhe, kako bi lekari imali jedinstven pristup za svakog pancijenta, kao i jednistvenu dijagnozu.

Na slici 14 je to prikazano.

Sl. 14 - Grafik i "iskačući" prozor na *web* sajtu

VI. DISKUSIJA

Uređaj za pravilno sedenje je osmišljen kako bi se otklonila određena grupa medicinskih problema koja se sve češće javlja i kod dece u najranijem dobu (dece školskog uzrasta). Korišćenjem dostupne tehnologije napravljen je prototip uređaja i predložena primena istog kako bi se smanjila pojava bola u leđima. Dalja istraživanja bi mogla dovesti do unapređenja uređaja i učinila da se on komercijalizuje i bude dostupan svima.

Na tržištu se mogu pronaći različiti uređaji u različitom cenovnom rangu. Lumo Lift je uređaj koji se pomoću magneta kači na odeću i koncentrisan je na gornji deo leđa, cena mu je oko 80 € [10]. UpRight je uređaj koji se lepi na gornji deo leđa (može se iskoristiti jednom za period od 15 min do 60 min). Njegova cena je oko 130 € [11]. Prana je još jedan uređaj koji je dostupan na tržištu. To je prenosivi uređaj koji se zakači u predelu struka i pomoću dijafragmalnog disanja i obrazaca disanja prati povijenost u lumbalnom delu. Cena je 100 € [12]. Svaki od njih je fokusiran samo na određeni deo leđa, torakali (gornji) ili lubalni (donji). Uređaj koji je opisan u ovom radu predstavlja celinu jer prati položaj celog tela u sedećem stavu. To je njegova najveća prednost. Takođe, uređaj se postavlja na samu stolicu, tako da korisniku ne prestavlja nikakvu smetnju prilikom korišćenja.

Pored toga, ne postoji ograničenje u starosnom dobu osobe koja koristi uređaj, mogu ga koristi i odrasli i deca. Takođe, zbog osam mernih ćelija masa koju uređaj može da podnese je 400 kg, pa ni u tom pogledu ne postoje ograničenja.

Najveća mana ovog uređaja je što se za pokrivanje sedalnog dela koriste *button load cell* ćelije koje imaju visoku cenu. Jedna ćelija se na tržištu može naći za 35 €, a nama je potrebno osam takvih. Taj problem je u budućnosti moguće rešiti tako što se umesto *button load cell* ćelija, mogu koristiti obične *load cell* ćelije koje se mogu naći u kućnim vagama. Njihova cena je oko 3 € i dostupne su svuda.

Uređaj trenutno ne poseduje baterijsko napajanje, već ga moramo postaviti blizu utičnice kako bi radio. To je još jedan način kako bismo unapredili uređaj. Mogu se dodati tri litijumske baterije od 3.7 V, koje bi malo povećale dimenzije uređaja, ali bi obezbedile da uređaj neko vreme radi i ako nije priključen na mrežno napajanje.

Uređaj se može koristiti u učionicama, ali bi za te svrhe bilo

 ISBN 978-86-7466-930-3

potrebno razviti aplikaciju pomoću koje bi učitelj mogao da prati sedeći stav svakog deteta. Tako bi se uticalo na stvaranje dobrih navika, ali i na prevenciji bola u najranijem periodu. Pored učitelja, pristup aplikaciji može se dati roditeljima, koji bi u kućnim uslovima mogli da utiču na pravilno sedenje svog deteta.

ZAKLJUČAK

Ovaj rad nudi rešenje kako smanjiti pojavu bola u leđima i kako podstaći dete u stvaranju dobrih navika. Primenom dostupnih senzora ali i IoT-a kao deo Industrije 4.0 nudi se mogućnost za realizaciju kompletnog uređaja za pravilno sedenje.

ZAHVALNICA

Ovaj rad je podržan od strane Fakulteta tehničkih nauka u Novom Sadu, Departmana za energetiku elektroniku i telekomunikacije, u okviru projekta MPNTR 200156: „Inovativna naučna i umetnička ispitivanja iz domena delatnosti FTN-a“. Takođe, zahvaljujem se na velikoj pomoći i podršci pri izradi ovog rada celoj Katedri za električna merenja na Fakultetu tehničkih nauka u Novom Sadu.

ABSTRACT

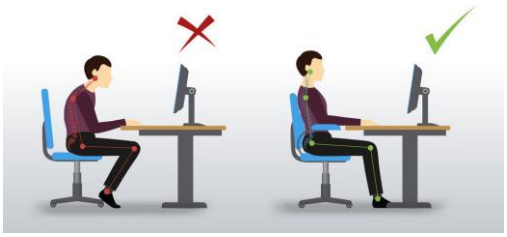
In this paper the prototype for a proper sitting posture device is presented, which would lead to decrease in back pain. Back pain is a recurring problem in all age groups nowadays. The device consists of Button load cells that detect if a user is sitting properly or not on the seating part of the chair. Apart from them, there is a touch sensor QT100, which detects if the user is set against the backrest of the chair. The acquired data is sent through UART to a web server, and is showed on a web site. On the web site the user has an insight in his sitting posture, but there are also warnings if his sitting posture is incorrect. Besides a red graphic and pop-up window on the site, there is a vibration motor which warns the user about his bad sitting posture by a haptic feedback.

Device for proper sitting posture based on measurement-information modules

Jovana Jović, Marjan Urekar

Merno-akvizicioni sisitem za pravilno sedenje

Mario Volaš, Dragan Pejić, *Member, IEEE,* Marjan Urekar, *Member, IEEE*



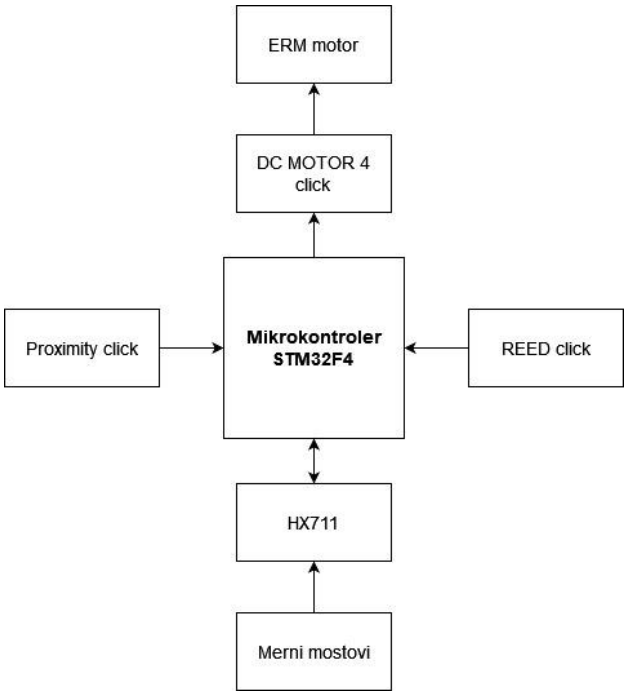
***Apstrakt*—U ovom radu predstavljeno je rešenje firmvera za prototip uređaja za pravilno sedenje, koji korisniku daje povratnu informaciju o položaju njegovog tela tokom sedenja. Ovaj uređaj je za cilj imao da popravi držanje korisnika, i tako smanji bolove koji nastaju posle višečasovnog sedenja. Za razvoj ovog prototipa korišćen je STM32F407 mikrokontroler sa razvojnom pločom STM32F4 Discovery. Na sedalnom delu stolice postavljene su merne ćelije za merenje sile, koje proveravaju položaj korisnika na sedalnom delu stolice. Izlazi mernih ćelija se na mikrokontroler dovode preko A/D konvertora HX711. Merenje udaljenosti korisnika od naslona stolice vrši Proximity click, dok povratnu informaciju o nepravilnom sedenju korisnik dobija preko vibro-motora koji se pokreće DC motor 4 click pločicom.**

***Ključne reči*—Embedded, STM32F407, Merne ćelije, Proximity click, HX711, Merenje**

I. Uvod

Bol u leđima postaje sve veći problem u modernom svetu. Istraživanja pokazuju da se od 1990. do 2016. godine broj godina provedenih sa invaliditetom (DALY- Disability adjusted life years) uzrokovanim bolom u leđima povećao za čak 50% [1]. Glavni uzrok ovih rezultat je stil života, u kom ljudi provode sve više i više vremena u sedećem položaju.

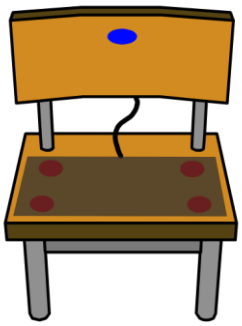
Kako bi što više smanjili rizik od bolova u leđima, potrebno je da osoba sedi pravilno. Dobar sedeći položaj podrazumeva položaj kada je telo uspravno ili lagano nagnuto napred, glava pravilno uzdignuta, te na taj način stimuliše lagano i stalno napetost dugih mišića kičme i kratkih mišića vrata. Gornji i donji udovi su u simetričnom položaju, stopala su paralelno postavljena i celom se površinom oslanjaju na pod. Ovakav položaj obezbeđuje najbolju udaljenost očiju od površine čitanja i manji zamor [2].



Sl. 1 - Nepravilan i pravilan položaj tela pri sedenju

Mario Volaš – Fakultet tehnikih nauka , Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: mariovolas@gmail.com)

Dragan Pejić – Fakultet tehnikih nauka , Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: pejicdra@uns.ac.rs).



Marjan Urekar – Fakultet tehnikih nauka , Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: urekarm@uns.ac.rs)

Kako bi se korisnik podstakao na pravilan položaj tela pri sedenju, razvijen je Uređaj za pravilno sedenje. Ovaj uređaj prati položaj tela korisnika na sedalnom delu stolice kao i na naslonu stolice. Za razvoj prototipa korišćeno je razvojno okruženje STM32F4 Discovery [3], čiji je centralni deo STM32F407 mikrokontroler. Sila kojom se korisnik naslanja na jednu ili na drugu nogu meri se load cell-ovima, a na naslonu stolice se nalazi Proximity click [4] koji meri da li je korisnik naslonjen na stolicu. Za obaveštavanje korisnika o njegovom nepravilnom položaju koristi se motor sa ERM (Ekscentrična rotirajuća masa). Korisnik takođe može da izabere između striktnog i opuštenog režima rada. Blok šema uređaja je prikazana na slici broj 2.

Sl. 2 - Blok šema uređaja za pravilno sedenje

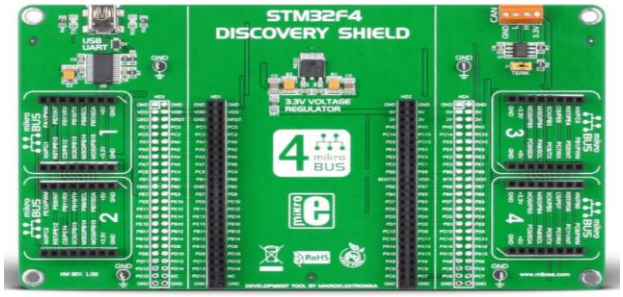
Na slici 3. prikazan je nacrt uređaja za pravilno sedenje.

Sl. 3 - Nacrt uređaja za pravilno sedenje

 ISBN 978-86-7466-930-3

II. HARDVER

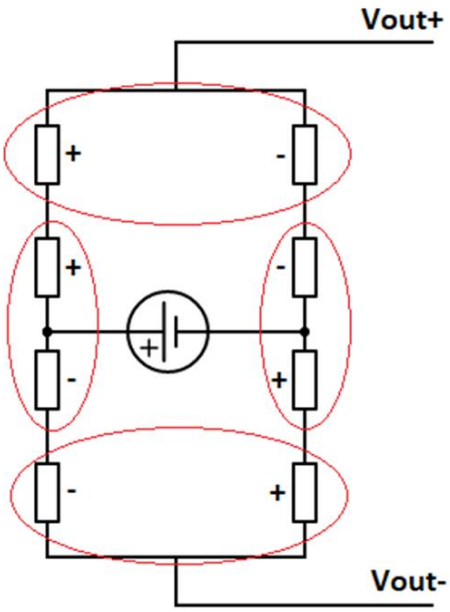
Radi bržeg, praktičnijeg i jednostavnijeg razvoja prototipa Uređaja za pravilno sedenje, korišćene su uglavnom modularne komponente i razvojne ploče.



A. Razvojno okruženje hardvera

STM32F4 Discovery razvojna ploča u sebi sadrži mikrokontroler STM32F407VG. On je 32-bitni mikrokontroler koji radi na frekvencijama do 168 MHz, 128 KB RAM memorije, 1024 KB FLASH memorije, 3xI2C, 2xUART, 3xSPI interfejsa, 17 tajmerskih modula, itd. Razvojna ploča takođe sadrži i ST-LINK/V2-A embeded alat za debagovanje.

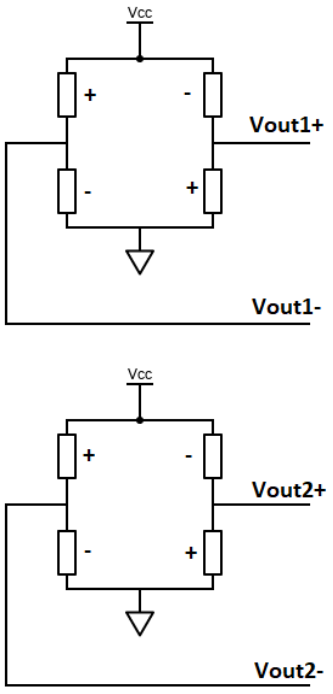
Sl. 4 - STM32F4 Discovery [3]



Kako bi na STM32F4 Discovery razvojnu ploču na najjednostavniji način priključili click pločice, korišćen je STM32F4 Discovery shield [5]. Na njega je moguće priključiti četiri click pločice, a pored toga poseduje i USB UART priključak, koji omogućava povezivanje mikrokontrolera na PC računar bez serijskog porta.

Sl 5 - STM32F4 Discovey shield [5]

B. Merne ćelije

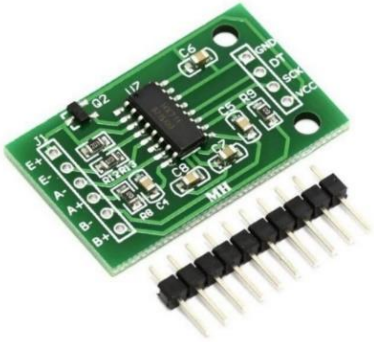


Za merenje sile pritiska na sedalnom delu stolice korišćene su merne ćelije koje se nalaze u komercijalnoj digitalnoj vagi za merenje telesne mase. U vagi se nalaze četiri merne ćelije, a svaka od njih predstavlja jedan polu-most.

Sl. 6 - Način povezivanja mernih mostova

Na slici 6. zaokruženi elementi predstavljaju jednu mernu ćeliju. Na ovaj način polu-mostovi čine jedan ceo most.

Uređaj za pravilno sedenje zahteva dva odvojena mosta, koja se nalaze na levoj i desnoj strani sedalnog dela stolice.



Sl. 7 - Način povezivanja mernih mostova u uređaju

Ovo prespajanje je izvršeno pomoću jumper-a kako bi izmena bila reverzibilna, te se nakon modifikacija uređaj može koristiti i kao vaga za merenje telesne mase, i kao uređaj za pravilno sedenje.

 ISBN 978-86-7466-930-3

C. HX711

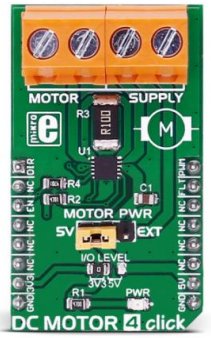
Za merenje izlaza mernih mostova korišćen je A/D konvertor HX711 [6]. HX711 je 24-bitni A/D konvertor, koji je dizajniran za vage i industrijske uređaje koji su bazirani na mernim mostovima. Poseduje dva kanala. Kanal A ima pojačanje od 128 ili 64, dok kanal B ima pojačanje od 32. Rezultati merenja se šalju na serijski interfejs, preko kog se informacije prenose na mikrokontroler. Da bi ovaj čip funkcionisao kako treba, potrebno mu je dodati i neke spoljašnje elemente, što je u ovom slučaju već urađeno na gotovoj štampanoj ploči (slika 8.).

Sl. 8 - Izgled štampane ploče sa HX711 [6]

HX711 sa mikrokontrolerom komunicira pomoću serijskog interfejsa za koji su potrebna dva pina, jedan za takt, a drugi za podatke.

D. Proximity click

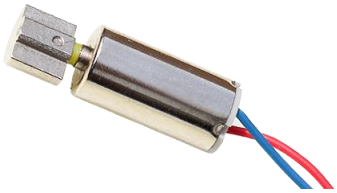
Proximity click na sebi sadrži integrisano kolo VCNL4010, koje služi kao senzor blizine i ambijentalnog svetla. On kombinuje emiter infracrvenog svetla i PIN fotodiode za merenje blizine u dometu do 20 cm. Čip VCNL4010 ima 16-bitnu rezoluciju. Takođe, može se koristiti i kao senzor ambijentalnog svetla. Proximity click komunicira sa mikrokontrolerom preko I2C komunikacije. Ova click pločica može da se napaja sa 3,3 V ili 5 V.



Sl. 9 - Izgled Proximity click-a [4]

VCNL4010 sadrži sedamnaest 8-bitnih registara za kontrolu, postavku parametara i baferovanje očitanih rezultata. Svi ovi registri su dostupni mikrokontroleru preko I2C komunikacije.

E. DC MOTOR 4 click



DC MOTOR 4 click [7] je click pločica koja ima mogućnost pokretanja motora sa naponima napajanja od 5 V do 36 V. Sadrži MAX14870 drajver motora od kompanije Maxim Integrated. Ova click pločica je dizajnirana da radi na 3,3 V ili 5 V. Takođe, na njoj postoji i jumper, pomoću kog se može podesiti da li se koristi unutrašnje napajanje od 5 V, ili neko spoljašnje napajanje.

Sl. 10 - Izgled DC MOTOR 4 click-a [7]

Za komunikaciju sa mikrokontrolerom koriste se linije PWM, FLT, DIR i EN. Kontrola brzine okretanja motora vrši se pomoću PWM signala. Veća ispunjenost PWM signala znači i brže okretanja motora. Integrisano kolo MAX14870 nudi i mogućnosti izbora smera kretanja motora pomoću linije DIR.

U ovom projektu DC MOTOR 4 click služi za pokretanje motora sa ekscentričnom rotirajućom masom (ERM), koji proizvodi vibracije, kako bi korisnik bio obavešten o nepravilnom sedenju.

Sl. 11 - Izgled ERM motora [8]

F. REED click

REED click [9] je jednostavna pločica koja na sebi sadrži standardni (jednopolni, jednopoložajni, normalno otvoren) reed relej. Kada se na ovaj relej utiče magnetnim poljem, njegovi kontakti se zatvore. Tada se na mikrokontroler šalje logička jedinica.

Za ovu aplikaciju REED click je izabran kako bi korisnik preko tkanine na stolici mogao da bira mod rada uređaja.

Sl. 12 - Izgled REED click-a [9]

 ISBN 978-86-7466-930-3

III. FIRMVER

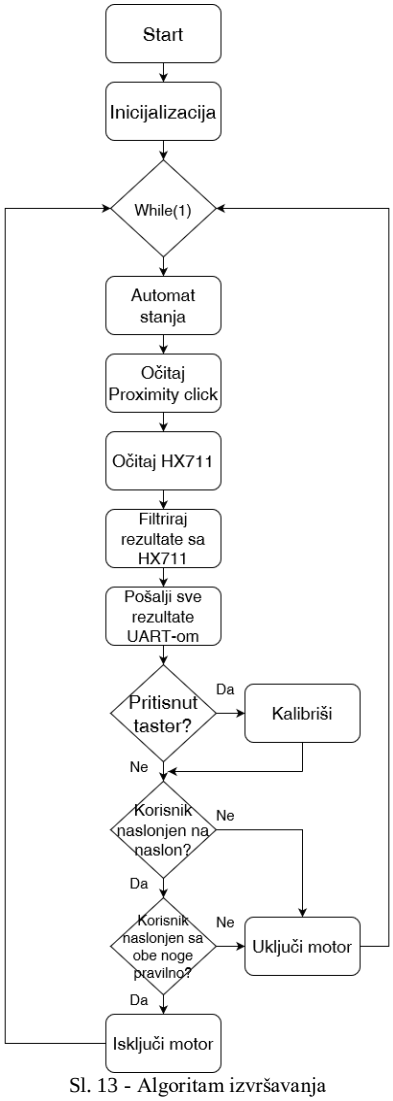
A. Razvojno okruženje firmvera

Firmver za prototip uređaja za pravilno sedenje napisan je u STM32CubeIDE [10] razvojnom okruženju.

Uređaj za pravilno sedenje se bazira na razvojnoj ploči STM32F4 Discovery koja u sebi sadrži STM32F407VG mikrokontroler. Kompanija STMicroelectronics za programiranje ovog mikrokontrolera nudi razvojno okruženje STM32CubeIDE. STM32CubeIDE je napredno C/C++ razvojno okruženje sa periferalnom konfiguracijom, generatorom koda, kompajlerom koda i svojstvima za debagovanje STM32 mikrokontrolere i mikroprocesore.

Pomoću ovog okruženja moguće je na jednostavan način konfigurisati sve periferije mikrokontrolera, GPIO pinove, takt rada, interne i eksterne interapte itd. Takođe sadrži i debager, pomoću koga se može pratiti izvršavanje koda korak po korak.

Jedan od glavnih prednosti STM32CubeIDE razvojnog okruženja je njegov Device configuration tool. On nam omogućava da na jednostavniji i brži način konfigurišemo pinove, oscilatore, periferije itd.



U ovom alatu najpre je podešena brzina takta koji zadaje brzinu rada mikrokontrolera. Brzina ovog takta je 168 MHz. Ova brzina se postiže pomoću eksternog oscilatora od 8 MHz, unutrašnjeg PLL-a (množača takta), i preskalera. Iako ova brzina nije neophodna za ovakvu primenu mikrokontrolera, veća brzina je omogućila da mikrokontroler sigurno izvršava sve zadatke.

Pomoću Device configuration tool-a su takođe podešeni i GPIO pinovi. Ovi pinovi služe kako bi se prikupljali podaci sa ostalih uređaja ili kako bi se njima upravljalo. Tako imamo pinove za upravljanje AD konvertorom HX711, za prikupljanje podataka sa Proximity click-a, itd.

Ovde su takođe podešeni i tajmeri. U ovom projektu oni su korišćeni za generisanje PWM signala, kao i za kreiranje funkcije koja pravi kašnjenje (eng. *delay*) od mikrosekunde.

Konfiguracija komunikacionih modula je takođe odrađena pomoću Device configuration tool-a. Za ovaj projekat bili su potrebni USART2 i I2C3 moduli, pomoću kojih je mikrokontroler komunicirao sa PC računarom i proximity click-om.

B. Algoritam izvršavanja i glavna programska petlja

Sl. 13 - Algoritam izvršavanja

U glavnoj programskoj petlji se nalazi glavni deo koda, koji se izvršava beskonačno puta. Prvo se izvršava automat stanja (eng. *state machine*) koji pomoću reed releja određuje u kojem modu rada treba da radi uređaj (opušteno ili striktno).

Sledeća celina se odnosi na čitanje razdaljine sa Proximity click-a. Prvo se upisuje vrednost za konfiguraciju čipa VCNL4010 tako da on prikuplja podatke sa senzora blizine. Nakon toga, posle kratkog delay-a čitaju se podaci iz njegovih registara, u kojima se skladište podaci o razdaljini. Ove podatke smeštamo u dve 8-bitne promenljive, a nakon toga ih spajamo u jednu 16-bitnu.

Posle isčitavanja vrednosti sa Proximity click-a sledi očitavanje vrednosti sa AD konvertora HX711. Kada su vrednosti očitane, njih je potrebno i filtrirati. Implementacijom FIR filtra ovo je odrađeno na jednostavan i efikasan način. Filter je dizajniran pomoću online alata Tfilter, koji za zadate vrednosti frekvencija i pojačanja sam generiše kod i konstante.

Kako bi ovaj uređaj odgovarao svakom korisniku, bez obzira na njegovu masu, potrebno je izvršiti kalibraciju. Kada korisnik sedne, pritiskom na taster za kalibraciju uređaj u

 ISBN 978-86-7466-930-3

promenljivu upisuje referentnu vrednost sa kojom će kasnije da upoređuje nove vrednosti.

Za komunikaciju sa PC računarom koristi se UART komunikacija. Kada su svi potrebni podaci prikupljeni, oni se upoređuju sa dozvoljenim vrednostima. Kada je neka vrednost van dozvoljenog opsega, uključuje se motor, i preko UART-a se ispisuje poruka. Ovo se radi za obe strane sedalnog dela, kao i za rastojanje od naslona.

IV. Diskusija

Uređaj za pravilno sedenje je uređaj koji bi pomogao ljudima u modernom svetu, a koji se bave poslom koji zahteva višečasovno sedenje. Pomoću njega, korisnik u svakom trenutku ima uvid u položaj svog tela, i na nepravilnosti u držanju. Dizajniran je tako da ga korisnik na jednostavan način može kalibrisati za svoje potrebe, a takođe ga može koristiti i kao vagu za telesnu masu uz jednostavnu rekonfiguraciju.

Kako je ova verzija uređaja dizajnirana pomoću razvojne ploče, njegova cena nije pristupačna za većinu korisnika, ali uz male modifikacije mogao bi biti veoma pristupačan. Naime, za potrebe ovog sistema mogao se koristiti i mikrokontroler sa slabijim karakteristikama i sa manje mogućnosti. Takođe, većina elemenata bi se mogla postaviti na jednu ploču, i tako uštedeti na izradi pojedinačnih click pločica.

Tokom izrade prototipa, osim izrade samog sistema, dodatne izazove predstavljalo je i samo mehaničko rešenje. Naime, kako bi Proximity click merio odstojanje korisnika od naslona stolice, bilo je potrebno probušiti rupu na naslonu stolice da bi infracrveni zraci iz senzora stigli do korisnika, a da pritom senzor ne bude sa prednje strane naslona i time izazove neudobnost pri sedenju. Takođe, za prototip nije izrađeno kućište, pa iz ovog razloga razvojna ploča nije mogla da se zašrafi na stolicu.

Još jedna mana prototipa je njegova udobnost. Da bi korisnik ovaj uređaj mogao da koristi svakodnevno i duže vremena, potrebno je dizajnirati sedalni deo koji bi za to bio pogodan.

Problem pri merenjima sa mernim ćelijama predstavljao je A/D konvertor HX711. Iako on poseduje dva kanala za merenje, oni nemaju isto pojačanje. Ovo je predstavljalo problem, jer je prvobitna ideja bila da se računa odnos između dve strane sedalnog dela, što nije moguće kada su pojačanja različita.

Ovaj uređaj bi se mogao i dodatno nadograditi tako što bi se podaci koji se sakupljaju mogli dalje slati na WEB server. Obrada mernih podataka zahteva veću procesorsku moć, kakvu imaju PC računari i serveri. Na taj način bi mikrokontroler mogao da se u potpunosti svede na minimalne specifikacije, jer ne bi obavljao komplekse obrade, kao što su filtriranje podataka. WEB server bi takođe mogao i da skladišti prethodne podatke, i na taj način bi korisnik mogao da prati poboljšanje svog sedećeg položaja. Takođe, razvojem aplikacije za Android ili IOS mogao bi se vršiti i nadzor pravilnog sedenja dece, i roditelj bi na jednostavan način mogao da utiče na razvoj deteta.

Prednost ovog uređaja u odnosu na već postojeće komercijalne uređaje je što pokriva i sedalni deo, kao i naslon stolice. Takođe, uređaj se može montirati na bilo koju stolicu, pa korisnik ne mora da brine o postavljanju uređaja svaki put kad ga koristi.

Sl. 14 - Izgled Uređaja za pravilno sedenje

V. Zaključak

Izradom ovog prototipa pokazana je osnovna funkcionalnost uređaja, koji može biti dobra osnova za gotov proizvod. On bi se, uz male nadogradnje, mogao koristit u svakodnevnom životu, obrazovanju, pa čak i za naučna istraživanja.

ABSTRACT

This paper presents the firmware solution for the “Device for proper sitting posture” prototype, which gives insight to the users’ posture during sitting. The devices goal is to correct the users posture and thus reduce the back pain which is caused by long sitting hours. The STM32F407 microcontroller, which is on theSTM32F4 Discovery development board, is used for the development of the prototype. Load cells are located on the sitting part of the chair which check the users sitting posture. The outputs of the load cells are connected to the microcontroller through an A/D convertor named HX711. The users’ distance from the back rest of the chair is measured with a Proximity click, while the feedback of the users’ posture is transmitted through a vibro-motor which is powered by a DC motor 4 click board.

Measurement and acquisition system for proper sitting posture

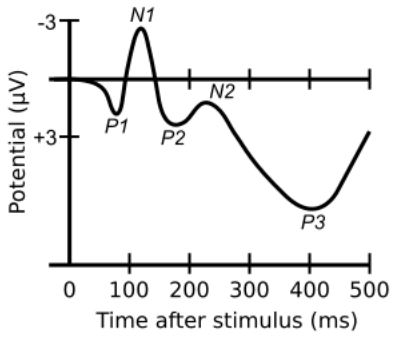
Razvoj softvera za merenje vremena reakcije na vizuelne i zvučne stimuluse

Milica Đorđević, Đorđe Novaković, *Member, IEEE*, Majran Urekar, *Member, IEEE*

***Apstrakt*—Ovaj rad prikazuje softversku aplikaciju koja služi za merenje vremena reakcije korisnika kod prepoznavanja simbola i tonova. Softver je napravljen za desktop uređaje, gde se od ispitanika očekuje da u što kraćem vremenskom periodu odgovori na svaki stimulus od interesa, nakon čega se izračunava prosečno vreme reakcije na iste. Pritom, arhitektura aplikacije je takva da se beleže i impulsivne reakcije nastale neposredno pre pojave samih stimulusa. U izgradnji ovog softvera korišćen je programski jezik Pajton u razvojnom okruženju Visual Studio Code. Za razvoj korisničkog interfejsa korišćena je PyQt5 biblioteka i Qt Designer.**

***Ključne reči*—Softver; Stimulus; Vizuelna stimulacija; Zvučna stimulacija; Pažnja; Vreme reakcije; Pajton; PyQt5.**

I. Uvod



Prvu stepenicu u saznajnom procesu kod čoveka predstavlja opažanje (opservacija) spoljašnjeg sveta, a drugu psihički procesi koji podrazumevaju pamćenje, mišljenje, zaključivanje i druge. Od svih mogućih stimulusa koji u svakom trenutku postoje u polju oko čoveka, samo oni koji su najznačajniji ili najdominantniji u odnosu na njegova interesovanja, namere i ciljeve, bivaju registrovani. Pažnja je bazična psihička funkcija koja omogućava selekciju informacija, usmerenost i usredsređenost psihičke aktivnosti na izvesne sadržaje (predmete, pojave, procese) iz neposredne i dalje okoline. Ona je uslov prijema i obrade informacija.

Karakteristika stalnosti ili postojanosti pažnje odnosi se na sposobnost usredsređenosti tokom dužeg vremenskog perioda. Ukoliko je potrebno duže vremena održavati pažnju, na nekom objektu recimo, postoji kolebanje u njenom intenzitetu. Pažnja je dinamična, pa su joj potrebni stalni voljni podsticaji da bi se održala na istoj, i posebno za subjekta neinteresantnoj aktivnosti. Nedostatak pažnje često se javlja među kliničkom populacijom, uključujući one sa poremećajem pažnje sa hiperaktivnošću (ADHD – Attention Deficit Hyperactivity Disorder) i traumatskim povredama mozga (TBI – Traumatic Brain Injury) [1]. Na sreću, pažnja se može tretirati i poboljšati uz odgovarajući kognitivni trening.

U kognitivnoj psihologiji, vremenski interval između predstavljanja stimulusa i pokretanja voljnog motoričkog odgovora naziva se vreme reakcije. Procena vremena reakcije daje predstavu o integritetu i sposobnostima centralnog nervnog sistema za obradu informacija, a takođe je jednostavan alat za određivanje motoričko-senzornog odnosa kod ispitanika [2]. Komponente pomenutog vremena su: detekcija, identifikacija, odluka i na kraju reakcija.

II. Motiv i ideja

Potencijali vezani za događaje (ERP) su fluktuacije napona koje se snimaju na skalpu i koje su vremenski vezane za događaje. Kao električno polje izazvano protokom informacija u neuronskim mrežama, mere se istim elektronskim uređajima kao EEG. Prošlo je više od pola veka od kada smo prvi put saznali da reči stimulusi, predstavljeni među češćim, izazivaju u EEG-u pozitivni talas sa tipičnim pikom latence nešto veće od 300 ms (Sl. 1.). Kasnije je utvrđeno da ovaj „zakasneli“ pozitivan potencijal povezan sa događajem, nazvan P300 ili P3, uključuje dve različite komponente, P3a i P3b [3]. Štaviše, pokazalo se čak da ni P3b nije jedinstven talas, već se sastoji od daljih podkomponenti.

Sl. 1. Komponente ERP-a.

Kako je P3 najčešće razmatrana ERP komponenta, a njena tačna struktura je do danas ostala nejasna, došli smo na ideju da smislimo modifikaciju standardnog testa koji se koristi pri snimanju ERP-a (poznatiji kao „Oddball“ paradigma) [4]. Zamisao je da ovaj modifikovani kompjuterizovani test bude predlog za dalje istraživanje podkomponenti i pre svega nađe eksperimentalnu primenu.

Postoji mnogo varijacija testova zasnovanih na Oddball paradigmi, a najčešće se tiču vrste predstavljenih stimulusa. Modifikacija prezentovana u ovom radu ogleda se u dužini vremenskih intervala između određenih događaja, što će dalje biti detaljnije objašnjeno.

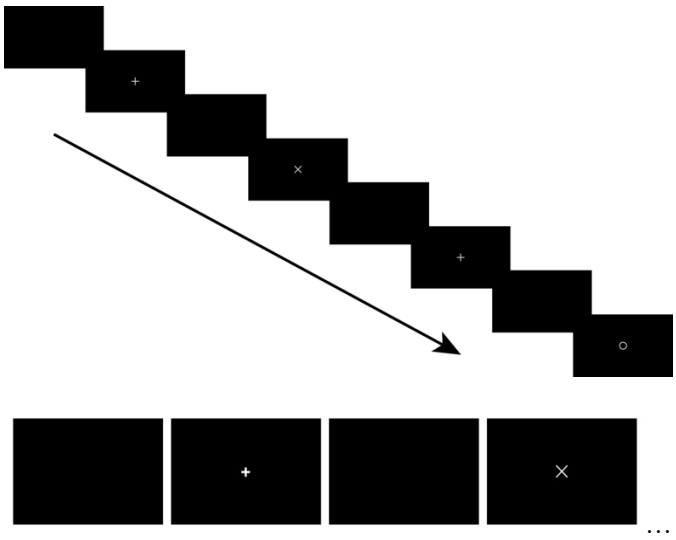
III. Opis rada aplikacije

Kroz celu aplikaciju, odnosno sve njene prozore korisniku se daju jasna uputstva za upotrebu, koja ukazuju na ono što se od njega zahteva. Takođe, korisniku je omogućeno da pritiskom na predviđeno dugme prelazi sa jednog prozora na drugi, intuitivno prateći proces ispitivanja. Prolazeći kroz nekoliko prozora grafičkog korisničkog interfejsa, korisnik unosi svoje lične podatke (Sl. 2.), bira jedan od dva ponuđena testa (Sl. 3.), odrađuje test i potom dobija rezultate.

Sl. 2. Prozor sa forma za popunjavanje ličnih podataka.



Sl. 3. Prozor sa instrukcijama i izborom testa.

U glavnom delu aplikacije, gde se vrši testiranje, korisnikov senzorni aparat stimuliše se sa 35 stimulusa, vizuelne ili zvučne prirode, od kojih je 24 standardnog karaktera, a 11 devijantnog. Redosled prikazivanja stimulusa je nasumičan. Od korisnika se traži da na svaki devijantni (ređi) stimulus, za koji se u ovoj aplikaciji podrazumeva iks (X), odgovori pritiskom na taster „Space“ na tastaturi računara na kom se vrši testiranje. Pod standradnim (češćim) stimulusom se u ovoj aplikaciji podrazumeva oks (O) i na njega korisnik ne treba da odgovori. Aplikacija meri vreme od generisanja devijantnog stimulusa do korisnikovog odgovora na isti, koje ne bi trebalo da bude duže od 1,5 s. Nakon generisanja svih 35 stimulusa, koristeći zabeležne podatke aplikacija izračunava prosečno vreme koje je korisniku bilo potrebno za davanje adekvatnog odgovora, kao i standardnu devijaciju. Ove vrednosti, zajedno sa ličnim podacima korisnika, smeštaju se u SQL tabelu koja se formira nakon prve upotrebe aplikacije. Svakim narednim testiranjem, dopunjavaće se već postojeća tabela bez kreiranja nove, osim u slučaju da je ona ručno izbrisana ili premeštena iz glavnog direktorijuma programa.

A. *Vizuelna stimulacija*

Kada se testiranje vrši uz pomoć vizuelne stimulacije, u centru crnog ekrana će se u krug i nasumično prikazivati stimulusi. Osim što je ekran potpuno crn pre i nakon pojavljivanja stimulusa, dodatno se pre svakog stimulusa prikazuje i fiksacioni objekat za fiksiranje pogleda na monitoru. Ovaj fiksacioni objekat se obično implementira u obliku krsta, vodeći računa o odgovarajućem kontrastu u odnosu na pozadinu. Sekvencijalni tok prikazivanja različitih objekata na ekranu može se videti na Sl. 4.

Sl. 4. Primer toka vizuelne stimulacije (gore) i redosled prikazivanja vizuelnih komponenti ispitaniku (dole).

B. *Zvučna stimulacija*

U slučaju testiranja sa zvučnom stimulacijom, umesto prikazivanja iks i oks na ekranu, oni će biti emitovani kao zvučni signali sa zvučnika.

IV. Upotrebljeni alati

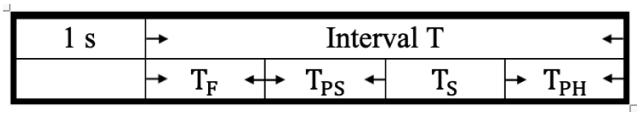
Za realizaciju ove aplikacije korišćen je programski jezik Pajton i njegove biblioteke: PyQt5 [5] i sqlite3 [6].

PyQt5 je sveobuhvatan skup Pajtonovih veza za paket Qt v5, koji omogućava da se Pajton koristi kao alternativa jeziku C++ za razvoj aplikacija na svim podržanim platformama. Uz pomoć pomenute biblioteke i Qt Designer-a napravljen je grafički korisnički interfejs.

Biblioteka sqlite3 korišćena je za kreiranje baze podataka i upisivanje dobijenih vrednosti.

V. Struktura vremenskih intervala

Kako bi se izbeglo formiranje navike kod ispitanika, vremenski intervali između određenih događaja nisu konstantni, već se njihova vrednost generiše kao slučajni parametar između dve granične vrednosti.



Granične vrednosti osnovnog intervala T su 2 s i 4 s, a redom ga sačinjavaju sledeći podintervali (Sl. 5.):

- T_F vreme prikazivanja fiksacionog objekta, graničnih

 ISBN 978-86-7466-930-3

vrednosti 200 ms i 600 ms;
- T_{PS} prestimulaciono vreme, graničnih vrednosti 300 ms i 500 ms;
- T_S vreme prezentovanja stimulusa, koje je konstantno i iznosi 200 ms;
- T_{PH} vreme praznog hoda, ono se ne definiše već je posledica prethodno definisanih intervala:

$$T_{\mathrm{PH}} = T - T_{\mathrm{F}} - T_{\mathrm{PS}} - T_{\mathrm{S}}. \quad (1)$$

Sl. 5. Prikaz vremenskih intervala

Osnovni intervali odvojeni su jednom sekundom radi lakšeg detektovanja.

VI. Rezultati

Pored osnovnog zahteva koji podrazumeva izračunavanje prosečnog vremena reakcije na ciljane stimuluse uz standardnu devijaciju, aplikacija beleži još neke bitne podatke (Sl. 6.):

1. broj tačnih odgovora – pritiskanje predviđenog tastera nakon emitovanja devijantnog stimulusa;
2. broj netačnih odgovora – pritiskanje tastera nakon emitovanja standardnog stimulusa;
3. broj propuštenih devijantnih stimulusa – usled isteka vremena koje je predviđeno za odgovor od strane ispitanika;
4. broj impulsnih odgovora – usled pritiskanja tastera tokom prikazivanja fiksacionog objekta ili neposredno pre pojave stimulusa.

Sl. 6. Prozor sa rezultatima testiranja.

Poslednje spomenut podatak predstavlja jednu od inovacija u ovoj vrsti testova, jer može ukazati i na probleme sa impulsivnošću. Takođe, napravljeno je ograničenje kod vremena koje je predviđeno za dobijanje odgovora od strane ispitanika kako bi se iz razmatranja izuzele ekstremne vrednosti usled slučajnih grešaka.

Srednja vrednost vremena rekacije $\bar{x}$ dobija se deljenjem sume eksperimentalno dobijenih vrednosti x_i sa ukupnim brojem merenja n:

$$\bar{x} = \frac{\sum_{i=1}^{n} x_i}{n}. \quad (2)$$

Standardna devijacija s predstavlja meru odstupanja razmatranih vremena reakcije x_i od njihove aritmetičke sredine, odnosno srednje vrednosti $\bar{x}$, a računa se po sledećoj formuli:

$$s = \frac{\sqrt{\sum_{i=1}^{n} (\bar{x} - x_i)^2}}{n-1}. \quad (3)$$

VII. Diskusija

U odnosu na zamišljene početne ideje i razvoj aplikacije prilagođene za snimanje evociranih potencijala, napravljen je jedan korak u nazad. Odnosno, realizovana je aplikacija koja meri prosečno vreme reakcije uz standardnu devijaciju i još neke indikatore. Ona svakako može naći primenu u eksperimentalnoj praksi kao prvi korak u ispitivanju potencijalnog uticaja promenljivih vremenskih intervala, u ovom slučaju na prosečno vreme reakcije. Takođe, aplikacija je napravljena tako da je korisniku jednostavna za samostalno korišćenje, pa može naći primenu i kao alat za vežbu u različite svrhe.

Ono što bi za početak moglo da se poboljša, kako bi aplikacija išla u zamišljenom pravcu, jeste grafičko prikazivanje rezultata uz markere kada je predstavljen stimulus i kada je korisnik na njega reagovao.

VIII. Zaključak

Merenje vremena reakcije ima široku primenu. Koristi se za procenu zdravstvenog stanja osobe, kao i za praćenje stanja pojedinca tokom njegovog svakodnevnog života radi boljeg obavljanja mentalnih aktivnosti, donošenja odluka i planiranja potrebnih za vožnju, bavljenje sportom i druge aktivnosti koje zahtevaju visok fokus i brzinu.

Vreme reakcije usko je povezano sa pažnjom, osnovnom funkcijom koja je neophodna za obavljanje svakodnevnih aktivnosti, među kojima su učenje, pamćenje, percepcija i rešavanje problema. Zbog toga se pažnja smatra polaznom kognitivnom funkcijom koja ako je oslabljena može dovesti do deficita u drugim kognitivnim domenima.

Zahvalnica

Ovaj rad je podržan od strane Fakulteta tehničkih nauka u Novom Sadu, Departmana za energetiku elektroniku i telekomunikacije, u okviru realizacije projekta MPNTR 200156 : „Inovativna naučna i umetnička ispitivanja iz domena

delatnosti FTN-a“.

ABSTRACT

This paper presents a software application that is used to measure user’s reaction time when recognizing symbols and tones. The software is made for desktop devices, where respondents are expected to respond to stimulus of interest in the shortest possible time, after which average reaction time is calculated. At the same time, the architecture of the application is such that impulsive reactions that occurred just before the appearance of the stimulus are also recorded. The Python programming language was used for building the application in Visual Studio Code development environment. The PyQt5 library and Qt Designer were used to develop the graphical user interface.

Software development for measuring reaction time to visual and audio stimuli

Projektovanje univerzalne razvojne ploče za merenje i regulaciju

Ninoslav Srdić, Marjan Urekar, Dragan Pejić, Platon Sovilj

***Apstrakt*—Ovaj rad opisuje projektovanje univerzalne razvojne ploče za merenje fizičkih veličina i regulaciju, na bazi AVR atmega32u4 mikrokontrolera. Prikazana je blok šema uređaja, šematici pojedinačnih blokova i navedeni su primeri primene ove razvojne ploče.**

***Ključne reči*: univerzalna razvojna ploča; mikrokontroler; industrijski senzori**

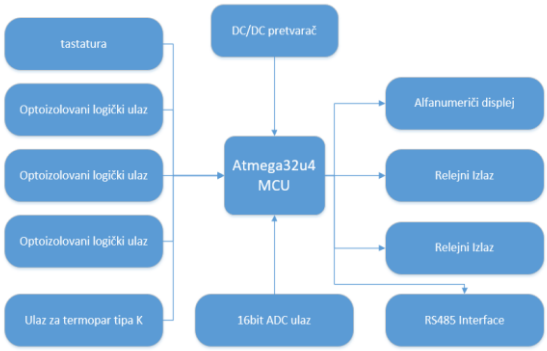
I. UVOD

Prilikom razvoja novog proizvoda, dok još ideja i tehničko rešenje nisu sasvim formirani i da bi nam početak razvoja bio lakši i ekonomski efikasniji, potreban nam je hardverski razvojni alat. Iako nije neuobičajeno da pravimo revizije hardvera, uvek je bolje da prvo svoju ideju proverimo na postojećoj platformi, odnosno na takozvanoj univerzalnoj razvojnoj ploči.

Ovaj rad ukratko objašnjava projektovanje univerzalne razvojne ploče za potrebe laboratorijskih vežbi na fakultetu kao i za prototipovanje proizvoda. Na tržištu već postoji mnoštvo ovakvog hardvera sa različitim kontrolerima, periferijama, različitih dimenzija i cena. Prednost ove ploče jeste što nudi dosta periferija u odnosu na druge ploče sa ATmega32u4 kontrolerom i to u kompaktnom formatu.

Ova razvojna ploča omogućava korisnicima da koriste različite industrijske senzore sa logičkim izlazom, termopar K tipa za merenje temperature, ulazima na koja se mogu dodati spoljašnji razdelnici napona za različita analogna merenja i da se sve to može programirati u Arduino okruženju ili pristupiti i programirati iz labview-a, tj. okruženja koja su studentima već poznata.

Ideja je da se od jedne kompaktne ploče mogu razviti uređaji za različite primene (npr. temperaturni regulator, merenja nekih fizičkih veličina, prenos izmerenih vrednosti preko serijske komunikacije RS485 i prikaz tih podataka na Labview SCADA sistemu) i da se ovaj sklop može primeniti za vežbe iz različitih predmeta na fakultetu, a da nije neophodno dodatno napajanje osim konekcije sa računarom.



Marjan Urekar – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg D. Obradovića 6, 21000 Novi Sad, Srbija (e-mail: urekarm@uns.ac.rs).
Platon Sovilj – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg D. Obradovića 6, 21000 Novi Sad, Srbija (e-mail: platon@uns.ac.rs).
Dragan Pejić – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg D. Obradovića 6, 21000 Novi Sad, Srbija (e-mail: pejicdra@uns.ac.rs).
Ninoslav Srdić – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg D. Obradovića 6, 21000 Novi Sad, Srbija (e-mail: ninosrdicd@gmail.com)

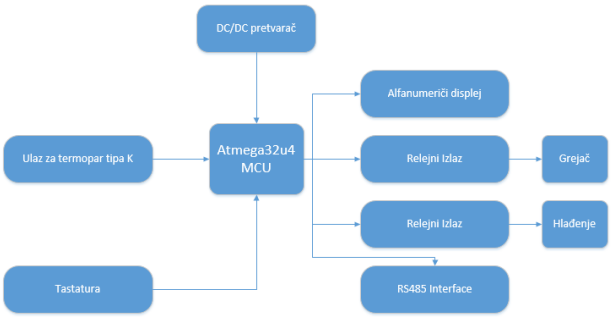
Primena ove razvojne ploče su predmeti koji se bave merenjem, embedded programiranjem i Labview okruženjem ili kao platforma za razvoj softvera za *embedded* aplikacije.

II. DIZAJN SKLOPA

Postavljen je zahtev da se napravi razvojna ploča koja će moći da se koristi sa industrijskim senzorima sa tranzistorskim izlazima, odnosno sa senzorima koji na svom izlazu daju logičku vrednost, kao i senzorima za merenje analognih vrednosti i jedan ulaz za merenje temperature termoparom tipa K. Za izvršavanje komande razvojna ploča ima dva relejna izlaza, a za prikazivanje merenih vrednosti alfanumerički displej kao i mogućnost slanja podataka serijskom komunikacijom. Takođe na ploči imamo četiri tastera. Još jedan od zahteva je da se ploča napaja sa 5 V a za potrebe napajanja industijskih senzora potreban je napon od 24 Vdc, pa je napravljen *Step-up* pretvarač (*converter*).

Prvi korak prilikom dizajna celog sklopa je bio da se napravi blok dijagram, gde su objedinjeni svi zahtevi pa su na osnovu toga izabrane komponente.

Sl. 1. Blok šema celog sklopa



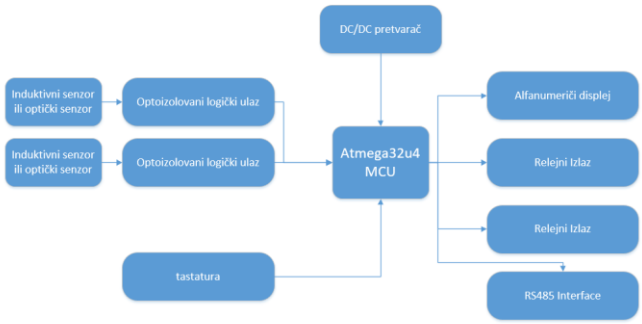
Kao što se na blok šemi može videti razvojna ploča se sastoji od:

- Tri optoizolovana logička ulaza za industrijske senzore
- AD konvertor sa dva ulaza za analogna merenja
- Ulaz za termopar sa pretvaračem koji vrši kompenzaciju hladnog kraja, kao i linearizaciju karakteristike termopara i AD konverziju
- DC/DC boost pretvarač sa 5 V na 24 V
- Dva relejna izlaza
- Alfanumerički displej
- RS485 interface
- Četiri programibilna tastera

 ISBN 978-86-7466-930-3

Primeri primena:

A. *Temperaturni regulator*

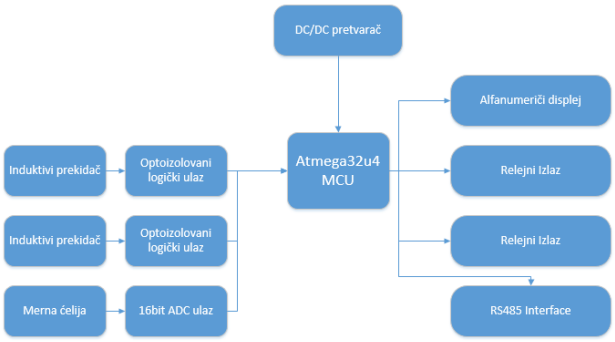


Sl. 2. Blok šema temperaturnog regulatora

Na slici 2. je prikazana blok šema temperaturnog regulatora koji se može napraviti uz korišćenje ove razvojne ploče.
Na ulaz razvojne ploče možemo povezati termopar tipa K.
Na relejne izlaze možemo povezati grejač i sistem za hlađenje.

Alfanumerički displej nam pruža mogućnost prikaza temperature i zadatih parametara. Tasterima dobijamo mogućnost promene parametara odnosno zadavanje graničnih vrednosti temperature. Na računaru možemo grafički predstaviti vrednosti promene temperature po vremenu, slanjem podataka preko RS485 komunikacije.

Ovakav sistem bi imao primenu za održavanje temperature alata prilikom brizganja plastike.



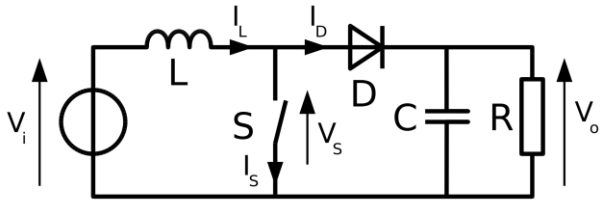
B. *Brojač komada*

Sl. 3. Blok šema brojača komada

Na slici 3. se može videti drugi primer primene (brojač komada). Induktivnim senzorima ili optičkim prekidačima na ulazu detektujemo prolazak komada ili neke referentne tačke za brojanje (npr. istureni vijak na osovini). U zavisnosti od redosleda okidanja senzora možemo da uvećavamo ili smanjujemo izbrojane vrednosti i to da predstavimo na displeju. Relejne izlaze možemo koristiti za uključivanje ili isključivanje pogona nakon postizanja zadatih vrednosti.

C. *Vaga za doziranje*

Sl. 4. Blok šema vage za doziranje



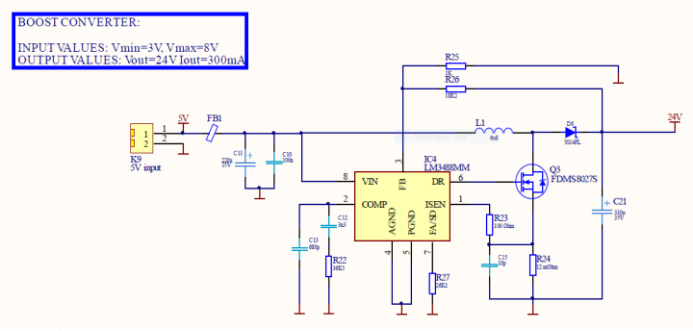
Još jedna primena razvojne ploče jeste razvoj softvera za vagu za doziranje praškastih ili zrnastih proizvoda (Sl. 4.).
Na ulazu AD konvertora imamo mernu ćeliju pomoću koje merimo masu, a relejne izlaze možemo iskoristiti za grubo i fino doziranje, tj. za otvaranje veće i manje klapne na košu vage. Induktivni prekidači nam služe za detektovanje položaja klapne. Na alfanumeričkom displeju prikazujemo izmerenu i zadatu vrednost i grešku doziranja.

III. TEHNIČKO OBJAŠNJENJE

Jedan od bitnih zahteva projekta, jeste mogućnost da se mikrokontroler može programirati preko Arduino okruženja, pa je na osnovu toga izabran kontroler iz AVR familije. Za ostale komponente napravljena je excel tabela sa nekim od ključnih parametara, kao i cene komponenti. Potom je sagledano koje komponente su optimalne u odnosu na cenu i karakteristike.

Nakon odabira ključnih komponenti i njihove dokumentacije sledi crtanje električne šeme, gde je korišten alat po imenu Altium Designer.

Za projektovanje DC/DC pretvarača korišten je alat Texas Instruments Power Designer, gde se definišu potrebni parametri i topologija pretvarača, a alat potom sam izračuna vrednosti komponenti.

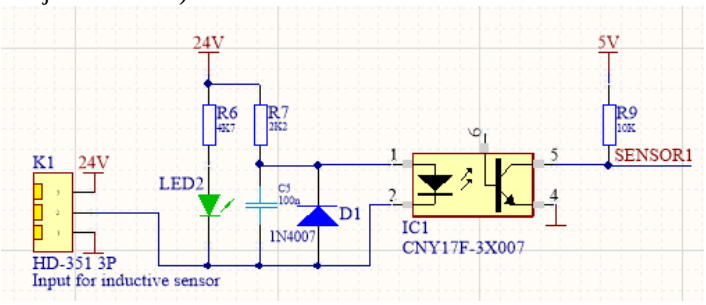


Sl. 5. Blok šema Boost pretvarača

Na slici 5. prikazan je primer pretvarača, podizača napona (*Boost converter*).

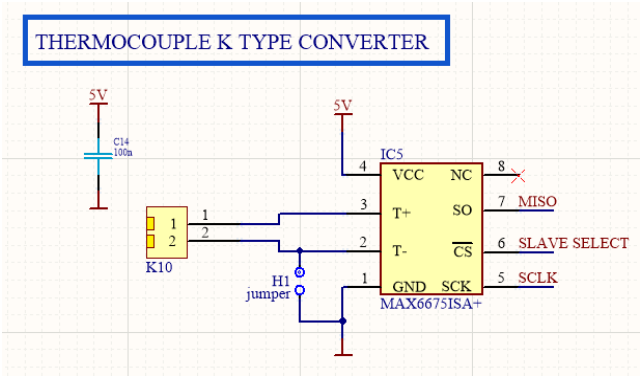
 ISBN 978-86-7466-930-3

U ovoj topologiji pretvarača, za prebacivanje energije iz jednosmernog izvora nižeg napona ka opterećenju na kome je viši napon, koristi se magnetna energija kalema.
Kada je prekidač zatvoren, struja izvora protiče kroz kalem *L* i prekidač *S*. Tada kalem skladišti energiju u svom magnetnom polju. Otvaranjem prekidača, struja kalema, koja je jednaka struji izvora počinje da pada. Pošto se kalem suprotstavlja promeni struje, dolazi do porasta napona u kalemu. Upravo ovaj efekat se koristi za podizanje napona u *boost* pretvaraču.



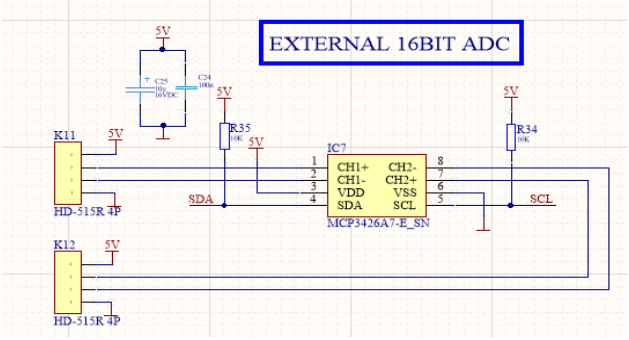
Sl. 6. Šema Boost pretvarača

Optički izolovan logički ulaz na slici 7. namenjen je za priključivanje industrijskih senzora sa logičkim izlazom. Optokapleri se koriste radi galvanskog odvajanja dva dela kola, tj. kao dodatan vid zaštite.



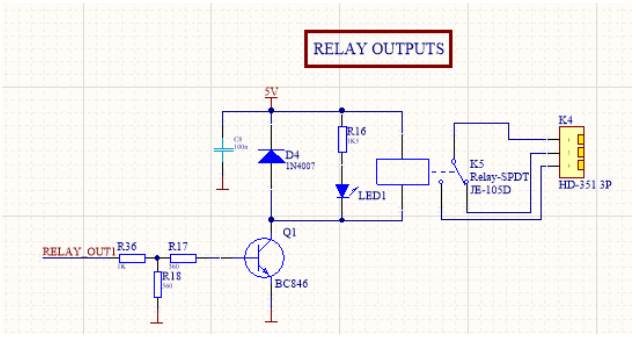
Pošto je za napajanje industrijskih senzora uglavnom potreban napon od 24 V, na ovaj ulaz je doveden napon sa *step-up (boost)* pretvarača.

Ukoliko želimo da imamo galvanski odvojen ulaz, ne smemo koristiti napajanje USB porta, nego koristimo posebno napajanje od 5 V (prethodno se mora skinuti *jumper* H2 vidljiv na Sl. 11.).



Sl. 7. Optički izolovan ulaz

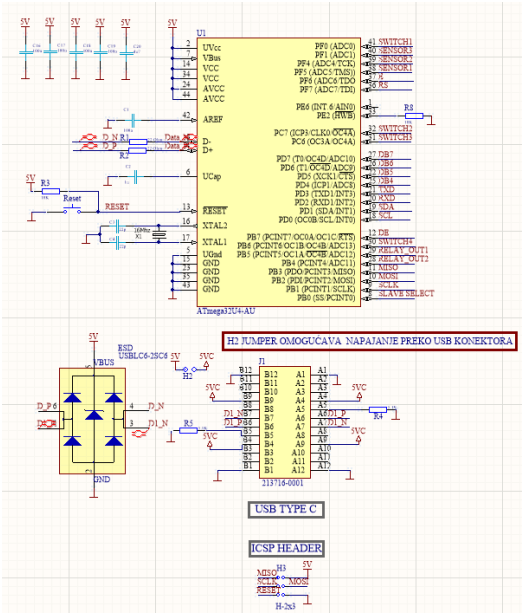
Ulaz za termopar (Sl. 8.) je omogućen uz pomoću MAX6675 pretvarača. Termopar tipa K nije linearan, pa je pored pojačavanja ulaznog signala potrebno i linearizovati isti. Ovaj pretvarač u sebi ima kompenzaciju hladnog kraja u opsegu od -20 °C do +85 °C, linearizaciju signala i 12-bitni AD konvertor. MAX6675 omogućava veome jednostavno merenje temperature termoparom tipa K, pošto na SPI izlazu dobijamo tačno izmerenu vrednost temperature.
Rezolucija ovog pretvarača je 0.25 °C i može se koristiti za merenja temperature do +1024 °C.
U ovom projektu koristimo napajanje od 5 V.
Podatke mikrokontroleru šaljemo pomoću SPI komunikacije.



Sl. 8. Ulaz za termopar

Sklopu je dodat i 16-bitni eksterni ADC (Sl. 9.) jer je ADC u mikrokontroleru 12-bitne rezolucije. Ovaj AD konvertor ima dva kanala, a sa mikrokontrolerom komunicira preko I2C-a.

Sl. 9. ADC ulaz



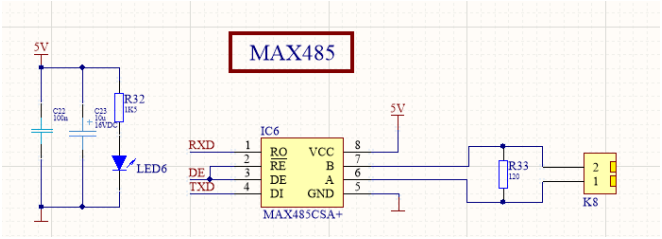
Na slici 10. se može videti primer relejnog izlaza, preko koga se može povezati neki izvršni element veće snage.

Sl. 10. Relejni izlaz

Na slici 11. se može videti 8-bitni, *RISC* mikrokontroler, Atmega32u4 sa malom potrošnjom struje, eksterni kristal od 16 MHz, ESD zaštita u vidu kola USBLC6 i USB type-C konektor.
Napajanje mikrokontrolera je od 2.7 V - 5.5 V.
Odlučili smo se za ovaj mikrokontroler jer je on odlična platforma za studente, hobiste i brzo prototipovanje zbog postojanja mnoštva *open-source* primera programa i kompatibilan je sa Arduino okruženjem. Još jedna prednost ovog mikrokontrolera jeste što se može programirati preko Usb priključka.

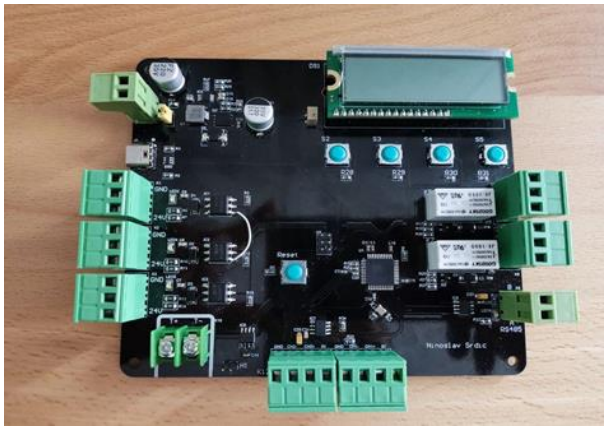
 ISBN 978-86-7466-930-3

Sl. 11. Mikrokontroler



Slika 12. pokazuje alfanumerički displej 2x16 karaktera. Komunikacija mikrokontrolera sa displejom je omogućena u 4-bit modu, kako bi smanjili broj potrebnih pinova na mikrokontroleru.

Da bi prikazali karakter na displeju u 4-bit modu, potrebna su dva ciklusa, tj. prvo se šalju viša 4 bita a potom preostala niža 4 bita.



Sl. 12. Displej

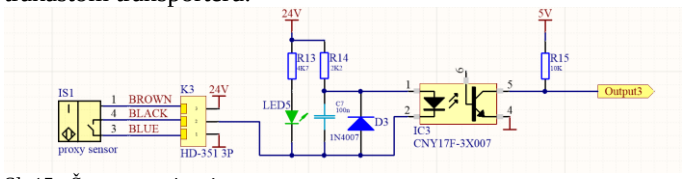
Na slici 13. se može videti deo šeme za RS485 komunikaciju. Projekat je osmišljen tako da se merene vrednosti mogu prikazati na displeju na ploči, ali takođe da se razvojna ploča može povezati sa računarom i da se preko RS485 komunikacije pošalju podaci na SCADA sistem.

Sl. 13. RS485 komunikacija

Na sledećoj slici se može videti gotova razvojna ploča.

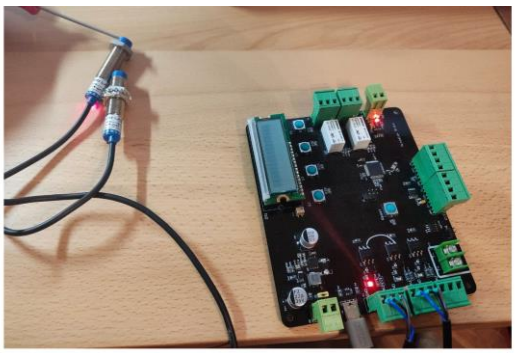
Sl. 14. Gotov sklop

U ovom projektu korištena je četvoroslojna štampa zbog boljih EMC karakteristika (“Elektromagnetna usaglašenost”). Svi električni uređaji utiču jedni na druge kada su ili međusobno povezani ili postavljeni u blizini. Zahtevi EMC-a su tako koncipirani da se ova sporedna dejstva svedu na minimum.



IV. PRIMER VEŽBE

Cilj prve vežbe jeste da se napravi prosto *flip-flop* prekidačko kolo.



Na optički izolovane ulaze povezali smo dva induktivna senzora sa NPN tranzistorskim izlazom. U svrhe ove vežbe nisu nam neophodni galvanski odvojeni ulazi, pa ceo sklop napajamo preko USB priključka.

Program za razvojnu ploču je napisan u *Microchip Studio* okruženju tako da jedan induktivni senzor uključuje oba relejna izlaza, jedan u momentu detektovanja a drugi sa zakašnjenjem. Drugi induktivni senzor isključuje oba relejna izlaza, jedan u momentu detektovanja a drugi sa zakašnjenjem.

Vežba je namenjena za kontrolu elektromotora na trakastom transporteru.

Sl. 15. Šema povezivanja senzora

Sl. 16. Primer vežbe

 ISBN 978-86-7466-930-3

V. ZAKLJUČAK

Nakon sklapanja i testiranja uređaja došli smo do zaključka da je projekat opravdao očekivanja i da se uspešno može primeniti za razvoj različitih merno-regulacionih uređaja. U sledećoj iteraciji bi se mogao dodati drajver za koračni motor, DA konvertor, sat realnog vremena i da se na opto-izolovanom ulazu mogu dodati kratkospojnici za izbor senzora sa tranzistorskim NPN ili PNP izlazom.

Prednost ovakve razvojne ploče jeste jednostavnost priključivanja periferija i relativno jednostavno programiranje.

Mana ove ploče je što nema mogućnost daljeg proširenja periferija.

Zahvalnica

ABSTRACT

This paper explains the design and making of a universal development board for measurements and regulation, based on the ATmega32u4 microcontroller. Block diagrams are also shown, as well as schematics of these block and even examples of how this board could be used in practice.

Designing a universal development board for industrial sensors

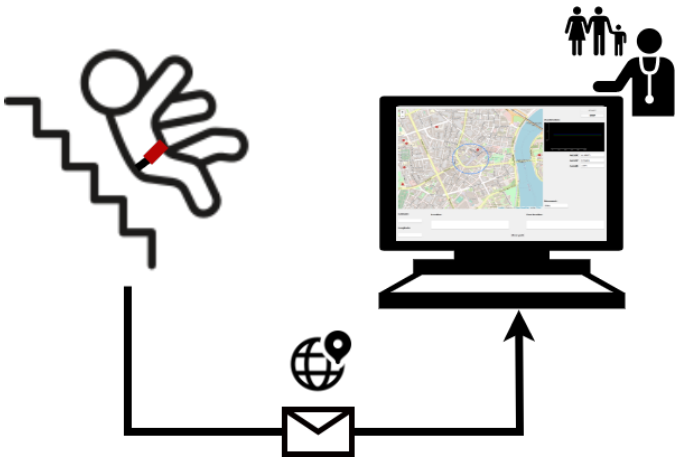
Merni sistem za detekciju padova zasnovan na akcelerometru, žiroskopu i GPS modulu



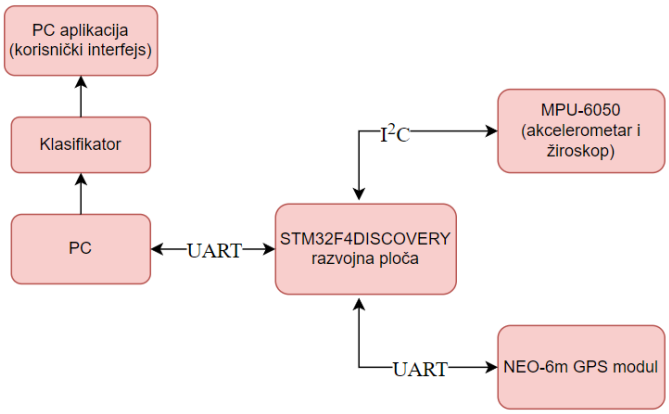
Sanja Mandić, Đorđe Novaković

***Apstrakt*—U ovom radu opisan je sistem za detekciju pada, sa ciljem pomoći starim i nemoćnim licima. Kroz rad je dat uvid u sve delove realizovanog sistema za detekciju pada. Sistem podrazumeva prikupljanje podataka o kretanju korisnika upotrebom akcelerometra i žiroskopa, prikupljanje podataka o lokaciji korisnika upotrebom GPS modula, klasifikaciju kretanja i detekciju pada, kao i prikaz informacija u okviru odgovarajućeg korisničkog interfejsa.**

***Ključne reči*— Detekcija pada; mikrokontroler; GPS; akcelerometar; žiroskop; mašinsko učenje; klasifikacija**

I. Uvod

Padovi su česte pojave kod starijih osoba usled različitih faktora kao što su gubitak oslonca, nesvestica, moždani ili srčani udar, poremećaji čula vida, slabost u mišićima, demencija i deformacija kičmenog stuba. Starenje za posledicu ima i nesposobnost da se na iznenadne promene položaja tela reaguje pravovremeno i da se održi ravnoteža, što značajno povećava verovatnoću pada kod starijih osoba. Istraživanja su pokazala da jedna trećina populacije starije od 65 godina doživi pad jednom ili više puta u toku jedne godine. Padovi predstavljaju jedan od vodećih uzroka povreda, preloma, gubitka mobilnosti i smrtnih ishoda izazvanih nezgodama kod starijih osoba. Kako bi se izbegle teške povrede usled padova, pa i fatalni ishodi padova, pravovremeno pružanje medicinske pomoći povređenoj osobi je od izuzetnog značaja. Teške posledice koje padovi mogu da izazovu kod starijih osoba i potreba za trenutnim pružanjem pomoći osobama koje su pretrpele pad dovele su do velikog broja istraživanja u oblasti uređaja za detekciju pada i praćenja kretanja.



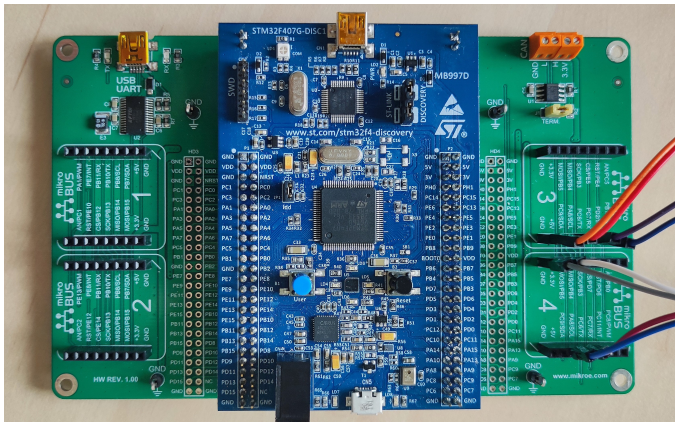
Slika 1. Ilustracija sistema za detekciju pada

Sanja Mandić – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: sanja.mandic@uns.ac.rs).

Đorđe Novaković – Fakultet tehničkih nauka, Univerzitet u Novom Sadu, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: djordjenovakovic@uns.ac.rs).

Cilj ovog rada je izrada prototipa sistema za detekciju pada koji bi služio kao pomoć starijim licima, a ilustracija ovakvog sistema prikazana je na slici 1. Kretanje korisnika prati se pomoću akcelerometra i žiroskopa MPU-6050 senzorskog modula. Na osnovu veličina prikupljenih datim senzorima izdvaja se vektor obeležja koji se prosleđuje prethodno obučenom modelu klasifikatora. Model vrši klasifikaciju uzorka u jednu od pet klasa - pad unapred, pad u stranu, sedenje, stajanje ili hodanje. Ukoliko je kretanje okarakterisano kao pad unapred ili pad u stranu, putem korisničkog interfejsa se prikazuje lokacija korisnika na osnovu podataka prikupljenih GPS modulom. Senzorski moduli sistema integrisani su na STM32F4DISCOVERY razvojnoj ploči, koja sadrži STM32F407VGT mikrokontroler. Blok dijagram realizovanog sistema prikazan je na slici 2.

Slika 2. Blok dijagram sistema za detekciju pada



II. Hardverske komponente sistema za detekciju pada

A. *STM32F4DISCOVERY razvojna ploča*

STM32F4DISCOVERY razvojna ploča (slika 3) je proizvod kompanije *STMicroelectronics*, koja na sebi integriše 32-bitni STM32F407VGT mikrokontroler. STM32F4DISCOVERY ploča sadrži mikro USB (*Universal Serial Bus*) AB konektore, pomoću kojih se ostvaruje veza računara i date razvojne ploče. U sistemima koji podrazumevaju 32-bitne STM mikrokontrolere zastupljen je USB full-speed interfejs za komunikaciju sa računarom. Na ploči se nalazi ST-LINK/V2-A kolo za programiranje i debagovanje mikrokontrolera. ST-LINK/V2-A komunicira sa STM 32-bitnim mikrokontrolerom putem SWIM (*Single Wire Interface Module*) interfejsa, odnosno, putem JTAG ili SWD (*Serial Wire Debugging*) interfejsa. Ploču je moguće napajati na nekoliko različitih načina - putem ST-LINK veze, putem USB konektora ili putem eksternih izvora napajanja. Na ploči se nalazi osam indikatorskih LED (*Light Emitting Diode*) - za USB komunikaciju, za napajanje od 3,3 V, četiri korisničke LED (narandžasta, zelena, crvena i plava) i dve LED za USB OTG (*On The Go*) interfejs. Na razvojnoj ploči nalaze se reset taster, kao i korisnički taster. Dodatno, data razvojna ploča sadrži MEMS (*Micro Electronic*

 ISBN 978-86-7466-930-3

Mechanical Systems) omni-direkcioni digitalni mikrofon, audio DAC (*Digital to Analogue Converter*), konektor za slušalice, kao i MEMS digitalni akcelerometar [1]. STM32F4DISCOVERY razvojna ploča postavljena je na STM32F4 Discovery Shield, kompanije *MikroElektronika*, u cilju lakšeg povezivanja sa senzorskim modulima.

Slika 3. STM32F4DISCOVERY razvojna ploča na STM32F4 Discovery Shield-u

Mikrokontroler STM32F407VGT nalazi se u okviru STM32DISCOVERY razvojne ploče u LQFP100 pakovanju sa sto pinova, čiji je prikaz dat na slici 4. STM32F407VGT sadrži ARM 32-bit Cortex CPU (*Central Processing Unit*). Kapacitet FLASH memorije datog mikrokontrolera je 1 MB, dok je kapacitet SRAM (*Static Random-Access Memory*) memorije 192 kB. Napon napajanja mikrokontrolera je u ospegu od 1,8 V do 3,6 V. Interni oscilator STM32F407VGT mikrokontrolera obezbeđuje frekvenciju takta od 16 MHz, a osim internog oscilatora, mikrokontroleru je moguće dovesti i spoljašnji izvor takta frekvencije od 4 MHz do 26 MHz. Signal takta vodi se na PLL (*Phase Locked Loop*), čime je obezbeđeno povećanje frekvencije do 168 MHz. STM32F407VGT sadrži tri 12-bitna ADC (*Analog to Digital Converter*) i dva DAC. Dati mikrokontroler sadrži dvanaest 16-bitnih tajmera i dva 32-bitna tajmera. Mikrokontroler sadrži tri SPI (*Serial Peripheral Interface*), dva CAN (*Controller Area Network*) i tri I^2C (*Inter-Integrated Circuit*) komunikaciona interfejsa, dok je broj USART (*Universal Synchronous/Asynchronous Receiver Transmitter*) modula mikrokontrolera šest [2].

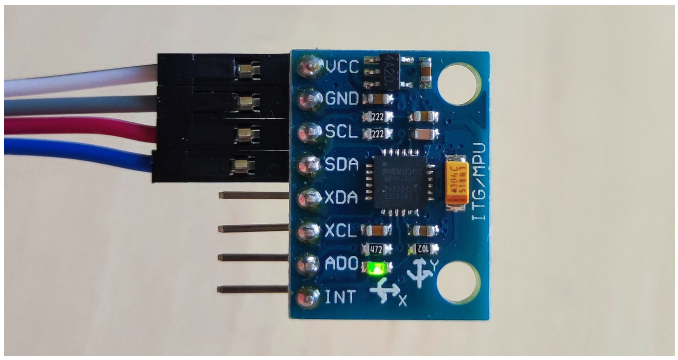
Slika 4. Pinovi STM32F407VGT mikrokontrolera

Odgovarajući firmver za STM32F407VGT mikrokontroler i čipove senzora napisan je u STM32CubeIDE razvojnom okruženju.

B. NEO-6m GPS modul

NEO-6m predstavlja GPS modul koji omogućava primanje podataka sa GPS (*Global Positioning System*) satelita. Dati modul sadrži kristalni oscilator. NEO-6m modul sadrži UART, USB, DDC (*Display Data Channel*) i SPI komunikacione interfejse. NEO-6m čip predstavlja prijemnik sa 50 kanala. Podaci se prenose kao kodirane poruke, definisane određenim protokolima. Jedan od protokola koji je podržan na NEO-6m GPS modulu jeste NMEA (*National Marine Electronics Association*) protokol. Svaka linija podataka koja se prenosi na ovaj način naziva se rečenicom, a sve sadrže specifične podatke o lokaciji. Neke od NMEA rečenica koje se mogu primiti putem NEO-6m prijemnika su GLL (Position Data), RMC (Recommended Minimum Sentence) i GGA (Global Positioning System Fix Data). U realizovanom sistemu za detekciju pada upotrebljene su GGA NMEA rečenice, koje sadrže podatke kao što su vreme, geografska širina, geografska dužina, broj satelita i nadmorska visina [3], [4].

Slika 5. NEO-6m GPS modul



Senzorski modul NEO-6m je povezan sa mikrokontrolerom STM32F407VGT posredstvom mikroBUS 3 socket-a STM32F4 Discovery Shield-a. Razmena podataka između NEO-6m i mikrokontrolera vrši se putem UART komunikacionog interfejsa, a brzina prenosa podataka je 9600 bps. Pin za prijem podataka (RX) NEO-6m povezan je na PC6 pin mikrokontrolera, koji odgovara predajnoj liniji njegovog USART 6 modula. Pin za slanje podataka (TX) NEO-6m povezan je na odgovarajući prijemni pin USART 6 modula mikrokontrolera, odnosno, na pin PC7. Na pločicu sa NEO-6m čipom dovodi se napajanje od 5 V, preko VCC pina, dok je GND pin povezan na GND pin mikroBUS 3 socket-a STM32F4 Discovery Shield-a.

C. MPU-6050 senzor

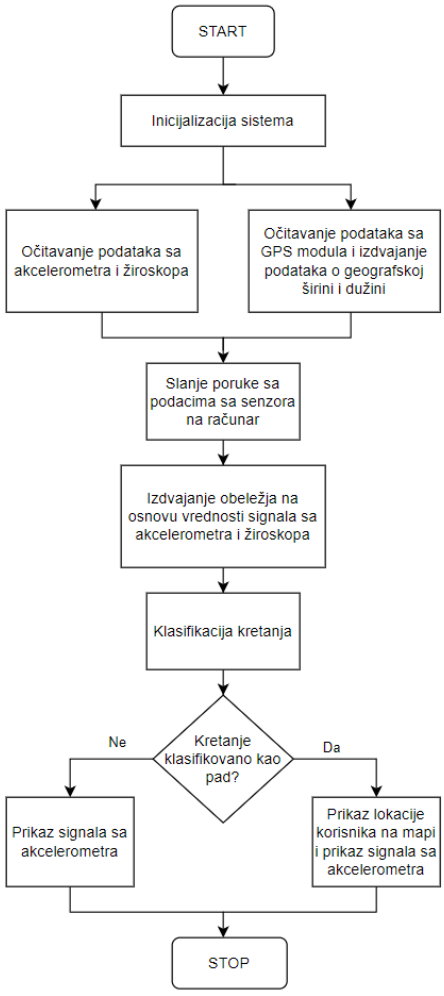
MPU-6050 senzor na pločici GY-521 (slika 6) integriše MEMS akcelerometar sa tri ose, MEMS žiroskop sa tri ose i DMP (*Digital Motion Processor*). Ovaj senzor koristi I^2C komunikaciju sa mikrokontrolerom razvojne ploče (pinovi SCL – clock i SDA – podaci). MPU-6050 čip sadrži tri 16-bitna ADC za podatke svake ose akcelerometra i tri 16-bitna ADC za podatke svake ose žiroskopa. Podaci sa senzora o sve tri ose, x, y i z, prikupljaju se istovremeno, a MPU-6050 sadrži adekvatne read-only registre u koje se smeštaju vrednosti sa senzora i kojima se pristupa putem serijskog interfejsa. Opseg pune skale za žiroskop može biti $\pm 250\ ^\circ/s$, $\pm 500\ ^\circ/s$, $\pm 1000\ ^\circ/s$ i $\pm 2000\ ^\circ/s$, dok su vrednosti za opseg pune skale akcelerometra ±2 g, ±4 g, ±8 g i ±16 g (g = 9,81 m/s2). Čip sadrži FIFO (*First In First Out*) bafer od 1024 bajta, koji služi za privremeno skladištenje

 ISBN 978-86-7466-930-3

izlaznih podataka, a korisnik može da bira koje podatke će skladištiti u baferu. Dodatno, MPU-6050 čip sadrži oscilator, kao i temperaturni senzor [5].

Slika 6. Senzor MPU-6050 na GY-521 pločici

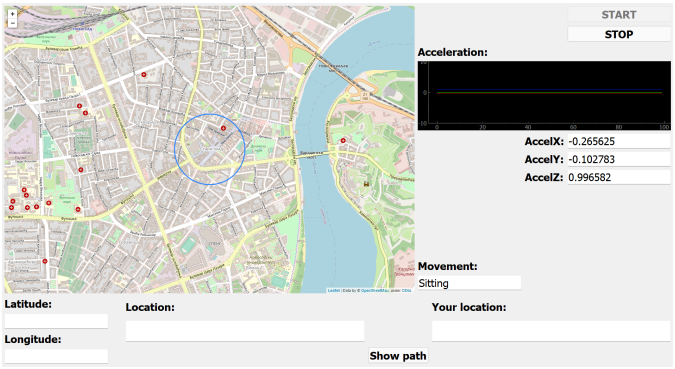
Za datu primenu MPU-6050 je konfigurisan tako da je opseg pune skale akcelerometra ±8 g, opseg pune skale žiroskopa ±2000 $^\circ/s$, a frekvencija odabiranja je 1 kHz. Pinovi GY-521 pločice povezani su na pinove mikrokontrolera posredstvom STM32 Discovery Shield-a. Pinovi Vcc i GND GY-521 povezani su na 3,3 V i GND mikroBUS 4 socket-a STM32 Discovery Shield-a, dok su SDA i SCL pin sa GY-521 povezani na odgovarajuće pinove mikroBUS 4 socket-a za I^2C komunikaciju, koji odgovaraju pinovima PC9 i PA8 mikrokontrolera, redom.



III. Softver sistema za detekciju pada

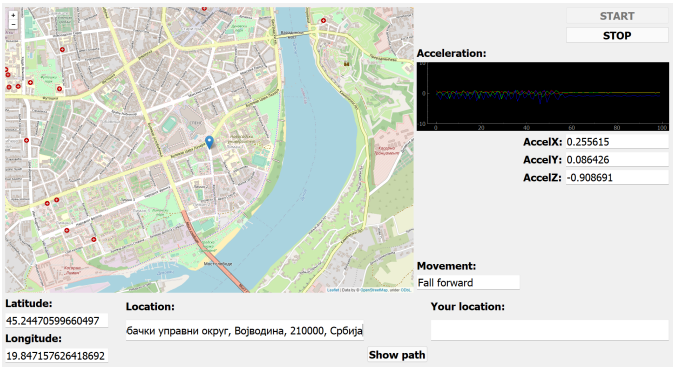
Kako bi bila omogućena razmena podataka i obaveštenje odgovornog lica o padu korisnika uređaja kreiran je grafički korisnički interfejs upotrebom Python programskog jezika. Na slici 7 prikazan je izgled aplikacije po pokretanju programa. U okviru kreiranog korisničkog interfejsa, u gornjem desnom uglu omogućen je prikaz signala sa akcelerometra, po x, y i z osi, kao i ispis trenutnih vrednosti ubrzanja za sve tri ose (polja AccelX, AccelY i AccelZ). Takođe, omogućen je prikaz mape, na kojoj se prikazuje lokacija korisnika uređaja. U polja označena sa Latitude, Longitude i Location ispisuju se podaci o geografskoj širini, geografskoj dužini i lokaciji korisnika uređaja, ukoliko dođe do pada. Korisničkim interfejsom omogućen je unos lokacije odgovornog lica i prikaz najkraće putanje do lokacije na kojoj se nalazi osoba koja je pala. U dodatnom polju, označenom kao Movement, prikazuje se jedna od pet mogućih radnji (stajanje, sedenje, hodanje, pad unapred, pad u stranu), određena na osnovu signala sa akcelerometra i žiroskopa.

Slika 7. Izgled aplikacije po pokretanju



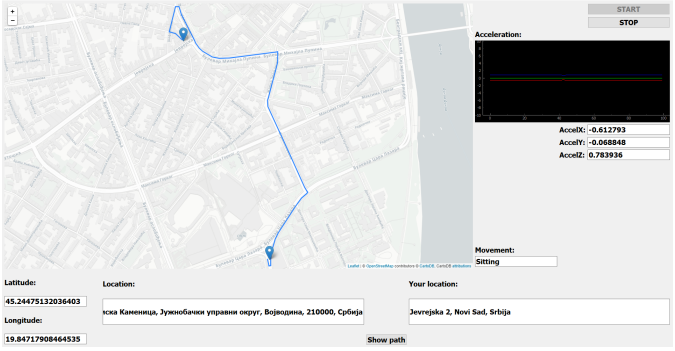
Na slici 8 prikazan je tok izvršavanja programa koji obuhvata inicijalizaciju hardverskih komponenti, slanje podataka sa mikrokontrolera, prijem, obradu i prikaz podataka na računaru, kao i klasifikaciju kretanja. Inicijalizacija sistema podrazumeva konfiguraciju odgovarajućih modula mikrokontrolera, kao i senzorskih modula. Nakon inicijalizacije svih celina neophodnih za rad sistema vrši se simultano očitavanje podataka sa akcelerometra MPU-6050, žiroskopa MPU-6050 i NEO-6m GPS modula. Kako bi se formirala odgovarajuća poruka koja se šalje na računar vrši se obrada podataka sa senzora. Obrada podataka podrazumeva konverziju sirovih vrednosti sa akcelerometra i žiroskopa u vrednosti izražene u vidu umnožaka ubrzanja Zemljine teže g - akcelerometar, i $^\circ/s$ - žiroskop. Takođe, proces obrade podataka podrazumeva parsiranje NMEA GGA rečenica, koje se prikupljaju sa GPS modula, i izdvajanja podataka od interesa iz njih. U sistemu za detekciju pada od interesa su elementi GGA rečenice koji daju podatke o geografskoj širini i dužini, kao i o odgovarajućim hemisferama. Obrađeni podaci šalju se na računar putem UART komunikacionog modula u vidu poruka sledećeg formata: <ax|ay|az|gx|gy|gz|geografska širina|hemisfera|geografska dužina|hemisfera|>.

Slika 8. Algoritam izvršavanja programa za detekciju pada



Pritiskom na taster START u aplikaciji, vrši se konfiguracija serijskog porta, započinje komunikacija računara i mikrokontrolera i iscrtava se mapa sa referentnom lokacijom. Podaci o ubrzanju po x, y i z osi se izdvajaju iz pristigle poruke i iscrtavaju na odgovarajućem grafiku u aplikaciji (slika 9).

 ISBN 978-86-7466-930-3



Slika 9. Prikaz referentne lokacije i signala sa akcelerometra

Dati podaci o ubrzanju, kao i podaci o orijentaciji koji pristižu na računar smeštaju se u odgovarajuće bafere, a kada pristigne 2000 odbiraka vrši se izdvajanje obeležja i formira se vektor obeležja koji opisuje jedan uzorak. Vektor obeležja prosleđuje se prethodno obučenom modelu mašinskog učenja i vrši se klasifikacija uzorka. Uzorak, koji karakteriše kretanje korisnika, može biti klasifikovan kao hodanje, stajanje, sedenje, pad u stranu ili pad unapred. Ukoliko je uzorak svrstan u klasu koja odgovara padu u stranu ili padu unapred, detektovan je pad i potrebno je obavestiti korisnika aplikacije o datom događaju. U tom trenutku se na mapi prikazuje trenutna lokacija na kojoj se nalazi korisnik uređaja za detekciju pada (slika 10).

Slika 10. Detekcija pada i prikaz trenutne lokacije korisnika uređaja

Unosom lokacije odgovornog lica u polje Your location i pritiskom na taster Show Path, na mapi se pored lokacije osobе koja je pala prikazuje i lokacija korisnika aplikacije, kao i optimalna putanja između te dve tačke, što je prikazano na slici 11.

Slika 11. Prikaz najkraće putanje od odgovornog lica, koje je primilo obaveštenje, do osobe koja je pretrpela pad

IV. Klasifikacija kretanja

A. Baza podataka

Bazu podataka čini 332 uzorka, a svaki uzorak opisan je pomoću 20 obeležja. Uzorak predstavlja prozor dužine 100 odbiraka. Dakle, kroz signale koji su prikupljeni sa akcelerometra i žiroskopa, prolazi se prozorom dužine 100 odbiraka, tako da je preklapanje dva susedna prozora 50 %. Za jedan prozor računaju se srednja, maksimalna i minimalna vrednost za signale sa akcelerometra po x, y i z osi, srednja, maksimalna i minimalna vrednost za signale sa žiroskopa po x, y i z osi, kao i roll i pitch uglovi. Navedene veličine predstavljaju obeležja u bazi podataka. Sva obeležja su numerička i nema nedostajućih vrednosti u bazi. Svaki uzorak potrebno je dodeliti jednoj od pet klasa - stajanje (ST - *Standing*), sedenje (SIT - *Sitting*), hodanje (WA - *Walking*), pad unapred (FF - *Fall Forward*) ili pad u stranu (FL - *Lateral Fall*). U datoj bazi podataka 6,41 % uzoraka je iz klase FF, 6,41 % uzoraka je iz klase FL, a uzorci iz klasa SIT, ST i WA su podjednako zastupljeni, sa udelom od 29,06 %, za svaku od navedene tri klase. U cilju obuke i testiranja modela mašinskog učenja oznake klasa pretvorene su u numeričke vrednosti dodelom brojeva 0, 1, 2, 3 i 4 klasama FF, FL, SIT, ST i WA, redom.

B. Obuka modela i rezultati

Kako bi bio kreiran optimalan model za klasifikaciju kretanja čoveka na osnovu date baze podataka, poređena su tri algoritma mašinskog učenja - metoda k najbližih suseda (kNN - *k Nearest Neighbors*), stabla odluke i mašine na bazi vektora nosača. Pre same obuke i evaluacije pojedinačnih modela, baza podataka je podeljena na dva skupa - trening skup i test skup. Trening skup čini 80 % ukupnih podataka, dok preostalih 20 % početne baze podataka čini test skup. Uzorci su podeljeni u dva navedena skupa tako da je za svaki od njih održana zastupljenost pojedinačnih klasa kao u početnom skupu. U okviru preobrade podataka izvršena je Z-normalizacija (standardizacija) obeležja, tako da sva obeležja imaju srednju vrednost 0 i standardnu devijaciju 1. Na ovaj način sva obeležja su skalirana na isti opseg vrednosti i time je sprečeno odlučivanje na osnovu onih obeležja koja variraju u većem opsegu vrednosti. Nakon preobrade podataka, kako bi optimalni modeli bili formirani, izvršena je unakrsna validacija sa deset podskupova na skupu za obuku i na taj način utvrđeni su optimalni parametri pojedinačnih modela. Za tako odabrane parametre izvršena je unakrsna validacija sa deset podskupova na skupu za obuku. Matrice konfuzije dobijene su akumulaciom matrica konfuzije svih deset iteracija. Kako bi se procenile performanse klasifikatora potrebno je uporediti predviđene i stvarne klasne oznake. Uzorci u bazi podataka klasifikovani su u pet klasa, te se kao mere uspešnosti klasifikatora analiziraju prosečna tačnost (prosek tačnosti po klasama), mikroprosečna osetljivost, preciznost i F-mera, kao i makroprosečna osetljivost, preciznost i F-mera. Završni korak u kreiranju klasifikatora jeste evaluacija modela na test skupu. Tabelom I dat je prikaz pojedinačnih mera uspešnosti za tri obučena klasifikatora.

Kao najuspešniji algoritam pri rešavanju datog problema pokazala se metoda k najbližih suseda. Tačnost od 88 % ostvarena je za deset najbližih suseda čija rastojanja se računaju na osnovu Manhattan metrike. Ukoliko se posmatra matrica konfuzije C (1) dobijena nakon testiranja kNN klasifikatora na test skupu, moguće je uočiti da klasifikator uspešno prepoznaje sve uzorke iz klase WA, da od 19 uzoraka iz klase SIT 17 uzoraka dodeljuje upravo toj klasi, dok dva uzorka pogrešno klasifikuje kao ST. Dati model pogrešno klasifikuje 4 uzorka iz klase ST, kao SIT, dakle, postoje poteškoće pri razlikovanju pokreta stajanja i sedenja. Klasa sa najvećom tačnošću je klasa FL, gde je lateralni pad za svih pet uzoraka klasifikovan ispravno, dok

 ISBN 978-86-7466-930-3

su uzorci iz klase FF greškom dodeljeni klasi WA (jedan uzorak) i klasi FL (jedan uzorak).

$$C = \begin{bmatrix} 19 & 0 & 0 & 0 & 0 \\ 0 & 17 & 2 & 0 & 0 \\ 0 & 4 & 15 & 0 & 0 \\ 1 & 0 & 0 & 3 & 1 \\ 0 & 0 & 0 & 0 & 5 \end{bmatrix} \quad (1)$$

TABELA I
MERE USPEŠNOSTI KLASIFIKATORA

	kNN	Stablo odluke	SVM
Tačnost	0.88	0.31	0.37
Preciznost (mikro)	0.88	0.31	0.37
Preciznost (makro)	0.89	0.21	0.19
Osetljivost (mikro)	0.88	0.31	0.37
Osetljivost (makro)	0.85	0.43	0.44
F mera (mikro)	0.88	0.31	0.37
F mera (makro)	0.86	0.28	0.26

V. ZAKLJUČAK

Usled pada, kod starijih osoba može doći do različitih povreda kao što su povrede ili prelomi ruke, ručnog zgloba, karlice, kuka, glave, unutrašnje povrede, poremećaj i gubitak mobilnosti. Ove povrede značajno mogu smanjiti kvalitet života povređene osobe. Sistem za detekciju pada mogao bi da doprinese pravovremenom pružanju pomoći starim licima, a time i prevenciji komplikacija nastalih usled povreda prilikom pada. Dalja istraživanja podrazumevaju proširenje baze podataka i poboljšanje performansi klasifikatora, kao i vršenje klasifikacije na nivou mikrokontrolera. Takođe, sve hardverske komponente sistema neophodno je integrisati u okviru jednog prenosivog uređaja koji bi korisnik mogao da nosi na kaišu ili ruci.

ZAHVALNICA

Ovaj rad je podržan od strane Fakulteta tehničkih nauka u Novom Sadu, Departmana za energetiku, elektroniku i telekomunikacije, u okviru realizacije projekta MPNTR 200156 : ”Inovativna naučna i umetnička isptivanja iz domena delatnosti FTN-a”.

ABSTRACT

In this paper, a fall detection system, whose main purpose is assistance to the elderly, is described. The paper gives an insight into all parts of the implemented fall detection system. Measurement system for fall detection includes the acquisition of user movement data using an accelerometer and a gyroscope, acquisition of location data using GPS module, classification of movements, and fall detection, as well as displaying this data within the user interface.

Measurement system for fall detection based on accelerometer, gyroscope, and GPS module

Sanja Mandić, Đorđe Novaković

Merenje karakteristika i modelovanje Hamonovoh etalon otpornika u naizmeničnom režimu

Stefan Mirković, Dragan Pejić, Aleksandar Dimitrijević

***Apstrakt*—Razmatranje primene Hamonovih etalon otpornika u naizmeničnom režimu, kao i ispitivanje njihovih karakteristika su tema ovog rada. U ranijim istraživanjima ustanovljeno je da prenosni odnos ovih etalona ne bi trebao da značajno zavisi od frekvencije. Drugim rečima, moduo transfera se očekuje da će biti blizak kvadratu broja otpornika od kojih se formira transfer, dok će fazni stav transfera biti blizak nuli. Sa dostupnom opremom koja je bila raspoloživa kada je vršeno istraživanje, merenja su obavljena na osnovu dve merne metode, čiji će rezultati biti prikazani u radu.**

***Ključne reči*—Hamonov etalon, transfer, električna otpornost.**

I. Uvod

Kao jedan veoma koristan alat kod određivanja odnosa napona, a pogotovo otpornosti su Hamonovi etalon otpornici. Ovi etaloni se sastoje od n redno vezanih otpornika iste nazivne vrednosti, gde je povezivanje obavljeno četvorožično tako da je omogućen direktan pristup bilo kojem naponskom i strujnom izvodu svakog otpornika pomoću ugrađenih terminala. Otpornost terminala ovih spojeva uračunata je u otpornost pojedinačih otpornika. Pojedinačnim merenjem i podešavanjem otpornosti svakog otpornika teži se da se postigne visoka tačnost. Prvenstvena uloga Hamonovih otpornika nije da budu etaloni otpornosti, već etaloni prenosnog odnosa otpornosti (transfer). Prespajanjem serijske u paralelnu vezu postiže se smanjenje otpornosti za približno n^2 puta. Četvorožični spoj se koristi kako bi se potisnuli negativni efekti otpornosti spojeva u cilju povećanja tačnosti Hamonovog etalona. Zahvaljujući dobrim karakteristikama, treba razmisliti o njihovoj primeni u ac režimu sa obzirom na ohrabrujuće rezultate nekih istraživanja [1]. Ovde je osnova tvrdnje da ako se svaki pojedinačni otpornik Hamonovog etalona modeluje kao redna veza otpornosti i reaktanse, moduo transfera će biti blizak broju n^2. Prvo su ove tvrdnje simulaciono proverene, a zatim su izvršena i merenja čiji su rezultati doveli do zaključka da ove tvrdnje imaju smisla. U cilju ispitivanja frekventnih karakteristika Hamovnog etalona, kao i provere da li je modelovanje pojedinačnih otpornika kao redne veze otpornosti i reaktanse dovoljno dobro, izvršena su merenja i proračuni.

II. Eksperimentalna merenja

Merenja su vršena u cilju prvenstveno procene modula transfera. Prva merna metoda se zasnivala na UI metodi, dok je druga metoda bila bazirana na direktnom merenju pomoću instrumenta namenjenog za ispitivanje impedansi. Za prvu metodu korištena je sledeća oprema: izvor stabilisanog napona (Time Electronics 5025), ac voltmetar (Fluke 8846A), ac ampermetar (Fluke 8846A), kao i transfer etalon SR1010 sa deset otpornika (sa transferom 10 kΩ : 100 Ω). Otpornost voltmetra i ampermetra su poznate i njihov uticaj na rezultat merenja je korigovan. Kapacitivnost voltmetra je deklarisana kao manja od 100 pF, ali nije poznata njena vrednost. Kako bi uticaj kapacitivnosti voltmetra bio minimalan, korišćene su različite varijante UI metode za merenje serijske i paralelne impedanse. Kod određivanja modula serijske impedanse korišten je strujni spoj, gde je ampermetar povezan redno sa etalonom, a voltmetar paralelno toj vezi. U slučaju paralelne impedanse korišten je naponski spoj kod koga je voltmetar povezan paralelno sa etalonom, a ampermetar redno toj vezi.

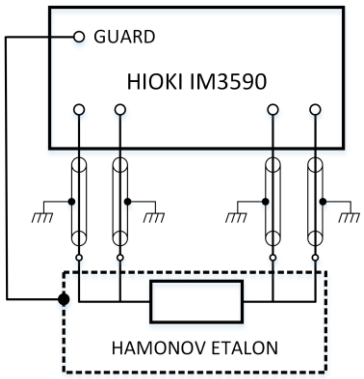
Sl. 1. Zavisnost normalizovanih vrednosti modula impedanse redne i paralelne veze i transfera T (UI metoda)

Kako su Hamonovi otpornici izvedeni četvorožično, logično se nameće korišćenje naponskog spoja. Problem je nepoznavanje stvarne kapacitivnosti voltmetra, pri čemu se pokazuje da to više smeta ako bi se koristio naponski spoj prilikom merenja na serijskoj konfiguraciji. Tada bi se, nazivnoj otpornosti od 10 kΩ, paralelno vezivao voltmetar

 ISBN 978-86-7466-930-3

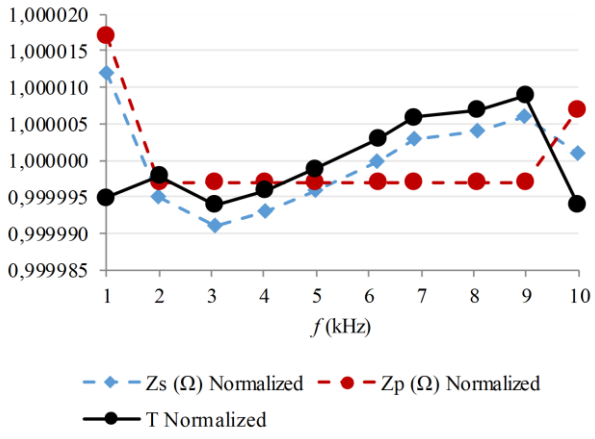
deklarisane ulazne otpornosti 1 MΩ ± 1 % i nepoznata kapacitivnost. Ova činjenica je prevagnula ka korišćenjem strujnog spoja pri merenju modula impedanse serijske konfiguracije. U tom slučaju se gube pozitivni efekti četvorožične izvedbe Hamonovih otpornika, ali se rešava problem nepoznavanja kapacitivnosti voltmetra. Moduo impedanse paralelne konfiguracije je meren primenom naponskog spoja uz korišćenje četvoržične izvedbe otpornika. Pri promeni frekvencije od 1 kHz do 10 kHz, očitavani su napon i struja, određivan je moduo impedanse uz korigovanje uticaja otpornosti instrumenata. Na Sl. 1. su prikazane normalizovane vrednosti rezultata merenja modula impedanse serijske i paralelne veze Hamonovih otpornika, kao i vrednost modula transfera. Postupak normalizacije je sproveden kako bi se pregledno, na jednom grafiku dao prikaz rezultata eksperimenta koji se razlikuju po vrednosti (serijska otpornost je približno 10 kΩ, redna otpornost je približno 100 Ω, moduo transfera je bezdimenziona veličina približno jednaka 100). Sa grafika se vidi da moduo serijske i paralelne veze Hamonovih otpornika raste sa frekvencijom, što opravdava pretpostavku o postojanju reaktivne komponente. Rezultati simulacija predviđaju da su ove dve zavisnosti približno iste, što rezultira pretpostavkom da transfer ne zavisi od frekvencije. S druge strane, merenjem dobijeni profil zavisnosti modula redne i modula paralelne veze nije potpuno isti, pa je dobijeno da i moduo transfera (količnik modula serijske i paralelne veze) takođe zavisi od frekvencije. Promena transfera usled frekvencije je primetno manja (oko pet puta), u poređenju sa promenom modula serijske i paralelne veze. U Tabeli I prikazani su rezultati merenja UI metodom.

TABELA I
REZULTATI UI METODE



f (kHz)	T	u(T) (*k*=1)
1	99.995	0.14
2	99.996	0.14
3	99.994	0.14
4	99.993	0.14
5	99.991	0.14
6	99.990	0.39
7	99.989	0.39
8	99.987	0.39
9	99.983	0.39
10	99.982	0.39

Postavlja se pitanje u kojoj meri nesavršenosti korištene opreme utiču na zavisnost modula transfera od frekvencije. Da bismo odgovorili na ovo pitanje, sproveden je postupak određivanja merne nesigurnosti. U obzir je uzeta merna nesigurnost usled deklarisanih grešaka korišćenog voltmetra i ampermetra, kao merna nesigurnost usled nepoznavanja prave vrednosti otpornosti voltmetra. U tabeli su date vrednosti modula transfera i procenjene merne nesigurnosti pri faktoru obuhvata 1.

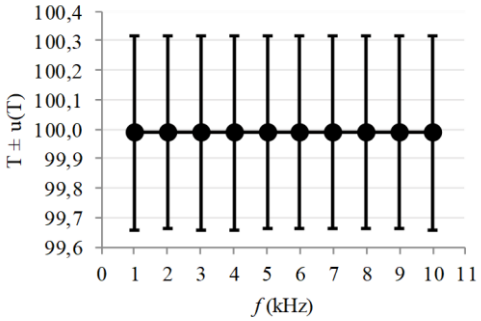


Sl. 2. Zavisnost modula transfera od frekvencije uz prikaz merne nesigurnosti za faktor obuhvata 1 (UI metoda)

Druga merna metoda je bazirana na određivanju impedanse serijski (Z_S) i paralelno (Z_P) konfigurisanog etalona, kao i faznih stavova (φ_s i φ_p) direktnim očitavanjem korištenjem instrumenta HIOKI IM3590, čija je glavna uloga analizator impedansi.

Sl. 3. Šema povezivanja pri merenju direktnom mernom metodom

Na početku je izvršena korekcija prilikom kratkog spoja i korekcija prilikom otvorene veze. Na ovaj način bi trebalo u najvećoj meri da su eliminisane parazitne induktivnosti i kapacitivnosti samih vodova korišćenih za četvorožično povezivanje merene imepdanse.



Sl. 4. Zavisnost normalizovanih vrednosti modula impedanse redne i paralelne veze i transfera (direktna metoda)

 ISBN 978-86-7466-930-3

TABELA II
REZULTATI DIREKTNE METODE (MODUO TRANSFERA)

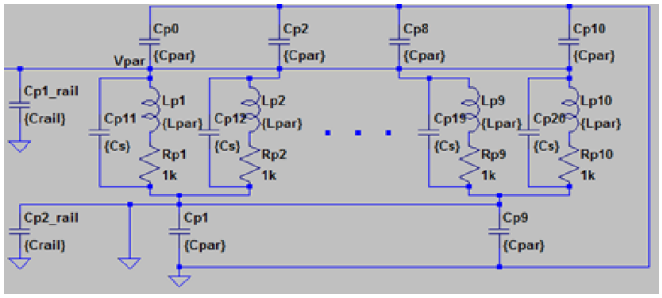
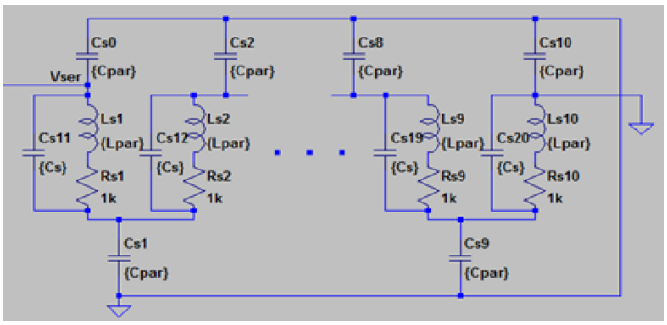
Sl. 6. Zavisnost argumenta transfera od frekvencije uz prikaz merne nesigurnosti za faktor obuhvata 1 (direktna metoda)



Kao posledica toga, ne može se zaključiti sa velikom sigurnošću kako se zaista ponaša moduo i fazni stav.

Kako bi se simulaciono analizirao uticaj parazitnih induktivnosti i kapacitivnosti na transfer, realizovana je LTSpice simulacija, gde je svaka pojedinačna impedansa Hamonovog etalona modelovana kao otpornost nazivne vrednosti 1 kΩ kojoj je redno vezana parazitna induktivnost L_{Par} a svemu tome paraleleno vezana parazitna kapacitivnost C_S. Sada pretpostavljamo da su sve vrednosti jednake kako bismo mogli proveriti/proceniti uticaj dodatnih parazitnih efekata na transfer. Ako se variraju vrednosti parazitnih induktivnosti i kapacitivnosti dobija se da je transfer nepromenljiv po frekvenciji, dok je faza transfera vrlo mala.

Sl. 7. Model pojedinačne impedanse Hamonog etalona u LTSpice simulaciji



Pored ovih parazitnih efekata, dodate su i kapacitivnosti svakog kontakta Hamonog etalona prema kućištu vrednosti C_{Par}. Kod paralelne konfiguracije, uticaj parazitnih kapacitivnosti ka kućištu utiče na jednostavniji način na sam transfer nego u slučaju serijske veze.

Sl. 8. Modelovan paralelno vezan Hamonov etalon u LTSpice okruženju

Kod paralelne veze, ove kapacitivnosti se usled kratkospojnika vezuju paralelno, ali podeljene u dve grupe (za jednu i drugu stranu priključaka). Kapacitivnosti jedne od ove dve grupe su ustvari kratkospojeni, jer je jedan kratkospojnik vezan na uzemljenje isto kao i kućište. Kod serijske konfiguracije pojedinačne impedanse i kapacitivnosti kao kućištu čine višestepeni filter, gde je logično da će se pri ovoj konfiguraciji dobiti veći fazni pomeraj. Dodatno je modelovano i da kratkospojnici imaju neku svoju kapacitivnost prema kućištu. Ovde se takođe dobija da je jedna kapacitivnost kratkospojena jer je samo kratkospojnik uzemljen, pa prema kućištu koje je takođe uzemljeno nema naponske razlike. Primećeno je da kapacitivnost kratkospojnika i pri značajnim vrednostima ne utiče značajano na transfer.

 ISBN 978-86-7466-930-3

Sl. 8. Modelovan serijski vezan Hamonov etalon u LTSpice okruženju

Ako se pretpostave redna induktivnost i paralelna kapacitivnost za svaki element u Hamonovoj kutiji, i da su im vrednosti za svaki element jednake, dobija se da transfer ne zavisi od frekvencije. Ako se pretpostavi parazitna kapacitivnost kontakata Hamonovih elemenata prema kućištu onda se dobija da moduo i fazni stav transfera zavise od frekvencije. Rezultati simulacija pokazuju šta od parazitnih elemenata utiče i u kojoj meri.

III. ZAKLJUČAK

Ono što se za sad može videti je da rezultati nisu opovrgnuli dosadašnje pretpostavke za ponašanje modula i faznog stava, ali ih i ne potvrđuju sa velikom sigurnošću. Rezultati sa kojima se trenutno raspolaže su dobijeni korištenjem najbolje raspoložive merne opreme. Pored ovog nedostatka usled velike greške instrumenata, postavlja se pitanje da li je model kada se etalon posmatra kao impedansa ispravan. Pored induktivnih i kapacitivnih efekata koji se javljaju na samim pojedinačnim otpornicima unutar etalona, postoje i drugi efekti. Kapacitivnost prema kućištu etalona, kapacitivnost kratkospojnika kojima se etalon konfiguriše iz serijsku u paralelnu vezu, kao i ulazna kapacitivnost instrumenata su samo jedna od stvari o kojima treba razmišljati. Različitim pristupima ovom problemu dobijeni su već neke procenjene vrednosti spomenutih parazitnih efekata, koje treba još detaljno ispitati. Procena je vršena pomoću raznih simulacijskih metoda i matematičkih modela. Ukoliko se ispostavi da ovi efekti značajno doprinose grešci etalona, moraće se trenutni modela komplikovati dok se ne dođe do zadovoljavajućih rezultata. Osnovni problem je nazivna greška instrumenata. Kako je Hamonov etalon etalon visoke tačnosti, potrebno je koristiti isto tako i instrumente visoke tačnosti kako bi se moglo sa velikom pouzdanošću proceniti njegovo ponašanje u zavisnosti od frekvencije. U prethodnim istraživanjima primenjena je Monte Carlo simulacija u cilju procene modula i faznog stava tansfera, ali pri jednostavnijem modelu nego što je ovde opisan. Tamo je pojedinačni otpornik posmatran kao redna veza otpornosti i reaktanse. Hipoteza da se moduo i fazni stav transfera neznatno menjaju sa promenom frekvencije nije potvrđena, ali isto tako nije ni opovrgnuta. Potrebna je merna oprema sa manjom mernom nesigurnošću. Jedan način rada jeste merenje na višim frekvencijama gde uticaj parazitnih efekata više dolazi do izražaja. Problem je što je i oprema kojom raspolažemo takva da sa porastom frekvencije dolazi do degradacije granica greške.

ABSTRACT

Consideration of the application of Hamon standard resistors in alternating mode, as well as examination of their characteristics are the topic of this paper. Previous research has found that the transmission ratio of these standards should not significantly depend on frequency. In other words, the transfer modu is expected to be close to the square of the number of resistors from which the transfer is formed, while the phase position of the transfer will be close to zero. With the available equipment that was available when the research was conducted, the measurements were performed on the basis of two measurement methods, the results of which will be presented in the paper.

Measurement of characteristics and modeling of Hamon standard resistors in alternating mode

I. UVOD

Pojavom i razvojem električnih automobila dolazi i do razvoja uređaja za skladištenje električne energije poput litijumskih baterija. Kako je eksploatacija litijuma i proizvodnja baterija štetna za okolinu, istraživanja su se usmerila ka pronalasku novih komponenata koje mogu da efikasno skladište energiju. Istraživanjem i razvojem došlo se do superkondenzatora [1][2][3] čija kapacitivnost može biti reda stotina Farada, ali namenjenih za nizak naponski nivo reda volti. Povezivanjem ovakvih kondenzatora u redne i paralelne veze, realizuju se superkondenzatori sa nazivnim naponom reda 100 V, kakvi su neophodni za korišćenje u auto industriji. Prednosti superkondenzatora u odnosu na baterije jesu brzina punjenja i količina energije koja se isporučuje u kratkom intervalu. Superkondenzatori pronalaze sve širu primenu, pa je potrebno poznavati njihove karakteristike kako bi se mogli adekvatno predstaviti u simulacijama i prilikom projektovanja novih uređaja. Ovaj rad se bavi sistemom za određivanje dve vrlo važne karakteristike superkondenzatora: modul i faznog stava impedanse superkondenzatora na frekvencijama u opsegu od 1 mHz do 50 Hz.

II. POSTAVKA PROBLEMA

Najčešći model superkondenzatora jeste model koji, pored kapacitivnosti *C* ima rednu *s* i paralelnu (otočnu) *o* otpornost. Redna otpornost predstavlja otpor priključnih krajeva i ploča superkondenzatora, a paralelna otpornost modeluje realan dielektrik. U ovom radu će se, kao test primer, koristiti superkondenzator [4] nazivne kapacitivnost 100 F, nazivnog napona 2.7 V, serijske otpornosti reda desetina mΩ i paralelne otpornosti reda 10 kΩ. Autori su rešavanju ovog problema pristupili polazeći od klasične šeme za određivanje kapacitivnosti elektrolitskog kondenzatora merenjem napona i struje, kao što je prikazano na Sl. 1.

Sl. 1 Osnovna šema za merenje napona i struje na polarisanom kondenzatoru

Ovo kolo je, po svojoj konstrukciji, slično kolu za merenje otpornosti UI metodom naponskim spojem. U kolu se nalazi izvor jednosmernog napona E, na koji se dodaje naizmenična komponenta iz generatora funkcije G. Uloga pomoćnog kondenzatora C, redno vezanog sa voltmetrom, je da potiskuje jednosmernu komponentu napona na krajevima Cx. U tom slučaju voltmetar V meri samo preostalu naizmeničnu komponentu napona.

Ako se ovakva šema primeni za merenje impedanse superkondezatora javljaju se sledeća ograničenja:

1. Kako bi pomoćni kondenzator C uspešno filtrirao jednosmernu komponentu i pri najnižim vrednostima frekvencije, njegova kapacitivnost bi morala biti

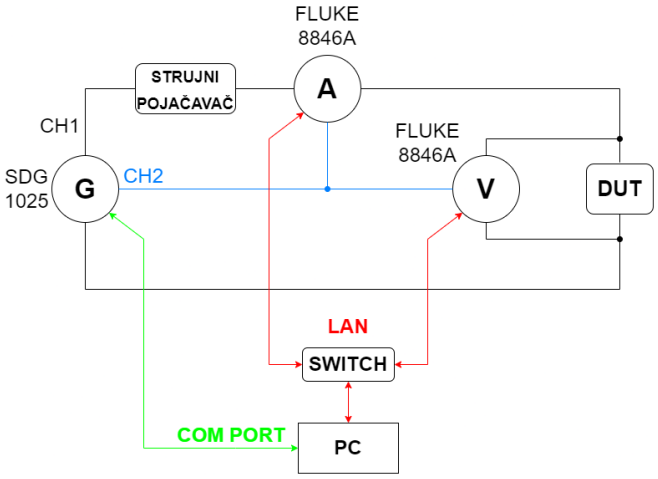
 ISBN 978-86-7466-930-3

izuzetno visoka – reda Farada.

2. Pri visokim vrednostima frekvencije signala, očekivana vrednost modula impedanse superkondenzatora je reda mΩ, pa otpornost vodova dolazi do izražaja.
3. Raspoloživi instrumenti namenjeni za merenje napona i struje nisu u stanju da mere pri frekvencijama manjim od 3 Hz.

III. PREDLOG REŠENJA

Kako bi se rešili navedeni problemi, autori predlažu rešenje prikazano na Sl. 2. Pomoćni kondenzator C je izbačen pa se filtriranje jednosmerne komponente napona vrši softverskim putem. Superkondenzator, na šemi označen kao DUT (*e ice nder Test*), je vezan četvorožično kako bi se uticaj otpornosti vodova eliminisao. Zbog nemogućnosti multimetara da ispravno mere efektivnu vrednost signala na frekvencijama manjim od 3 Hz, multimetri su konfigurisani da rade u DC režimu. Prikupljanjem odbiraka signala napona i struje direktnim očitavanjem rezultata analogno-digitalne (A/D) konverzije i korišćenjem softverskih alata mogu biti određene amplitude (efektivne vrednosti, takođe) napona i struje.



Sl. 2 Prikaz predloženog električnog kola

Kao ampermetar i voltmetar su korišćeni FLUKE 8846A [6] digitalni 6-½ cifarski multimetri koji imaju *multi-slope* A/D konvertor kao i mogućnost programiranja putem SCPI (*Standard Commands for Programmable Instruments*) komandi. Ampermetar i voltmetar su povezani u šemu za četvorožično merenje impedanse. Opseg merenja ampermetra je postavljen na 1 A, a opseg voltmetra na 1 V. Kao izvor naizmeničnog signala koristi se Siglent SDG 1025 [7] dvokanalni generator funkcija koji generiše, na svom prvom kanalu, sinusni signal amplitude 0.5 V i frekvencije u rasponu od 1 mHz do 50 Hz. Generisan napon je superponiran na jednosmernu komponentu kako bi se obezbedilo ispravno polarisanje superkondenzatora. Za pojačavanje strujnih mogućnosti funkcijskog generatora korišćen je baferski (jediničnog naponskog pojačanja) strujni pojačavač koji, na svom izlazu, daje vrednost struje do 2 A.

Sinhronizacija rada dva multimetra je izvedena korišćenjem eksternog trigera u obliku povorke pravougaonih impulsa dobijenih na drugom kanalu dvokanalnog izvora. Multimetri su podešeni da prihvate eksterni triger signal. Korišćenjem eksternog trigera eliminiše se pojava fazne greške usled neistovremenog odabiranja napona i struje. Raspon frekvencija periodičnog signala je veoma širok. Prilikom odabiranja tri periode signala najmanje frekvencije vrednosti 1 mHz, uzimanje odbiraka traje 50 minuta. Pri povećanju frekvencije se smanjuje vreme merenja na postavljenoj frekvenciji. Ukupno trajanje merenja počevši od najniže pa sve do najviše frekvencije je oko dva sata.

Posle obavljenog umrežavanja dobijeno kolo je predstavljeno na Sl. 3.

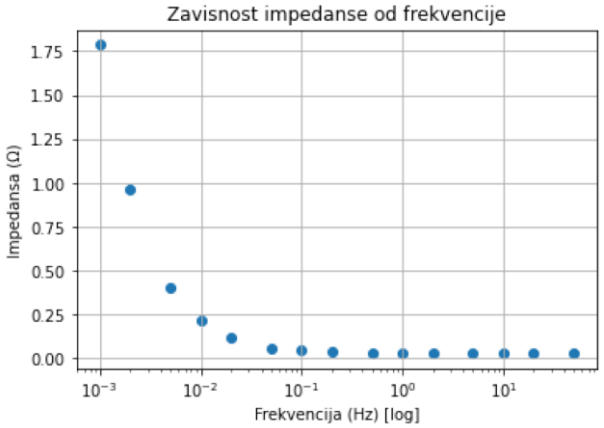
Sl. 3 Konačan izgled šeme za merenje

Strujni pojačavač je četvoropol, ali je na blok šemi predstavljen kao dvopol, kako bi šema bila lakša za čitanje. Multimetri su povezani na LAN (*ocal Area Network*) dok je generator funkcije povezan na jedan COM port na računaru. Upravljanje celokupnim sistemom se vrši preko računara na kome se nalazi skripta napisana u Python [8] programskom jeziku. Operater ovakvog sistema treba da unese željene frekvencije naizmeničnog signala i pokrene skriptu. Kao izlaz, skripta isporučuje vrednosti modula impedanse i faznog stava u zavisnosti od frekvencije, u tabelarnom i grafičkom obliku.

IV. KONTROLA SISTEMA I OBRADA PODATAKA

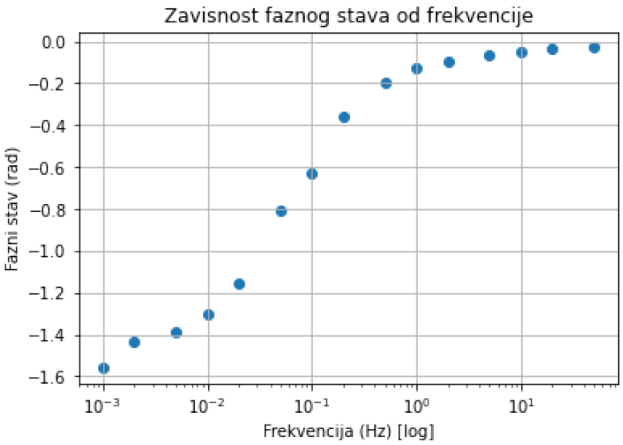
Kontrola sistema se vrši pomoću skripta napisane u Python programskom jeziku. Korišćene su biblioteke za mrežnu i serijsku komunikaciju [9], biblioteka *scipy* [10] za matematičke proračune i *matplotlib* [11] za grafički prikaz podataka. Kontrola sistema se odvija po sledećem principu:

- provera prisutnosti uređaja,
- postavljanje uređaja u početna stanja,
- ciklus merenja,
- obrada podataka i
- prikaz podataka.



U ciklusu merenja se vrši odabiranje talasnih oblika napona i struje. Na kraju ciklusa merenja od multimetara se traže podaci koji pristižu u obliku liste vrednosti pojedinačnih odbiraka. Za određivanje amplituda i faznih stavova napona i struje, prikupljani odbirci se prosleđuju funkciji *cur e fit* [12] koja je deo *scipy* biblioteke. Pored odbiraka, funkcija zahteva i definiciju očekivanog talasnog oblika. Za napon je to suma jednosmerne i prostoperiodične komponente poznate frekvencije, dok se za struju (u ustaljenom režimu) očekuje samo prostoperiodična komponenta. Kao povratne vrednosti, funkcija *cur e fit* vraća vrednosti jednosmerne i naizmenične

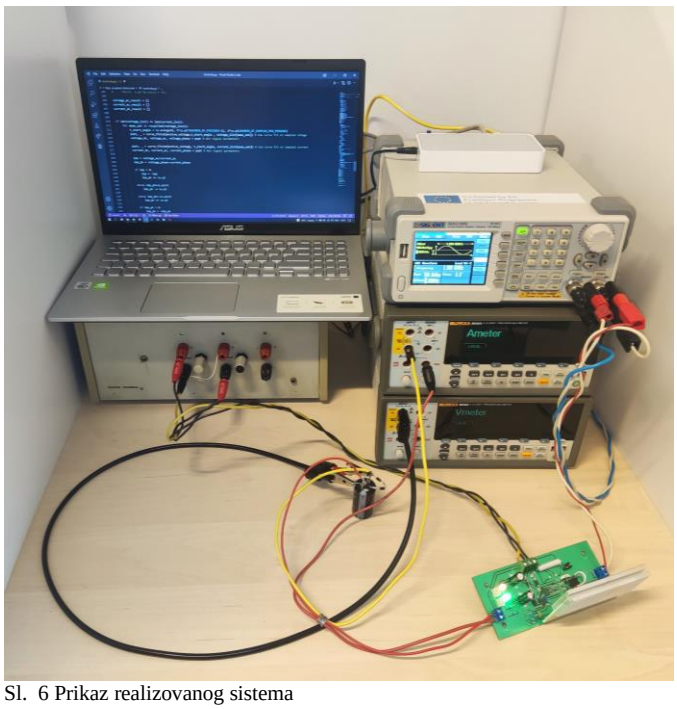
 ISBN 978-86-7466-930-3



komponente napona, naizmeničnu komponentu struje i fazne stavove za obe veličine. Količnik vrednosti amplitude napona i struje predstavlja vrednost modula impedanse. Fazni stav impedanse se dobija oduzimanjem faznih stavova napona i struje. Na kraju izvršavanja skripte podaci se zapisuju u CSV (*Comma Separated alues*) fajl koji se može naknadno obrađivati. Dodatno, rezultati obrade se prikazuju grafički pomoću biblioteke *matplotlib* kako bi se dobio grafički prikaz vrednosti koje su merene.

V. Diskusija

Predloženi sistem je u potpunosti realizovan i izvršena su merenja. Podešen je da uzima sedam odbiraka po periodi. Merenje se vrši tokom tri periode signala na svakoj zadatoj frekvenciji. Parametar NPLC (*Number of Power ine Cycles*) je podešen na 0.02, što je najmanja moguća vrednost. Za mrežnu učestanost 50 Hz definisano je vreme integraljenja od 0.4 ms. Na kraju ciklusa rada dobijeni su grafici na kojima je predstavljena zavisnost vrednosti modula impedanse i faznog stava od frekvencije signala. Na Sl. 4 i 5 je dat prikaz navedenih zavisnosti, pri čemu je x-osa na kojoj se nalazi frekvencija predstavljena u log razmeri.



Sl. 4 Zavisnost vrednosti modula impedanse od frekvencije signala

Sl. 5 Zavisnost vrednosti faznog stava od frekvencije signala

Na Sl. 6 je data fotografija opreme koja je korišćena u ovom radu.

Sl. 6 Prikaz realizovanog sistema

VI. Zaključak

Prikazani sistem je uspešno realizovan. Primećeno je da postoji prelazni proces prilikom promene frekvencije signala pa je potrebno sačekati sa merenjem dok se ne postigne ustaljeno stanje. Ovde je potrebno dodatno ispitati prelazne procese i optimizovati vreme čekanja, gde, sa povećanjem frekvencije, prelazni procesi kraće traju. Dalji planovi uključuju simuliranje rada sistema i određivanje merne nesigurnosti ovakvog merenja impedanse i faznog stava superkondenzatora na unapred zadatim frekvencijama. Ove simulacije bi se realizovale u Python programskom jeziku, koristeći Monte Karlo princip. U daljem razmatranju i testiranju može se povećati vrednost NPLC-a kod nižih frekvencija kako bi princip rada *multi-slope* A/D konvertora došao do izražaja u potiskivanju smetnji mrežne učestanosti. Na nižim frekvencijama je moguće povećavati broj odbiraka po periodi. Pri višim frekvencijama (kraće periode) postoji ograničenje u pogledu vrednosti vremena integraljenja.

Na osnovu dosadašnjih merenja se stiče utisak da nema potrebe za prevelikim brojem odbiraka po periodi, kao i da nema potrebe za povećanjem broja perioda. Moguće obrazloženje je činjenica da se poznaje talasni oblik napona i struje, pa zbog toga *cur e fit* funkcija već na osnovu malog broja odbiraka uspeva da odredi potrebne parametre signala napona i struje.

ABSTRACT

This paper presents the implemented measurement system for measuring the impedance modulus and phase angle of a supercapacitor. The system consists of a two-channel function generator, two digital multimeters and a buffer current amplifier connected into an electrical circuit used for four-wire resistance measurement. The Siglent SDG 1025 function generator is used as the signal generator, which generates a sine wave signal superimposed on a DC value. Two FLUKE 8846A 6-½ digit digital multimeters are used as digital multimeters, one of which is used as a voltmeter and the other as an ammeter. The capacitance of the supercapacitor is of the order of hundreds of Farads, so it is necessary to use a current amplifier to provide the required current. In order to synchronize the operation of the devices, they are networked and managed using a computer that contains a script written in the Python programming language. The frequencies at which the impedance modulus and phase position are measured are in the range of 1 mHz to 50 Hz.

easurement system for determining the modulus and phase angle of the impedance based on virtual instrumentation

Simulaciona analiza metode pogodne za metrološku karakterizaciju impedanse na niskim frekvencijama

Milan Šaš, Dragan Pejić, Nemanja Gazivoda, Đorđe Novaković, Bojan Vujičić, *Members, IEEE*

***A stra t*— radu je pri azana simulaciona analiza metode oja je primenjiva za metrološku ara terizaciju dvo rajnih elemenata na nis im fre vencijama. Program napisan u programs om jezi u Python simulira rad dva multimetra tipa 4 A, od ojih je jedan onfigurisan ao ampermetar, a drugi ao voltmetar. dbirci napona i struje se obrađuju u programu, oji na osnovu odbira a određuje vrednost amplitude naizmenične komponente i faznog stava napona i struje, a onda na osnovu tih vrednosti izračunava moduo i fazni stav impedanse. Program uračunava deklarisane greške oba instrumenta i daje mogućnost za procenu merne nesigurnosti rezultata merenja.**

***Ključne reči*— imulacija, moduo i fazni stav impedanse, merna nesigurnost, onte arlo metoda, 4 A.**

I. UVOD

Pojam impedanse je definisao Oliver Hevisajd (Oliver Heaviside) 1886. godine [1], a kompleksnu notaciju je uveo Artur Keneli (Arthur Kennelly) 1893. godine [2]. Kompleksna vrednost impedanse sadrži dva podatka: a) moduo impedanse predstavlja količnik amplitude napona i amplitude struje prostoperiodičnog talasnog oblika i b) fazni stav impedanse predstavlja razliku faznih stavova napona i struje. Ako se ograničimo na sempling metodu i prostoperiodični režim, potrebno je:

a) sinhrono odabirati talasni oblik napona i struje,

b) na osnovu odbiraka odrediti amplitude i fazne stavove napona i struje i

c) odrediti moduo i fazni stav impedanse.

Za dobijanje odbiraka napona i struje su korišćena dva multimetra FLUKE 8846A, od kojih je jedan konfigurisan kao ampermetar, a drugi kao voltmetar. Oba instrumenta su konfigurisana za rad u jednosmernom (DC, *direct current*) režimu, kako bi se pristupanjem njihovim analogno-digitalnim (AD) konvertorima dobili odbirci merenih veličina. Ampermetar i voltmetar mogu da se konfigurišu da rade i u naizmeničnom (AC, *alternate current*) režimu, što se na prvi pogled čini logičnijim, jer se pojam impedanse i definiše u AC režimu. U tom slučaju bismo dobijali efektivnu vrednost napona i struje, što je dovoljno za određivanje modula impedanse. Određivanje faznog stava impedanse bi ostao nerešen problem, jer se ovakvim pristupom ne raspolaže vrednošću faznog stava napona i struje.

Korišćeni multimetri imaju ugrađen integrišući (*multi slope*) AD konvertor [3]. Umesto da vrše odabiranje u tački, ovi AD konvertori ustvari određuju srednju vrednost ulazne veličine na intervalu integraljenja zadatog trajanja. Integrišući AD konvertori imaju osobinu da potiskuju smetnje čija je perioda ceo broj puta duža od trajanje integraljenja, zbog čega se vrlo često koriste u industrijskim uslovima gde se očekuje značajno prisustvo smetnje mrežne frekvencije. Trajanje vremena integraljenja se zadaje parametrom NPLC (*Number of Power ine Cycles*). Kod korišćenih multimetara, pored celobrojnih vrednosti za NPLC, postoje i vrednosti manje od jedan, a najmanja je 0.02. Za minimalnu vrednost parametra NPLC, pri mrežnoj frekvenciji od 50 Hz, se dobija najkraće vreme integraljenja od 0.02/50 Hz = 0.4 ms. Vrednost najkraćeg vremena integraljenja i željeni broj odbiraka po periodi su dva parametra koji ograničavaju primenjivost ove metode pri višim frekvencijama prostoperiodične pobude. Kada se vreme integraljenja ponderiše i iskaže u odnosu na trajanje periode signala čije odabiranje se vrši, onda se koristi termin ugao integraljenja i iskazuje se u radijanima.

II. SIMULACIONI MODEL

Simulacioni model je realizovan u programskom jeziku Python [4] sa ciljem da se ispita uticaj bitnih parametara (broj odbiraka po periodi, trajanje/ugao integraljenja, greška ampermetra i voltmetra) na rezultate merenja (greška određivanja modula i faznog stava impedanse). Drugi razlog korišćenja simulacija je određivanje merne nesigurnosti dobijenih rezultata merenja simulacionim putem, odnosno primenom Monte Karlo metode.

Na Sl. 1. je prikazana ilustracija prostoperiodičnog talasnog oblika (crna linija) koji je doveden na ulaz integrišućeg AD konvertora. Vrednosti ulaznog talasnog oblika koje pripadaju periodima integraljenja su obeležene debljom linijom crvene boje. Rezultat AD konverzije se saopštava na kraju intervala integraljenja (plava tačka) i predstavlja srednju vrednost ulazne veličine u toku trajanja AD konverzije.

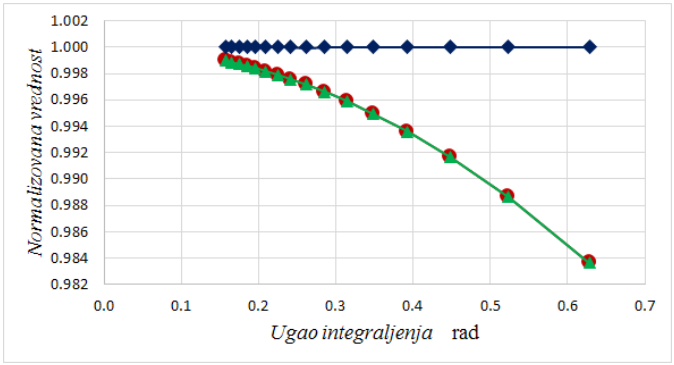
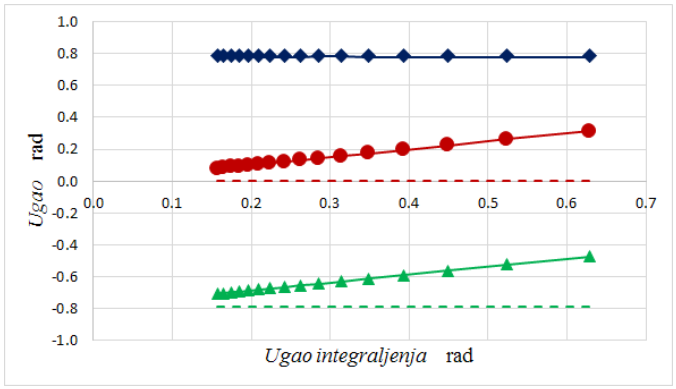
 ISBN 978-86-7466-930-3



Sa Sl. 1. se vidi da rezultati AD konverzije (plave tačke) ne leže na ulaznom talasnom obliku (crna kriva), nego su fazno pomereni. Što je duži interval integraljenja u odnosu na periodu signala, dobija se sve veće fazno kašnjenje. Slična greška se javlja i u pogledu amplitude talasnog oblika koja bi bila određena na osnovu dobijenih odbiraka. Fazna i amplitudska greška teže nuli kada interval integraljenja teži nuli, odnosno kada integrišući AD konvertor postaje *sampling* AD konvertor.

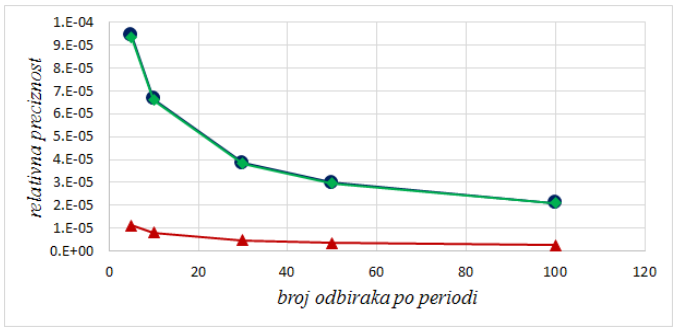
Sl. 1. Ilustracija uticaja ugla integraljenja. Ulazni talasni oblik (tanka crna linija), integracioni period (debela crvena linija) i rezultat AD konverzije (plave tačke).

Postavlja se pitanje opravdanosti korišćenja integrišućeg AD konvertora za određivanje modula i faznog stava impedanse, kada međurezultati (amplitude i faze napona i struje) u sebi sadrže opisane greške. Simulacionim postupkom je proveravana navedena nedoumica.



Pretpostavljeni su prostoperiodični talasni oblici napona i struje na ulazu AD konvertora zadatog vremena integraljenja. Simulirano je odabiranje u svega pet tačaka po periodi, a onda je na osnovu odbiraka, postupkom fitovanja, određena amplituda i fazni stav napona. Na Sl. 2. je prikazan grafik zavisnosti normalizovane vrednosti (količnik vrednosti izmerene i zadate amplitude) opisanim postupkom određene amplitude napona i struje, kao i izračunatog modula impedanse. Na horizontalnoj osi je ugao integraljenja iskazan u radijanima, kako bi bio uporediv prema periodi prostoperiodične funkcije koja iznosi 2π rad.

Sl. 2. Zavisnosti normalizovane vrednosti određene amplitude napona (crveni krugovi) i struje (zeleni trouglovi), kao i izračunatog modula impedanse (plavi rombovi).

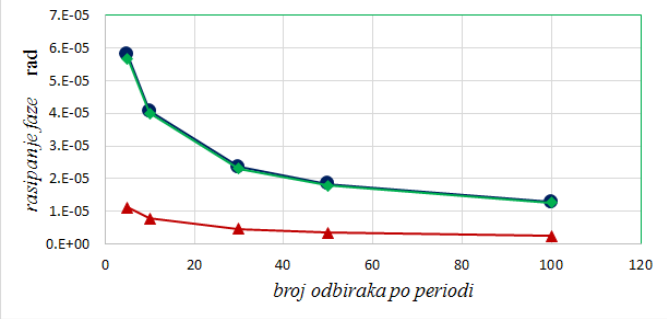


Sa porastom ugla integraljenja javlja se sve primetnija sistematska greška, za koju se pokazuje da zavisi samo od ugla integraljenja. Greška je multiplikativnog tipa, jednaka je za napon (crvena karakteristika) i struju (zelena karakteristika). Prilikom određivanja modula impedanse (plava karakteristika) kao količnika napona i struje dolazi do potiranja polaznih sistematskih greška. Ovo je vrlo korisna osobina jer se mogu sprovoditi merenja sa vrlo velikim uglom integraljenja koja za posledicu ima značajnu sistematsku grešku od nekoliko procenata, a da se to ne odrazi na performanse određivanja modula impedanse.

Na Sl. 3. je data zavisnost određenog faznog stava napona (crveni krugovi), struje (zeleni trouglovi) i impedanse (plavi rombovi) od ugla integraljenja. Za zadatu vrednost faznog stava napona (crvena isprekidana linija) i struje (zelena isprekidana linija), izmereni fazni stav napona i struje sadrži sistematsku grešku koja zavisi od ugla integraljenja. Ta greška je aditivnog tipa i jednaka je za napon i struju. Prilikom određivanja faznog stava impedanse (razlika faznog stava napona i faznog stava struje) dolazi do potiranja polaznih aditivnih sistematskih grešaka faznog stava napona i struje.

Sl. 3. Zavisnost rezultata određivanja faznog stava napona (crveni krugovi), struje (zeleni trouglovi) i faznog stava impedanse (plavi rombovi) od vrednosti ugla integraljenja.

Nakon eliminacije uticaja sistematskih grešaka pri određivanju modula i faznog stava impedanse, u rezultatu merenja preostaju slučajne greške. Na Sl. 4. je prikazana zavisnost relativno iskazanog rasipanja (količnik standardne devijacije i srednje vrednosti rezultata merenja) prilikom određivanja amplitude naizmenične komponente napona (crveni trouglovi) i struje (zeleni rombovi), kao i modula impedanse (plavi krugovi).



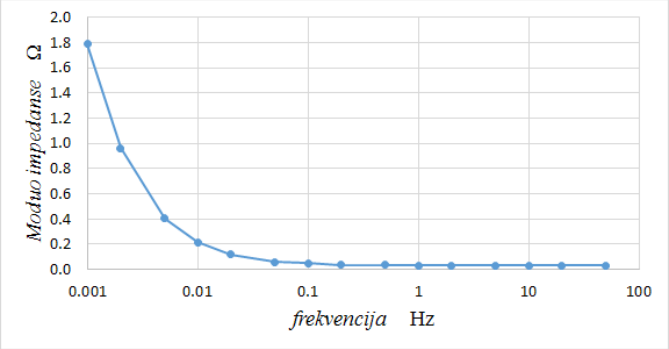
Sl. 4. Zavisnost relativno iskazane preciznosti (rasipanje) amplitude napona (crveno), struje (zeleno) i modula impedanse (plavo) od broja odbiraka po periodi.

 ISBN 978-86-7466-930-3

Korišćeni voltmetar ima značajno manju grešku (desetak puta) nego ampermetar, pa je greška merenja struje dominantna prilikom određivanja modula impedanse. Ako se broj odbiraka po periodi poveća sa 5 na 100 (20 puta), dobije se nesrazmerno manje poboljšanje u preciznosti određivanja modula impedanse (svega 4.5 puta).

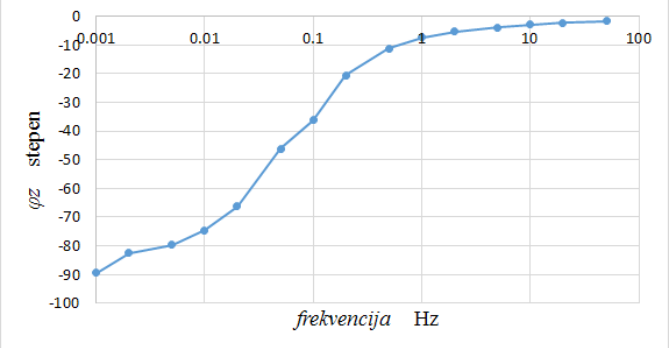
Na Sl. 5 je prikazana zavisnost rasipanja faznog stava napona (crveni trouglovi), struje (zeleni rombovi) i impedanse (plavi krugovi) od broja odbiraka po periodi. Važe slični zaključci u pogledu zavisnosti navedenih parametara od broja odbiraka po periodi.

Sl. 5. Zavisnost preciznosti (rasipanja) rezultata određivanja faznog stava napona (crveni trouglovi), struje (zeleni rombovi) i impedanse (plavi krugovi) od broja odbiraka po periodi.



III. Merna nesigurnost

Dokument [5] predstavlja preporuke za iskazivanje merne nesigurnosti polazeći od matematičkog modela merenja. Matematički model merenja je izraz koji predstavlja zavisnost izlazne veličine od uticajnih veličina. U konkretnom slučaju, izlazne veličine (čiju mernu nesigurnost želimo da odredimo) su moduo i fazni stav impedanse. Neke od uticajnih veličina su: greške ugrađene u odbirke napona i struje, greška postupka određivanja amplitude i faznog stava napona prostoperiodične veličine na osnovu odbiraka i trajanje intervala integraljenja. Pristupom opisanim u [5] se vrši analiza propagacije mernih nesigurnosti ulaznih veličina na izlaznu veličinu.

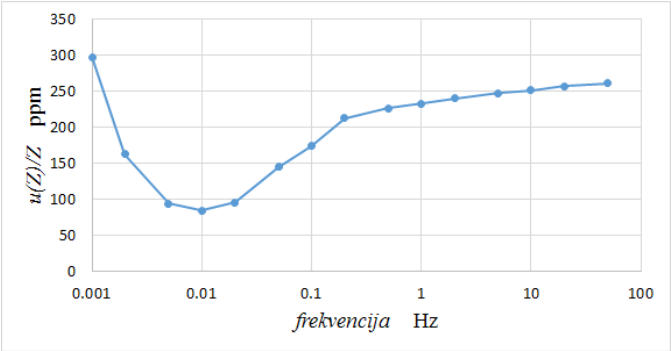


Pored velikog broja uticajnih veličina, poseban problem u konkretnom slučaju je nepoznavanje načina funkcionisanja Python-ove funkcije *cur e fit*, koja je preuzeta iz biblioteke *scipy* [7]. Ova funkcija je korišćena za fitovanje prostoperiodične funkcije kroz dobijeni skup odbiraka, radi određivanja amplitude i faznog stava napona i struje.

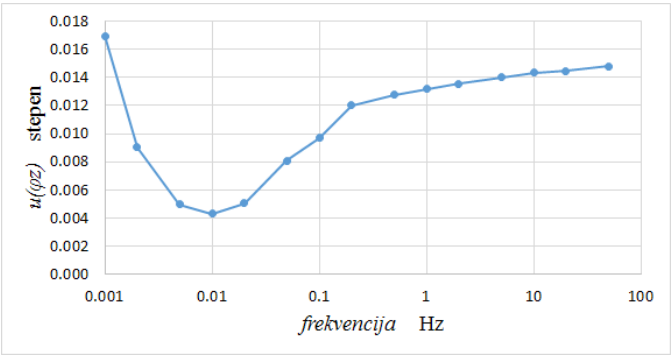
Drugi način za određivanje merne nesigurnosti, opisan u [6], je zasnovan je na simulacionom postupku, odnosno na primeni Monte Karlo metode. Kod ovog postupka se uticajne veličine posmatraju kao slučajne promenljive i vrši se analiza propagacije funkcije gustine uticajnih veličina na funkciju gustine izlazne veličine. Veliki broj puta (preko 10^5) se simulira postupak merenja uz uvažavanje funkcije gustine svake od uticajnih veličina. Za dobijene vrednosti izlazne veličine se određuje funkcija gustine, srednja vrednost i standardna devijacija. Srednja vrednost se saopštava kao najbolja procena izlazne veličine, dok vrednost standardne devijacije predstavlja standardnu mernu nesigurnost.

Na Sl. 6 i Sl. 7. su prikazani rezultati određivanja modula i faznog stava impedanse superkondenzatora za frekvencije počev od 1 mHz do 50 Hz. Za sva merenja je definisano najkraće vreme integraljenja (0.4 ms), uzimano je sedam odbiraka po periodi u tri susedne periode napona i struje. Odbirci napona i struje su kao argument prosleđivani funkciji *cur e fit,* a kao izlaz su dobijene najbolje procene amplitude i faznog stava naizmenične komponente pretpostavljenog prostoperiodičnog oblika. Moduo impedanse se određuje kao količnik amplituda prostoperiodične komponente napona i struje. Fazni stav impedanse se određuje oduzimanjem faznog stava napona i struje.

Sl. 6. Zavisnost modula impedanse superkondenzatora od frekvencije.



Sl. 7. Zavisnost faznog stava superkondenzatora od frekvencije.



Korišćenjem Monte Karlo postupka je određena standardna merna nesigurnost (standardna devijacija) modula i faznog stava impedanse superkondenzatora. U simulaciji su modelovane: greška AD konvertora na naponskom i strujnom kanalu za svaki odbirak [4], vreme integraljenja zadato parametrom NPLC, broj tačaka po periodi i broj perioda. U nedostatku dodatnih informacija, sve greške su modelovane uniformnom raspodelom. Zavisnost relativno iskazane standardne merne nesigurnosti modula impedanse superkondenzatora od frekvencije je prikazana na Sl. 8.

Standardna merna nesigurnost faznog stava impedanse superkondenzatora je prikazana u apsolutnom obliku na Sl. 9.

 ISBN 978-86-7466-930-3

Sl. 8. Zavisnost relativno iskazane standardne merne nesigurnosti modula impedanse superkondenzatora od frekvencije.

Sl. 9. Zavisnost apsolutno iskazane standardne merne nesigurnosti faznog stava impedanse superkondenzatora od frekvencije.

Relativno iskazana standardna merna nesigurnost modula impedanse superkondenzatora je manja od 300 ppm, dok je apsolutno iskazana standardna merna nesigurnost faznog stava impedanse superkondenzatora manja od 18 m˚, odnosno 0.6 mrad.

IV. Zaključak

U radu je prikazana simulaciona analiza metode pogodne za snimanje modula i faznog stava impedanse dvokrajnog elementa na niskim učestanostima. Kao ampermetar i voltmetar su korišćeni standardni multimetri sa integrišućim AD konvertorom. Simulacioni postupak je korišćen iz dva razloga: a) da se oceni doprinos uticajnih veličina i b) da se odredi merna nesigurnost. Pokazano je da:

- prilikom određivanja modula impedanse (deljenjem procenjene vrednosti amplitude prostoperiodične komponente napona i struje) dolazi do potiranja multiplikativne sistematske greške,
- prilikom određivanja faznog stava impedanse (razlika procenjenog faznog stava napona i struje), dolazi do potiranja aditivne sistematske greške,
- povećanje broja odbiraka po periodi ne doprinosi srazmerno poboljšanju metroloških performansi rezultata merenja,
- pod pretpostavkom uniformnih raspodela greške AD konvertora na naponskom i strujnom kanalu, primenom Monte Karlo metode je određena merna merna nesigurnost rezultata merenja.

Abstract

The paper presents a simulation analysis of a method that is applicable for the metrology characterization of two-end elements at low frequencies. The program written in the Python programming language simulates the operation of two multimeters of the FLUKE 8846A, one of which is configured as an ammeter and the other as a voltmeter. Voltage and current samples are processed in a program, which determines the value of the amplitude of the alternating component and the phase position of voltage and current based on the samples, and then calculates the modulus and phase position of the impedance based on these values. The program takes into account the declared errors of both instruments and provides an opportunity to assess the measurement uncertainty of the measurement results.

imulation analysis of methods suitable for metrology characterization of impedance at low frequencies

Two Color Photodiodes Mounted on the Micromachined Carrier

Žarko Lazić, Milče M. Smiljanić, Dušan Nešić, Ljubiša Zeković

***Abstract*— In this paper, two color detector based on silicon photodiodes is studied and fabricated. Standard IHTM photodiode's design is modified to allow mounting one photodiode above another using special micromachined carrier. The carrier is fabricated using wet silicon etching in 25% TMAH water solution and anodic bonding of etched silicon and Pyrex glass. The fabricated carrier also allows easy wire thermocompression bonding from the photodiode's pads to TO-5 housing. Output currents of the photodiodes were measured by applying light of 900 nm and 1060 nm. Obtained results verify applicability of the new packaging for two color detector.**

***Index Terms*—Two color detector, photodiodes, micromachined packaging, silicon, Pyrex glass**

I. Introduction

IN the Institute of Chemistry, Technology and Metallurgy (IHTM) various types of silicon photodiodes were explored and developed for decades [1]. In this work, we will study a modified IHTM silicon photodiodes as two color detectors [2-4]. Two color detectors represent a sandwich structure that contains two photodiodes arranged along the same optical axis and they measure different ranges of wavelengths. Commercially available detectors [3-4] are using two photodiodes based on silicon or silicon and InGaAs. These detectors are mostly utilized for remote temperature measurements and for wide wavelength ranges of detection. The temperature is measured using ratio of radiation intensities at two wavelengths or wavelengths ranges and comparing it with the standard black body radiation [3]. Special advantages of these optical remote temperature measurements are solving problems of physical obstacles on target's optical axes. Two color detectors are used in applications for flame temperature sensing, spectrophotometer, dual-wavelength detection and IR thermometers [3].

In this paper, we will explore design of the silicon-silicon photodiodes sandwich, in which the top silicon photodiode is placed above the other bottom photodiode, as shown in Fig.1. The idea of design is that the photons of shorter wavelengths must be absorbed in the top photodiode and the photons of longer wavelengths are absorbed in the bottom photodiode. The sandwich design is obtained using special carrier for photodiodes. Carrier is fabricated using processes of micromachining of silicon in 25% wt. TMAH water solution and anodic bonding of etched silicon and Pyrex glass. In order to provide electrical connections, design and fabrication of the photodiodes are modified. After mounting of sandwich carrier on the TO-5 housing, measurements were performed to confirm detection of two different wavelengths.

II. Fabrication

In the research and development of two color detector we modified photodiodes using know-how of our previous commercial silicon photodiodes. Problem of thermocompression bonding of golden wires to aluminum electrical connection is solved with design of the lateral photodiodes. The IHTM standard photodiodes have electrical connections on the both sides-the top and the bottom. In two color detection the top photodiode must allow transmission of wavelengths to be absorbed by the bottom photodiode. For this reason, the bottom side of the top photodiode must be designed without any metallization and reflective layer.

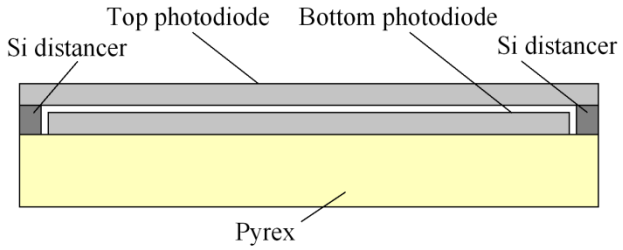

Fig. 1. Cross section of two photodiodes mounted on the micromachined carrier.

In order to simplify fabrication processes, the top and the bottom photodiodes are produced using the identical design, as shown in Fig.1-2. The photodiodes are in the shape of silicon rectangles with surface dimensions of 4000 μm x 3345 μm, as shown in Fig.1-2. The rectangular shape resolves the problem of thermocompression bonding of gold wires to both mounted photodiodes on fabricated carrier and TO-5 housing since both are rotated for 90˚ relative to each other, as shown

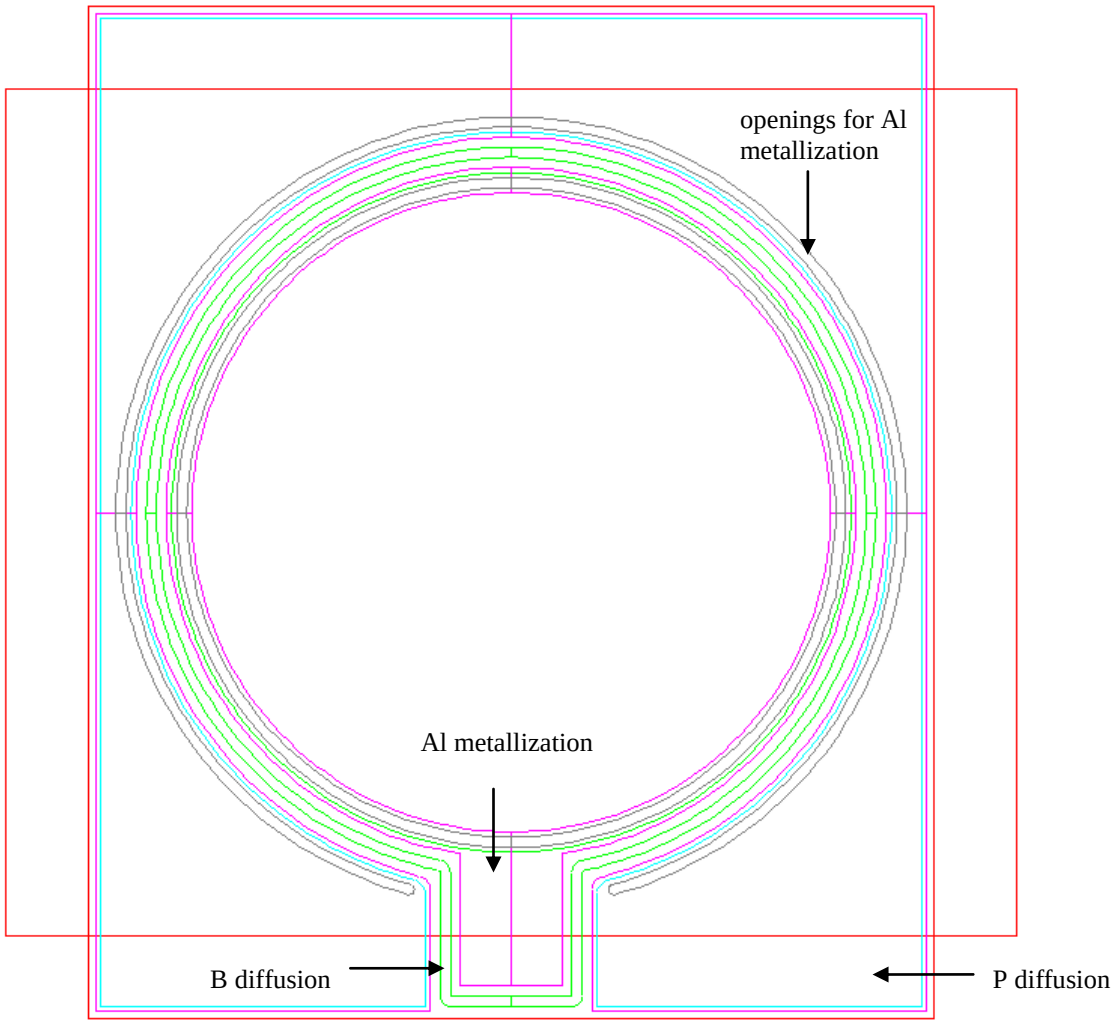

Fig. 2. Two color photodiodes design. Green color-I photolithographic process for boron diffusion. Blue color-II photolithographic process for phosphorus diffusion. Grey color-III photolithographic process for openings for Al metallization in SiO2. Pink color-IV photolithographic process for Al metallization. Red color-rectangular borders of sawed photodiode.

in Fig.2. We used two types of the silicon substrates in fabrication. For the top photodiodes, the silicon wafers of n type, resistivity of 2000 Ωcm and thickness of 180 μm are used. For the bottom photodiodes, we used silicon wafers of n type, resistivity of 500-1000 Ωcm and thickness of 300 μm. Prior to predetermined technological processes, the photolithographic processes were performed to define patterns given in Fig.2. The fabricated photodiodes were obtained according to following list of technological processes:

1. I wet thermal oxidation for boron diffusion (T=1100 ℃, t=120 min)
2. I photolithographic process for boron diffusion
3. Boron diffusion (T=1025 ℃, t=60 min)
4. II wet thermal oxidation for phosphorus diffusion (T=1100 ℃, t=100 min)
5. II photolithographic process for phosphorus diffusion
6. Phosphorus diffusion (T=950 ℃, t=60 min)
7. SiO_2 thinning on the top side and its removing on the bottom side of wafer
8. III photolithographic process for openings in SiO_2
9. Al sputtering
10. IV photolithographic process for Al metallization.

Finally, Au layer was sputtered only on the bottom side of the bottom photodiode as reflective layer.

Photodiodes' carrier is micromachined using anisotropic wet etching in 25% wt. water solution at the temperature of 80 ℃ [5-7]. We used phosphorus-doped {100}-oriented 3" silicon wafers with double-sided polished surfaces. The resistivity of the wafers is 1-5 Ωcm and its thickness is 400 μm. Prior to etching, we performed wet thermal oxidations to obtain SiO_2 masking layer of 1 μm and 0.5 μm thicknesses and three photolithographic processes to define patterns for double side etching. First, we performed etching to define appropriate cavities on the top side of silicon substrate. Then the thinner silicon dioxide was removed. Next, wafer had been double side etched until membrane of 50 μm was obtained. Etched wafer was anodically bonded to the Pyrex

glass wafer, as shown in Fig.3. The thickness of Pyrex glass wafer is 700 μm. Finally, the last etching of the previously obtained membrane determines distancers on glass support, as shown in Fig.1. The distance between vertical etched silicon inner walls is 3345 μm. Finally, the Pyrex glass wafer was sawed into 4000 μm x 4000 μm carriers.

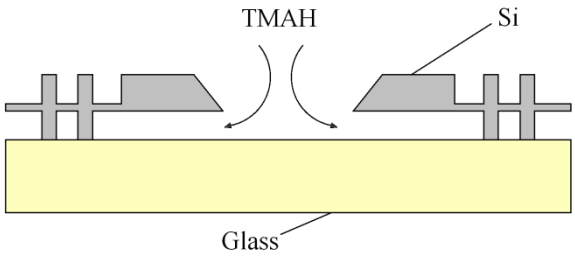

Fig. 3. Schematic picture of partly micromachined silicon wafer anodically bonded to Pyrex glass wafer.

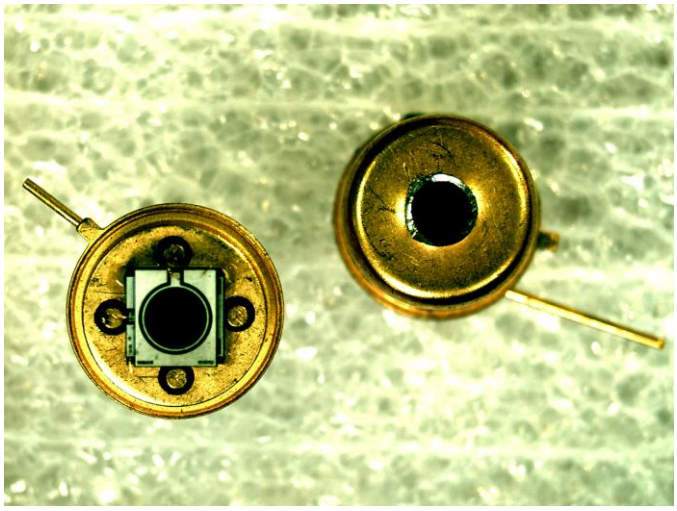

Fig. 4. Two photodiodes mounted on TO-5 housing with and without cap.

III. RESULTS AND DISCUSSION

The photodiodes were measured separately before mounting in order to confirm their quality and compare with IHTM commercial photodiodes. Sensitivities for both photodiodes were 0.65 A/W for 900 nm and 0.2-0.3 A/W for 1060 nm. Breakdown voltages of about 100 V were obtained. These parameters are similar to IHTM commercial photodiodes [1].

The top and bottom photodiodes are mounted on obtained carriers as shown in Fig.1. The carriers are then mounted on TO-5 housing, as shown in Fig.4,5 where the photodiodes are bonded to four pins using 25 μm gold wires. At the end, the cap with aperture was glued to TO-5 housing. Aperture is designed for the optical fiber as shown in Fig.5.

.

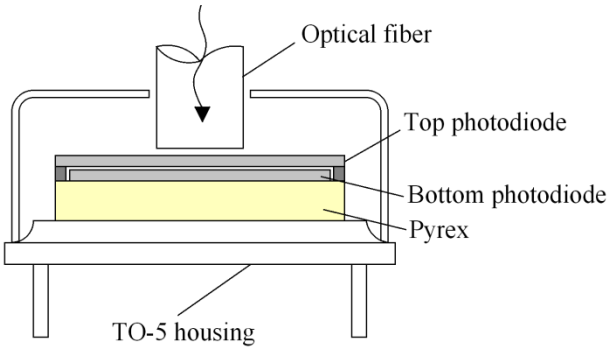

Fig. 5. Schematic picture of cross section packaging of mounted two photodiodes with optical fiber.

The light is applied through optical fiber in order to measure ratios between the photodiodes' output currents. We used the filters for 900 and 1060 nm when the light is applied. The obtained ratios between the photodiodes' output currents are given in Table 1 for three different detectors. For each two color detector ratios were measured for three different light intensities. From outputs and ratios given in Table 1, we can

 ISBN 978-86-7466-930-3

conclude that the designed carrier can be used as a part of packaging for two color detector. Our future work will be to improve our modified photodiodes presented in this paper in order to obtain better output characteristics.

IV. Conclusion

In this paper, we explored and developed two color detector based on silicon photodiodes. We modified IHTM photodiodes in order to allow mounting of one photodiode above another and easy thermocompression bonding to TO-5 housing. We fabricated special carrier for photodiodes using wet silicon etching in 25% TMAH water solution. Output currents of the produced two color detectors were measured by applying light with the wavelengths of 900 nm and 1060 nm. Performed measurements confirm usability of the new designed carrier for two color detector.

Optimization of electrodeposition parameters to improve composite hardness of nickel coatings on brass substrate for varying film thicknesses and applied indentation loads

Ivana Mladenović, Jelena Lamovec, Marko Obradov, Milena Rašljić Rafajilović, Vesna Radojević, Dana Vasiljević Radović, *Member, IEEE* and Nebojša Nikolić

***Abstract*—In this investigation, nickel coatings were electrodeposited on brass substrate. The effects of electrodeposition process parameters such as, current density and deposition time (coatings thickness), on surface morphology and composite hardness values were studied. The value of the measured composite hardness by Vickers microindentation technique of the selected "hard film on soft substrate" composite system type depends on the applied indentation loads. For this reason, the microindentation loads are also included in the analysis. According to the experiment plan obtained by Design-Expert software, nickel coating has been produced on the brass cathode using galvanostatic regime (DC) with magnetic stirring of the electrolyte. The nickel sulphamate electrolyte with saccharine additive was used for Ni electrodeposition. Then, response surface methodology (RSM) was used to establish an adequate mathematical model. Subsequently, a mathematical model was developed to weight the effects of each input parameters (coating thickness, current density and indentation load) on the output parameter (composite hardness) of electrodeposited nickel coatings on brass substrate. According to the obtained results, the coating thickness and indentation load greatly influenced resulting composite hardness. On the other hand, coating current density primarily influenced microstructure and surface roughness. The topographic modification of the Ni coating surface depending on the post-treatment (mechanical and chemical) after deposition was studied using AFM microscopy.**

***Index Terms*— electrodeposition; composite hardness; RSM; AFM; optimization; nickel coating.**

I. Introduction

THIN metallic coatings are often used for fabrication of different microelectronic and micromechanical devices. Thin coatings and bulk substrates constitute a composite system which mechanical properties depend not only on material characteristics of constituent materials but also on the mechanical interaction between the two such as the adhesion strength, residual stress, toughness and elastic-plastic properties [1-3]. In general, strong adhesion of the coating to the substrate is desired because it results in improved mechanical properties of the composite system. Additionally, reduction of the residual stress is paramount to prevent spontaneous delamination of the coating due to micro-crack growth between the thin coating and the bulk substrate [3].

Nickel (Ni) is one of the most common metals used to synthesize composite electrochemical coatings (CECs). It is characterized by superior corrosion and wear resistance, and enhanced mechanical and tribological properties [4]. Nickel coatings attract a huge attention from both scientific and technological communities owing to their unique properties, such as excellent friction coefficient during the wear testing of LIGA (lithographic) fabrication micro-rotors [5]. Ni alloys such as Co-Ni possess the high aspect ratio (HAR) during electrodeposition process and excellent magnetic and electrochemical properties [6].

Main methods of Ni thin film synthesis include: electrodeposition (ED), electroless plating (EL), physical vapour deposition (PVD), chemical vapour deposition (CVD), thermal spray and RF sputtering [1]. An interesting approach used for growing both pure Ni coatings and Ni alloys is electrochemical deposition technique. Conventional electrodeposition (ED) or new emulsion supercritical ED technique are very suitable ways to obtain nickel of desired characteristics suitable for application in above mentioned purposes [7, 8]. A common problem that exists during electrodeposition of Ni coatings is formation of hydrogen during ED process. The formation of hydrogen may create several pinholes on the coating [8], but the problem is solved by the adding surfactants (organic additives).

The most common electroplating solution for electrodeposition of Ni coatings met in the literature consists of nickel sulfate, nickel chloride, boric acid, saccharine and 1,4-butynediol [8]. In addition to the sulfate electrolyte, sulphamate electrolyte is also used [9]. Deposition parameters affect many properties of the electroplated material both during and after synthesis. By altering the synthesis parameters such as type of electrolyte and substrate, mixing condition, deposition time, applied current regime and density, post-deposition treatment, etc. we can control the grain size and microstructure of Ni coatings resulting in strengthened and hardened films with little or no loss in coating ductility.

Indentation testing is a reliable method for evaluation of material mechanical properties [3]. However, it cannot be

applied directly for characterization of thin films due to plastic deformation of the sample during the indentation process [9, 10]. For this reason, indentation method is applied to measure composite hardness (thin film on bulk substrate). Various mathematical models have been developed to calculate thin film microhardness based on the directly measured composite hardness of the film [11-14].

The Response Surface Methodology (RSM) is the most insightful method of evaluating a factorial experiment performance [15, 16]. The aim of this paper, in addition to synthesis of excellent quality Ni coatings on brass by the ED method and microindentation characterization of the material, is also to design an optimal experiment (DoE) according to RSM (Response Surface Methodology) [15-20]. Modification of the coating structure after deposition is another contribution of this paper.

II. Experimental

For electrodeposition of fine-grained nickel coatings we chose brass foil (260 1/2 hard, ASTM B36, K&S Engineering, 250 μm thick; composition: 66 % Cu, 34 % Zn) as a substrate (cathode). The surface area of the brass cathode was (2.0 × 1.0) cm^2. The pure Ni anode (rectangular in shape; positioned along the wall of the glass cell) and 500 ml of electrolyte were used. The nickel depositing apparatus is shown in Fig. 1. Prior to deposition, the cathode was mechanically polished and activated in a solution of sulfuric acid.

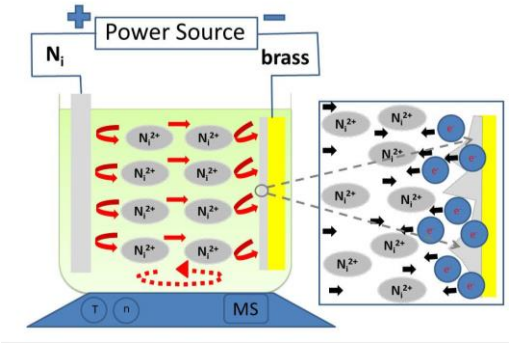

Fig. 1. Schematic presentation of nickel coating electrodeposition on brass substrate from sulphamate electrolyte in DC regime with magnetic stirrer (DC/MS).

Electrodeposition was performed in an open cell type using the direct current galvanostatic regime (DC) from a lab-made sulphamate electrolyte consisting of: 300 g/l Ni $(NH_2SO_3)_2{\cdot}4H_2O$, 30 g/l $NiCl_2{\cdot}6H_2O$, 30 g/l H_3BO_3 and 1 g/l saccharine as the wetting agent, with pH-value and the temperature of the process maintained at 4.20 and 50°C, respectively. The electrolytes were stirred by an application of magnetic stirrer (MS) (300 rpm, Heidolph Instruments GmbH & Co. KG, Schwabach, Germany). The DC/MS electrodeposited regime will be used below in the text.

The current density values were maintained at 10 mA cm^{-2} and 50 mA cm^{-2}. The deposition time was determined according to projected thickness of the coating. Five different coating thicknesses were formed: 2, 5, 10, 20 and 50 μm for each applied current density. Cathodic efficiency of 100% was taken to calculate the deposition time. The thickness was checked across the cross-section using an optical microscope.

The cross-section preparation for characterization was done in a fallowing manner: samples were embedded in a self-curing methyl methacrylate-polymer (Palavit G, Heraeus, Germany) and mechanically polished with different SiC papers (#800 and #1200) and finished with emulsion of alumina powder with different grain size (1-0.3 μm) [21]. Then, rinsing in sodium-carbonate solution and dried in nitrogen flow. The cross-section was prepared in order to validate the thickness of the coating, to observe the adhesion at the coating-substrate interface and to assess the hardness of the coating at the cross-section, see Fig. 2.

The mechanical properties of the composite system and substrate on top side and cross-section were characterized utilizing a Vickers microhardness tester ″Leitz, Kleinharteprufer DURIMET I″ using up to 15 loads ranging from 500 gf (4.9 N) down to 5 gf (0.049 N), see Figs. 2, 3 and 4. Five different loads were selected for optimization (10, 50, 100, 150 and 300 gf). Three indentations were made and the average value of the diagonal was determined by measuring six indentation diagonals, for each load. With the average value of the diagonals, the mean value of the hardness was calculated [9].

The topographic analysis of coatings surface after post-treatment was investigated using an atomic force microscope in the non-contact mode (AFM-Auto Probe CP Research; TM Microscopes-Veeco Instruments, Santa Barbara, CA, USA). The scan area was (20 × 20) μm^2. A histogram analysis of the coatings and bearing rate curve [22, 23] were done by an application of WSxM AFM software [24]. The analysis was performed in order to assess the resistance of the coating and the change in roughness during mechanical treatment and exposure to aggressive reagents such as hydrochloric acid (Fig. 5).

III. Results and Discussion

A. *Indentation on different locations*

The microhardness of Ni coating and influence of the substrate hardness during penetration of indenter is shown to depend on the indentation site. The hardness measured on the cross-section of brass (Fig. 2a) corresponds to the absolute bulk substrate hardness that is used in proportional specimen resistance (*PSR)* model (H_s = 1.41 GPa) [25].

If the indentation is performed on the coating surface, the structural-morphological properties of the coating affect the measurement, and the contribution of the substrate must be taken into account. The measured value of hardness is called composite hardness, H_c. In the case of cross-sectional indentation (Fig. 2b), the measured hardness, $H_{c\text{-}s}$ is constant and equal to the hardness of the bulk material without effects of substrate hardness and morphology of coating surface. Comparative values are shown in Table I. The diagonal size measured on the cross-section of the coating ($d_{c\text{-}s}$) is smaller than on the surface of composite (d), for the same applied load. For the "hard film on soft substrate" composite system type, the cross-sectional hardness value is higher than the composite hardness.

The interfacial indentation [3] hardness test (Figs. 2c and 2d) is a quick way to assess interlayer adhesion strength of the coating to the substrate and indentation toughness

 ISBN 978-86-7466-930-3

properties. The interfacial hardness and diagonal interfacial size (d_i) measurement is complex. The problem with this method of measurement is a possible difference in the height of nickel and brass due to the different wear rate of the material when preparing the cross-section. The delamination of the Ni coating did not occur, so the adhesion of the Ni coating for brass substrate is good. For very thin coatings (2, 5, 10 μm), it is not possible to measure hardness on the cross-section, because the Vickers indent size is larger than the projected thickness of the coating.

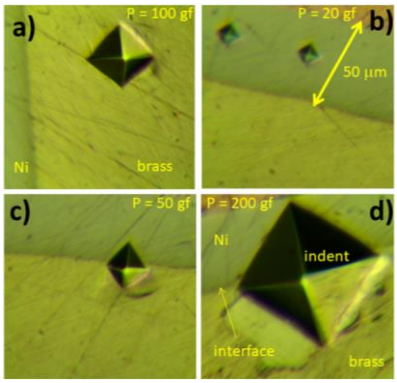

Fig. 2. Indentation on different location of cross-section with variation applied load on Ni/brass composite system: a) indentation on brass substrate, P = 100 gf, b) indentation on Ni coating, P = 20 gf, c) interfacial indentation, P = 50 gf and d) interfacial indentation, P = 200 gf. Nickel coating was obtained in DC/MS electrodeposition regime at 50 mA cm^{-2} current density.

TABLE I
CHANGE IN THE HARDNESS OF THE NICKEL COATING DEPENDING ON THE MEASURING LOCATION

P / gf	d / μm	$d_{c\text{-}s}$ / μm	H_c / GPa	$H_{c\text{-}s}$ / GPa
20	11.08	10.50	2.945	3.278
50	18.88	15.40	2.535	3.810

200	36.50	34.05	2.713	3.117

B. Indentation on the top surface of the Ni coatings on brass substrate

Different load-indentation depth curves can be obtained by changing the coating thickness of Ni coatings and current densities (Fig. 3). It can be seen that the coating thickness is the dominant parameter in the loading indentation process, while current density has very little effect, especially for small coating thicknesses.

The dependencies of the composite hardness (H_c) on the relative indentation depth (*RID*) for the given Ni coatings are shown in Figure 4. The *RID* is defined as a ratio between an indentation depth, h and a coating thickness, δ (*RID* = h /δ), where an indentation depth depends on a diagonal size as h = d /7 [9, 11-14, 21]. The contribution of substrate to composite hardness increases with the increasing *RID* value and applied load P, suggesting that the composite hardness matches the substrate hardness at high *RID* values.

Figure 4 clearly shows three characteristic zones depending on the influence of coating and substrate hardness on the composite hardness: 1) dominant influence of the coatings corresponds to 0.01 < *RID* < 1 (for thick 50 μm coatings), 2) the composite zone corresponds to 0.1 < *RID* < 1 for medium-thick films (10 and 20 μm) and 3) the dominant influence of the substrate is characteristic when *RID* > 1; for thin coatings (2 and 5 μm).

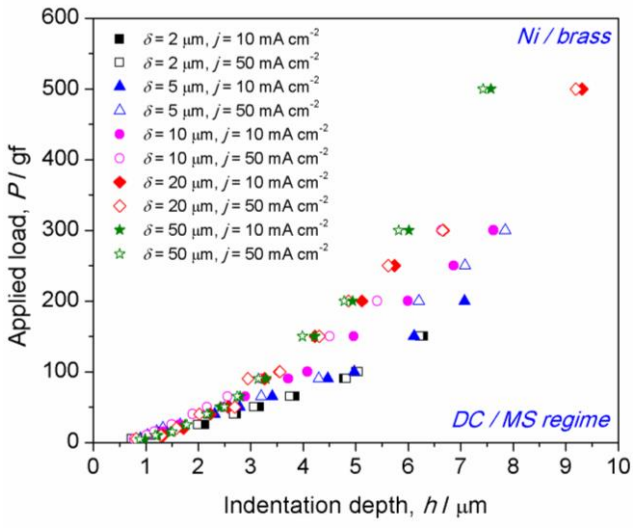

Fig. 3. Load-indentation depth experimental points of different Ni coating thickness electrodeposited on brass substrate in DC/MS regime at two current densities (10 and 50 mA·cm^{-2}).

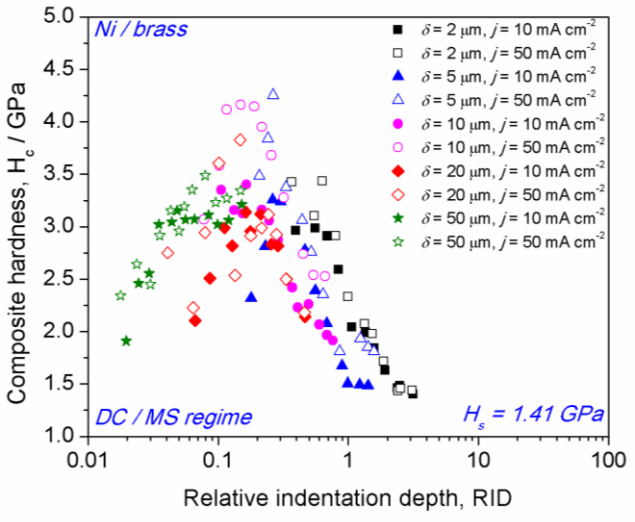

Fig. 4. The dependencies of the composite hardness (H_c) on the RID for the Ni coatings electrodeposited on the brass from the sulphamate electrolyte.

Figure 4 also shows a characteristic turning point, corresponding to a value of *RID* of 0.14. For the *RID* values smaller than 0.14, the measured composite hardness corresponds closely to the hardness of the coating. By crossing this critical point, the value of hardness decreases, which indicates the contribution of the softer substrate below. The Ni coatings obtained with a higher current density (50 mA·cm^{-2}) appeared harder than those deposited with 10 mA·cm^{-2}. For hard coating on soft substrate composite systems, with increasing the relative indentation depth (0.1 ≤ *RID* ≤ 1), the composite hardness H_c decreases until the hardness of the substrate is reached as shown on Fig.4 (H_s = 1.41 GPa).

C. Modification of Ni surface after deposition by mechanical and chemical treatments

Stochastically roughened of metallic thin coatings can be obtained with various methods including dry etching, wet chemical etching or mechanical treatment (abrasion). Depending on the applied method, different surface profiles are obtained with microstructural modifications of surface coatings. The goals of this work were to explore the correlations between the AFM-based and treatment method for samples with different roughness and therefore different areas. For example, the difference in mechanical properties on the cross-section and the surface of the coating is one of the consequences of the treatment (mechanical). The roughness of each of the samples was determined using AFM topographic measurements. Figures 5 present the 3D AFM images of Ni / brass systems obtained at 50 mA·cm^2 (left) and histograms (right) with different treatment: mechanical (Figs. 5 a, b), chemical (Figs. 5 c, d) and no-treatment (Figs. 5 e, f).

Comparing the topography of nickel coatings, mechanical treated (Fig. 5a) and chemical treated coating (Fig. 5c) have similar roughness and stochastically nodular topography. Ni coating with mechanical treatment (Fig. 5a) can be observed to have a rather irregular surface with distributed nodular surface features. Deep channels as a result of sanding and scratching the surface were observed, too. From the values of the arithmetic average of the absolute roughness parameter (R_a) of the surfaces presented in Fig. 5, it could be observed that the roughness increases for Ni coatings including either chemical or mechanical treatment relative to non-treated coating (R_a = 28.68 nm for no-treated, R_a = 82.43 for chemical and R_a = 78.14 for mechanical treated coatings).

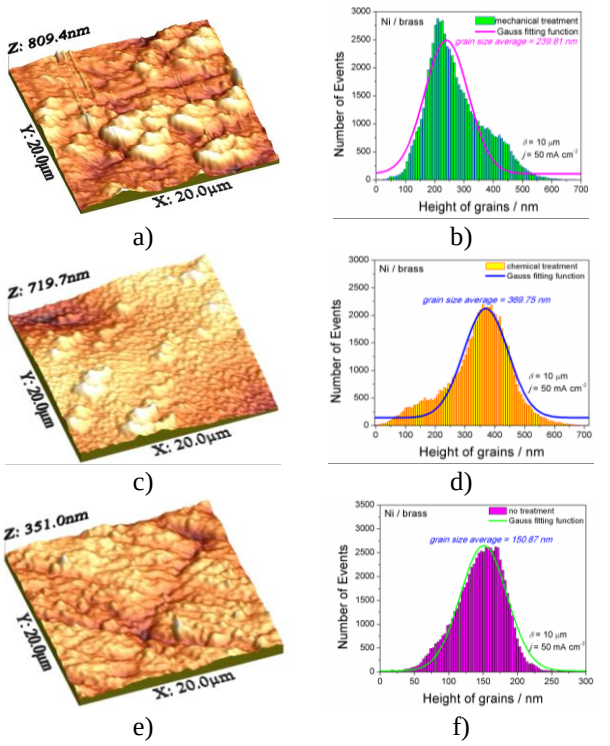

Fig. 5. Examples (20 × 20) μm^2 AFM topographic measurements for a Ni coating (10 μm thick) on brass substrate (left) and corresponding histograms (right) after electrodeposition and roughened surface treatment: a) and b) mechanical; c) and d) chemical; e) and f) no treatment. Ni coatings were obtained by electrodeposition technique in DC/MS regime at a current density of 50 mA cm^{-2} from the sulphamate electrolyte.

Although the topography of the untreated sample and the chemically etched one is very similar, based on the average height of grains obtained via the Gaussian distribution fitting function, it can be seen that the chemically treated sample has higher peaks (369.75 nm). However, mechanical treatment of the surface leads to the suppression of high peaks (Fig. 5b), which results in a reduction of total roughness (239.81 nm), i.e. smoothing of the surface.

Figures 6 show the relationship of bearing ratio (in %) with the grain height (Firestone–Abbott bearing curve, standards DIN4776; STN ISO 13 565-2). The bearing curve is the cumulative probability density function of the surface profile's height which is calculated by integrating the profile of the AFM trace [22]. As can be seen, if the bearing area rate reached 95 %, the order of the corresponding grain height of these treated Ni coatings are mechanical (800 nm) > chemical (700 nm) > no treatment (350 nm), see Fig. 6a.

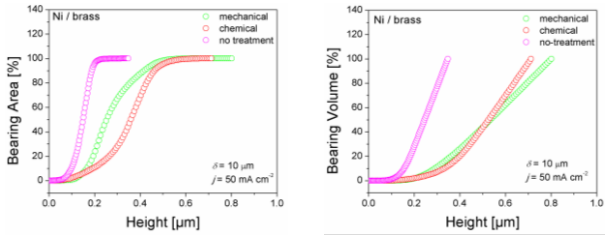

Fig. 6. Bearing ratio curves of Ni coatings on brass substrate with a variation of treatment: a) bearing area and b) bearing volume curve.

With application of post-treatment, the distribution range of nodule sizes shifts to the direction of larger values, see Fig. 6a. It indicated that the Ni coating without any treatment has the finest granule size, comparatively. It suggested that the Ni benefits smooth and fine-grained structure. Bearing flooded volume or bearing area curve indicated that the critical dimension point is 500 nm for peak height (Figs. 6a and 6b) for treated surface.

D. Optimization of composite hardness of Ni/brass systems

Design-Expert 12 (Stat-Ease, US) software and Optimal Design was used for the response methodology to examine correlation between the input variables (coating thickness, current density and applied indentation load) and output parameter (composite hardness). The factors (3 numerical) and factor levels (numerical) are shown in Table II.

TABLE II

INFLUENCE FACTORS ON NI COATING COMPOSITE HARDNESS

Mark	Parameters	Value limit Lower	Value limit Upper	unit
P	Applied indentation loads	10	300	gf
δ	Thickness of the Ni coatings	2	20	μm
j	Current densities	10	50	mA cm^{-2}

 ISBN 978-86-7466-930-3

Using data given in Table II, a regression mathematical model was developed to describe the function between the input parameters and measured response values. The relationship enabling a prediction of the composite hardness (H_c) values of the Ni/brass systems in a function of applied variables (indentation load (P), thickness of the coating (δ) and current density (j) is given by Eq. 1:

$$H_c^{-1}=0.3833+0.0534A-0.11191B-0.024C-0.835AB-$$
$$-0.0391AC-0.033BC-0.0433A^2+0.01374B^2+0.0318C^2 \quad (1)$$

where A, B and C represent numerical factors from Table II corresponding to the input variables, i.e. applied load, coating thickness and current density. Figure 7 shows the dependence of H_c values predicted by the RSM based on the regression model generated by coded Eq. 1 for every combination of two input parameters: applied load, coating thickness and current density (Fig. 7a load and thickness; Fig.7c current density and load; Fig. 7e current density and thickness). Each combination has a positive and statistically significant effect on composite hardness as also revealed by the contour lines presented in Figs. 7b, 7d and 7f. The red color corresponds to high values of composite hardness i.e. dominant influence of the coatings ($H_c \rightarrow 3.4$ GPa), yellow and green correspond to the composite zone and the blue indicates the dominant influence of the substrate i.e. composite hardness approaches to the hardness of the substrate ($H_c \rightarrow H_s$).

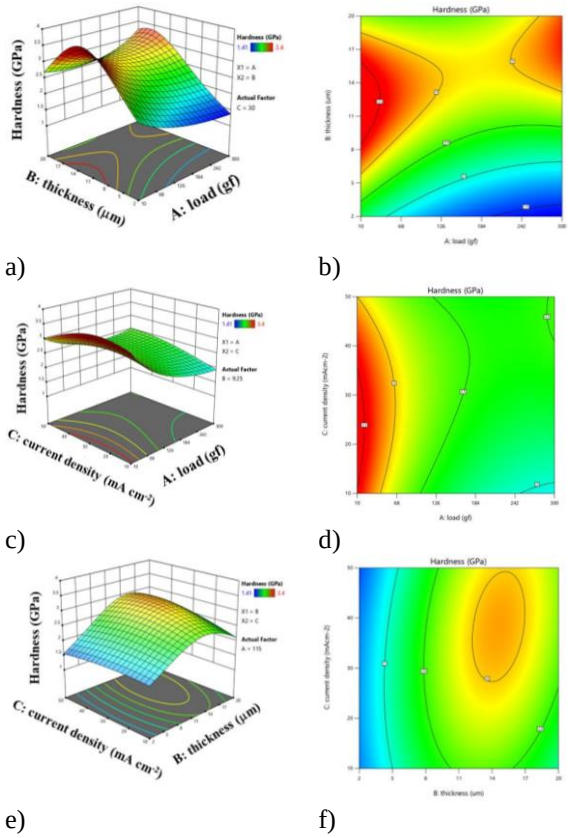

Fig. 7. 3D response surface (left) and contour plot (right) of Ni/brass composite hardness for different coded values: a) and b) of A (indentation load) and B (thickness), c) and d) of A (indentation load) and C (current density), e) and f) for B (thickness) and C (current density).

An increase in current density also indicates an increase in composite hardness value, but for indentation loads corresponding to the "film zone" (up to 50 gf), see Fig. 7d. It can be seen from Fig. 7 that the coating thickness and applied loads have a significant impact on the Ni/brass composite hardness systems. The current density is the least dominant factor in composite hardness change (Figs. 7f).

IV. Conclusion

The parameters suitable for fabrication of hard, compact and uniform Ni coatings on brass substrate were obtained in the direct current regime with magnetic stirring (DC/MS) from lab-made sulphamate electrolyte. Nickel coatings of various thickness were obtained utilizing different current densities. The maximal composite hardness of Ni/brass composite system was achieved for a current density of 50 mA·cm^{-2}, 15 µm coating thickness and with applied indentation load of 50 gf (0.49 N).

Two ways of measuring micro hardness are presented: on the cross-section and the top of surface coating. The measured hardness at the cross-section of depth Ni is higher than composite hardness on top surface. Based on the interfacial indentation test, good adhesion between the coating and the substrate was determined, and no delamination occurred.

Stochastically roughened of electrodeposited Ni thin coatings can be obtained with various methods including mechanical and chemical treatment after electrodeposition process. Based on topographic analysis, it has been shown that each additional treatment after electrochemical deposition introduces an increase in stochastic roughness. That means, after deposition, it is not necessary to treat the surface of the coating before micro indentation.

The RSM optimization of operating parameters for the synthesis of the Ni/brass composite system was applied. Analysis of variance confirmed that the proposed regression model is in good agreement with the experimental data, providing a high determination and adjusted determination coefficients. The results suggested that the used adequate micro indentation loads, as well as the synthesis parameters, can directly affect the material mechanical properties such as composite hardness.

Electrically Programmable Analog Device As An Ultraviolet Light Sensor

Stefan D. Ilić, *Student Member, IEEE*, Milija Sarajlić, *Member, IEEE*, Dana Vasiljević-Radović, *Member, IEEE*, Marko S. Andjelković, Alberto Palma, Russell Duane, and Goran S. Ristić

***Abstract*—Electrically Programmable Analog Device (EPAD) is a commercial semiconductor device based on a floating gate MOS transistor. It is possible to charge the EPADs floating gate with electrons and thus increase the threshold voltage of the MOS transistor. Decapsulation of the ALD1108E integrated circuit containing four EPADs was performed to expose the semiconductor structure to ultraviolet light. By irradiating with different UV light sources, the threshold voltage of an EPAD with a pre-charged floating gate decreases, indicating a possibility for UV radiation detection. The sensitivity of EPAD to the UV light range of 311 to 400 nm was investigated. The floating gate MOS transistor (EPAD), which has a more charged floating gate with electrons, i.e. higher threshold voltage value, shows higher sensitivity compared to EPAD with a lower charged floating gate, i.e. lower threshold voltage value.**

I. Introduction

MEMORIES that remember content even after a power failure are called Non-Volatile Memories. First came the Mask ROM (Read Only Memory) memory, i.e. mask programmed ROM. A whole array of memory cells is formed on the chip in the form of a matrix. Then, according to the user's request, a mask for the photolithographic procedure is created, which defines the openings for drawing the lines of connection between cells and the power supply. Cells that should contain a logic "1" are connected to the power supply (highly doped polysilicon is applied through the opening on the mask to make contact), while cells that should contain a logic "0" remain unbound to the power supply. The Mask ROM stores data permanently, the process is very expensive, and every change requires a change of the photolithography mask.

In order to solve the problem of expensive production, PROM (Programmable ROM) memory is created; here, the data is stored by the user himself with specialized electrical devices. Namely, PROM is produced so that all cells have a logic "1", and they are all connected to the power supply. The interruption of connection lines between individual cells is done by passing a high-density current, which melts the desired line. Once programmed, the PROM cannot be reprogrammed.

The next memory that emerged with technology development is an EPROM (Erasable & Programmable ROM). For the first time, it is possible to delete data, which is done by exposing the memory to UV rays. EPROM is the first memory to have a floating gate (FG) in its structure, and thanks to such a device, it is possible to erase the charge on the pre-charged floating gate and thus change the threshold voltage of the MOS transistor. Decreasing the threshold voltage leads to a change in the logical state of the cell from "0" to "1". The memory is byte-addressable when writing and reading, while the deletion process covers the entire memory. When deleting, the memory chip must be removed from the motherboard and exposed to UV radiation for 20 minutes [1]. The complete deletion process needs to be done even though only one byte needs to be changed.

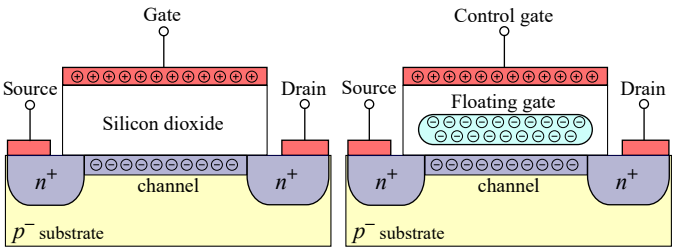

Fig. 1. Left: Cross-section of a MOS transistor. Right: Cross-section of a MOS transistor with a floating gate

Figure 1 shows the structure of a MOS transistor, and the structure of a MOS transistor with a floating gate (FG). During ultraviolet radiation, photons reach the floating gate and generate electron-hole pairs in the vicinity of the floating gate. Due to the electric field that originates from the floating gate, the generated carriers are separated because it is charged with electrons. The holes recombine with the electrons located on the floating gate, and thus the amount of charge is reduced, which leads to a lower threshold voltage value of the MOS transistor.

II. Materials and Experimental Setup

The experiment consisted of irradiating the decapsulated IC ALD1108E [2] with three different types of UV sources. Decapsulation of the ALD1108E integrated circuit is a high-tech process that requires the removal of plastic above the chip so that light can reach the semiconductor device, while the bonds connecting the chip to the package must not be damaged. This process was performed at the Tyndall National Institute, Cork, Ireland. Since decapsulated integrated circuits are extremely sensitive to handling and potential mechanical damage and chip contamination if handled in dirty conditions, the experiment was performed in a cleanroom at the Center of Microelectronic Technologies, Institute of Chemistry, Technology and Metallurgy, Serbia. The number of particles in a cleanroom was controlled using a PCE-PCO 1 particle counter. During the experiment, all measured particle sizes were filtered to zero. The measurement of particles was done in 21 seconds, which corresponds to airflow of 1 litre.

In order to protect the decapsulated chip from mechanical damage during the handling and measurements, special housing for UV experiments made of polylactic acid (PLA) material with a quartz window was designed, as shown in Figure 2.

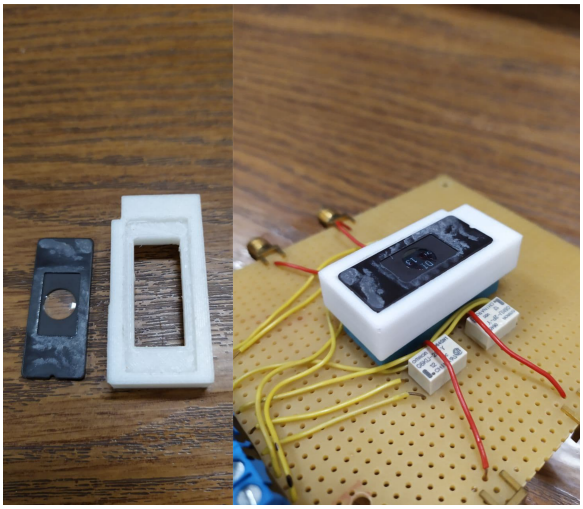

Fig. 2. Left: A quartz window and housing for decapsulated IC made of PLA material. Right: Assembled housing on the IC ALD1108E inserted in the ZIF socket.

The housing was designed in the Solid Edge 2021 Academic version and then fabricated using the Creality Ender 6 Core-XY 3D printer. The decapsulated integrated circuit has a weakened plastic housing and therefore needs to be handled very carefully, especially when inserted into the IC socket. Therefore, an electric circuit for measuring the characteristics of EPAD on the IC ALD1108E with a zero insertion force (ZIF) socket has been designed.

The housing is designed to protect the decapsulated IC from all sides but not to touch the plastic DIP of the integrated circuit due to potential damage to the bonds during handling. Therefore the housing is mounted on the ZIF socket in which the integrated circuit is inserted.

Since it is necessary for UV light to penetrate the housing, a quartz window has been installed to enable this. Old EPROM memories had a quartz window on their package so that UV light could erase the memory, and this gave the idea to the authors to use a quartz window from an old memory from ST Microelectronics.

To ensure that a sufficient amount of UV light passes through the selected quartz window, the transmission of our housing was measured using a UV-Visible Spectrophotometer Evolution 60 from Thermo Scientific, and shown in Figure 3.

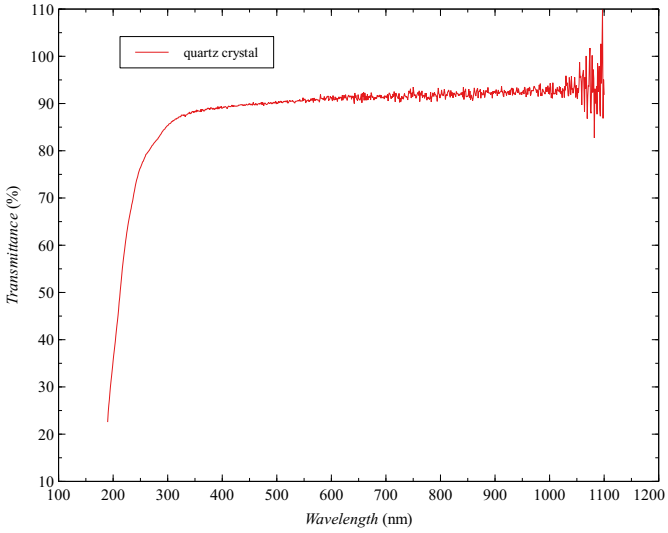

Fig. 3. Transmittance of quartz window mounted in housing made of PLA material.

For a wavelength value of 300 nm, the transmittance is 85% and then increases to 90% for the visible part of the spectrum. The wavelength range for this research is from 300 to 400 nm. The UV light sources used for the purposes of this experiment are: a UV lamp with a 311 nm peak, a UV lamp with a 365 nm peak and a UV LED with a 400 nm peak; their spectrographs are shown in Figures 4 to 6, respectively.

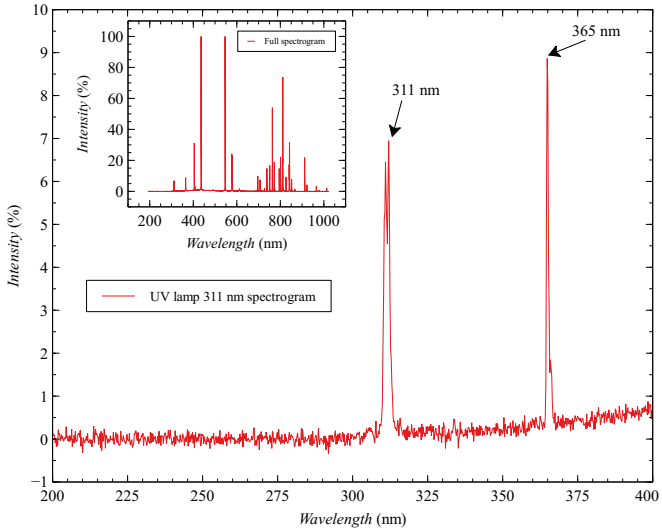

Fig. 4. Spectrogram of UV lamp with 311 nm peak.

 ISBN 978-86-7466-930-3

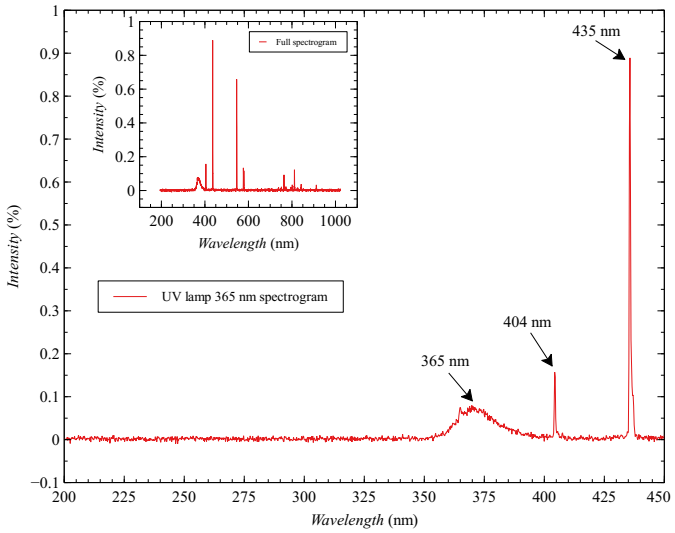

Fig. 5. Spectrogram of UV lamp with 365 nm peak.

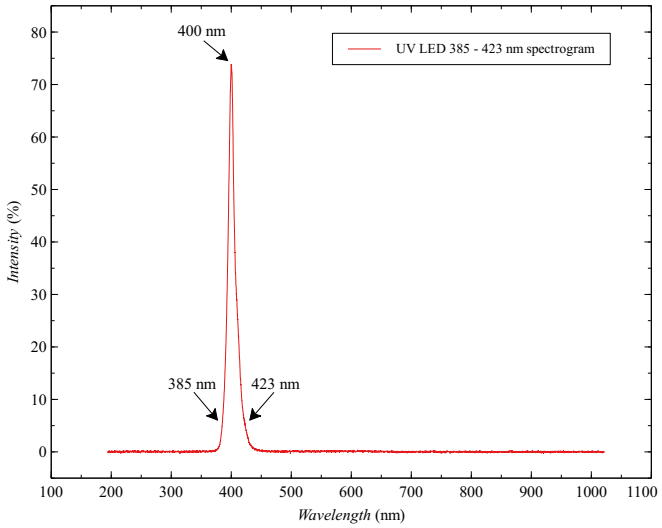

Fig. 6. Spectrogram of UV LED with 400 nm peak.

A UV lamp that emits light with a peak at 311 nm is used for the phototherapeutic treatment of skin diseases by producing vitamin D. As can be seen in Figure 4, this lamp has two peaks in the ultraviolet part of the spectrum at 311 nm and then at 365 nm. Other emitted light is in the visible part of the spectrum.

The following UV lamp used in the experiment has an application as a gel nail dryer. This lamp has only one broad peak in the ultraviolet part of the spectrum at 365 nm, while the others are in the visible part of the spectrum, as can be seen in Figure 5.

The third UV source used in this experiment is a matrix of UV LEDs. The spectrum of this source is clear, unlike UV lamps and has only one peak at 400 nm, at the border of UV and visible light.

III. Results

During the irradiation of the ALD1108E chip, the drift of two floating gate MOS transistors (EPADs) was measured using a Keithley 2636A source measure unit connected to a computer. Drift is monitored at one point of the current-voltage characteristic called the zero temperature coefficient (ZTC) point [3]. Monitoring the change in the drift at this point cancels the influence of temperature on the measurements, which is an essential factor.

ZTC voltage drifts before, during and after UV irradiation for two EPADs with the same value of threshold voltage (initial Vth = 4 V) is shown in Figure 7.

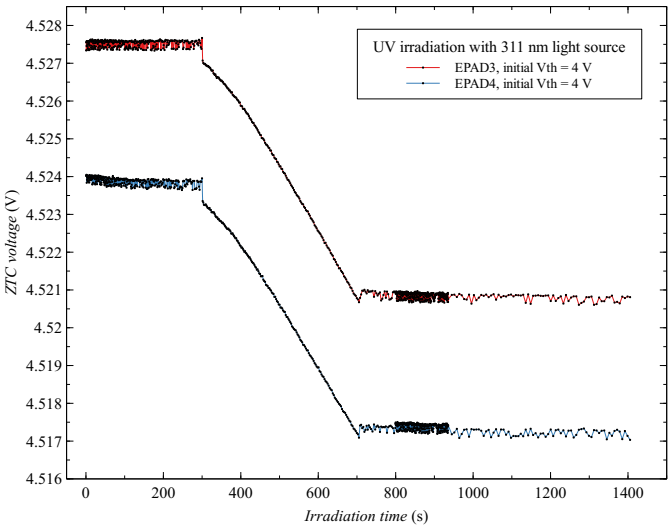

Fig. 7. ZTC voltage drift of EPAD3 and EPAD4 before, during and after UV irradiation of 311 nm light source.

Based on the ZTC point, it is possible to calculate the threshold voltage of the MOS transistor and thus indirectly monitor the threshold voltage but without the influence of temperature because for a fixed temperature (e.g. 25 °), the difference between the threshold voltage value and the ZTC point voltage value is constant. Figure 8 shows the threshold voltage shift during irradiation of two EPADs with a UV lamp of 311 nm peak.

The figure 8 shows EPADs that during the first irradiation had an initial threshold voltage of Vth = 3 V, and during the second irradiation, under the same conditions, EPADs had a threshold voltage of Vth = 4 V. It can be noticed that EPADs have higher sensitivity with higher threshold voltage means with a larger amount of electrons on the floating gate, which can be compared as an analogy to gamma radiation [4]. Also, it is possible to recharge the EPADs floating gate without degradation of its dosimetric characteristics [5].

Figure 9 shows the EPAD threshold voltage shift with the initial threshold voltage value Vth = 4 V.

The weakest response of the EPAD was observed for the UV LED light source, where the threshold voltage shift values are shown in Figure 10.

A linear dependence during irradiation can be observed for all types of UV radiation sources. The same behaviour of this sensor at small threshold voltage shifts was observed

 ISBN 978-86-7466-930-3

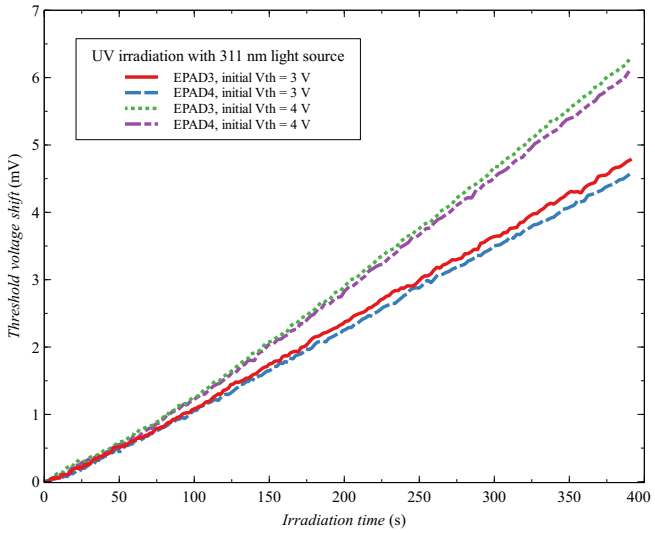

Fig. 8. Threshold voltage shift of EPAD3 and EPAD4 during irradiation of 311 nm light source with different charge on the floating gate.

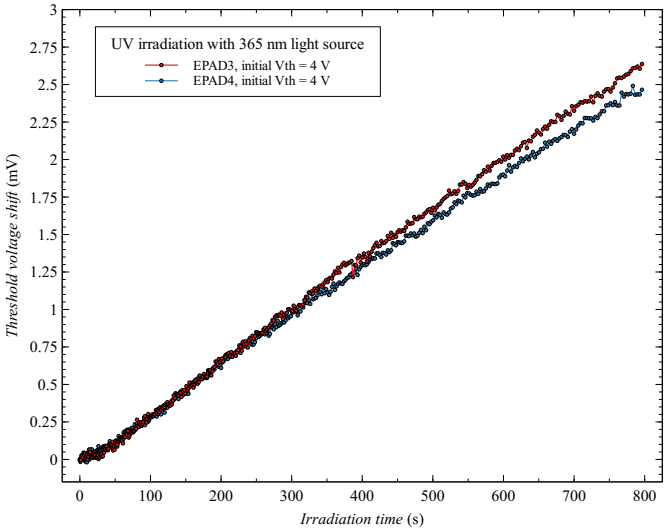

Fig. 9. Threshold voltage shift of EPAD3 and EPAD4 during irradiation of 365 nm light source.

for gamma radiation [4]. These results indicate that it is possible to record UV irradiation with the presented floating gate structure.

IV. Discussion

By analyzing the spectrum of the UV lamp 311 nm in Figure 4 and the spectrum of the UV lamp 365 nm in Figure 5, we can see that both have a peak at 365 nm, which may indicate the possibility that the Vth shift from the first lamp with a peak at 311 nm (presented in Figure 8) originates from the peak at 365 nm. However, the nature of the floating gate device is that the electrons in the floating gate need to receive the minimum energy to surmount the energy barrier (similar to the photoelectric effect), and all photons with minimum or higher energy can decrease the charge on the floating gate and thus reduce the threshold voltage of the transistor

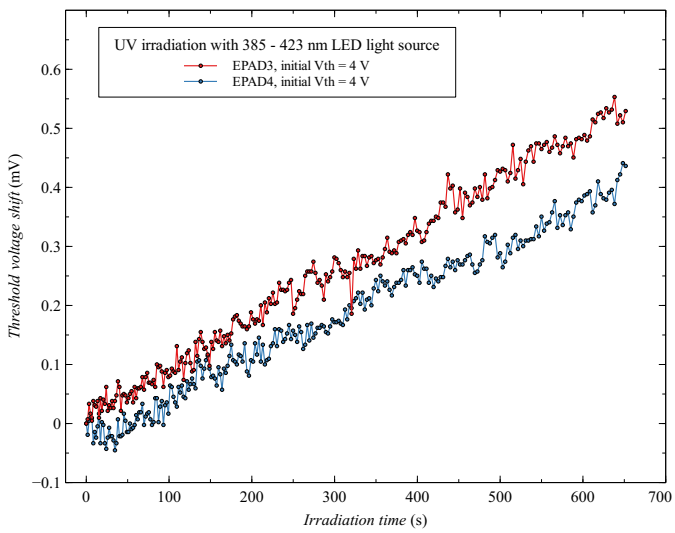

Fig. 10. Threshold voltage shift of EPAD3 and EPAD4 during irradiation of UV LED source.

[6]. This means that all photons with a smaller wavelength of 400 nm (higher energy than 3.09 eV) can decrease the threshold voltage. It is necessary to examine the photon energy limit value of this FG dosimeter in the future.

The UV sensor enables the detection of dangerous wavelengths for human health. The floating gate MOS transistor has good properties as an ionizing radiation dosimeter, so it is possible to use the same component for ultraviolet radiation dosimetry. However, it is necessary to provide a special housing with the quartz window in which the integrated circuit is mounted.

V. Conclusion

The paper presents the possibility of using a floating gate MOS transistor as an ultraviolet sensor. The EPAD has been shown to respond to an ultraviolet radiation range of 311 to 400 nm. A sensor with a floating gate charged with a larger amount of electrons shows higher sensitivity. This component shows promising possibilities for dosimetry of UV radiation for medical purposes such as monitoring the received dose of patients during phototherapy.

Origin of the Open Circuit Voltage and Important Processes that Affect its Value in Organic Solar Cells

Teodora Pavličević, Jovana P. Gojanović, Nataša A. Ćirović and Sandra Živanović, Member, IEEE

***Abstract*—In this paper, the origin of an open circuit voltage (V_{oc}) in organic solar cells (OSCs) and processes which have a dominant impact on it were examined. The measured light current-voltage (*I-V*) characteristics of ITO/PEDOT:PSS/P3HT:PCBM/LiF/Al solar cells fabricated and characterized under similar conditions were collected from literature. The gathered V_{oc} data was statistically processed and 75 % of the results belonged to the range $0.52 - 0.64$ V and obeyed Gaussian distribution. However, 12.5 % results had a value around 0.4 V, and another 12.5 % around 0.48 V. Three *I-V* curves with different V_{oc} values belonging to three observed V_{oc} ranges were simulated by the drift-diffusion model (DDM). By changing the photogeneration, transport, recombination, and extraction parameters, but with the same value of a built-in voltage (V_{bi}), which corresponds to a difference between electrodes work functions, the measured *I-V* curves were excellently reproduced. The experimental light *I-V* curves from literature of solar cells with different polymer blends used as an active layer (PTB7:PCBM, or MDMO-PPV:PCBM) but having the same electrodes and transport layers were also successfully simulated in the same way. Based on our review of published experimental results and our theoretical investigations, we confirm that the difference between electrode work functions is the source of the V_{oc}. The difference between acceptor's lowest unoccupied molecular orbital (LUMO) and donor's highest occupied molecular orbital (HOMO) affects the V_{oc} indirectly through photogeneration, transport and recombination parameters, and extraction efficiency.**

***Index Terms*— Organic solar cells; open circuit voltage; drift-diffusion model.**

INTRODUCTION

Organic solar cells (OSCs) have been getting a great deal of attention due to their potential as low-cost, simply processed and environment-friendly photovoltaic devices [1]. An improvement of OSCs is demonstrated through an increase in their power conversion efficiency (PCE), the most important performance parameter. So far, the PCE has reached value of 18 % for a single-layer OSC, 12 % for organic photovoltaic modules and even 23.6 % for perovskite/organic tandem solar cells [2–4]. Although these results are commendable, a further progress in properties of active layer blends, and an improvement of OSCs' long-term stability are seen as a path to their commercialization [5].

To reach a full potential of OSCs, we need to clarify their basic working principles. Knowledge of OSCs physics would help us to single out the basic prerequisites for an efficient photoconversion and identify loss mechanisms. However, research so far was not focused much on elucidating physics but rather on increasing OSCs efficiency through new donor and acceptor materials to improve the photoconversion in the active layer, as well as through new transport layer materials to maximize the charge carrier collection [5,6]. The metal-semiconductor-metal (MSM) drift-diffusion model (DDM) [7] has been widely used for modeling the OSCs. This model is successful to a certain extent, but it is not able to reproduce the experimentally observed OSCs behavior to a full extent. Thus, a refinement of the DMM for OSCs has yet to be done by clarifying vague parts of it.

One of the parameters with unclear origin that directly affects the OSC's PCE is an open-circuit voltage (V_{oc}). There are many presumptions about processes that influence the V_{oc} and how they can be correlated [1]. Frequently, the V_{oc} is defined as $e \cdot V_{oc} = (E_g - 0.3)$ eV, where E_g is an active layer energy gap determined as a difference between the highest occupied molecular orbital level (HOMO) of the donor and the lowest molecular orbital level (LUMO) of the acceptor, and e is the elementary charge [8]. Trying to resolve 0.3 V voltage loss in the V_{oc} and other aspects of the V_{oc} behavior, many factors have been found that directly or indirectly have impact on it [1]. These include temperature, light intensity, active layer morphology, microstructure, recombination processes, quality and properties of donor/acceptor (D/A) interface area, density of states (DOS), electrode work functions, existence of charge transfer (CT) states, carrier density, reverse saturation current, defect states, and crystallinity [1]. All these factors are interrelated, and for a complete analysis of the V_{oc} all of them should be considered. The V_{oc} dependence on temperature and light intensity are most often researched and analyzed in the literature [9, 10]. It was found that the V_{oc} decreases as temperature increases, and for a wide temperature range that dependence is nearly linear [9]. On the other hand, the V_{oc} showed a logarithmic dependence on light intensity [10]. The reverse saturation current is one of the important parameters that influences the V_{oc}, and it was found that the V_{oc} is inversely proportional to it [11]. The influence of the charge carrier recombination on the V_{oc} was described through a correlation between the V_{oc} and the recombination rate [12] that differs for different recombination types – monomolecular, bimolecular or their combination. The monomolecular recombination implies a recombination through a recombination center or a trap state, while the bimolecular recombination indicates that holes and

 ISBN 978-86-7466-930-3

electrons are mutually recombined [12]. Higher recombination rates mean a reduced number of carriers and eventually a smaller V_{oc} [12]. A lower carrier density leads to a decreased V_{oc}. The improvement of the microstructure can minimize recombination rates, improve carrier dynamics, and benefit the V_{oc} [13]. Defect states introduce irregularities into the material structure, and thus energy disorders and a reduced crystallinity. In organic materials, these disorders are usually modelled via the Gaussian or exponential DOS, and it was shown that they degrade the performance of OSCs by degrading the V_{oc} [14]. Losses in the V_{oc} are also related to a non-radiative decay of the CT states on the D/A interface [15]. The impact of the morphology is mostly related to the quality of D/A interface (e.g., whether it is homogenous or not) [15]. In addition, it was shown that a reduction of the D/A interface area can contribute to a higher V_{oc} [16]. One of the most debatable matters is the influence of electrode work functions on the V_{oc}. It was shown that if the Fermi levels are well inside the energy gap of the active layer polymer-fullerene blend, the V_{oc} is strongly affected even by a small variation of each electrode work function [17]. However, if the anode work function is close to the donor's HOMO and the cathode work function is close to the acceptor's LUMO, the V_{oc}value reaches a plateau and is less sensitive to work functions variations [17]. In this case, the device operation is the most effective [17].

To investigate the origin of the V_{oc} and analyze important processes which affect its value, we have collected measured light current-voltage (*I-V*) characteristics of ITO(indium tin oxide)/PEDOT(poly(3,4-ethylene dioxythiophene):PSS(poly(styrenesulfonate)/ P3HT (poly(3-hexyl-2,5-dimethylthiophene):PCBM([6,6]-phenyl-C_{61}-butyric acid methyl ester)/LiF(lithium fluoride)/Al solar cells fabricated and characterized under nearly same conditions available in the literature [19-40]. We statistically processed the collected V_{oc} data and analyzed the obtained distribution function by determining its mean value and standard deviation. Three *I-V* curves (each with a representative and significantly different value of V_{oc}) were selected and simulated by the DDM. Viewing the OSC as an MSM structure, the built-in voltage (V_{bi}) was taken to be the difference between the two electrode work functions. The *I-V* characteristics with different V_{oc} values were successfully simulated by varying the reduction factor of the Langevin bimolecular recombination rate and by changing the effective density of states (N_c, N_v) at boundaries.

To inspect the influence of E_g on V_{oc}, two more solar cells with the same electrode contacts but different active layer polymer-fullerene blends, PTB7 (poly [[4,8-bis[(2-ethylhexyl)oxy]benzo[1,2-b:4,5-b′] dithiophene-2,6-diyl][3-fluoro–2-[(2-ethylhexyl)carbonyl]thieno[3,4-b] thiophenediyl]]):PCBM [41] and IMDMO-PPV (poly[2-methoxy-5-(30,70-dimethyloctyloxy)-1,4-phenylenevinylene]):PCBM [42] were considered. Their measured *I-V* characteristics obtained from literature were successfully fitted with the DDM by varying active layer transport and recombination parameters together with the N_c, and N_v at the boundaries. Based on the statistically processed experimental V_{oc} data and our DDM *I-V* curve simulations, we confirm that the V_{oc} originates from the difference of electrode work functions and that the contact phenomena and the recombination losses have the greatest impact on its value.

Open Circuit Voltage in ITO/PEDOT:PSS/Polymer-Fullerene Blend/LiF/Al Organic Solar Cells

A. Review of Experimental Data

We started the investigation of the V_{oc} in OSCs by choosing one of the most researched device structure ITO/PEDOT:PSS/P3HT:PCBM/LiF/Al. This OSC structure is used as a reference in a large number of experimental research papers aimed at improving the OSC performance. The performance parameters for considered OSCs together with fabrication and characterization conditions are presented in Table 1. The gathered V_{oc} data are statistically processed and graphically presented in Fig. 1. The three distinct V_{oc} ranges are observed (see Fig. 1). The dominant range contains 75 % of collected data. Two smaller ranges each contain 12.5 % of the V_{oc} results. The largest number of collected V_{oc} values belongs to the 0.52–0.64 V range and the data follows the standard Gaussian distribution with the expected value $\mu = 0.58$ V and the standard deviation $\sigma = 0.024$ V. The V_{oc} values in the range of 0.46–0.48 V are mostly obtained for the devices illuminated by 3 sun (see Table 1), where 1 sun corresponds to standard illumination at AM1.5, or 1 kW/m^2. The V_{oc} of about 0.40 V is obtained mainly for the OSCs in which P3HT:PCBM active layer is produced from chloroform solution rather than from chlorobenzene solution (see Table 1).

According to the literature [17, 18], if injection barriers at electrode contacts are significant (i.e., rectifying junctions), the V_{oc} is defined as the difference between electrode work functions, while for optimised devices with Ohmic contacts, the V_{oc} is interpreted as the difference between the LUMO of the acceptor and the HOMO of the donor (i.e., with a mysterious loss of 0.3 V). From Fig. 1, it is clear that even for the OSCs with the same electrodes and the same D/A polymer-fullerene blend, a wide distribution of the V_{oc} values exists. This led us to the conclusion that the active layer photogeneration, transport and recombination parameters, as well as the charge extraction efficiency differ in the considered devices probably due to a different quality of the active layer, hole and electron transport layers and electrode junctions.

Additionally, the OSCs with PTB7:PCBM or MDMO-PPV:PCBM active layers with the same electrodes (ITO, Al) and transport layers (PEDOT:PSS, LiF) were examined. Although $E_g^{MDMO-PPV:PCBM} < E_g^{P3HT:PCBM}$ [35] and $E_g^{PTB7:PCBM} > E_g^{P3HT:PCBM}$[43], the V_{oc} values obtained for these devices ($V_{oc}^{MDMO-PPV:PCBM} = 0.82$ V, and $V_{oc}^{PTB7:PCBM} = 0.75$ V) are larger than any $V_{oc}^{P3HT:PCBM}$ from Table 1. Thus, we proposed that the difference between the acceptor LUMO and the donor HOMO is not crucial for the V_{oc}, but rather the parameters of photogeneration, transport, recombination, and extraction.

B. Drift-Diffusion Modeling

It has been shown that photoconductive polymer-fullerene blend placed between identical electrodes fabricated under the same environment, does not exhibit a rectifying effect and their V_{oc} is zero [44–46]. This means that the D/A interface in polymer-fullerene blends does not contribute to the built-in voltage. Accordingly, the direct source of the V_{oc} in OSCs is the difference between the electrode work functions. The difference between the acceptor's LUMO and the donor's HOMO level influences the V_{oc} indirectly through the Fermi-level pinning [47], photogeneration, transport and recombination parameters, or extraction efficiency. In this paper, the metal-semiconductor-metal DDM was used for modeling the *I-V* characteristics of several OSCs. The model is based on the Poisson's equation, the hole and electron continuity equations, and the drift-diffusion transport equation for holes and electrons inside the active layer [48]. The photogeneration rate was calculated by using the transfer matrix theory and by assuming that the electric field is independent of the exciton dissociation efficiency [48]. Constant hole and electron mobilities were applied, and a reduced Langevin recombination was proposed. The Dirichlet boundary conditions were used. The solving of the equations system was done based on the finite difference discretization improved by the Scharfetter and Gummel approach and the Newton algorithm [48]. In all our calculations, a built-in voltage V_{bi} of 0.9 V as the difference between the electrode work functions was used along with the dielectric permittivity of 3.4 and the room temperature of 293.9 K.

The light *I-V* characteristic of three ITO/PEDOT:PSS/P3HT:PCBM/LiF/Al devices with $V_{oc} = 0.40$ V [21], $V_{oc} = 0.48$ V [24], and $V_{oc} = 0.59$ V [27] were simulated and compared with the measured ones in Fig. 2 (a), (b), and (c), respectively. The parameter values used in simulations are listed in the Insets of Fig. 2, where $\mu_{n(p)}$ is the electron (hole) mobility, $N_{c(v)}$ is the effective density of states for electrons (holes), d is the active layer thickness, g is the photoconductive gain [49], and ξ is the reduction factor of the Langevin recombination rate [50]. All three measured *I-V* curves are reproduced very well by the DDM, which means that the difference in the photogeneration (g), transport (μ_n, μ_p), recombination (ξ) and extraction (N_c, N_v) parameter values may explain the observed V_{oc} diversity (see Table 1, Fig. 1). The occurrence of the photoconductive gain may be explained through a volume modulation effect, where the light illumination can increase the conductive area of the cell, thus, the generated photocurrent becomes larger [51]. The N_c and N_v are used as the boundary majority charge carrier concentrations at cathode and anode, respectively, and they are the fitting parameters in the OSCs modeling of Koster et al. [7].

These parameters are representatives of contact physics in OSCs and they have a large impact on the V_{oc}. The reduction of recombination losses in OSCs quantified by ξ leads to an improvement of the V_{oc}. In most OSCs, $\xi \leq 0.2$ [52], and its higher value indicates that CT states are significant in polymer-fullerene blend and that they recombine very rapidly. The existence of CT states and their participation in the charge carrier photogeneration and recombination [7] was not considered in our DDM. Therefore, $\xi > 1$ is possible in our simulations. A higher electron mobility leads to a lower V_{oc} [53], and an increased hole mobility slightly improves the V_{oc}.

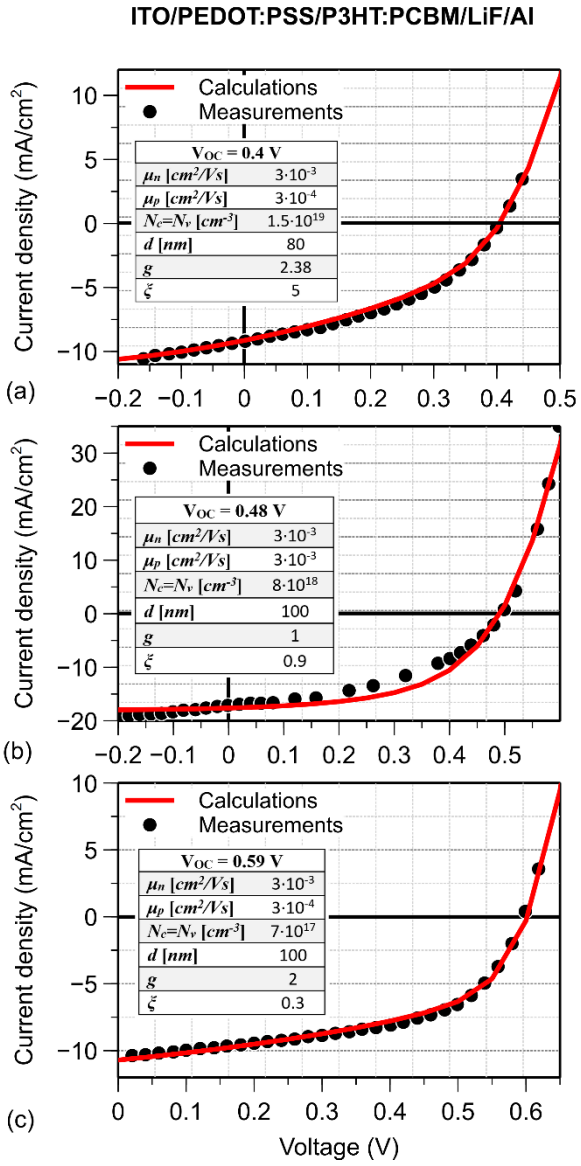

Fig 2. DDM simulated *I-V* curves compared to experimental ones taken from (a) Ref. [17], (b) Ref. [33], (c) Ref. [25]. The corresponding simulation parameters are given in the Insets.

In Figs. 3, and 4, calculated light *I-V* characteristics for the PTB7:PCBM and MDMO-PPV:PCBM based solar cells are compared with the measured ones. The simulation parameters are given in the Insets of Figs. 3, and 4.

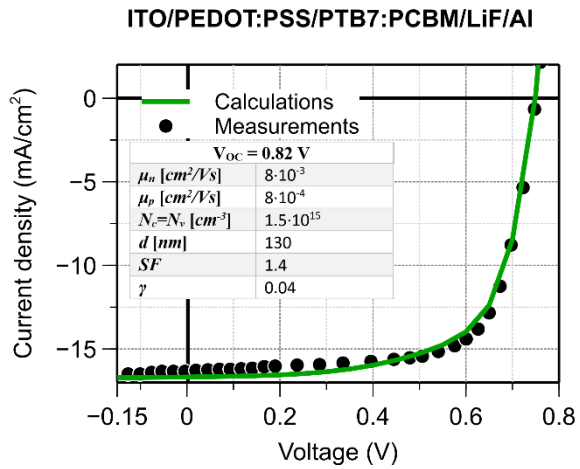

Fig. 3 DDM simulated *I-V* curve compared to experimental one taken from Ref. [39]. The corresponding simulation parameters are given in the Inset.

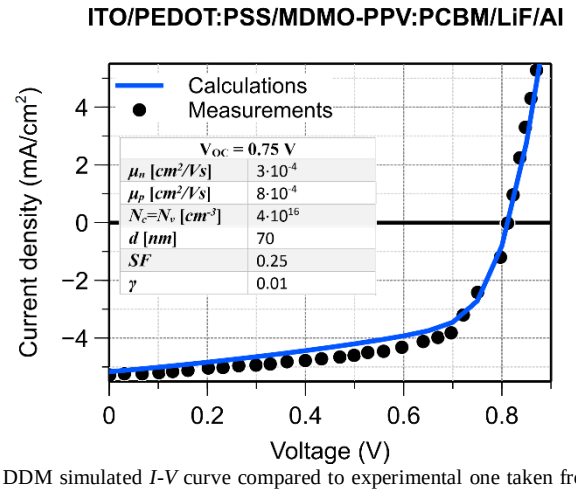

Fig.4 DDM simulated *I-V* curve compared to experimental one taken from Ref. [33]. The corresponding simulation parameters are given in the Inset.

Again, the experimentally obtained and theoretically predicted *I-V* curves coincide very well. This proves that even if a D/A polymer blend in an OSC is changed, the V_{oc} can be reproduced by tuning of parameters $g, \mu_n, \mu_p, N_c, N_v$, and ξ.

CONCLUSION

The experimental light *I-V* data extracted from literature showed that the V_{oc} can significantly differ for ITO/PEDOT:PSS/P3HT:PCBM/LiF/Al solar cells produced and tested under similar conditions. Three measured light *I-V* characteristics with $V_{oc} = 0.4$ V, $V_{oc} = 0.48$ V, and $V_{oc} = 0.59$ V were successfully reproduced by our DDM simulations by applying the same value of $V_{bi} = 0.9$ V corresponding to the difference between the LiF/Al and the ITO/PEDOT:PSS work functions, while the charge carrier photogeneration, transport, recombination, and extraction were varied. For the OSCs based on the PTB7:PCBM or MDMO-PPV:PCBM polymer-fullerene blends, our DDM simulations were, again, able to reproduce the measured *I-V* curves well. We concluded that the difference between the work functions of the electrodes is the source of the V_{oc} in OSCs and the difference between the acceptor's LUMO and the donor's HOMO influences the V_{oc} through charge carrier photogeneration, recombination, transport, and extraction. These processes have a significant impact on the V_{oc} value. Future work will be dedicated to research of how the LUMO and HOMO energy levels of the polymer-fullerene D/A blend as well as the CT states formed at the D/A interfaces influence the V_{oc}.

Design Consideration for Low-Power Step-Up Converter

Jana Vračar, *Student Member, IEEE*, Milan Stojanović, *Student Member, IEEE*, Zoran Prijić, *Member, IEEE*, Aneta Prijić, *Member, IEEE* and Ljubomir Vračar

***Abstract*— This paper describes the comparison of different MOSFETs and transformers used in a step-up circuit under initial voltages of 50 mV and 100 mV. Two MOSFETs, BSP149 and CPC3701CTR, and two transformers, CST-100LC and MID-SNS CS, were cross-connected, and the results of charging a 2200 µF capacitor were shown. This circuit consists of a Meissner oscillator and a voltage doubler circuit. Experimentally, the time it takes for different MOSFETs and transformers to increase the voltage and charge the capacitor at the circuit's output was measured, as well as the maximum output voltage generated by the circuit, and the resonant frequency for each of the given pairs of MOS transistors and transformers.**

***Index Terms*—step-up converter, transformers, MOSFET, power management.**

I. Introduction

In recent years, the WSNs technology create more interest in researching from macro to micro-level to develop systems without using conventional power supplies and exploring alternative power sources for WSNs (Wireless Sensor Nodes). Energy harvesting is a viable option for replacing low-power devices batteries or power supply. Energy harvesting necessitates the collaboration of three distinct technologies. For developing systems based on energy harvesting, there must be three separate technologies combined in working together: energy harvesters - used to convert ambient energy into electrical energy, power management - for amplifying and regulating the generated energy and energy storage - for powering low power consumption systems, such as sensors, actuators, microcontrollers, RF transceivers, etc. [1].

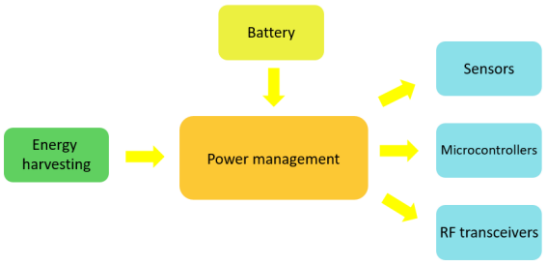

Fig. 1. Block scheme of energy harvesting system.

The block diagram of this kind of system is shown in Fig. 1. Low voltage and ultra-low power circuit design have become increasingly important recently. Low-power systems, such as those used in energy harvesting systems, wearable electronic devices, autonomous sensor nodes powered by non-conventional energy sources, the Internet of Things, and other similar applications, may require even lower supply voltage [2].

II. Voltage Step-Up Circuit and Experimental Setup

A. Voltage step-up circuit

For the supply of an embedded system, it is required to employ an electrical boost converter to boost the harvested voltage to a voltage of higher values. When used in combination with energy harvesting, a step-up converter should be self-starting from as low as feasible input voltages without the usage of additional power. A low-voltage start circuit with an oscillator followed by a voltage multiplier is used to meet these design constraints. The electric circuit of a step-up circuit is shown in Fig 2.

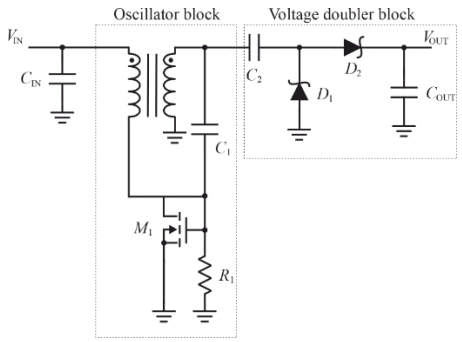

Fig. 2. Electric circuit of a voltage booster without energy harvesting block

 ISBN 978-86-7466-930-3

The minimal input voltage may be amplified significantly by changing the input DC energy into an AC form via an oscillator, then converting it back to DC with a boosted level by a voltage multiplier [3]. The oscillator block in this paper consists of a Meissner oscillator. It is needed to have an appropriate step-up ratio and have an adequate power conversion efficiency also.

At low input voltages, with the appropriate selection of MOS transistors and transformers, the Meissner oscillator begins to oscillate. If the input voltage is high enough, it undergoes a transition from its linear into a non-linear operation regime. The Meissner oscillator serves as a start-up circuit providing the supply voltage for a separate, inductor-based step-up converter from an input voltage of 50 mV and 100 mV for this experiment, followed by a voltage doubler circuit. When comparing different step-up converters, the parameters of start-up voltage and self-supply, as well as the employed circuit idea, are key factors to take into account. Low-voltage step-up converters are a popular subject of research, and of course, there are commercially produced devices. These converters have start-up voltages as low as 20 mV in some cases [4]. The capacitor C_2, which is part of the voltage doubler circuit, influences the maximum output current value. When utilizing a transformer with a ratio of 1:100 and working from very low input voltages, a minimum value of 1 nF is advised [4]. When operating at low input voltage or with high resistance sources, a large capacitor value may affect circuit performance. In this circuit, the gate coupling capacitor C_1 is employed. When the input voltage surpasses 50 mV, the capacitor's voltage value capacitor is increased to the point where oscillations occur rapidly. The experimentally established value for capacitor C_1 is 4.7 nF. Because of resistor R_1, the circuit's oscillations start consistently. The resistor R_1 of 2.2 MΩ is the predefined value. Schottky diodes are being used in this circuit for the voltage doubler (D_1 and D_2). The selected diodes have better frequency response and lower forward voltage than standard Si diode due to the lower forward voltage, and that is the reason for their implementation in this circuit. The energy is stored in the electrolytic capacitor C_{OUT}, which has a capacitance of 2200 μF. The choice of transformer is crucial in the circuit design process, and it will be considered in the experimental setup. High quality factor Q, compact footprint area, and high turns ratio are the main characteristics of the transformer for low voltage step-up oscillators. The step-up oscillator is coupled to the voltage source that drives the current through the primary trnasformer winding L_1 and the depletion-mode MOSFET. This current causes a positive voltage to be induced on the secondary transformer winding L_2, which raises the gate voltage of transistor M_1 and hence the primary winding current. The secondary winding voltage begins to diminish when this current reaches core saturation. The transistor begins to switch off the current via the transformer's main winding, resulting in a voltage reversal at the secondary winding and a negative gate voltage. The transistor is promptly turned on and remains active until the primary winding current reaches saturation, at which point the oscillation process restarts. The signal from the step-up oscillator is received by a half wave voltage doubler (V_{OSC}). In the voltage doubler circuit, capacitor C_2 and diode D_1 create a clamp, while the diode D_2 and capacitor C_{OUT} create a peak rectifier. Diode D_1 conducts during the negative half cycle of an input voltage signal, charging capacitor C_2 to the voltage $V_{C2}= V_{D1}-V_{OSC}$. Diode D_1 is turned off during the positive half cycle of the input signal, while diode D_2 conducts charging capacitor C_{OUT} [5]. The output voltage will be:

$$V_{OUT} = V_{OSC} - V_{C2} - V_{D2} = 2(V_{OSC} - V_D) \quad (1)$$

B. Experimental setup

The major purpose of this study is to see how different pairings of transformers and transistors affect the generation of output voltage in the stated circuit, depending on whether a 50 mV or 100 mV voltage is provided to the circuit's input. The BSP149 and CPC3701CTR NMOS depletion mode transistors were used for the experiment. Since of its negative threshold voltage (V_{th}), the depletion mode n-type MOSFET BSP149 (M_1) was chosen because it is in a normally-on state at low voltages [6]. The transistor's low drain-source on-state resistance, which ranges from 1.7 Ω to 3.5 Ω, is the transistor's second advantage.

The CPC3701CTR transistor has lower drain-source on-state resistance of 1 Ω than transistor BSP149 [7]. The drain-source on-state resistance is an important characteristic of the depletion mode n-type MOSFET for the reason that this resistance affects power loss, and can be calculated as:

$$R_{DS(ON)} = \frac{1}{\mu_n \cdot C_{OX} \frac{W}{L}(V_{GS} - V_{th})} \quad (2)$$

where is μ_n – carrier mobility, C_{OX} – oxide capacitance, W – channel width, L – channel length, V_{GS} – gate-source voltage, and V_{th} – threshold voltage.

As previously noted in the paper, the micro transformer with a ratio of 1:100 was chosen. For this experiment, transformers from different manufacturers were taken, but with similar characteristics and the same transformation ratio. The first transformer is CST-100LC, which has an inductance of 2 mH and a resistance of 5 Ω [8], while the second is a MID-SNS-CS with an inductance of 5.6 mH and a resistance of 0.85 Ω [9].

Since it is necessary to use a pair of transistor and transformer in the circuit, based on an input voltage of 50 mV in the first case and 100 mV in the second, it was decided to test all possible transistor and transformer combinations and then compare the output values of various parameters. These combinations are BSP149 MOSFET and CST-100LC transformer, BSP149 MOSFET and MID-SNS CS transformer, CPC3701CTR MOSFET and CS-100LC transformer, and CPC3701CTR MOSFET and MID-SNS CS transformer.

The expected results are that the MOS transistor CPC3701CTR in combination with some of the transformers can generate the highest output voltage since it has better characteristics than the BSP149 transistor, specified in the datasheet.

 ISBN 978-86-7466-930-3

III. Results and Discussion

The input voltage V_{IN} simulates the generated voltage given by one of the energy harvesting block. In this case, DC voltage input is generated by a voltage supply at 50 mV and 100 mV instead of an energy harvesting voltage source. Fig. 3 shows the time that elapsed until the voltage on the capacitor reached 3.3 V and 5 V. The result of this measurement shows that the CPC3701CTR MOSFET and CST-100LC transformer take the longest time to generate specified output voltages. The shortest time to generate these values of voltage is measured for CPC3701CTR MOSFET and MID-SNS CS transformer, which indicates that they are the most efficient MOSFET-transformer pair in this research.

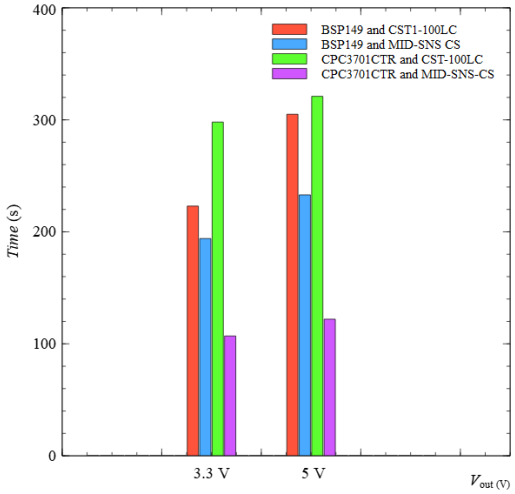

Fig. 3 Measured time for generating 3.3 V and 5 V on the output capacitor C_{OUT} (2200 µF) for different pairs of transformers and MOS transistors.

Fig. 4 shows the maximum output voltage at the capacitor C_{OUT} when the circuit reaches a steady-state and the given results are for 50 mV and 100 mV of the input voltage.

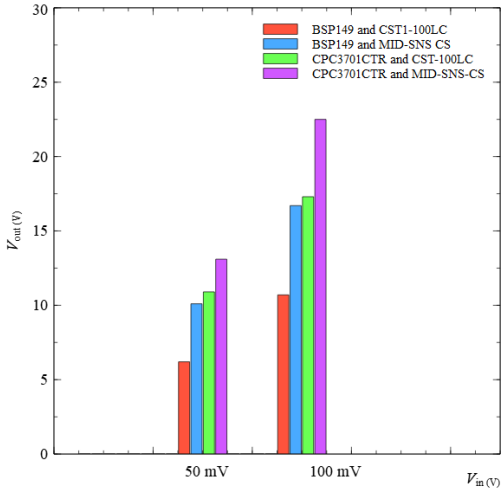

Fig. 4 Maximum generated output voltage on the capacitor C_{OUT} for different pairs of transformers and MOS transistors at the input voltages of 50 mV and 100 mV.

It is measured that CPC3701CTR along with MID-SNS CS transformer can generate the biggest output voltage at the capacitor C_{OUT}, and the lowest produced voltage in these combinations of MOSFETs and transformers is for BSP149 MOSFET in pair with CST-100LC transformer. For the stated measurements, the best performances of the MOSFET-transformer pair are for the CPC3701CTR MOSFET and MID-SNS CS transformer, as expected. The resonate frequency of each MOSFET-transformer pair is presented in Fig 5. The highest resonating frequency is measured for CPC3701 MOSFET and CST-100LC transformer, and the lowest resonating frequency is measured for BSP149 MOSFET with MID-SNS CS transformer. Fig. 6 – Fig. 9 represent the output voltage generation for all of the measured MOSFET-transformer pairs, at the initial voltage of 100 mV, captured by the Tektronix DPO4034 oscilloscope.

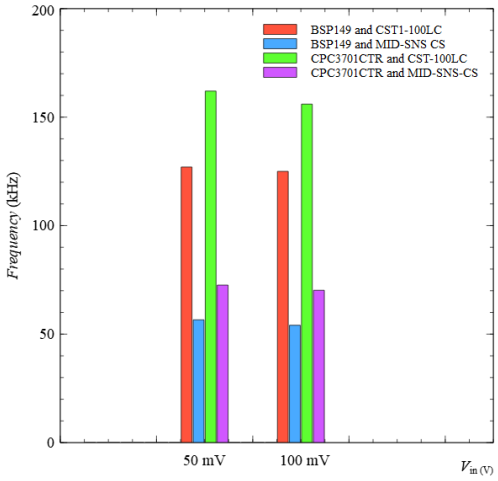

Fig. 5 Measured resonant freaquency for generating 3.3 V and 5 V on the output capacitor (2200 µF) for different pairs of transformers and MOS transistors.

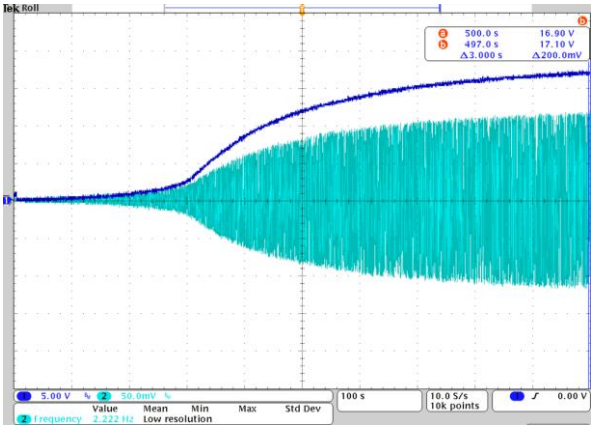

Fig. 9 CPC3701CTR MOSFET and MID-SNS CS transformer pair: The oscillator voltage (light blue) and the voltage at the output capacitor C_{OUT} (deep blue) as a function of time for the initial voltage of 100 mV. X-axis: 100 s/div, Y-axis: 5 V/div for V_{OUT} and 50 mV for V_{OSC}.

IV. Conclusion

It is a great challenge to choose the components that will provide the highest efficiency of the power management circuit, but it is one that must be addressed depending on the purpose of the circuit behind the power management block. Depending on that, it is necessary to pay attention to how the components affect the power loss, which ones generate the highest output voltage, which ones reach a certain value of the output voltage for the shortest time, etc. This paper shows how different transformers and MOS transistors affect all of the parameters stated above, and it is possible to choose a pair depending on the needs of the circuit powered by such a system. In terms of generating the highest possible output voltage on the C_{OUT} capacitor it is best to use a CPC3701CTR MOSFET with a MID-SNS CS transformer, for a lower input voltage at 50 mV but at 100 mV as well. If the user needs a power management circuit that generates an output voltage in the shortest time, the best option is a pair of CPC3701CTR MOSFET and a MID-SNS CS transformer. The pair of a CPC3701CTR MOSFET and CST-100LC transformer is the second-best for generating maximum output voltage, but it needs the longest time to generate the desired voltage. In the future, this type of step-up converter will be improved by adding and testing additional components to the circuit in order to give the shortest time for the oscillation process.

Osnovi teorije diferencnih jednačina sa primenom na analizu svojstava nanostruktura

Akademik, prof. dr Jovan P. Šetrajčić,
prof. dr Vjekoslav D. Sajfert i prof. dr Siniša M. Vučenović

***Apstrakt*— Trend naglog razvoja nanotehnologija je uzrokovan otkrićima da nanostrukture poseduju fizičke karakteristike koje se znatno razlikuju od istih koje poseduju strukture velikih dimenzija (balk). Nanostrukture karakteriše i serija kvalitativno sasvim novih i izmenjenijih efekata. Npr. superkonduktivne, termoizolacione, akustičke i druge osobine koje karakterišu nanomaterijale su bolje ili sasvim drugačije od onih u balk-strukturi. Posebno je intrigantna potencijalna primena u inoviranoj farmaciji i medicini uopšte. Na neki način nanostrukturni efekti su povezani sa efektima u masivnoj strukturi slično kao što su povezani kvantni i klasični efekti. Teorijsko izučavanje balk-stuktura uglavnom zahteva rešavanje diferencijalnih jednačina sa kontinualnim promenljivama. U istraživanju mehanizama u nanostrukturama, koji su vinovnici drastičnih izmena njihovih svojstava, pojavljuju se diferencne jednačine, ali sa koeficijentima koji zavise od prostornih koordinata zbog neophodnosti da se obračunaju dimenzioni – kvantni i granični (konfajnment) uslovi, kao i uticaj vakancija i primesa. Zbog tog uvećanog interesovanja i velikih iščekivanja za korist od novootkrivenih efekata, a posebno zbog nerazvijene teorije, mi smo ovde izložili teoriju koja ima za cilj da prezentuje tehniku izračunavanja diferencnih jednačina i da to demonstrira na seriji primena u analizama različitih – otkrivenih i još neotkrivenih fizičkih svojstava nanostruktura.**

***Ključne reči*—diferencne jednačine; dimenziona kvantizacija, konfajnment efekti, fizička svojstva nanostruktura.**

I. Uvod

Fizika nanostruktura doživljava intenzivan razvoj i predstavlja jedan od udarnih frontova istraživanja u savremenoj fizici [1–5]. Osnovni matematički instrument teorijskih proračuna osobina nanostuktura je diferencni račun. U skladu sa ovim, ovu prezentaciju posvećujemo diferencnom računu i njegovoj primeni na analize struktura sa narušenom translacionom simetrijom.

Osnovni trend ovde je isticanje operacionih računskih moći diferencnog računa. Zbog toga su i pri izlaganju osnova diferencnog računa i u nizu njegovih primena na nanostrukture, najčešće korišćeni translacioni operatori. Preko njih se najbrže dolazi do željenog rezultata. Udarni deo izlaganja je, zbog toga, posvećen isključivo diferencnom računu i on je operativan, bez matematičkih fundamenata tipa korolara, teorema i komplikovanih dokaza (koji se mogu naći u literaturi, npr. [6–11]).

Manji deo sadrži primene diferencnog računa u analizi fizičkih pojava u sistemima sa narušenom simetrijom, tačnije primenu te metodologije na ispitivanje nanostruktura koje su translaciono invarijantne. Uglavnom je korišćen metod Grinovih funkcija (GF) zbog toga što je ovaj metod samousaglašen, tj. on rešava i dinamiku i termodinamiku problema.

Treba naglasiti da je ovde razvijena posebna metodologija izračunavanja GF u uslovima narušene simetrije, pri čemu ovo narušenje simetrije može biti duž jednog, dva pravca i duž sva tri prostorna pravca. Problem izračunavanja GF struktura sa narušenom simetrijom je u tome što one zavise od prostornih promenljivih ponaosob, a ne od njihove razlike, kao što je to kod struktura idealne simetrije, gde GF zavisi od razlike prostornih promenljivih, a zbog homogenosti sredine pri računima se može koristiti zakon održanja impulsa [12–14]. Ovaj zakon ne važi za strukture sa narušenom simetrijom, što unosi glavnu matematičku poteškoću. Ovde je to prevaziđeno reprezentacijom stojećih talasa za Kronekerov simbol, umesto ravnih talasa kao za analize balk-struktura.

Jedan od najznačajnijih uspeha u analizi narušene simetrije u strukturama sa vodoničnim vezama je objašnjenje Krik-Votsonove teorije [15] o raspadu DNK dvostrukog lanca i objašnjenje daljeg ponašanja dva DNK makromolekula dobijena u ovom procesu. Analize difuzije eksitona u nanofilmovima [16,17] ukazuju na tačnost Sent Đerđijevih ideja [18] da eksitonski mehanizam igra značajnu ulogu u transportu elektromagnetne energije kroz biostrukture [19]. Analize elektrona u provodnim nanofilmovima i u kvantnim gredama [20,21] predstavljaju dokaz egzistencije skin-efekta. Rezultat od velikog praktičnog interesa je postojanje energijskog gepa u fononskom spektru ultratankog filma [22,23]. Poznato je da fononi u balk-strukturama nemaju gep, pa pojava u ultratankom filmu, koji je za troslojni film reda preko 100 k_B, navodi na ideju da bi on mogao da bude superprovodan i preko 100 K.

II. Elementi diferencnog računa

Diferencije i diferencne jednačine pojavljuju se u prebrojivim skupovima varijabli ([6–12]). Poznato je da se u skupovima kontinualnih varijabli pojavljuju diferencijali i diferencijalne jednačine i ta teorija je mnogo razrađenija od teorije diferencnih jednačina. S'druge strane, diferencne jednačine su bliže praksi, naročito kada se radi o problemima vezanim za kristalnu nanostrukturu. U krajnjem, celokupna materija u prirodi je diskretan entitet, pa je prirodno da se u njenom izučavanju koriste diskretne zakonitosti sa diskretnim veličinama.

 ISBN 978-86-7466-930-3

Po analogiji sa izvodima u neprebrojivim skupovima, koje ćemo zvati kontinualnim izvodima, uvešćemo diskretne izvode u prebrojivim skupovima. Probleme rešavanja diferencnih jednačina vezaćemo za probleme rešavanja diferencijalnih jednačina, da bismo koristili prilaze i postupke iz ove poslednje, bolje razvijene oblasti.

A. Diferencije i diskretni izvodi

Kod diskretnih varijabli, priraštaj argumenta jednak je jedinici, pa se ovaj priraštaj ne piše u formulama. Formalna oznaka za priraštaj argumenta koristi se samo da bi se znalo po kojoj promenljivoj se diferencira.

Diskretan izvod funkcije diskretne promenljive n, dakle F_n, definiše se kao:

$$\frac{\Delta}{\Delta n}F_n = F_{n+1} - F_n \tag{II.1}$$

i on je linearan operator. Na osnovu toga mogu se potražiti i viši izvodi, npr. za drugi izvod imamo:

$$\begin{aligned}\frac{\Delta^2}{\Delta n^2}F_n &= \frac{\Delta}{\Delta n}\frac{\Delta}{\Delta n}F_n = \frac{\Delta}{\Delta n}\left(F_{n+1}-F_n\right) = \\ &= F_{n+2} - 2F_{n+1} + F_n; \\ \Rightarrow \frac{\Delta^m}{\Delta n^m}F_n &= \sum_{k=0}^{m}(-1)^k\binom{m}{k}F_{n+m-k}.\end{aligned} \tag{II.2}$$

Sada ćemo potražiti diskretan izvod proizvoda dve funkcije:

$$\begin{aligned}\frac{\Delta}{\Delta n}F_n\,H_n &= F_{n+1}H_{n+1} - F_nH_n = \\ &= F_{n+1}H_{n+1} - F_{n+1}H_n + F_{n+1}H_n - F_nH_n = \\ &= F_{n+1}\frac{\Delta H_n}{\Delta n} + H_n\frac{\Delta F_n}{\Delta n}.\end{aligned}$$

Međutim, vidljivo je da se ovo može izraziti i kao:

$$\begin{aligned}\frac{\Delta}{\Delta n}F_n\,H_n &= F_{n+1}H_{n+1} - F_nH_n = \\ &= F_{n+1}H_{n+1} - F_nH_{n+1} + F_nH_{n+1} - F_nH_n = \\ &= H_{n+1}\frac{\Delta F_n}{\Delta n} + F_n\frac{\Delta H_n}{\Delta n}.\end{aligned}$$

Zbog toga se izvod proizvoda definiše preko aritmetičke sredine ova dva izraza, pa nakon sređivanja sledi:

$$\frac{\Delta}{\Delta n}F_nH_n = H_n\frac{\Delta F_n}{\Delta n} + F_n\frac{\Delta H_n}{\Delta n} + \frac{\Delta F_n}{\Delta n}\frac{\Delta H_n}{\Delta n}. \tag{II.3}$$

Drugi izvod proizvoda funkcija je onda jednak:

$$\begin{aligned}\frac{\Delta^2}{\Delta n^2}F_nH_n = H_n\frac{\Delta^2F_n}{\Delta n^2} + F_n\frac{\Delta^2H_n}{\Delta n^2} + 2\frac{\Delta H_n}{\Delta n}\frac{\Delta^2F_n}{\Delta n^2} + \\ + 2\frac{\Delta F_n}{\Delta n}\frac{\Delta^2H_n}{\Delta n^2} + 2\frac{\Delta F_n}{\Delta n}\frac{\Delta H_n}{\Delta n} + \frac{\Delta^2F_n}{\Delta n^2}\frac{\Delta^2H_n}{\Delta n^2}.\end{aligned} \tag{II.4}$$

Zatim, potrebno je naći i izvod količnika dve funkcije:

$$\begin{aligned}\frac{\Delta}{\Delta n}\frac{F_n}{H_n} &= \frac{F_{n+1}}{H_{n+1}} - \frac{F_n}{H_n} = \frac{F_{n+1}H_n - F_nH_{n+1}}{H_{n+1}H_n} = \\ &= \frac{F_{n+1}H_n - F_nH_n - F_nH_{n+1} + F_nH_n}{H_{n+1}H_n} = \\ &= \frac{H_n\dfrac{\Delta F_n}{\Delta n} - F_n\dfrac{\Delta H_n}{\Delta n}}{H_{n+1}H_n}.\end{aligned} \tag{II.5}$$

I konačno, potrebno je naći izvod složene diskretne funkcije:

$$\frac{\Delta}{\Delta n}F_{\varphi_n} = \frac{\Delta F_{\varphi_n}}{\Delta\varphi_n}\frac{\Delta\varphi_n}{\Delta n}. \tag{II.6}$$

B. Translacioni operatori i diskretna integracija

Pomoću translacionog operatora sa osobinama:

$$\begin{aligned}&\hat{T}_kF_n = F_{n+k}; \\ &\hat{T}_k^{-1} = \hat{T}_{-k};\quad \hat{T}_k = \left(\hat{T}_1\right)^k;\quad \left(\hat{T}_k\right)^n = \hat{T}_{nk},\end{aligned} \tag{II.7}$$

može se redefinisati diskretni izvod iz (II.1):

$$\begin{aligned}&\frac{\Delta}{\Delta n}F_n = F_{n+1} - F_n = \left(\hat{T}_1 - 1\right)F_n; \\ &\Rightarrow \frac{\Delta^m}{\Delta n^m}F_n = \left(\hat{T}_1 - 1\right)^m F_n = \\ &\qquad = \sum_{k=0}^{m}(-1)^k\binom{m}{k}\hat{T}_{m-k}\,F_{n+m-k}.\end{aligned} \tag{II.8}$$

Uvođenje translacionih operatora korisno je u prvom redu zbog toga što se pomoću njih može definisati operacija diskretne integracije: $\frac{\Delta^{-1}}{\Delta n}$, kao inverznu operaciju u odnosu na diskretno diferenciranje. Pošto se diskretni izvod dobija primenom operatora $\hat{T}_1 - 1$ na funkciju diskretne promenljive F_n, očigledno je da se primenom operatora $\left(\hat{T}_1 - 1\right)^{-1}$ na tu istu funkciju dobija njen diskretni integral:

$$\frac{\Delta^{-1}}{\Delta n}F_n = \left(\hat{T}_1 - 1\right)^{-1}F_n, \tag{II.9}$$

ali je sada potrebno naći odgovarajuću operativnu formulu za operator: $\left(\hat{T}_1 - 1\right)^{-1}$, posebno jer se može napisati u dve forme:

$$\begin{aligned}&\left(\hat{T}_1 - 1\right) = \begin{cases}\hat{T}_1\left(1 - \hat{T}_{-1}\right), \\ -\left(1 - \hat{T}_1\right).\end{cases} \Rightarrow \\ &\Rightarrow \left(\hat{T}_1 - 1\right)^{-1} = \begin{cases}\left(1 - \hat{T}_{-1}\right)^{-1}\hat{T}_{-1} = \sum_{k=0}^{\infty}\hat{T}_{-k-1}, \\ -\left(1 - \hat{T}_1\right)^{-1} = -\sum_{k=0}^{\infty}\hat{T}_k.\end{cases}\end{aligned} \tag{II.10}$$

Zbog ovoga i diskretni integral funkcije F_n ima dve forme:

 ISBN 978-86-7466-930-3

$$\hat{J}_1 F_n \equiv \frac{\Delta^{-1}}{\Delta n} F_n = \sum_{k=0}^{\infty} \hat{T}_{-k-1} F_n = \\ = F_{n-1} + F_{n-2} + F_{n-3} + \ldots \tag{II.11a}$$

$$\hat{J}_2 F_n \equiv \frac{\Delta^{-1}}{\Delta n} F_n = -\sum_{k=0}^{\infty} \hat{T}_k F_n = \\ = -F_n - F_{n+1} - F_{n+2} - \ldots \tag{II.11b}$$

Ukoliko red iz (II.11a) ne konvergira, onda se može koristiti (II.11b) jer će on konvergirati. Važi i obrnuto.

Definisanje diskretnog integrala pomoću translacionih operatora pogodno je jer daje gotove recepte po kojima se mogu izračunavati. Metod računa sa translacionim operatorima primenljiv je na eksponencijalne, logaritamske, trigonometrijske i hiperbolične funkcije, ali i na stepene funkcije. Kod ovih poslednjih postoje izvesne specifičnosti u računu, na koje ćemo posebno ukazati. Razmotrićemo sada nekoliko diskretnih izvoda i diskretnih integrala navedenih tipičnih funkcija.

1) *Eksponencijalna funkcija* tipa: $F_n = A^{\alpha n};\ A > 1;\ \alpha > 0.$

Diskretni izvod jednak je:

$$\frac{\Delta}{\Delta n} A^{\alpha n} = A^{\alpha(n+1)} - A^{\alpha n} = A^{\alpha n}\left(A^{\alpha} - 1\right), \tag{II.12}$$

a diskretni integral, korišćenjem (II.11a):

$$\frac{\Delta^{-1}}{\Delta n} A^{\alpha n} \equiv \hat{J}_1 A^{\alpha n} = A^{\alpha(n-1)} + A^{\alpha(n-2)} + A^{\alpha(n-3)} + \ldots \\ = A^{\alpha n}\left[-1 + \sum_{k=0}^{\infty}\left(A^{-\alpha}\right)^k\right] = \frac{A^{\alpha n}}{A^{\alpha} - 1}. \tag{II.13}$$

Za funkciju $A\mathrm{e}^{-\alpha n};\ A > 1;\ \alpha > 0,$ sa (II.11a) red bi bio divergentan, zato se mora primeniti formula (II.11b):

$$\frac{\Delta^{-1}}{\Delta n} A\mathrm{e}^{-\alpha n} = \hat{J}_2 A\mathrm{e}^{-\alpha n} \equiv -\sum_{k=0}^{\infty} \hat{T}_k A\mathrm{e}^{-\alpha n} = \\ = -A\mathrm{e}^{-\alpha n}\left(1 + \mathrm{e}^{-\alpha} + \mathrm{e}^{-2\alpha} + \ldots\right) = -\frac{A\mathrm{e}^{-\alpha n}}{1 - \mathrm{e}^{-\alpha}}. \tag{II.14}$$

2) *Logaritamska funkcija* tipa: $F_n = \log_A n.$

Diskretni izvod ove funkcije je:

$$\frac{\Delta}{\Delta n} \log_A n = \log_A (n+1) - \log_A n = \log_A \frac{n+1}{n}, \tag{II.15}$$

a diskretni integral ove funkcije će biti:

$$\frac{\Delta^{-1}}{\Delta n} \log_A n = \log_A (n-1) + \log_A (n-2) + \\ + \log_A (n-3) + \ldots + \log_A 2 = \log_A [(n-1)!] \tag{II.16}$$

3) *Trigonometrijska funkcija* tipa: $F_n = \cos n\alpha.$

Prema definiciji, diskretni izvod ove funkcije je:

$$\frac{\Delta}{\Delta n} \cos n\alpha = \cos(n+1)\alpha - \cos n\alpha = \\ = \cos n\alpha \cos\alpha - \sin n\alpha \sin\alpha - \cos n\alpha = \\ = -2 \sin\frac{\alpha}{2} \sin\left(n + \frac{1}{2}\right)\alpha, \tag{II.17}$$

a njen diskretni integral se nalazi:

$$\frac{\Delta^{-1}}{\Delta n} \cos\alpha n = \left(\hat{T}_1 - 1\right)^{-1} \cos\alpha n = \sum_{k=0}^{\infty} \hat{T}_{-k-1} \cos\alpha n = \\ = \left(\hat{T}_{-1} + \hat{T}_{-2} + \hat{T}_{-3} + \ldots\right)\frac{1}{2}\mathrm{e}^{i\alpha n} + \left(\hat{T}_{-1} + \hat{T}_{-2} + \hat{T}_{-3} + \ldots\right)\frac{1}{2}\mathrm{e}^{-i\alpha n} = \\ = \frac{1}{2}\mathrm{e}^{i(n-1)\alpha}\left(1 + \mathrm{e}^{-i\alpha} + \mathrm{e}^{-2i\alpha} + \ldots\right) + \frac{1}{2}\mathrm{e}^{-i(n-1)\alpha}\left(1 + \mathrm{e}^{i\alpha} + \mathrm{e}^{2i\alpha} + \ldots\right).$$

U prvoj zagradi se uzme $\alpha \to \alpha - i\delta,$ a u drugoj $\alpha \to \alpha + i\delta,$ pa se traži granična vrednost sume kada $\delta \to +0$:

$$\frac{\Delta^{-1}}{\Delta n} \cos\alpha n = \frac{1}{2}\mathrm{e}^{in\alpha}\frac{1}{\mathrm{e}^{i\alpha}}\frac{1}{1 - \mathrm{e}^{-i\alpha}} + \frac{1}{2}\mathrm{e}^{-in\alpha}\mathrm{e}^{i\alpha}\frac{1}{1 - \mathrm{e}^{i\alpha}} = \\ = \mathrm{Re}\left\{\mathrm{e}^{in\alpha}\frac{1}{\mathrm{e}^{i\alpha} - 1}\right\} = \frac{\cos(n-1)\alpha - \cos n\alpha}{4\sin^2\frac{\alpha}{2}} = \frac{\sin\left(n - \frac{1}{2}\right)\alpha}{2\sin\frac{\alpha}{2}}. \tag{II.18}$$

4) *Hiperbolična funkcija* tipa: $F_n = \cosh\ n\alpha.$

Diskretni izvod ove funkcije nalazi se preko kombinacije dve eksponencijalne funkcije:

$$\frac{\Delta}{\Delta n} \cosh n\alpha = \frac{1}{2}\frac{\Delta}{\Delta n}\mathrm{e}^{\alpha n} + \frac{1}{2}\frac{\Delta}{\Delta n}\mathrm{e}^{-\alpha n} = \frac{1}{2}\left[\mathrm{e}^{\alpha(n+1)} - \mathrm{e}^{\alpha n} + \right. \\ \left. + \mathrm{e}^{-\alpha(n+1)} - \mathrm{e}^{-\alpha n}\right] = 2\ \sinh\frac{\alpha}{2}\sinh\left(n + \frac{1}{2}\right)\alpha. \tag{II.19}$$

Diskretan integral ove funkcije mora se, takođe nalaziti preko eksponencijalnih funkcija, ali za eksponencijalnu funkciju sa pozitivnim predznakom mora se primeniti operator $\hat{J}_1$, dok za onu sa negativnim predznakom $\hat{J}_2$:

$$\frac{\Delta^{-1}}{\Delta n} \cosh n\alpha = \left(\frac{\Delta^{-1}}{\Delta n}\right)_1 \frac{1}{2}\mathrm{e}^{\alpha n} + \left(\frac{\Delta^{-1}}{\Delta n}\right)_2 \frac{1}{2}\mathrm{e}^{-\alpha n} \equiv \\ \equiv \frac{1}{2}\left(\hat{J}_1 \mathrm{e}^{\alpha n} + \hat{J}_2 \mathrm{e}^{-\alpha n}\right) = \\ = \frac{1}{2}\left[\left(\hat{T}_{-1} + \hat{T}_{-2} + \hat{T}_{-3} + \ldots\right)\mathrm{e}^{\alpha n} - \right. \\ \left. - \left(\hat{T}_1 + \hat{T}_2 + \hat{T}_3 + \ldots\right)\mathrm{e}^{-\alpha n}\right] = \\ = \frac{1}{2}\left[\frac{\mathrm{e}^{\alpha n}}{\mathrm{e}^{\alpha}}\left(1 + \mathrm{e}^{-\alpha} + \mathrm{e}^{-2\alpha} + \ldots\right) - \right. \\ \left. - \mathrm{e}^{-\alpha n}\left(1 + \mathrm{e}^{-\alpha} + \mathrm{e}^{-2\alpha} + \ldots\right)\right] = \\ = \frac{1}{2}\left(\frac{\mathrm{e}^{\alpha n}}{\mathrm{e}^{\alpha} - 1} + \frac{\mathrm{e}^{-\alpha n}}{\mathrm{e}^{-\alpha} - 1}\right) = \\ = \left(2\ \sinh\frac{\alpha}{2}\right)^{-1} \sinh\left(n - \frac{1}{2}\right)\alpha. \tag{II.20}$$

 ISBN 978-86-7466-930-3

Sličnim postupkom mogu se odrediti diskretni izvodi i diskretni integrali za funkciju tipa $F_n = \sinh\ n\alpha$:

$$\frac{\Delta}{\Delta n}\sinh n\alpha = 2\sinh\frac{\alpha}{2}\cosh\left(n+\frac{1}{2}\right)\alpha. \tag{II.21}$$

$$\frac{\Delta^{-1}}{\Delta n}\sinh n\alpha = \left(2\ \sinh\frac{\alpha}{2}\right)^{-1}\cosh\left(n-\frac{1}{2}\right)\alpha. \tag{II.22}$$

5) *Stepena funkcija* tipa: $F_n = n^{-\alpha\cdot}; \alpha > 0.$

Diskretni izvod ove funkcije nalazi se preko definicije:

$$\frac{\Delta}{\Delta n}n^{-\alpha} = \left(\hat{T}_1 - 1\right)n^{-\alpha} = (n+1)^{-\alpha} - n^{-\alpha} = -n^{-\alpha}\left[1-\left(\frac{n}{n+1}\right)^{\alpha}\right], \tag{II.23}$$

a diskretni integral obavezno se mora računati pomoću operatora $\hat{J}_2$, jer bi se u računu pomoću operatora $\hat{J}_1$, pojavili singulariteti:

$$\begin{aligned}&\frac{\Delta^{-1}}{\Delta n}n^{-\alpha} = \hat{J}_2 n^{-\alpha} = -\sum_{k=0}^{\infty}\hat{T}_k n^{-\alpha} = \\ &= n^{\alpha} + (n+1)^{-\alpha} + (n+2)^{-\alpha} + \ldots = -\sum_{k=0}^{\infty}(n+k)^{-\alpha}.\end{aligned} \tag{II.24}$$

U slučaju da je: $f_n = n^{\alpha\cdot}; \alpha > 0,$ onda je diskretni izvod:

$$\frac{\Delta}{\Delta n}n^{\alpha} = \left(\hat{T}_1 - 1\right)n^{\alpha} = (n+1)^{\alpha} - n^{\alpha} = (n+1)^{\alpha}\left[1-\left(\frac{n}{n+1}\right)^{\alpha}\right], \tag{II.25}$$

A za izračunavanje diskretnog integrala mora primeniti operatora $\hat{J}_1$:

$$\begin{aligned}&\frac{\Delta^{-1}}{\Delta n}n^{\alpha} = \hat{J}_1 n^{\alpha} = \sum_{k=0}^{\infty}\hat{T}_{-k-1}n^{\alpha} = (n-1)^{\alpha} + (n-2)^{\alpha} + \ldots = \\ &= \sum_{q=1}^{\infty}(n-q)^{\alpha} \Rightarrow = \sum_{q=1}^{n-1}(n-q)^{\alpha}.\end{aligned} \tag{II.26}$$

(beskonačni red morao je da se "preseče" za $q = n$).

C. Diferencne jednačine prvog reda

U ovom delu posmatraćemo linearne diferencne jednačine sa promenljivim koeficijentima.

1) *Homogena linearna diferencna jednačina* je tipa:

$$\frac{\Delta Y_n}{\Delta n} + a_n Y_n = 0. \tag{II.27}$$

Rešavanje ove diferencne jednačine svodi se na nalaženje rekurentnog obrasca sa jednom diferencijom:

$$Y_{n+1} - Y_n + a_n Y_n = 0 \quad \Rightarrow \quad Y_{n+1} = (1-a_n)Y_n,$$

a odatle:

$$Y_1 = (1-a_0)Y_0;\ Y_2 = (1-a_1)Y_1 = (1-a_0)(1-a_1)Y_0;\ \cdots$$

$$\begin{aligned}Y_n &= (1-a_0)(1-a_1)(1-a_2)\ldots(1-a_{n-1})Y_0 = \\ &= Y_0\prod_{s=0}^{n-1}(1-a_s).\end{aligned} \tag{II.28}$$

2) *Nehomogena linearna diferencna jednačina* ima oblik:

$$\frac{\Delta Y_n}{\Delta n} + a_n Y_n = b_n \tag{II.29}$$

i ona se rešava operatorskim putem:

$$\left[\left(\hat{T}_1 - 1\right) + a_n\right]Y_n = b_n \quad \Rightarrow \quad Y_n = \left[\left(\hat{T}_1 - 1\right) + a_n\right]^{-1} b_n. \tag{II.30}$$

Operator $\left(\hat{T}_1 - 1\right) + a_n$ može se izraziti na dva nezavisna načina:

$$\left(\hat{T}_1 - 1\right) + a_n = \begin{cases} a_n\left[1 + a_n^{-1}\left(\hat{T}_1 - 1\right)\right]; \\ \left(\hat{T}_1 - 1\right)\left[1 + \left(\hat{T}_1 - 1\right)^{-1}a_n\right], \end{cases}$$

pa imamo i dve forme inverznih operatora:

$$\begin{aligned}\hat{J}_1 &= \sum_{k=0}^{\infty}(-1)^k\left[a_n^{-1}\left(\hat{T}_1 - 1\right)\right]^k a_n^{-1}; \\ \hat{J}_2 &= \sum_{k=0}^{\infty}(-1)^k\left[\left(\hat{T}_1 - 1\right)^{-1}a_n\right]^k\left(\hat{T}_1 - 1\right)^{-1}.\end{aligned} \tag{II.31}$$

Pošto operator $\hat{T}_1$ i multiplikativni operator a_n ne komutiraju, imamo:

$$\begin{aligned}&\left(\hat{T}_1 - 1\right)a_n F_n = a_{n+1}F_{n+1} - a_n F_n; \\ &a_n\left(\hat{T}_1 - 1\right)F_n = a_n\left(F_{n+1} - F_n\right) = a_n F_{n+1} - a_n F_n,\end{aligned}$$

pa se stepeni iz (II.29) moraju uzeti u formi:

$$\left[a_n^{-1}\left(\hat{T}_1 - 1\right)\right]^k = \underbrace{a_n^{-1}\left(\hat{T}_1 - 1\right)a_n^{-1}\left(\hat{T}_1 - 1\right)\ldots a_n^{-1}\left(\hat{T}_1 - 1\right)}_{k\text{ puta}};$$

$$\left[\left(\hat{T}_1 - 1\right)^{-1}a_n\right]^k = \underbrace{\left(\hat{T}_1 - 1\right)^{-1}a_n\left(\hat{T}_1 - 1\right)^{-1}a_n\ldots\left(\hat{T}_1 - 1\right)^{-1}a_n}_{k\text{ puta}}.$$

Rešenje jednačine (II.27) dobija se primenom samo jednog od operatora $\hat{J}_1$, odnosno $\hat{J}_2$ i to onog koji primenjen na b_n daje konvergentan red. Znači, rešenje jednačine (II.30) je:

$$Y_n = \hat{J}_1 b_n, \quad \text{ili} \quad Y_n = \hat{J}_2 b_n. \tag{II.32}$$

Ako funkcije *a* i *b* ne zavise od promenljive *n* onda se ovim operatorskim metodom relativno jednostavno mogu rešiti nehomogene diferencne jednačine prvog reda. Ukoliko pak obe funkcije *a* i *b* zavise od promenljive *n,* rešenje je glomazno, ali se i ono lako nalazi. Tu nam uvek pomože smena funkcije:

$$Y_n = U_n Z_n \Rightarrow \frac{\Delta Y_n}{\Delta n} = U_n\frac{\Delta Z_n}{\Delta n} + Z_n\frac{\Delta U_n}{\Delta n} + \frac{\Delta U_n}{\Delta n}\frac{\Delta Z_n}{\Delta n}, \tag{II.33}$$

jer se polazna jednačina (II.29) uprosti: ona se rešava po Z_n, a funkciju U_n odredimo tako da jednačina za Z_n bude uprošćena. Zamenom smene u (II.29) i deobom sa U_n, dobija se:

 ISBN 978-86-7466-930-3

$$\left(1+\frac{1}{U_n}\frac{\Delta U_n}{\Delta n}\right)\frac{\Delta Z_n}{\Delta n}+\left(\frac{1}{U_n}\frac{\Delta U_n}{\Delta n}+a_n\right)Z_n=\frac{b_n}{U_n}.$$

I sada se U_n određuje da „otpadne“ član uz Z_n:

$$\frac{1}{U_n}\frac{\Delta U_n}{\Delta n}=-a_n\Rightarrow\frac{\Delta U_n}{\Delta n}=-a_nU_n\Rightarrow$$
$$\Rightarrow U_{n+1}-U_n=-a_nU_n\Rightarrow U_{n+1}=(1-a_n)U_n,$$

odnosno, za *n* = 0, 1, 2, ...:

$$U_1=(1-a_0)U_0,$$
$$U_2=(1-a_1)U_1=(1-U_0)(1-a_1)U_0,$$
$$U_3=(1-a_2)U_2=(1-U_0)(1-a_1)(1-a_2)U_0,$$
$$\ldots\quad\ldots\quad\ldots\quad\ldots$$
$$U_n=U_0\prod_{k=0}^{n-1}(1-a_k).$$

Dalje ćemo uzeti da je $U_0=1$, pa jednačina za Z_n postaje:

$$(1-a_n)\frac{\Delta Z_n}{\Delta n}=\frac{b_n}{U_n}\Rightarrow\frac{\Delta Z_n}{\Delta n}=\frac{b_n}{1-a_n}\frac{1}{U_n}\Rightarrow$$
$$\Rightarrow\frac{\Delta Z_n}{\Delta n}=\frac{b_n}{1-a_n}\frac{1}{\prod_{k=0}^{n-1}(1-a_k)}\Rightarrow$$
$$\Rightarrow Z_n=\frac{\Delta^{-1}}{\Delta n}\left\{\frac{b_n}{1-a_n}\left[\prod_{k=0}^{n-1}(1-a_k)\right]^{-1}\right\}+C.$$

Nakon zamene u (II.33), rešenje polazne jednačine je:

$$Y_n=C\prod_{k=0}^{n-1}(1-a_k)+ \\ +\prod_{k=0}^{n-1}(1-a_k)\frac{\Delta^{-1}}{\Delta n}\left\{\frac{b_n}{1-a_n}\left[\prod_{k=0}^{n-1}(1-a_k)\right]^{-1}\right\}. \quad \text{(II.34)}$$

D. Snižavanje reda diferencne jednačine drugog reda

U opštem slučaju, diferencne jednačine drugog reda sadrže argument funkcije, diskretnu funkciju, prvi izvod diskretne funkcije i drugi izvod diskretne funkcije.

Jedan od načina rešavanja diferencnih jednačina drugog reda je njihovo svođenje na diferencne jednačine prvog reda. Red diferencne jednačine može se sniziti ako u njoj figurišu argument, kao i prvi i drugi diskretni izvod funkcije. Drugi slučaj, kada je moguće snižavanje reda, predstavljaju diferencne jednačine u kojima figurišu funkcija diskretne promenljive i njen prvi i drugi diskretni izvod.

Prvi pomenuti slučaj je zadat relacijom:

$$\Phi\left(n,\frac{\Delta Y_n}{\Delta n},\frac{\Delta^2Y_n}{\Delta n^2}\right)=0, \quad \text{(II.35)}$$

koja smenom:

$$\frac{\Delta Y_n}{\Delta n}=p_n\Rightarrow\frac{\Delta^2Y_n}{\Delta n^2}=\frac{\Delta p_n}{\Delta n},$$

prelazi u diferencnu jednačinu prvog reda:

$$\Phi\left(n,p_n,\frac{\Delta p_n}{\Delta n}\right)=0. \quad \text{(II.36)}$$

Drugi pomenuti slučaj je jednačina ovog oblika:

$$\Psi\left(Y_n,\frac{\Delta Y_n}{\Delta n},\frac{\Delta^2Y_n}{\Delta n^2}\right)=0. \quad \text{(II.37)}$$

I ovde se uzima ista smena: $\frac{\Delta Y_n}{\Delta n}=p_n$, ali se drugi izvod nalazi na sledeći način:

$$\frac{\Delta^2Y_n}{\Delta n^2}=\frac{\Delta p_n}{\Delta n}=\frac{\Delta Y_n}{\Delta Y_n}\frac{\Delta p_n}{\Delta n}=\frac{\Delta Y_n}{\Delta n}\frac{\Delta p_n}{\Delta Y_n}=p_n\frac{\Delta p_n}{\Delta Y_n},$$

čime (II.35) prelazi u diferencnu jednačinu prvog reda:

$$\Psi\left(Y_n,p_n,\frac{\Delta p_n}{\Delta Y_n}\right)=0. \quad \text{(II.38)}$$

E. Linearne diferencne jednačine sa stalnim koeficijentima

1) *Nehomogena linearna diferencna jednačina I reda*

je oblika:

$$\frac{\Delta Y_n}{\Delta n}+aY_n=0, \quad \text{(II.39)}$$

a rešava se prema definiciji (II.1):

$$Y_{n+1}-Y_n+aY_n=0\Rightarrow Y_{n+1}-(1-a)Y_n=0$$

i uvođenjem smene: $Y_n=x^n$, pa sledi:

$$x^{n+1}-(1-a)x^n=0\Rightarrow x=1-a.$$

Konačno rešenje je onda:

$$Y_n=(1-a)^n. \quad \text{(II.40)}$$

2) *Nehomogena linearna diferencna jednačina II reda* ima oblik:

$$\frac{\Delta^2Y_n}{\Delta n^2}+a_1\frac{\Delta Y_n}{\Delta n}+a_2Y_n=0 \quad \text{(II.41)}$$

i ona se, prema definiciji (II.1) i (II.2) svodi na:

$$Y_{n+2}-(2-a_1)Y_{n+1}+(1-a_1+a_2)Y_n=0,$$

koja se rešava istom smenom: $Y_n=x^n$, te sledi:

$$x^2-(2-a_1)x+(1+a_2)=0\Rightarrow x_{1,2}=1-\frac{a_1}{2}\pm\sqrt{\frac{a_1^2}{4}-a_1-a_2}.$$

To znači da polazna jednačina ima dva partikularna integrala:

 ISBN 978-86-7466-930-3

$$Y_n^{(1)} = x_1^n = \left(1 - \frac{a_1}{2} + \sqrt{\frac{a_1^2}{4} - a_1 - a_2}\right)^n, \qquad (II.42)$$
$$Y_n^{(2)} = x_2^n = \left(1 - \frac{a_1}{2} - \sqrt{\frac{a_1^2}{4} - a_1 - a_2}\right)^n.$$

3) *Primer iz fizike kristala*

Jednačina kojom se opisuje jednodimenziono prostiranje poremećaja u kristalima sa pravilnom rešetkom je oblika [24]:

$$Y_{n+1} + Y_{n-1} + \rho\, Y_n = 0, \qquad (II.43)$$

gde je parametar $\rho \neq \rho(n)$ = const – za neograničene kristale sa translacionom simetrijom (idealne balk kristalne strukture). Ukazanom smenom $Y_n = x^n$, jednačina (II.43) prelazi u:

$$x + x^{-1} + \rho = 0 \Rightarrow x^2 + \rho x + 1 = 0 \;\Rightarrow x_{1,2} = -\frac{\rho}{2} \pm \sqrt{\frac{\rho^2}{4} - 1}.$$

Dva partikularna rešenja jednačine (II. 43) su onda:

$$Y_n^{(1)} = \left(-\frac{\rho}{2} + \sqrt{\frac{\rho^2}{4} - 1}\right)^n; \quad Y_n^{(2)} = \left(-\frac{\rho}{2} - \sqrt{\frac{\rho^2}{4} - 1}\right)^n,$$

a opšte rešenje:

$$Y_n = C_1 Y_n^{(1)} + C_2 Y_n^{(2)}, \qquad (II.44)$$

gde se konstante C_1 i C_2 određuju iz početnih uslova.

III. OPERATORSKO REŠAVANJE DIFERENCNIH JEDNAČINA DRUGOG REDA I PRIMENA

A. Opšti slučaj – pristup rešavanja

Posmatramo diferencnu jednačinu oblika:

$$\frac{\Delta^2 Y_n}{\Delta n^2} + \hat{f}_n Y_n = 0, \qquad (III.1)$$

koja se, s´obzirom na (II.2) može napisati kao:

$$\left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right] Y_n = 0. \qquad (III.2)$$

Sada formiramo odgovarajuću nehomogenu jednačinu:

$$\left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right] y_n = \Phi_n \Rightarrow y_n = \left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right]^{-1} \Phi_n. \qquad (III.3)$$

Ovo je formalno rešenje polaznog problema, a prema opštoj teoriji diferencnih jednačina, treba da ima dva nezavisna partikularna integrala: $y_n^{(1)}$ i $y_n^{(2)}$:

$$\left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right] y_n^{(1)} = \Phi_n; \quad \left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right] y_n^{(2)} = \Phi_n. \qquad (III.4)$$

Lako je uočiti da se oduzimanjem ove dve jednačine dobija traženo rešenje jednačine u formi (III.2):

$$\left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right]\left(y_n^{(1)} - y_n^{(2)}\right) = 0 \;\Rightarrow\; Y_n \equiv y_n^{(1)} - y_n^{(2)}. \qquad (III.5)$$

To znači da je potrebno odrediti ova dva partikularna rešenja.

Kako se operator $\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n$ može se napisati na dva potpuno različita načina:

$$\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n = \begin{cases} \hat{f}_n\left[1 + \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2\right]; \\ \left(\hat{T}_1 - 1\right)^2\left[1 + \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n\right], \end{cases}$$

onda i operator $\left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right]^{-1}$ ima sledeće dve forme:

$$\left[\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n\right]^{-1} = \begin{cases} \hat{J}_1 \equiv \left[1 + \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2\right]^{-1} \hat{f}_n^{-1} = \\ \quad = \sum_{k=0}^{\infty} (-1)^k \left[\hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2\right]^k \hat{f}_n^{-1}; \\ \hat{J}_2 \equiv \left[1 + \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n\right]^{-1} \left(\hat{T}_1 - 1\right)^{-2} = \\ \quad = \sum_{k=0}^{\infty} (-1)^k \left[\left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n\right]^k \left(\hat{T}_1 - 1\right)^{-2}. \end{cases} \qquad (III.6)$$

Operatori $\hat{J}_1$ i $\hat{J}_2$ napisani u eksplicitnoj formi su:

$$\hat{J}_1 = \left[1 - \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2 \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2 - \ldots\right] \hat{f}_n^{-1};$$
$$\hat{J}_2 = \left[1 - \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n + \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n \left(\hat{T}_1 - 1\right)^{-2} - \ldots\right]\left(\hat{T}_1 - 1\right)^{-2}$$

i moraju se pisati i računati u datom poretku, jer operatori $\hat{f}_n$ i $\hat{T}_1 - 1$ ne komutiraju! Dva partikularna integrala nalaze se onda kao:

$$y_n^{(1)} = \hat{J}_1 \Phi_n; \quad y_n^{(2)} = \hat{J}_2 \Phi_n. \qquad (III.7)$$

Sada treba konkretizovati funkciju Φ_n, a treba je odabrati tako da se jedan od dva beskonačna reda iz (III.6) preseče. Pošto je: $\left(\hat{T}_1 - 1\right)^2 C = 0$, biramo: $\Phi_n = f_n$, pa su onda:

$$y_n^{(1)} = \left[1 - \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2 + \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2 \hat{f}_n^{-1}\left(\hat{T}_1 - 1\right)^2 - \ldots\right] \hat{f}_n^{-1} f_n = 1;$$
$$y_n^{(2)} = \left[1 - \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n + \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n \left(\hat{T}_1 - 1\right)^{-2} - \ldots\right]\left(\hat{T}_1 - 1\right)^{-2} f_n,$$

a ukupno traženo rešenje polazne jednačine je:

$$Y_n = 1 - \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n + \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n \left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n - \ldots = \sum_{k=0}^{\infty} (-1)^k \left[\left(\hat{T}_1 - 1\right)^{-2} \hat{f}_n\right]^k. \qquad (III.8)$$

B. Diferencna jednačina stanja kristalnih nano-struktura

Kao što je rečeno, u problemima fizike kristala [24-28] često se pojavljuje diferencna jednačina tipa:

$$Y_{n+1} + Y_{n-1} + \rho_n Y_n = 0, \qquad (III.9)$$

koja se od (II.41) razlikuje po tome što parametar ρ (bitno!) zavisi od argumenta n, tj. $\rho = \rho_n$, čime se opisuje translaciona

 ISBN 978-86-7466-930-3

neinvarijantnost (realnih i posebno nano) kristala, a argument definiše položaj molekula (atoma, jona) u kristalu.

Upotrebom translacionih operatora ova jednačina može se napisati u sledećem obliku:

$$\left(\hat{T}_1 + \hat{T}_{-1} + \hat{\rho}_n\right) Y_n = 0. \qquad \text{(III.10)}$$

U prethodnom paragrafu je naglašeno da se krucijalan zahtev za nalaženje rešenja ovom metodom sastojao u tome da jedan od operatora primenjen na konstantu u rezultatu daje nulu. Ovde imamo operatore $\hat{T}_1 + \hat{T}_{-1}$ i $\hat{\rho}_n$. Ni jedan od njih primenjen na konstantu, ne može dati nulu. Zato izraz (III.10) moramo transformisati u:

$$\left[\left(\hat{T}_1 + \hat{T}_{-1} - 2\right) + \left(\hat{\rho}_n + 2\right)\right] Y_n = 0,$$

jer operator $\left(\hat{T}_1 + \hat{T}_{-1} - 2\right)$, primenjen na konstantu, daje nulu:

$$\left(\hat{T}_1 + \hat{T}_{-1} - 2\right)C = \hat{T}_1 C + \hat{T}_{-1} C - 2C = C + C - 2C = 0.$$

Radi pojednostavljenja, uvedemo oznake:

$$\hat{a} = \hat{T}_1 + \hat{T}_{-1} - 2;\ \hat{b}_n = \hat{\rho}_n + 2,$$

pa jednačina (III.10) postaje:

$$\left(\hat{a} + \hat{b}_n\right) Y_n = 0, \qquad \text{(III.11)}$$

pri čemu je $\hat{a}\,C = 0$.

Pošto je ova jednačina homogena, njeno rešenje ćemo tražiti, kao i u prethodnom paragrafu, preko odgovarajuće pomoćne nehomogene jednačine:

$$\left(\hat{a} + \hat{b}_n\right) y_n = \Phi_n, \qquad \text{(III.12)}$$

koja ima dva linearno nezavisna rešenja: $y_n^{(1)} = \hat{J}_1 \Phi_n$ i $y_n^{(2)} = \hat{J}_2 \Phi_n$, a pomoću kojih je traženo opšte rešenje jednako: $Y_n \equiv y_n^{(1)} - y_n^{(2)}$. Ostaje da nađemo ove partikularne integrale. Na osnovu dvostrukog razvoja operatora:

$$\hat{a} + \hat{b}_n = \begin{cases} \hat{b}_n\left(1 + \hat{b}_n^{-1}\hat{a}\right), \\ \hat{a}\left(1 + \hat{a}^{-1}\hat{b}_n\right). \end{cases}$$

odnosno inverznog operatora:

$$\left(\hat{a} + \hat{b}_n\right)^{-1} = \left(1 + \hat{b}_n^{-1}\hat{a}\right)\hat{b}_n^{-1} = \\ = \sum_{k=0}^{\infty} (-1)^k \left(\hat{b}_n^{-1}\hat{a}\right)^k \hat{b}_n^{-1} \equiv \hat{J}_1 :$$

$$\left(\hat{a} + \hat{b}_n\right)^{-1} = \left(1 + \hat{a}^{-1}\hat{b}_n\right)^{-1} \hat{a}^{-1} = \\ = \sum_{k=0}^{\infty} (-1)^k \left(\hat{a}^{-1}\hat{b}_n\right)^k \hat{a}^{-1} \equiv \hat{J}_2,$$

dobijamo:

$$y_n^{(1)} = \hat{J}_1 \Phi_n = \left(1 - \hat{b}_n^{-1}\hat{a} + \hat{b}_n^{-1}\hat{a}\hat{b}_n^{-1}\hat{a} + \ldots\right)\hat{b}_n^{-1}\Phi_n;$$
$$y_n^{(2)} = \hat{J}_2 \Phi_n = \left(1 - \hat{a}^{-1}\hat{b}_n + \hat{a}^{-1}\hat{b}_n\hat{a}^{-1}\hat{b}_n - \ldots\right)\hat{a}^{-1}\Phi_n.$$

Ukoliko sada specificiramo funkciju Φ_n – uzmemo da je: $\Phi_n = \hat{b}_n$, onda se prvo rešenje dobija u vidu:

$$y_n^{(1)} = \left(1 - \hat{b}_n^{-1}\hat{a} + \hat{b}_n^{-1}\hat{a}\hat{b}_n^{-1}\hat{a} - \ldots\right)\hat{b}_n^{-1}\hat{b}_n = 1,$$

a dobijen je zahvaljujući činjenici da je $\hat{a} \cdot 1 = 0$.

Drugo rešenje se izražava kao:

$$y_n^{(2)} = \hat{a}^{-1}\hat{b}_n - \hat{a}^{-1}\hat{b}_n\hat{a}^{-1}\hat{b}_n + \hat{a}^{-1}\hat{b}_n\hat{a}^{-1}\hat{b}_n\hat{a}^{-1}\hat{b}_n - \ldots$$

i da bi se izračunalo treba naći eksplicitnu formu operatora $\hat{a}^{-1}$. Kako operator $\hat{a}$ ima dva oblika:

$$\hat{a} = \hat{T}_1 + \hat{T}_{-1} - 2 = \begin{cases} -2\left[1 - \frac{1}{2}\left(\hat{T}_1 + \hat{T}_{-1}\right)\right], \\ \left(\hat{T}_1 + \hat{T}_{-1}\right)\left[1 - 2\left(\hat{T}_1 + \hat{T}_{-1}\right)^{-1}\right]. \end{cases}$$

onda postoje i dve forme njemu inverznog operatora:

$$\hat{a}^{-1} = -\left[1 - \frac{1}{2}\left(\hat{T}_1 + \hat{T}_{-1}\right)\right]^{-1} = -\sum_{k=0}^{\infty} \frac{1}{2^{k+1}}\left(\hat{T}_1 + \hat{T}_{-1}\right)^k \equiv \hat{A}_1;$$
$$\hat{a}^{-1} = \left[1 - 2\left(\hat{T}_1 + \hat{T}_{-1}\right)^{-1}\right]^{-1}\left(\hat{T}_1 + \hat{T}_{-1}\right)^{-1} = \\ = -\sum_{k=0}^{\infty} 2^k \left(\hat{T}_1 + \hat{T}_{-1}\right)^{-k-1} \equiv \hat{A}_2, \qquad \text{(III.13)}$$

ali se i operator $\left(\hat{T}_1 + \hat{T}_{-1}\right)^{-1}$ može napisati u dve različite forme, jer je:

$$\hat{T}_1 + \hat{T}_{-1} = \begin{cases} \hat{T}_1\left(1 + \hat{T}_{-2}\right); \\ \hat{T}_{-1}\left(1 + \hat{T}_2\right), \end{cases}$$

pa su:

$$\left(\hat{T}_1 + \hat{T}_{-1}\right)^{-1} = \left(1 + \hat{T}_{-2}\right)^{-1}\hat{T}_{-1} = \sum_{k=0}^{\infty} (-1)^k \hat{T}_{-2k-1} \equiv \hat{\theta}_1;$$
$$\left(\hat{T}_1 + \hat{T}_{-1}\right)^{-1} = \left(1 + \hat{T}_2\right)^{-1}\hat{T}_1 = \sum_{k=0}^{\infty} (-1)^k \hat{T}_{2k+1} \equiv \hat{\theta}_2.$$

Operatorske forme $\hat{A}_1$, $\hat{A}_2$, $\hat{\theta}_1$ i $\hat{\theta}_2$ biraju se tako da rezultat njihove primene na datu funkciju diskretne promenljive bude konvergentan red. Kada je taj izbor napravljen, može se izračunati $y_n^{(2)}$. Rešenje polazne homogene jednačine biće dato preko:

$$Y_n = y_n^{(1)} - y_n^{(2)} = 1 - \hat{a}^{-1}\hat{b}_n + \hat{a}^{-1}\hat{b}_n\hat{a}^{-1}\hat{b}_n - \ldots = \\ = \sum_{k=0}^{\infty} (-1)^k \left(\hat{a}^{-1}\hat{b}_n\right)^k. \qquad \text{(III.14)}$$

C. Jedan karakterisičan primer

Kao primer posmatraćemo slučaj kada je: $\rho_n = A\mathrm{e}^{n\alpha} - 2$, tj. diferencnu jednačinu:

 ISBN 978-86-7466-930-3

$$Y_{n+1}+Y_{n-1}+\left(A\mathrm{e}^{n\alpha}-2\right)Y_n=0, \qquad \text{(III.15)}$$

gde zaključujemo da je: $\hat{b}_n = A\,\mathrm{e}^{n\alpha}$, pa zbog toga što je to eksponencijalna funkcija, neke od operatora ne moramo tražiti preko beskonačnih redova. Tako se vidi da je:

$$\left(\hat{T}_1+\hat{T}_{-1}\right)A\mathrm{e}^{n\alpha}=2\cosh\alpha\;A\mathrm{e}^{n\alpha},$$

a kako je: $\left(\hat{T}_1+\hat{T}_{-1}\right)^{-1}\left(\hat{T}_1+\hat{T}_{-1}\right)=1$, znači da je:

$$\left(\hat{T}_1+\hat{T}_{-1}\right)^{-1}A\mathrm{e}^{n\alpha}=\frac{1}{2\cosh\alpha}A\mathrm{e}^{n\alpha}.$$

S obzirom da je $\cosh\alpha>1$, moramo koristiti one operatorske redove u kojima figuriše operator $\left(\hat{T}_1+\hat{T}_{-1}\right)^{-1}$. Takav je red (III.13). To znači da će u (III.14) operator $\hat{a}^{-1}$, primenjen na funkciju $A\mathrm{e}^{n\alpha}$, dati rezultat:

$$\hat{a}^{-1}\hat{b}_n=\hat{a}^{-1}A\mathrm{e}^{n\alpha}=\sum_{k=0}^{\infty}2^k\left(\hat{T}_1+\hat{T}_{-1}\right)^{-k-1}A\mathrm{e}^{n\alpha}=$$
$$=A\mathrm{e}^{n\alpha}\sum_{k=0}^{\infty}2^k\frac{1}{2^{k+1}\cosh^{k+1}\alpha}=\frac{A\mathrm{e}^{n\alpha}}{2\cosh\alpha}\sum_{k=0}^{\infty}\frac{1}{(\cosh\alpha)^k}=$$
$$=\frac{A\mathrm{e}^{n\alpha}}{2(\cosh\alpha-1)},$$

pa dalje sledi:

$$\hat{a}^{-1}\hat{b}_n\hat{a}^{-1}\hat{b}_n=\hat{a}^{-1}A\mathrm{e}^{n\alpha}\frac{A\mathrm{e}^{n\alpha}}{2(\cosh\alpha-1)}=$$
$$=\frac{A^2\mathrm{e}^{2n\alpha}}{2^2(\cosh\alpha-1)(\cosh2\alpha-1)}.$$

Prema tome, izraz (III.15) se može pisati kao:

$$Y_n=1-\frac{A\mathrm{e}^{n\alpha}}{2(\cosh\alpha-1)}+\frac{A^2\mathrm{e}^{2n\alpha}}{2^2(\cosh\alpha-1)(\cosh2\alpha-1)}-\cdots=$$
$$=\sum_{k=1}^{\infty}(-1)^k\left(\frac{A\mathrm{e}^{n\alpha}}{2}\right)^k\frac{1}{\prod_{s=1}^{k}(\cosh s\alpha-1)}. \qquad \text{(III.16)}$$

Sada treba pokazati da ovo rešenje zadovoljava polaznu jednačinu (III.15). Kada se rešenje (III.16) uvrsti u tu jednačinu, lako se vidi da suma prvog, drugog i četvrtog člana iznosi:

$$\sum_{k=1}^{\infty}(-1)^k\left(\frac{A\mathrm{e}^{n\alpha}}{2}\right)^k\frac{2(\cosh k\alpha-1)}{\prod_{s=0}^{k}(\cosh,s\alpha-1)}$$

a treći član se može napisati na sledeći način:

$$-\sum_{k=1}^{\infty}(-1)^k\left(\frac{A\mathrm{e}^{n\alpha}}{2}\right)^{k+1}\frac{2[\cosh(k+1)\alpha-1]}{\prod_{s=0}^{q}(\cosh s\,\alpha-1)}$$

i on, posle zamene sumacionog indeksa $k+1=q$, postaje:

$$-\sum_{q=1}^{\infty}(-1)^q\left(\frac{A\mathrm{e}^{n\alpha}}{2}\right)^q\frac{2(\cosh\alpha q-1)}{\prod_{s=0}^{q}(\cosh s\,\alpha-1)}.$$

Vidi se da je ovaj rezultat jednak onom od sume prvog, drugog i četvrtog člana, ali sa suprotnim znakom, što znači da je njihov zbir jednak nuli. Dakle, rešenje (III.16) upravo predstavlja rešenje polazne jednačine (III.15).

Na kraju ćemo potražiti konkretan fizički sistem kod koga se pojavljuje jednačina tipa (III.15). Ako se posmatra oscilovanje jednodimenzionog lanca molekula [12,13,22,23,29,30], onda je popravka potencijalne energije lanca, koja potiče od oscilovanja molekula, data sa:

$$V=\frac{C}{2}\sum_m\left(u_m-u_{m-1}\right)^2, \qquad \text{(III.17)}$$

gde je u_m pomeraj molekula iz ravnotežnog položaja čija je koordinata označena sa *m*, dok je *C* – Hukova konstanta istezanja i predstavlja drugi izvod međumolekulske interakcije po rastojanju između molekula. Torzione konstante (i odgovarajući modovi!) se zanemaruju. Oscilatorna sila, koja deluje na molekul u tački *n*, definiše se klasično preko:

$$F_n=-\frac{\partial V}{\partial u_n},\ \text{odnosno:}\ F_n=-\frac{\Delta V}{\Delta u_n} \qquad \text{(III.18)}$$

i jednaka je proizvodu između mase molekula *M* i njegovog ubrzanja: $M\ddot{u}_n=F_n$. Na osnovu (III.17) i (III.18) sledi:

$$M\ddot{u}_n=C\left(u_{n+1}+u_{n-1}-2u_n\right)\Rightarrow\frac{M}{C}\ddot{u}_n=u_{n+1}+u_{n-1}-2u_n. \qquad \text{(III.19)}$$

Ovo je jednačina kretanja fononskog poremećaja. Kako pomeraj mora biti realan, uzećemo da je:

$$u_n(t)=\psi_n\cos\omega t;\ \psi_n=u_n(0);$$

što znači da je $\ddot{u}_n=-\omega^2\psi_n\cos\omega t$. Ako se ovo uvrsti u izraz (III.19), dobija se sledeća diferencna jednačina:

$$\psi_{n+1}+\psi_{n-1}+\left(\frac{M\omega^2}{C}-2\right)\psi_n=0. \qquad \text{(III.20)}$$

U slučaju idealne (translaciono invarijantne) strukture, pod normalnim pritiskom, veličina $\frac{M\omega^2}{C}\equiv\rho$ ne zavisi od indeksa čvora *n*. Ako u graničnim delovima lanca dođe do njegovog sabijanja i to tako da međumolekulsko rastojanje eksponencijalno opada ka drugom kraju lanca, onda se može uzeti da se Hukova konstanta ponaša po zakonu:

$$C=C_0\,\mathrm{e}^{-\alpha n},$$

što znači da se ρ može napisati u obliku $A(\omega)\,\mathrm{e}^{\alpha n}$, gde je $A(\omega)=\frac{M\omega^2}{C}=\frac{\omega^2}{\Omega_{\mathrm{D}}^2}$, a $\Omega_{\mathrm{D}}=\sqrt{\frac{C_0}{M}}$. Na osnovu ovoga

 ISBN 978-86-7466-930-3

jednačina (III.20) postaje:

$$\psi_{n+1}+\psi_{n-1}+\left[A(\omega)\mathrm{e}^{\alpha n}-2\right]\psi_n=0, \qquad \text{(III.21)}$$

i ona je po obliku identična sa (III.15). Prema tome, rešenje tipa (III.16) može se koristiti za izračunavanje molekulskih pomeraja u 1D lancu u kome su molekuli na jednom kraju sabijeni.

IV. ELEKTRONI U ULTRATANKIM FILMOVIMA

Na konferencijama ETRAN još od početka ovog veka predstavljali smo različite metode za analizu sistema elementarnih pobuđenja uglavnom u ultratankim kristalnim filmovima, npr. fonone i termodinamičke osobine 2003. – 2021., eksitone i optička svojstva 2004. – 2013, te elektrone i provodnost 2003. – 2013. Ovde ćemo demonstrirati primenu izložene teorije na elektronski sistem, a u posebnom radu i eksitonsku difuziju u modelu filma sa nanoskopskom debljinom.

A. Model elektrona u ultratankom metalnom filmu

Ultratanki metalni filmovi (UTF) jesu strukture sa narušenom simetrijom, pa se kao glavni problem analize UTF pojavljuje problem korektnog nalaženja Grinove funkcije (GF) filma. Kako je već ranije napomenuto, ovaj problem nije trivijalan, jer GF u strukturi sa narušenom simetrijom duž jednog pravca zavise od dva prostorna indeksa ponaosob, a ne od njihove razlike kao u balk-strukturi [31,32]. Zbog toga je cillj ove analize razvijanje takve tehnike sa GF koja će korektno reprodukovati karkateristike konkretnog UTF.

U analizi elektrona u UTF, koristićemo uprošćeni Habardov model [34,35], uzet u aproksimaciji najbližih suseda. Pretpostavićemo da je film „isečen“ iz idealne proste kubne stukture, pa hamiltonijan ovog podsistema ima oblik:

$$H=\sum_{\vec{n},\vec{\lambda}}W_{\vec{n},\vec{n}+\vec{\lambda}}A^{+}_{\vec{n}}A_{\vec{n}}-\sum_{\vec{n},\vec{\lambda}}W_{\vec{n},\vec{n}+\vec{\lambda}}A^{+}_{\vec{n}+\vec{\lambda}}A_{\vec{n}}+\sum_{\vec{n},\vec{\lambda}}W_{\vec{n},\vec{n}+\vec{\lambda}}A^{+}_{\vec{n}}A_{\vec{n}+\vec{\lambda}}. \qquad \text{(IV.1)}$$

U ovoj formuli W predstavlja energiju elektronskog transfera, tj. jon-jon interakciju, vektor $\vec{\lambda}$ spaja najbliže susede sa onim koji se nalazi u tački rešetke označenoj sa $\vec{n}$, a Fermi operatori A^{+} i A kreiraju i anihiliraju elektrone, respektivno. Dakle, UTF je tanslaciono invarijantan u XY ravnima, a simetrija je narušena samo u z-pravcu. U skladu sa ovim, vrednosti ideksa n_x, n_y i n_z kreću se u sledećim intervalima:

$$-\frac{N_i}{2}+1\le n_i\le\frac{N_i}{2};\ N_i\sim 10^8;\ i=x,y;$$
$$n_z=0,1,2,\cdots,N_z;\ N_z\le 10.$$

B. GF i korelaciona funkcija ultratankog metalnog filma

U analizi biće korišćena antikomutatorska GF [24,12–14]:

$$G_{\vec{n},\vec{m}}(t)\equiv\left\langle\left\langle A_{\vec{n}}\,\middle\|\,A^{+}_{\vec{m}}\right\rangle\right\rangle=\theta(t)\left\langle\left\{A_{\vec{n}},A^{+}_{\vec{m}}\right\}\right\rangle, \qquad \text{(IV.2)}$$

gde je $\theta(t)$ Hevisajdova step-funkcija ($\theta = 0$, za $t < 0$ i $\theta = 1$, za $t > 0$). Diferencirajući po vremenu (IV.2) uz korišćenje jednačina kretanja dolazimo do sledeće jednačine:

$$\begin{aligned}i\hbar\frac{d}{dt}G_{n_x,n_y,n_z;m_x,m_y,m_z}(t)&=i\hbar\delta(t)\delta_{n_x,m_x}\delta_{n_y,m_y}\delta_{n_z,m_z}+6WG_{n_x,n_y,n_z;m_x,m_y,m_z}(t)-\\&-W\left[G_{n_x+1,n_y,n_z;m_x,m_y,m_z}(t)+G_{n_x-1,n_y,n_z;m_x,m_y,m_z}(t)+G_{n_x,n_y+1,n_z;m_x,m_y,m_z}(t)+\right.\\&\left.+G_{n_x,n_y-1,n_z;m_x,m_y,m_z}(t)+G_{n_x,n_y,n_z+1;m_x,m_y,m_z}(t)+G_{n_x,n_y,n_z-1;m_x,m_y,m_z}(t)\right]\end{aligned} \qquad \text{(IV.3)}$$

U ovoj jednačini biće izvršene Furije-tansformacije vreme – frekvencija: $G_{n_x,n_y,n_z;m_x,m_y,m_z}(t)=\int_{-\infty}^{+\infty}d\omega\,\mathrm{e}^{-i\omega t}G_{n_x,n_y,n_z;m_x,m_y,m_z}(\omega)$;

$\delta(t)=\int_{-\infty}^{+\infty}d\omega\mathrm{e}^{-i\omega t}$; $\hbar\omega=E$, nakon čega ona prelazi u:

$$\begin{aligned}(E-6W)G_{n_x,n_y,n_z;m_x,m_y,m_z}(\omega)&=\frac{i\hbar}{2\pi}\delta_{n_x,m_x}\delta_{n_y,m_y}\delta_{n_z,m_z}-\\&-W\left[G_{n_x+1,n_y,n_z;m_x,m_y,m_z}(\omega)+G_{n_x-1,n_y,n_z;m_x,m_y,m_z}(\omega)+G_{n_x,n_y+1,n_z;m_x,m_y,m_z}(\omega)+\right.\\&\left.+G_{n_x,n_y-1,n_z;m_x,m_y,m_z}(\omega)+G_{n_x,n_y,n_z+1;m_x,m_y,m_z}(\omega)+G_{n_x,n_y,n_z-1;m_x,m_y,m_z}(\omega)\right]\end{aligned} \qquad \text{(IV.4)}$$

Na ovom mestu moramo uzeti u obzir da je simetrija narušena u z-pravcu, što znači da u račun moramo uvesti granične uslove u ovom pravcu, a koristićemo najjedostavnije – koji su u odsustvu slojeva za $n_z = –1$ i $n_z = N_z + 1$ jednaki:

$$W_{n_x,n_y,0;m_x,m_y,-1}=W_{n_x,n_y,N_z+1;m_x,m_y,N_z}=0.$$

Treba naglasiti da realističniji granični uslovi treba da uključe promene interakcija u graničnim slojevima i promenu interakcija između graničnog sloja i prvog unutrašnjeg sloja. Ovi opštiji granični uslovi bili su korišćeni u analizi sistema Frenkelovih eksitona [24,34,35]. U skladu sa usvojenim graničnim uslovima jednačina (IV.4) raspada se na sistem od 3^l jednačina, gde je l broj pravaca narušenja simetrije (u razmatranom slučaju je $l = 1$), pa sledi:

$\underline{n_z=0:}$

$$\begin{aligned}(E-5W)G_{n_x,n_y,0;m_x,m_y,m_z}&=\frac{i\hbar}{2\pi}\delta_{0,m_x}\delta_{0,m_y}\delta_{n_z,m_z}-\\&-W\left(G_{n_x+1,n_y,0;m_x,m_y,m_z}+G_{n_x-1,n_y,0;m_x,m_y,m_z}\right)-\\&-W\left(G_{n_x,n_y+1,0;m_x,m_y,m_z}+G_{n_x,n_y-1,0;m_x,m_y,m_z}\right)-\\&-WG_{n_x,n_y,1;m_x,m_y,m_z};\end{aligned} \qquad \text{(IV.5a)}$$

$\underline{1\le n_z\le N_z-1:}$

$$\begin{aligned}(E-6W)G_{n_x,n_y,n_z;m_x,m_y,m_z}&=\frac{i\hbar}{2\pi}\delta_{n_x,m_x}\delta_{n_y,m_y}\delta_{n_z,m_z}-\\&-W\left(G_{n_x+1,n_y,n_z;m_x,m_y,m_z}+G_{n_x-1,n_y,n_z;m_x,m_y,m_z}\right)-\\&-W\left(G_{n_x,n_y+1,n_z;m_x,m_y,m_z}+G_{n_x,n_y-1,n_z;m_x,m_y,m_z}\right)-\\&-W\left(G_{n_x,n_y,n_z+1;m_x,m_y,m_z}+G_{n_x,n_y,n_z-1;m_x,m_y,m_z}\right);\end{aligned} \qquad \text{(IV.5b)}$$

$\underline{n_z=N_z:}$

$$\begin{aligned}(E-5W)G_{n_x,n_y,N_z;m_x,m_y,m_z}&=\frac{i\hbar}{2\pi}\delta_{n_x,m_x}\delta_{n_y,m_y}\delta_{N_z,m_z}-\\&-W\left(G_{n_x+1,n_y,N_z;m_x,m_y,m_z}+G_{n_x-1,n_y,N_z;m_x,m_y,m_z}\right)-\\&-W\left(G_{n_x,n_y+1,N_z;m_x,m_y,m_z}+G_{n_x,n_y-1,N_z;m_x,m_y,m_z}\right)-\\&-WG_{n_x,n_y,N_z-1;m_x,m_y,m_z}.\end{aligned} \qquad \text{(IV.5c)}$$

Imajući u vidu da je film translatorno invarijantan u svim XY ravnima izvršićemo delimičnu transformaciju prostor-impuls:

 ISBN 978-86-7466-930-3

$$G_{n_x,n_y,n_z;m_x,m_y,m_z}(\omega)=\frac{1}{N_xN_y}\sum_{k_xk_y}\mathrm{e}^{iak_x(n_x-m_x)+iak_y(n_y-m_y)}G_{k_x,k_y}(\omega)\alpha_{n_z,m_z}(\omega),$$

sa Kronekerovim simbolima u reprezentaciji ravnih talasa:

$$\delta_{n_x;m_x}=\frac{1}{N_x}\sum_{k_x}\mathrm{e}^{iak_x(n_x-m_x)};\ \ \delta_{n_y;m_y}=\frac{1}{N_y}\sum_{k_y}\mathrm{e}^{iak_y(n_y-m_y)},$$

gde je a kostanta kristalne rešetke. Posle zamene ovih transformacija ovaj sistem jednačina se uprošćava i postaje:

$n_z=0$: $$G_{k_x,k_y}\left[W\alpha_{1,m_x}+(\varepsilon+W)\alpha_{0,m_x}\right]=\frac{i\hbar}{2\pi}\delta_{0,m_z};\tag{IV.6a}$$

$1\le n_z\le N_z-1$: $$G_{k_x,k_y}\left[W\left(\alpha_{n_z+1,m_x}+W\alpha_{n_z-1,m_x}\right)+\varepsilon\alpha_{n_z,m_z}\right]=\frac{i\hbar}{2\pi}\delta_{n_z,m_z};\tag{IV.6b}$$

$n_z=N_z$: $$G_{k_x,k_y}\left[W\alpha_{Nz-1,m_x}+(\varepsilon+W)\alpha_{N_z,m_x}\right]=\frac{i\hbar}{2\pi}\delta_{N_z,m_z},\tag{IV.6c}$$

gde je: $\varepsilon=E-2W-4W\sin^2\frac{ak_x}{2}-4W\sin^2\frac{ak_y}{2}$. Funkciju α podobno je uzeti u sledećem obliku:

$$\alpha_{n_z,m_z}(\omega)=\sum_\nu a_\nu(m_z,\omega)\left[\sin(n_z+1)\varphi_\nu-\sin n_z\varphi_\nu\right],$$

u kojem se nepoznate funkcije određuju tako da granične jednačine (IV.6a) i (IV.6c) budu zadovoljene. Ako se ovo zameni u (IV.6b) dobija se:

$$\sum_\nu G_{k_x,k_y}(2W\cos\varphi_\nu+\varepsilon)a_\nu\times\left[\sin(n_z+1)\varphi_\nu-\sin n_z\varphi_\nu\right]=\frac{i\hbar}{2\pi}\delta_{n_z,m_z},\tag{IV.7}$$

a zamenom u (IV.6a), ona postaje:

$$\sum_\nu G_{k_x,k_y}(2W\cos\varphi_\nu+\varepsilon)a_\nu\sin\varphi_\nu=\frac{i\hbar}{2\pi}\delta_{0,m_z}.$$

Lako se uočava da ova jednačina predstavlja specijalan slučaj jednačine (IV.7) za nultu vrednost indeksa n_z. Ako se izraz za $\alpha_{n_z,m_z}(\omega)$ zameni u (IV.6c), dobija se jednačina koja predstavlja specijalan slučaj izraza (IV.7) za $n_z = N_z$, pod uslovom:

$$(1-\cos\varphi_\nu)\sin(N_z+1)\varphi_\nu=0\ \ \Rightarrow\ \ \varphi_\nu=\frac{\nu\pi}{N_z+1},\tag{IV.8}$$

gde je $\nu=1,2,3,...,N_z$.

Konačan izraz za GF onda postaje:

$$G_{n_x,n_y,n_z;m_x,m_y,m_z}(\omega)=\frac{i}{2\pi}\frac{1}{N_x}\frac{1}{N_y}\sum_{k_x}\sum_{k_y}\sum_{\nu=1}^{N_z}\frac{\mathrm{e}^{iak_x(n_x-m_x)+iak_y(n_y-m_y)}}{\omega-\omega_{k_x,k_y,\nu}}\times\left[\sin(n_z+1)\frac{\nu\pi}{N_z+1}-\sin n_z\frac{\nu\pi}{N_z+1}\right]\sum_{\nu'=1}^{N_z}L^z_{\nu\nu'}\sin(m_z+\nu')\frac{\nu\pi}{N_z+1},\tag{IV.9}$$

a koeficijenti $L^z_{\nu\nu'}$ određuju se iz algebarske jednačine:

$$\delta_{n_z,m_z}=\sum_{\nu=1}^{N_z}\left[\sin(n_z+1)\frac{\nu\pi}{N_z+1}-\sin n_z\frac{\nu\pi}{N_z+1}\right]\times\times\sum_{\nu'=1}^{N_z}L^z_{\nu\nu'}\sin(m_z+\nu')\frac{\nu\pi}{N_z+1},$$

tako da ona bude zadovoljena kada je: $\delta_{n_z,m_z}=1$ za $n_z=m_z$ i $\delta_{n_z,m_z}=0$ za $n_z\ne m_z$.

Na osnovu definicije, npr. iz [36], spektralna intenzivnost elektronske GF će biti:

$$I_G=\left.\frac{G(\omega+i\delta)-G(\omega-i\delta)}{\mathrm{e}^{\frac{\hbar\omega}{\Theta}}+1}\right|_{\delta\to0^+}=\tag{IV.10}$$

$$=\frac{1}{N_x}\frac{1}{N_y}\sum_{k_x}\sum_{k_y}\sum_{\nu=1}^{N_z}\frac{\mathrm{e}^{iak_x(n_x-m_x)+iak_y(n_y-m_y)}}{\mathrm{e}^{\frac{\hbar\omega}{\Theta}}+1}\delta(\omega-\omega_{k_x,k_y,\nu})\times\left[\sin(n_z+1)\frac{\nu\pi}{N_z+1}-\sin n_z\frac{\nu\pi}{N_z+1}\right]\sum_{\nu'=1}^{N_z}L^z_{\nu\nu'}\sin(m_z+\nu')\frac{\nu\pi}{N_z+1},$$

a ona je potrebna radi proračuna korelacione funkcije [12-14]:

$$\left\langle A^+_{m_x,m_y,m_z}(0)A_{n_x,n_y,n_z}(t)\right\rangle=\int_{-\infty}^{+\infty}d\omega\,\mathrm{e}^{-i\omega t}I_G(\omega)=\tag{IV.11}$$

$$=\frac{1}{N_x}\frac{1}{N_y}\sum_{k_x}\sum_{k_y}\sum_{\nu=1}^{N_z}\frac{\mathrm{e}^{-i\omega_{k_x,k_y,\nu}t}}{\mathrm{e}^{\frac{E_{k_x,k_y,\nu}}{\Theta}}+1}\mathrm{e}^{iak_x(n_x-m_x)+iak_y(n_y-m_y)}\times\left[\sin(n_z+1)\frac{\nu\pi}{N_z+1}-\sin n_z\frac{\nu\pi}{N_z+1}\right]\cdot\sum_{\nu'=1}^{N_z}L^z_{\nu\nu'}\sin(m_z+\nu')\frac{\nu\pi}{N_z+1},$$

gde je:

$$E_{k_x,k_y,\nu}\equiv\hbar\omega_{k_x,k_y,\nu}=4W\left(\sin^2\frac{ak_x}{2}+\sin^2\frac{ak_y}{2}+\sin^2\frac{\nu}{N_z+1}\frac{\pi}{2}\right).\tag{IV.12}$$

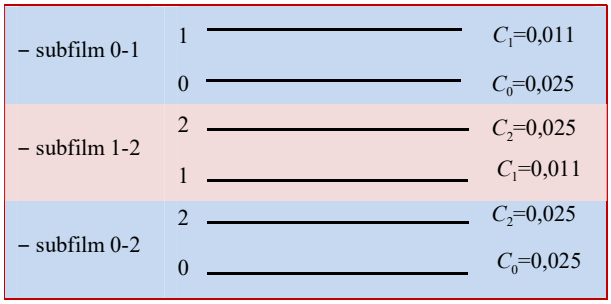
energija elektronskih stanja.

C. *Elektronske koncentracije u uskom sloju oko E_F*

Izraz za elektronsku koncentraciju dobija se preko (IV.11) ako se uzme $t = 0$ i $m_i = n_i$, $i = x,y,z$. Međutim, elektronske koncentracije moraju se računati u reprezentaciji hemijskog potencijala, tj. po statističkim formulama velikog kanonskog ansambla, zbog toga što se broj elektrona u sistemu održava. Hemijski potencijal biće uzet [13,24] kao najveća vrednost energije elektronskih stanja u prvoj Briluenovoj zoni [14], tj.

$$\mu=\left(E_{k_x,k_y,\nu}\right)_{\max}=4W\left(2+\sin^2\frac{N_z}{N_z+1}\frac{\pi}{2}\right).$$

Vodeći računa o ovoj napomeni, u (IV.11) mora se izvršiti zamena $E_{kx,ky,v} \rightarrow E_{kx,ky,v} - \mu$. Osim toga, elektroni koji se nalaze u uskom impulsnom sloju oko Fermi-površi najaktivniji su u fizičkim procesima [12,13], pa ćemo odrediti koncentracije u ovom sloju i to u formi:



$$C_{n_z}\equiv\left\langle A^+_{n_x,n_y,n_z}(0)A_{n_x,n_y,n_z}(0)\right\rangle.\tag{IV.13}$$

 ISBN 978-86-7466-930-3

s´tim da se sumiranje po k_x i k_y zamenjuje odgovarajućom integracijom: $\frac{1}{N_x}\frac{1}{N_y}\sum_{k_x}\sum_{k_y} \to \frac{a^2}{(2\pi)^2}\iint dk_x dk_y$ u aproksimaciji malih talasnih vektora.

Posmatraćemo ilustrativni primer: troslojni film (film sa tri XY paralelne neograničene kristalografske ravni – dve granične i jedna u sredini filma), dakle $N_z = 2$.

Na osnovu prethodnih rezultata upadljivo je da impulsni indeks ν uzima jednu vrednost manje nego konfiguracioni indeks n_z. Za izabrani primer: $n_z \in [0,1,2]$, dok $\nu \in [1,2]$. To fizički znači da u jednom sloju troslojnog filma nema provodnih elektrona sa zakonom disperzije (IV.12). U ovom slučaju elektroni ostaju lokalizovani ili se, eventualno, film jonizuje tako što elektroni iz jednog sloja napuste film. Na osnovu ovoga očigledno je da se troslojni film ponaša kao jedan od tri navedena subfilma. Ti subfilmovi su: subfilm sa $n_z = 0$ i $n_z = 1$ (u daljem tekstu oznaka 0-1), subfilm sa $n_z = 1$ i $n_z = 2$ (oznaka 1-2) i subfilm sa $n_z = 0$ i $n_z = 2$ (oznaka 0-2). Za svaki od pomenutih subfilmova ćemo izračunati koncentracije elektrona uz podatke da je: $W = 1{,}885 \cdot 10^{-19}$ J, a temperatura sobna, dakle: $\Theta = k_B T = 4{,}14 \cdot 10^{-21}$ J. Na osnovu ovoga, izračunali smo raspodelu koncentracija uzduž (nano)debljine filma za:

Rezultati analize pokazuju da se troslojni metalni film ponaša kao dvoslojni, jer se provodni elektroni pojavljuju samo u dva sloja. Za troslojni film postoje tri dvoslojna subfilma i to 0-1, 1-2 i 0-2, pri čemu su 0-1 i 1-2 fizički identični. Pošto su ti subfilmovi isti, verovatnoća njihovog pojavljivanja u eksperimentu iznosi 2/3, dok verovatnoća pojavljivanja filma 0-2 iznosi 1/3.

U svim subfilmovima zapaža se skin efekt. Kod subfilmova 0-1 i 1-2 skin efekt je asimetričan, dok je kod subfilma 0-2 simetričan. Skin efekt kod subfilma 0-2 može se nazvati pravim skin efektom, jer su koncentracije na granicama jednake, a u srednjem sloju nema provodnih elektrona. Mišljenje je da ova varijanta subfilma ima najbolje aplikativne perspektive.

V. Zaključak

Teorijsko izučavanje stuktura velikih dimenzija uglavnom zahteva rešavanje diferencijalnih jednačina sa konstantnim koeficijentima. U istraživanjima nanostruktura javljaju se difrerencne jednačine, ali i njihovi koeficijenti zavise od prostornih koordinata zbog neophodnosti da se u račun uvedu granični uslovi, kao i uticaj vakancija i primesa. Zbog povećanog interesovanja za ove probleme naša namera je da doprinesemo ovoj tematici. Cilj je da se prikaže kompletna tehnika izračunavanja diferencnih jednačina i demonstrira primena diferencnog računa u analizama fizičkih karakteristika savremenih nanostruktura.

Udarni trend ovog rada je čisto operativan, tj. ima za cilj da se razvije sposobnost za opisivanje i rešavanje konkretnih problema uvođenjem teorije diferencnog računa. Matematički fundamenti diferencnog računa u vidu korolara, teorema i komplikovanih dokaza nekih stavova ispušteni su jer se sve to može naći u predloženoj matematičkoj literaturi. Treba još napomenuti da se za niz rešenja različitih problema lako dokazuje da ona stvarno zadovoljavaju početnu jednačinu. Ovo je učinjeno prvenstveno zbog toga da se čitalac privikne na operativnu tehniku diferencnog računa. Najčešće korišćena matematička struktura u rešavanju problema diferencnog računa je ovde zastupljena uvođenjem translacionih operatora, jer se njihovim korišćenjem najefikasnije dolazi do rešenja opisanog problema. Dakle, ova prikazana teorija daje neophodno oruđe istraživačima – teoretičarima kako bi se iznašla odgonetka na pitanja kako i zašto dolazi do tako drastičnih izmena svojstava struktura kada se oni proizvedu sa nano-dimenzijama.

Najveći doprinos ove teorije diferencija i antidiferencija je mogućnost opisivanja vrlo specifičnih i bitno različitih osobina nanoskopskih u odnosu na balkovske kristalne strukture. Na konferencijama ETRAN još od početka ovog veka predstavljali smo različite metode za analizu sistema elementarnih pobuđenja uglavnom u ultratankim kristalnim filmovima i njihove karakteristične osobine, a ovde smo demonstrirali primenu izložene teorije na elektronski i eksitonski sistem. Od rezultata treba istaći upečatljiv skin-efekat i različitu prostornu distribuciju i različitu koncentraciju elementarnih pobuđenja.

Zahvalnica

Za ovako bogatu teoriju diferencija i antidiferencija, kao i diferencnih jednačina, najzaslužniji je pokojni akademik, prof. dr Bratislav Tošić (1935–2010).

Ovaj rad je finansijski podržan od strane Ministarstva za naučnotehnološki razvoj, visoko obrazovanje i informaciono društvo Republike Srpske (Projekti br. 19.032/961-36/19 i 19.032/961-42/19).

ABSTRACT

The trend of rapid development of nanotechnologies is caused by the discovery of nanostructures – materials that have significantly different physical characteristics when compared with large structures (balk). Nanostructures also have a series of qualitatively completely new and changed effects. For example, superconductive, thermal insulation, acoustic and other properties of nanomaterials are better or completely different from those properties in bulk structures. In general, the potential application in innovative pharmacy and medicine is particularly intriguing. In a way, differences between effects in nanostructures and massive structures can be compared to differences between quantum and classical effects. Theoretical study of balk structures generally requires solving differential equations with continuous variables. In the study of mechanisms in nanostructures, which are the culprits of drastic changes in their properties, differential equations have discrete variables. This is caused by the fact that coefficients depend on spatial coordinates due to the need to calculate dimensional – quantum and boundary (confinement) conditions, as well as the influence of vacancies and impurities. Due to increased interest and high expectations for the benefits of newly discovered effects, and especially due to undeveloped theory, we have presented a theory that aims to present the technique of calculating differential equations and to demonstrate this in a series of applications in the analysis of different – discovered and more undiscovered physical properties of nanostructures.Ovde dolazi prevod apstrakta na engleski. Srpski i engleski tekst apstrakta moraju se slagati.

Fundamentals of the Theory of Difference Equations Applied to the Analysis of the Properties of Nanostructures

Difuzija optičkih pobuđenja u tankim molekulskim filmovima

Jovan P. Šetrajčić i Siniša M. Vučenović

***Apstrakt*— Analizirana je difuzija Frenkelovih eksitona u ultratankom molekulskom filmu. Koeficijent difuzije je jedna od kinetičkih karakteristika materijala i zbog toga se analiza eksitonske difuzije može tretirati kao doprinos boljem poznavanju difuzionih procesa u molekulskim kristalima. Iz opšte teorije Grinovih funkcija izračunat je tenzor difuzije, a proračun testiran za primer molekulskog filma za 4 paralelna sloja. Pokazano je da su koeficijenti difuzije jednaki za unutrašnje slojeve, što je posljedica simetričnosti polja sila usljed dipol-dipol interkacije.**

***Ključne reči*—Eksitoni; koeficijent difuzije, molekulski film.**

I. Uvod

Eksitoni su pobuđenja koja u kristalima nastaju pod dejstvom svetlosti [1–4]. U poluprovodnicima pod dejstvom svetlosti nastaju eksitoni Vanije-Mota, koji se još nazivaju eksitoni velikog radijusa. Frenkelovi eksitoni su optička pobuđenja koja se javljaju u molekulskim kristalima (antracen, naftalin, naftacen, benzol u čvrstom stanju itd). Svetlosni kvant stvara par elektron-šupljina, ali ovaj par se, za razliku od situacije kod poluprovodnika, zadržava u molekulu u kome je stvoren. Ovo se dešava zbog toga što se elektronske talasne funkcije susednih molekula slabo prekrivaju. Pošto par ostaje u granicama molekula (u relativno malom prostoru u odnosu na prostor koji par zauzima u poluprovodnicima) ovi eksitoni su eksitoni malog radijusa.

Nastanak eksitonskog talasa može se opisati na sledeći način [1,2]: svetlosni kvant prevede elektron iz osnovnog stanja koje karakteriše skup kvantnih brojeva koji ćemo označiti indeksom 0 u pobuđeno stanje koje karakteriše skup kvantnih brojeva *f*. Pošto molekuli interaguju između sebe, pobuđenje se prenosi na susedni molekul i sa ovoga se prenosi dalje. Na taj način stvara se talas pobuđenja koji se naziva Frenkelov eksiton. Ako se posmatraju osnovno stanje elektrona i samo jedno pubuđeno stanje sa indeksom *f*, onda su očigledne sledeće mogućnosti: a) u osnovnom i u pobuđenom stanju nema elektrona; b) u osnovnom stanju se nalazi jedan elektron, a pobuđeno stanje je prazno; c) osnovno stanje je prazno, a u pobuđenom stanju se nalazi jedan elektron i d) osnovno i pobuđeno stanje sadrže po jedan elektron. To znači da je elektronski Hilbertov prostor u molekulu koji ćemo označiti sa *h* sadrži četiri vektora:

$$\left|0_0 0_f\right\rangle;\ \left|1_0 0_f\right\rangle;\ \left|1_f 0_0\right\rangle;\ \left|1_0 1_f\right\rangle.$$

Prostor *h* može se razdvojiti na dva pot prostora:

$$h_1 = \left\{\left|0_0 0_f\right\rangle, \left|1_0 1_f\right\rangle\right\};\quad h_2 = \left\{\left|1_0 0_f\right\rangle, \left|1_f 0_0\right\rangle\right\}.$$

S obzirom na opisani nastanak Frenkelovog eksitona očigledno je da proizvod elektronskih operatora $a_f^+ a_0$ odgovara stvaranju pobuđenja molekula, dok prozvod $a_0^+ a_f$ odgovara gašenju pobuđenja. Navedeni proizvodi elektronskih operacija ostaju zavoreni u potprostoru h_2 što znači da delujući na vektore iz potprostora h_2 daju vektore koji takođe pripadaju potprostoru h_2. Svojstvene vrednosti operatora $a_f^+ a_0$ i $a_0^+ a_f$ jednake su nuli u potprostoru h_1. Takođe je očigledno da je zbir svojstvenih vrednosti operatora brojeva elektrona $a_f^+ a_f$ i $a_0^+ a_0$ jednak jedinici u potprostoru h_2.

Proizvod operatora $a_f^+ a_0$ obeležava se sa P^+ i predstavlja operator kreacije eksitona, dok se operator $a_0^+ a_f$ označava sa P i predstavlja operator anihilacije eksitona. Operatori P^+ i P nazivaju se Pauli-operatori i ne zadovoljavaju ni bozonske ni fermionske komutatorske relacije. Njihove komutacione relacije su date [1] sa:

$$\left[P_{\vec{n}}, P_{\vec{m}}^+\right] = \left(1 - 2P_{\vec{n}}^+ P_{\vec{n}}\right)\delta_{\vec{n},\vec{m}};\ \left[P_{\vec{n}}, P_{\vec{m}}\right] = \left[P_{\vec{n}}^+, P_{\vec{m}}^+\right] = 0;$$

$$P_{\vec{n}}^2 = \left(P_{\vec{n}}^+\right)^2 = 0,$$

gde su $\vec{n}$ i $\vec{m}$ vektori kristalne rešetke molekulskog kristala. Vidi se da su komutacione relacije za Pauli-operatore delimično bozonskog, a delimično fermionskog tipa.

Do otkrića lasera pobuđivanje molekulskih kristala svetlošću iz standardnih izvora (živina lampa na primer) stvaralo je male koncentracije eksitona reda 10^{-15}, pa je analiza eksitonskog sistema sa kvadratnim bozonskim hamiltonijanom davala rezultate koji su se slagali sa eksperimentom.

Laseri velike snage stvaraju eksitonske koncentracije reda 10^{-3} i tada se mora uzeti u obzir i kinematička i dinamička interakcija eksitona, da bi se objasnili eksperimenti. Posle otkrića lasera [2], naglo se razvila tzv. nelinearna optika, koja je proučavala efekte eksiton-eksiton interakcije, kao što su stvaranje viših harmonika, pomeraj eksitonskih energetskih nivoa i multifotonska apsorpcija. Posebno je bio interesantan efekat multifotonske apsorpcije, koji se sastojao u tome što je molekulski kristal, osvetljen crvenom svetlošću, emitovao ljubičastu svetlost. Ovo se moglo objasniti time što je zbog visokih koncentracija eksitona i njihove međusobne interakcije dolazilo do fuzije dva crvena eksitona u jedan novi eksiton sa približno dvostrukom energijom. U današnjoj etapi

Akademik Jovan P. Šetrajčić, Akademija nauka i umjetnosti Republike Srpske, Bana Lazarevića 1, 78 000 Banja Luka, RS-BiH (e-mail: jovan.setrajcic@gmail.com).

Prof. dr Siniša M. Vučenović, Univerzitet u Banjoj Luci, PMF, Mladena Stojanovića 2, 78000 Banja Luka, RS-BiH (e-mail: sinisa.vucenovic@pmf.unibl.org)

 ISBN 978-86-7466-930-3

izučavanja eksitona uglavnom se radi na problemima nelinearne optike.

Pretpostavićemo da je molekulski kristal "isečen" iz anizotropne kubne strukture (ortorombičke strukture) [5–9] i da su mu konstante rešetke u pravcima *x*, *y* i *z*: a_x, a_y i a_z, respektivno. Takođe ćemo pretpostaviti da padajući na molekul, svetlosni kvanti prevode elektron iz osnovnog stanja u samo jedno pobuđeno stanje (dvonivoska šema molekulskih pobuđenja [10–16]). Tada su eksitonski operatori-Pauli-operatori.

Tenzor difuzije je dat izrazom:

$$D_{\vec{m},\vec{n}} = \int_0^\infty \mathrm{d}t e^{-\varepsilon t} < v_{\vec{m}}(0) v_{\vec{n}}(t) > ;\ \delta \to 0+ \tag{1}$$

gde je $< v_{\vec{m}}(0) v_{\vec{n}}(t) >$ korelaciona funkcija eksitonskih brzina.

II. Korelaciona funkcija brzina eksitona u molekulskom filmu

Brzina eksitona definiše se kao izvod po vremenu vektora rešetke koji je dat u operatorskoj formi [10–13]. Vektor rešetke je jednočestični operator, pa se preko elektronskih operatora a_s^+ i $a_{s'}$ daje u obliku kvadratne forme:

$$\hat{\vec{n}} = \sum_{s,s'} \vec{M}_{ss'} a_{\vec{n}s}^+ a_{\vec{n}s'} , \tag{2}$$

gde su: $\vec{M}_{ss'} = \int d^3\xi_{\vec{n}} \psi_s^+(\xi_{\vec{n}}) \hat{\vec{n}} \psi_{s'}(\xi_{\vec{n}})$ matrični elementi operatora $\hat{\vec{n}}$, dok su $\xi_{\vec{n}}$ unutrašnje koordinate molekula.

Pošto je pretpostavljeno da je šema molekulskih pobuđenja dvonivoska, indeksi *s* i *s'* uzimaju vrednosti 0 i *f*. Dijagonalni matrični elementi $\vec{M}_{0,0}$ i $\vec{M}_{f,f}$ jednaki su nuli, pa zbog toga formulu (2) možemo napisati na sledeći način:

$$\hat{\vec{n}} = \vec{M}_{0,f} a_{\vec{n}0}^+ a_{\vec{n}f} + \vec{M}_{f,0} a_{\vec{n}f}^+ a_{\vec{n}0} = \vec{M}_{0,f} P_{\vec{n}} + \vec{M}_{f,0} P_{\vec{n}}^+ ;$$
$$\vec{M}_{f,0} = \vec{M}_{0,f}^* . \tag{3}$$

Naglašavamo da je poslednji stav u ovoj formuli dobijen na osnovu definicije da je $P_{\vec{n}}^+ = a_{\vec{n}f}^+ a_{\vec{n}0}$, tj. $P_{\vec{n}} = a_{\vec{n}0}^+ a_{\vec{n}f}$.

Na osnovu definicije operatora brzine, može se pisati:

$$\vec{v}_{\vec{n}} = \dot{\hat{\vec{n}}} = \frac{1}{i\hbar}[\vec{n}, H], \tag{4}$$

a kombinujući sa (3), dobijamo:

$$\vec{v}_{\vec{n}}(t) = \frac{1}{i\hbar}\left\{\vec{M}_{0,f}\left[P_{\vec{n}}(t), H\right] + \vec{M}_{0,f}^*\left[P_{\vec{n}}^+(t), H\right]\right\}.$$

U trenutku $t = 0$ i $\vec{n} \to \vec{m}$, ovaj izraz postaje:

$$\vec{v}_{\vec{m}}(0) = \frac{1}{i\hbar}\left\{\vec{M}_{0,f}\left[P_{\vec{m}}(0), H\right] + \vec{M}_{0,f}^*\left[P_{\vec{m}}^+(0), H\right]\right\}.$$

Kombinacijom dve poslednje formule dobija se izraz za korelacionu funkciju eksitonskih brzina:

$$< v_{\vec{m}}(0) v_{\vec{n}}(t) > = \frac{1}{\hbar^2}\left\{M_{0f}^2 < \left[P_{\vec{m}}(0), H\right] \cdot \left[P_{\vec{n}}(t), H\right]_t > + \right.$$
$$+ \left(M_{f0}^*\right)^2 < \left[P_{\vec{m}}^+(0), H\right] \cdot \left[P_{\vec{n}}^+(t), H\right] > +$$
$$\left. + \left|M_{0f}\right|^2 < \left[P_{\vec{m}}^+(0), H\right] \cdot \left[P_{\vec{n}}(t), H\right] > \right\}. \tag{5}$$

Korelacione funkcije koje figurišu u ovom izrazu mogu se odrediti preko paulionskih Grinovih funkcija [15,16] i to:

- napredne (retardovane): $\Gamma_R = << P_{\vec{n}}(t) \left| P_{\vec{m}}^+(0) \right. >>$ (6)
- nazadne (avansovane): $\Gamma_A = << P_{\vec{n}}^+(t) \left| P_{\vec{m}}(0) \right. >>$ (7)

Pošto operatori P^+ i P kreiraju i anihiliraju eksitone, funkcije Γ biće dalje nazivane eksitonske Grinove funkcije.

III. Eksitonske Grinove funkcije u tankom molekulskom filmu

Za dvonivosku šemu molekulskih pobuđenja, hamiltonijan Frenkelovih eksitona ima oblik:

$$H = \sum_{\vec{n},\vec{m}} A_{\vec{n},\vec{m}} P_{\vec{n}}^+ P_{\vec{n}} + \sum_{\vec{n},\vec{m}} B_{\vec{n},\vec{m}} P_{\vec{n}}^+ P_{\vec{m}} + \sum_{\vec{n},\vec{m}} C_{\vec{n},\vec{m}} P_{\vec{n}}^+ P_{\vec{n}} P_{\vec{m}}^+ P_{\vec{m}} , \tag{8}$$

sa: $A_{\vec{n},\vec{m}} = \Delta\delta_{\vec{n},\vec{m}} + D_{\vec{n},\vec{m}}$; $D_{\vec{n},\vec{m}} = D_{\vec{m},\vec{n}}$; $B_{\vec{n},\vec{m}} = B_{\vec{m},\vec{n}}$; $C_{\vec{n},\vec{m}} = C_{\vec{m},\vec{n}}$.

Prvo ćemo potražiti nazadnu Grinovu funkciju:

$$\Gamma_{\vec{n},\vec{m}} = << P_{\vec{n}}(0) \left| P_{\vec{m}}^+(0) \right. >> = \theta(t) < [P_{\vec{n}}(t), P_{\vec{m}}^+(0)] > , \tag{9}$$

gde je $\theta(t) = \begin{cases} 1, & t > 0 ; \\ 0, & t < 0 , \end{cases}$ – Hevisajdova step-funkcija.

Diferencirajući izraz (9) po vremenu, dobijamo:

$$\frac{\mathrm{d}}{\mathrm{d}t}\Gamma_{\vec{n},\vec{m}} = \delta_{\vec{n},\vec{m}}\delta(t)\left(1 - 2 < P^+ P >\right) +$$
$$+\theta(t) < \left[\frac{\mathrm{d}P_{\vec{n}}(t)}{\mathrm{d}t}, P_{\vec{m}}^+(0)\right] > \tag{10}$$

Jednačine kretanja za operatore *P* su: $\frac{\mathrm{d}P_{\vec{n}}(t)}{\mathrm{d}t} = \frac{1}{i\hbar}[P_{\vec{n}}(t), H]$, pa se posle zamene ovoga u (10) dobija:

$$i\hbar\frac{\mathrm{d}}{\mathrm{d}t}\Gamma_{\vec{n},\vec{m}} = i\hbar\delta_{\vec{n},\vec{m}}\delta(t)\left(1 - 2P^+P\right) + << \left[P_{\vec{n}}, H\right]_t \left| P_{\vec{m}}^+(0) \right. >> \tag{11}$$

Pošto je, na osnovu (1) i (2):

$$\left[P_{\vec{n}}, H\right] = \Delta P_{\vec{n}} + D(0) P_{\vec{n}} + \sum_{\vec{g}} B_{\vec{n},\vec{g}} P_{\vec{g}} -$$
$$-2\sum_{\vec{g}} B_{\vec{n},\vec{g}} P_{\vec{n}}^+ P_{\vec{n}} P_{\vec{g}} + 2\sum_{\vec{g}} C_{\vec{n},\vec{g}} P_{\vec{g}}^+ P_{\vec{g}} P_{\vec{n}} \tag{12}$$

jednačina (11) postaje:

$$i\hbar\frac{\mathrm{d}}{\mathrm{d}t}\Gamma_{\vec{n},\vec{m}} = i\hbar\delta_{\vec{n},\vec{m}}\delta(t)\left(1 - 2P^+P\right) + \Delta\Gamma_{\vec{n},\vec{m}}(t) + D(0)\Gamma_{\vec{n},\vec{m}}(t) +$$
$$+\sum_{\vec{g}} B_{\vec{n},\vec{g}} << P_{\vec{g}} \left| P_{\vec{m}}^+(0) \right. >> - 2\sum_{\vec{g}} B_{\vec{n},\vec{g}} << P_{\vec{n}}^+ P_{\vec{n}} P_{\vec{g}} \left| P_{\vec{m}}^+(0) \right. >> +$$
$$+\sum_{\vec{g}} C_{\vec{n},\vec{g}} << P_{\vec{g}}^+ P_{\vec{g}} P_{\vec{n}} \left| P_{\vec{m}}^+(0) \right. >> . \tag{13}$$

Analizom ovog izraza vidi se da, pored jednočestičnih paulionskih Grinovih funkcija, ovde figurišu i dvočestične paulionske Grinove funkcije. Dvočestične Grinove funkcije izrazićemo preko jednočestičnih koristeći aproksimaciju Tjablikova (vidi [14–16]):

$$<< P_{\vec{n}}^+(t) P_{\vec{n}}(t) P_{\vec{m}}(0) \left| P_{\vec{l}}^+(0) \right. >> \approx$$
$$\approx << P_{\vec{n}}^+(t) P_{\vec{n}}(t) >> << P_{\vec{m}}(t) \left| P_{\vec{l}}^+(0) \right. >> \tag{14}$$

Navedena aproksimacija praktično znači da se proces rasejanja eksitona na realom potencijalu zamenjuje procesom pre-

 ISBN 978-86-7466-930-3

nosa na "umekšanom" potencijalu, koji predstavlja proizvod realnog potencijala i srednjeg broja eksitona. Koristeći ovu aproksimaciju, jednačinu (13) svodimo na:

$$i\hbar\frac{\mathrm{d}}{\mathrm{d}\,\mathrm{t}}\Gamma_{\vec{n},\vec{m}} = i\hbar\delta_{\vec{n},\vec{m}}\delta(\mathrm{t}) + \sigma[\Delta + \mathrm{D}(0) + 2 < P^{+}P > C(0)]\Gamma_{\vec{n},\vec{m}}(t) + \\ + \sigma\sum_{\vec{g}} B_{\vec{n},\vec{g}}\Gamma_{\vec{g}\vec{m}}(t). \quad (15)$$

Pošto analiziramo film "isečen" iz ortorombičke strukture, veličine navedene u (15) moramo predstaviti u obliku:

$$C(0) = 2C_x + 2C_y + 2C_z,\ D(0) = 2D_x + 2D_y + 2D_z.$$

U toj jednačini figuriše i veličina σ, koja zapravo predstavlja parametar uređenosti eksitonskog sistema i koja je data (vidi [14–16]) sa: $1 - 2 < P_{\vec{n}}^{+}P_{\vec{n}} >= \sigma$. U eksitonskom sistemu parametar uređenosti je blizak jedinici, pošto su najveće do sada postignute koncentracije eksitona $< P^{+}P >$ reda 10^{-3}.

Poslednji član na desnoj strani jednačine (15) uzećemo u aproksimaciji najbližih suseda (ostali članovi u ovoj jednačini već su uzeti u ovoj aproksimaciji. Posle ovoga ona postaje:

$$i\hbar\frac{\mathrm{d}}{\mathrm{d}\,\mathrm{t}}\Gamma_{n_x,n_y,n_z;m_x,m_y,m_z}(t) = i\hbar\delta_{\vec{n},\vec{m}}\delta(\mathrm{t})\sigma + \\ \left[\Delta + 2\left(\mathrm{D}_x + \mathrm{D}_y + \mathrm{D}_z\right) + 4 < P^{+}P > \left(C_x + C_y + C_z\right)\right]\Gamma_{n_x,n_y,n_z;m_x,m_y,m_z}(t) + \\ + \sigma\left\{\Delta B_x\left[\Gamma_{n_x+1,n_y,n_z;m_x,m_y,m_z}(t) + \Gamma_{n_x-1,n_y,n_z;m_x,m_y,m_z}(t)\right] + \right. \quad (17) \\ + B_y\left[\Gamma_{n_x,n_y+1,n_z;m_x,m_y,m_z}(t) + \Gamma_{n_x,n_y-1,n_z;m_x,m_y,m_z}(t)\right] + \\ \left. + B_z\left[\Gamma_{n_x,n_y,n_z+1;m_x,m_y,m_z}(t) + \Gamma_{n_x,n_y,n_z-1;m_x,m_y,m_z}(t)\right]\right\},$$

gde su *B* interakcije koje odgovaraju prenosu eksitona sa čvora na čvor uzete u aproksimaciji najbližih suseda.

U jednačini (17) izvršićemo Furije transformacije tipa vreme-frekvencija:

$$f(t) = \int_{-\infty}^{+\infty}\mathrm{d}\omega\mathrm{e}^{-i\omega t}f(\omega);\ \ \delta(t) = \frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}\omega\mathrm{e}^{-i\omega t},$$

a takođe i transformacije tipa prostor-talasni vektor:

$$\Gamma_{n_x,n_y,n_z;m_x,m_y,m_z}(\omega) = \frac{1}{N_x N_y}\sum_{k_x,k_y}\gamma_{n_z,m_z}(k_x,k_y,\omega)\mathrm{e}^{ik_x a_x(n_x-m_x)+ik_y a_y(n_u-m_u)}$$

$$\delta_{n_x,m_x} = \frac{1}{N_x}\sum_{k_x}\mathrm{e}^{ik_x a_x(n_x-m_x)};\ \ \delta_{n_y,m_y} = \frac{1}{N_y}\sum_{k_y}\mathrm{e}^{ik_y a_y(n_y-m_y)},$$

u kojima je iskorišćena činjenica da je film translatorno invarijantan u *XY* ravnima. Na taj način jednačina (17) se svodi na:

$$b\gamma_{n_z+1,m_z} + b\gamma_{n_z-1,m_z} + \rho\gamma_{n_z,m_z} = f_{n_z m_z};\ f_{n_z,m_z} \equiv -\frac{i\hbar}{2\pi}\sigma\delta_{n_z,m_z} \quad (18)$$

gde su: $\sigma B_z = b$;

$$\rho \equiv \rho(k_x,k_y) = \Delta + 2\left(D_x + D_y + D_z\right) + 4 < P^{+}P > \left(C_x + C_y + C_z\right) + \\ + 2\sigma\left(B_x\cos\mathrm{a_x}\,k_y + B_y\cos\mathrm{a}_y\,k_y\right) - E.$$

Dobijena jednačina (18) važi za idealnu balk-strukturu, jer u njoj nisu iskorišćeni granični uslovi duž *z* pravca. Uzećemo da se ovi granični uslovi sastoje u odsustvu slojeva $n_z = -1$ i $n_z = N_z + 1$. S obzirom na ovo, granični uslovi se mogu formulisati na sledeći način:

$$B_{n_x,n_y,0;n_x,n_y,-1} = B_{n_x,n_y,N_z;n_x,n_y,N_z+1} = 0;$$

$$C(0) = 2C_x + 2C_y + C_z;\ D(0) = 2D_x + 2D_y + D_z.$$

Primenom navedenih graničnih uslova jednačina (18) se razbija na sistem od $(N_z + 1)$ diferencnih jednačina:

$\underline{1 \le n_z \le N_z}$: $\quad b\gamma_{n_z+1,m_z} + b\gamma_{n_z-1,m_z} + \rho\gamma_{n_z,m_z} = f_{n_z,m_z}$ (19a)

$\underline{n_z = 0}$: $\quad b\gamma_{1,m_z} + (\rho - a_0)\gamma_{0,m_z} = f_{0,m_z}$ (19b)

$\underline{n_z = N_z}$: $\quad b\gamma_{N_z-1,m_z} + (\rho - a_0)\gamma_{N_z,m_z} = f_{N_z,m_z}$ (19c)

U ovim formulama veličina a_0 je data sa:

$$a_0 = D_z + 2 < P^{+}P > C_z.$$

Treba naglasiti da parametar uređenosti takođe može da zavisi od n_z, jer zavisi od srednje vrednosti $< P^{+}P >$. Ova zavisnost je zanemarena zbog malih vrednosti koje u eksitonskom sistemu imaju veličine $< P^{+}P >$.

Rešenje sistema (19a–c) potražićemo u obliku [17–20]:

$$\gamma_{n_z,m_z} = \sum_{\mu=1}^{N_z'}\left[\alpha_{\mu,m_z}\sin(n_z+1)\phi_\mu + \beta_{\mu,m_z}\sin n_z\phi_\mu\right], \quad (20)$$

u kojoj će veličina gornje granice sume N_z' biti određena kasnije. Zamenom (20) u (19a) dobijamo:

$$\sum_{\mu=1}^{N_z'}(2b\cos\phi_\mu + \rho)\left[\alpha_{\mu,m_z}\sin(n_z+1)\phi_\mu + \beta_{\mu,m_z}\sin n_z\phi_\mu\right] = f_{n_z,m_z}, \quad (21)$$

a zamena u (19b) daje:

$$\sum_{\mu=1}^{N_z'}\left(2b\cos 2\phi_\mu + \rho + b\frac{\beta_{\mu,m_z}}{\alpha_{\mu,m_z}} - a_0\right)\alpha_{\mu,m_z}\sin\phi_\mu = f_{0,m_z}. \quad (22)$$

Odavde je lako zaključiti da (22) postaje analogno jednačini (21) ako je:

$$b\frac{\beta_{\mu,m_z}}{\alpha_{\mu,m_z}} - a_0 = 0 \Rightarrow \beta_{\mu,m_z} = \frac{a_0}{b}\alpha_{\mu,m_z}. \quad (23)$$

S obzirom na ovo, izraz (20) prelazi u:

$$\gamma_{n_z,m_z} = \sum_{\mu=1}^{N_z'}\alpha_{\mu,m_z}\left[\sin(\mathrm{n}_z+1)\phi_\mu + \frac{a_0}{b}\sin\mathrm{n}_z\,\phi_\mu\right], \quad (24)$$

a ako se ovaj izraz zameni u (19c) dobija se:

$$\sum_{\mu=1}^{N_z'}\left[\frac{b\sin N_z\phi_\mu + a_0\sin(N_z-1)\phi_\mu}{\sin(N_z-1)\phi_\mu + \frac{a_0}{b}\sin N_z\phi_\mu} + \rho - a_0\right]\alpha_{\mu,m_z}\cdot \\ \cdot\left[\sin(N_z-1)\phi_\mu + \frac{a_0}{b}\sin N_z\phi_\mu\right] = f_{N_z,m_z}, \quad (25)$$

odakle je očigledno da ona postaje analogna relacijama (21) i (22), ako je ispunjen uslov

$$\frac{b\sin N_z\phi_\mu + a_0\sin(N_z-1)\phi_\mu}{\sin(N_z-1)\phi_\mu + \frac{a_0}{b}\sin N_z\phi_\mu} + \rho - a_0 = 2b\cos\phi_\mu,$$

koji se svodi na:

$$b^2\sin(N_z+2)\phi_\mu + a_0^2\sin N_z\phi_\mu + 2a_0 b\sin(N_z+1)\phi_\mu = 0. \quad (26)$$

 ISBN 978-86-7466-930-3

U opštem slučaju ova jednačina ima N_z' realnih rešenja. Može se pokazati da je $N_z' = N_z - 1$, ako je $\left|\frac{b}{a_0}\right| < 1$. Ukoliko je $\left|\frac{b}{a_0}\right| = 1$, broj N_z' jednak je N_z. Ukoliko je $\left|\frac{b}{a_0}\right| > 1$, dobija se da je $N_z' = N_z + 1$.

Rezime ove etape analize može se formulisati na sledeći način. Smena (21) svodi sve jednačine sistema (19a–c) na jednu jedinstvenu jednačinu:

$$\sum_{\mu=1}^{N_z'} \left(2b\cos\phi_\mu + \rho\right) \alpha_{\mu,m_z} \left(\sin\left(n_z+1\right)\phi_\mu + \frac{a}{b}\sin n_z\phi_\mu\right) = \\ = -\frac{i\hbar}{2\pi}\sigma\delta_{n_z,m_z} \tag{27}$$

koja važi za sve indekse $n_z = 0,1,2,...,N_z$ ukoliko je ispunjen uslov (26). Pošto je kod eksitonskog sistema $\left|\frac{b}{a_0}\right| < 1$, gornja granica sume je $N_z' = N_z - 1$.

Dalje ćemo uzeti da je α_{μ,m_z} u (26), koje zavisi od k_x, k_y i ω dato sa:

$$\alpha_{\mu,m_z}\left(k_x,k_y,\omega\right) = G_\mu\left(k_x,k_y,\omega\right)\sum_{\nu=1}^{N_z'-1} \mathrm{L}_{\mu\nu}\sin\left(m_z+\nu\right)\phi_\mu \tag{28}$$

a Kronekerov simbol u obliku:

$$\delta_{\mathrm{n_z,m_z}} = \sum_{\mu=1}^{N_z'-1}\left(\sin\left(n_z+1\right)\phi_\mu + \frac{a_0}{b}\sin n_z\phi_\mu\right)\cdot\sum_{\mu=1}^{N_z'-1}\mathrm{L}_{\mu\nu}\sin\left(m_z+\nu\right)\phi_\mu \tag{29}$$

Koeficijente $L_{\mu\nu}$ u ovim izrazima odredićemo kasnije.

Kombinujući (28), (29) i (26) dobijamo:

$$G_\mu\left(k_x,k_y,\omega\right) = -\frac{i\hbar}{2\pi}\sigma\frac{1}{2b\cos\phi_\mu + \rho}. \tag{30}$$

Izraz za funkciju *G* može se napisati u obliku [14,20]:

$$G_\mu\left(k_x,k_y,\omega\right) = -\frac{i\hbar}{2\pi}\sigma\frac{1}{E-E_k}, \tag{31}$$

gde je energija eksitona:

$$E_k = \Delta + 2\left(D_x + D_y + D_z\right) + 4 < P^+P > \left(C_x + C_y + C_z\right) + \\ +2\sigma\left(B_x\cos a_x k_x + B_y\cos a_y k_y + B_z\cos\phi_\mu\right); \tag{32}$$

gde je $< P^+P >= \frac{1-\sigma}{2}$.

Spektralnu intezivnost funkcije *G* nalazimo na osnovu opšte formule [1,2,15]:

$$I_G\left(\omega\right) = \frac{G_\mu\left(\omega+i\delta\right) - G_\mu\left(\omega-i\delta\right)}{\mathrm{e}^{\frac{\hbar\omega}{\Theta}} - 1};\ \delta\to+0;\ \omega_k = \frac{E_k}{\hbar},$$

gde je $\Theta = k_B T$ i dobijamo u obliku:

$$I_G\left(\omega\right) = \sigma\frac{\delta\left(\omega-\omega_{k_x,k_y,\mu}\right)}{\mathrm{e}^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}} - 1}. \tag{33}$$

Korelaciona funkcija u impulsnom prostoru, na osnovu definicionog izraza [1,2,15]:

$$< P^+_{k_x,k_y,\mu}\left(0\right)P_{k_x,k_y,\mu}\left(t\right) >= \int_{-\infty}^{+\infty} d\omega\,\mathrm{e}^{-i\omega_{k_x,k_y,\mu}t} I_G\left(\omega\right),$$

postaje:

$$< P^+_{k_x,k_y,\mu}\left(0\right)P_{k_x,k_y,\mu}\left(t\right) >= \sigma\frac{\mathrm{e}^{-it\omega_{k_x,k_y,\mu}}}{\mathrm{e}^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}} - 1}. \tag{34}$$

Izraz za korelacionu funkciju u konfiguracionom prostoru dobija se operatorskom primenom Kronekerovog simbola na korelacionu funkciju (34). Pod operatorskom primenom Kronekerovog simbola se podrazumeva sledeće: ako je Kronekerov simbol dat sa: $\delta_{n,m} = \frac{1}{N}\sum_{k=1}^{N}\mathrm{e}^{\mathrm{ik(n-m)}}$, onda njegova operatorska primena na funkciju $F\left(k\right)$ znači primenu operatora $\frac{1}{N}\sum_{k=1}^{N}$ na proizvod $\mathrm{e}^{\mathrm{ik(n-m)}}\cdot F\left(k\right)$. Za neku drugu reprezentaciju Kronekerovog simbola funkcija $F\left(k\right)$ se množi faktorom $f_{n,m}\left(k\right)$, koji definiše Kronekerov simbol, i na proizvod se primenjuje operator $\frac{1}{N'}\sum_{k=1}^{N}$. Tako dobijamo:

$$< P^+_m\left(0\right)P_n\left(t\right) >= \frac{\sigma}{N_z N_y}\sum_{k_z,k_y,\mu}\frac{\mathrm{e}^{-it\omega_{k_x,k_y,\mu}}}{\mathrm{e}^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}} - 1}\mathrm{e}^{i\left(n_x-m_x\right)a_x k_x + i\left(n_y-m_y\right)a_y k_y}\cdot \\ \cdot\left[\sin\left(n_z+1\right)\phi_\mu + \frac{a}{b}\sin n_z\phi_\mu\right]\sum_{\nu=1}^{N_z'-1}\mathrm{L}_{\mu\nu}\sin\left(m_z+\nu\right)\phi_\mu. \tag{35}$$

Pošto je Kronekerov simbol δ_{n_z,m_z} definisan relacijom (29), očigledno je da su koeficijenti $L_{\mu\nu}$ određeni sistemom algebarskih jednačina, tako da zadovolje definiciju:

$$\delta_{n_z,n_z} = \begin{cases} 1, n_z = m_z \\ 0, n_z \neq m_z \end{cases}$$

Formula (35) biće iskorišćena za nalaženje korelacione funkcije tipa brzina-brzina.

IV. TENZOR DIFUZIJE U TANKOM MOLEKULSKOM FILMU

Tenzor difuzije se izražava preko korelacione funkcije $< v_{\vec{m}}\left(0\right)v_{\vec{n}}\left(t\right) >$, koja je data formulom (5). Dva prva člana u tom izrazu jednaki su nuli, pošto su izraženi preko srednjih vrednosti koje ne sadrže jednak broj kreacionih i anihilacionih operatora. Srednja vrednost u četvrtom članu formule (5) može se odrediti preko nazadne Grinove funkcije (6). Srednje vrednosti u trećem članu (5) određuju se preko napredne Grinove funkcije (7).

Iz opšte teorije Grinovih funkcija poznato je da za Furijelikove funkcija Γ_R i Γ_A, koji su označeni sa *G* važi:

$$G_A\left(\omega\right) = G_R\left(-\omega\right).$$

Pošto je, na osnovu formule (31):

$$G_R\left(\omega\right) = \frac{i\sigma}{2\pi}\frac{1}{\omega-\omega_{k_x,k_y,\mu}}, \tag{36}$$

 ISBN 978-86-7466-930-3

gde je $\omega_{k_x,k_y,\mu} \equiv \frac{E_k}{\hbar}$ – definisano izrazom (32), dobija se:

$$G_A(\omega) = -\frac{i\sigma}{2\pi}\frac{1}{\omega+\omega_{k_x,k_y,\mu}}. \quad (37)$$

Spektralna intenzivnost napredne Grinove funkcije je onda:

$$I_G(\omega) = \frac{G(\omega+i\delta)-G(\omega-i\delta)}{e^{\frac{\hbar\omega}{\Theta}}-1} =$$

$$-\frac{i\sigma}{2\pi}\left(\frac{1}{\omega+\omega_0+i\delta}-\frac{1}{\omega+\omega_0-i\delta}\right)\cdot$$

$$\cdot\frac{1}{e^{\frac{\hbar\omega}{\Theta}}-1} = -\frac{\sigma}{e^{-\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}\delta\left(\omega+\omega_{k_x,k_y,\mu}\right) \quad (38)$$

dok je korelaciona funkcija u konfiguracionom prostoru:

$$< P_{\vec{m}}(0)P^{+}_{\vec{n}}(t) >= -\frac{\sigma}{N_xN_y}\sum_{k_z,k_y,\mu}\frac{e^{it\omega_{k_x,k_y,\mu}}}{e^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}e^{-i(n_x-m_x)a_xk_x-i(n_y-m_y)a_yk_y}\cdot$$

$$\cdot\left[\sin(n_z+1)\phi_\mu+\frac{a}{b}\sin n_z\phi_\mu\right]\cdot\sum_{\nu=1}^{M'}L_{\mu\nu}\sin(m_z+\nu)\phi_\mu. \quad (39)$$

Korelaciona funkcija iz izraza (5), sadrži dvočestične korelacione funkcije, koje predstavljaju srednje vrednosti četiri operatora. Koristeći Tjablikovu aproksimaciju [1,2,6,7], mi ćemo izraziti ove korelacione funkcije preko jednočestičnih korelacionih funkcija, koje se određuju preko nazadne Grinove funkcije. Pri tome će svi članovi koji sadrže kvadrate eksitonskih koncentracija biti zanemareni.

U isto vreme za dvočestične korelacione funkcije, koje se pojavljuju u trećem članu formule (5), koristi se Tjablikova aproksimacija i one se izražavaju preko jednočestičnih naprednih korelacionih funkcija, koje su date izrazom (39).

Koristeći formule (35) i (39) i aproksimaciju, kojom se u izrazu za $< v_{\vec{m}}(0)v_{\vec{n}}(t) >$ zadržavaju samo članovi proporcionalni Δ^2, $D\cdot\Delta$ i $B\cdot\Delta$, za korelacionu funkciju $< v_{\vec{m}}(0)v_{\vec{n}}(t) >$ dobijamo sledeći izraz:

$$< v_{\vec{m}}(0)v_{\vec{n}}(t) >= \frac{(M_{f0})^2}{(i\hbar)^2}\frac{\sigma}{N_zN_y}\sum_{k_z,k_y,\mu}e^{i(n_x-m_x)a_xk_x+i(n_y-m_y)a_yk_y}\cdot$$

$$\cdot\left[\sin(n_z+1)\phi_\mu+\frac{a_0}{b}\sin n_z\phi_\mu\right]\cdot$$

$$\cdot\sum_{\nu=1}^{N'_z}L_{\mu\nu}\sin(m_z+\nu)\phi_\mu\left(\frac{e^{-it\omega_{k_x,k_y,\mu}}}{e^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}-\frac{e^{it\omega_{k_x,k_y,\mu}}}{e^{-\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}\right)\cdot \quad (40)$$

$$\cdot\left\{\left[-\Delta^2-2\Delta D(0)-\left(D(0)\right)^2\right]-\right.$$

$$\left.-2\left[\Delta-D(0)\right]\sigma\left[B_x\cos a_x k_x+B_y\cos a_y k_y+B_z\cos\phi_\mu\right]\right\}.$$

Na osnovu definicione formule:

$$\vec{D}_{\vec{n}\vec{m}} = \int_0^\infty dt\, e^{-\varepsilon t} < v_{\vec{m}}(0)v_{\vec{n}}(t) >;\ \varepsilon\to 0$$

sledi da tenzor difuzije ima oblik:

$$\vec{D}_{\vec{n}\vec{m}} = \frac{2(M_{f0})^2}{\hbar\Delta}\frac{\sigma}{N_zN_y}\sum_{k_z,k_y,\mu}\frac{1}{\omega_{k_x,k_y,\mu}}e^{i(n_x-m_x)a_xk_x+i(n_y-m_y)a_yk_y}\cdot$$

$$\cdot\left[\sin(n_z+1)\phi_\mu+\frac{a_0}{b}\sin n_z\phi_\mu\right]\cdot$$

$$\cdot\sum_{\nu=1}^{N'_z}L_{\mu\nu}\sin(m_z+\nu)\phi_\mu\left(\frac{1}{e^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}-\frac{1}{e^{-\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}\right)\cdot \quad (41)$$

$$\left\{\left[-\Delta^2-2\Delta D(0)-\left(D(0)\right)^2\right]-\right.$$

$$\left.-2\left[\Delta-D(0)\right]\sigma\left[B_x\cos a_x k_x+B_y\cos a_y k_y+B_z\cos\phi_\mu\right]\right\}.$$

Dobijeni izraz je komplikovan, a radi dobijanja jasnije predstave o uticaju narušene simetrije na difuziju, izvršićemo dalja uprošćavanja. Zanemarićemo sve članove izuzev člana proporcionalnog Δ. Takođe ćemo bozonsku raspodelu zameniti bolcmanovskom, što se svodi na:

$$\frac{1}{e^{\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}\approx e^{-\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}};\quad \frac{1}{e^{-\frac{\hbar\omega_{k_x,k_y,\mu}}{\Theta}}-1}\approx -1.$$

Pored toga navešćemo samo dijagonalne elemente tenzora difuzije:

$$|D| = \frac{(M_{f0})^2}{\hbar}\sigma\Delta\left\{1+e^{-\frac{\Delta}{\Theta}}\left(1-\frac{6D+12<P^+P>C}{\Theta}\right)+\right.$$

$$+\frac{2\sigma B_0}{\Theta}e^{-\frac{\Delta}{\Theta}}\sum_{\mu=1}^{N'_z}\left[\sin(n_z+1)\phi_\mu+\frac{a_0}{b_0}\sin n_z\phi_\mu\right]\cdot \quad (42)$$

$$\left.\cdot\cos\phi_\mu\sum_{\mu=1}^{N'_z}L_{\mu\nu}\sin(n_z+\nu)\phi_\mu\right\}.$$

Pošto su svi dijagonalni elementi tenzora difuzije međusobno jednaki, dalje možemo govoriti o koeficijentu difuzije eksitona. U izrazu (42) je pretpostavljeno da eksitoni imaju pozitivnu disperziju, pa je zbog toga b iz formule (41) zamenjeno sa $-b_0$, gde je $b_0>0$, dok je B zamenjeno sa $-B_0$.

Kao ilustrativni primer ispitaćemo koeficijent difuzije u ultratankom molekulskom filmu koji sadrži četiri molekulska sloja. Ovi slojevi označeni su sa $n_z =$ 0,1,2 i 3. Uzećemo da je $\frac{a_0}{b_0}=8$. Za navedeni izbor parametara jednačina (26), u kojoj je b zamenjeno sa $-b_0$, ima dva realna rešenja:

$$\phi_1 = 1.12635\,\text{rad};\ \phi_2 = 2.15902\,\text{rad}. \quad (43)$$

To znači da se u četvoroslojnom filmu pojavljuju samo dva eksitona. Ova dva eksitona, ako pretpostavimo da se oni nalaze u dva susedna sloja, mogu se nalaziti u slojevima $n_z=0$ i $n_z=1$, ili u slojevima $n_z=1$ i $n_z=2$ ili u slojevima $n_z=2$ i $n_z=3$. Subfilmovi 0–1 i 2–3 su potpuno ekvivalentni pa je dovoljno ispitati samo jedan od njih. Zbog toga ćemo ispitati samo subfilmove 0–1 i 1–2.

Za subfilm 0–1 vrednosti koeficijenata L su:

$$L_{11} = 2,01347;\ L_{21} = 2,02689;$$
$$L_{12} = 4,25651;\ L_{22} = 6,54585. \quad (44)$$

 ISBN 978-86-7466-930-3

To znači da je korekcioni član u (42) – treći član na desnoj strani te jednačine:

$$\delta|D| = 4\frac{(M_{f0})^2}{\hbar}\Delta\cdot\frac{2\sigma^2 B_0}{\Theta}\mathrm{e}^{-\frac{\Delta}{\Theta}} \tag{45}$$

za $n_z = 0$. Za $n_z = 1$ ova korekcija je:

$$\delta|D| = -4\frac{(M_{f0})^2}{\hbar}\Delta\cdot\frac{2\sigma^2 B_0}{\Theta}\mathrm{e}^{-\frac{\Delta}{\Theta}}. \tag{46}$$

Zapaža se da u subfilmu 0–1 koeficijent difuzije zavisi od prostornog indeksa n_z, kojim se numerišu slojevi.

Za subfilm 1–2 koeficijenti L su dati sa:

$$\begin{aligned} &L_{11} = -0,07075;\ L_{21} = 0,08599;\\ &L_{12} = 0,09624;\quad L_{22} = 0,06963. \end{aligned} \tag{47}$$

Kada se ove vrednosti uvrste u izraz za koeficijent difuzije dobija se da su obe korekcije $\delta|D|$ i za $n_z = 1$ i za $n_z = 2$ jednake nuli. Ovaj rezultat je razumljiv pošto se slojevi 1 i 2 nalaze u istim poljima sila dipol-dipolne interakcije.

V. ZAKLJUČAK

Rezimirajući izvršene analize možemo navesti sledeće dve činjenice.

1. U tankom molekulskom filmu broj eksitona je manji od broja molekula u filmu za $2\cdot10^{16}$.
2. U graničnim slojevima četvoroslojnog filma (0–1 i 2–3) eksitoni imaju različite koeficijente difuzije. U centralnom sloju četvoroslojnog filma (1–2) eksitoni u oba sloja imaju isti koeficijent difuzije. Ovaj rezultat je fizički prihvatljiv s obzirom na činjenicu da se slojevi $n_z = 0$ i $n_z = 3$ nalaze u asimetričnim poljima sila dipol-dipolne interakcije, dok je polje ovih sila simetrično za molekule koji se nalaze u unutrašnjosti filma.

ZAHVALNICA

Ovaj rad je finansijski potpomoglo Ministarstvo za nauku, tehološki razvoj, visoko obrazovanje i informaciono društvo Vlade Republike Srpske (Projekti br. 19.032/961-36/19 i 19.032/961-42/19).

ABSTRACT

The diffusion of Frenkel excitons in a thin molecular film was analyzed. The diffusion coefficient is one of the kinetic characteristics of the material and therefore the analysis of exciton diffusion can be treated as a contribution to better knowledge of diffusion processes in molecular crystals. The diffusion tensor was calculated from the general theory of Green's functions, and the calculation was tested for the example of a molecular film with 4 parallel layers. It is shown that the diffusion coefficients are the same for the inner layers, which is a consequence of the symmetry of the force field due to the dipole-dipole interaction.

Diffusion of optical excitations in thin molecular films

I. UVOD

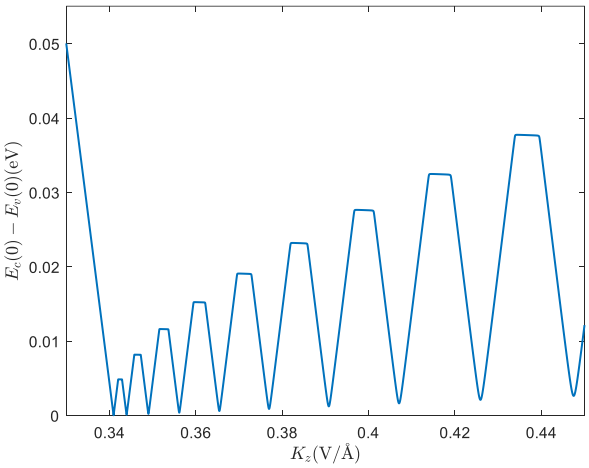
Proizvodnja tankih slojeva poluprovodničkih materijala pokrenula je novu eru razvoja elektronskih komponenti koja je započela uspešnim izdvajanjem nekoliko monoslojeva tankog filma grafita iz masivnog kristala [1]. Velika popularnost monosloja grafita, koji je poznat pod imenom grafen [2], dovela je do porasta interesovanja za takozvane dvodimenzione (2D) materijale. Prva teorijska istraživanja su ukazala da smanjena dimenzionalnost u jednom pravcu dovodi do manifestacije specifičnih elektronskih osobina kod tankoslojnih materijala u odnosu na masivne materijale od kojih su dobijeni [3], što ih je učinilo atraktivnim za potencijalne primene u elektronici. Za razliku od tankih slojeva grafita kod kojih energetski procep praktično ne postoji, tanki slojevi crnog fosfora se odlikuju velikom vrednošću energetskog procepa koja je nekoliko puta veća od vrednosti u masivnom uzorku što ga, zajedno sa velikom pokretljivošću šupljina, čini odličnim kandidatom za izradu pMOS tranzistora [4,5]. Istraživanja predviđaju da izražena anizotropija strukture crnog fosfora može dovesti do intenzivne manifestacije interesantnih efekata kod tankih slojeva materijala, takozvanog fosforena, kao rezultat anizotropije optičkih, električnih, mehaničkih i termalnih svojstava [6]. U cilju zaštite od spoljašnjih uticaja slojevi fosforena se umeću između monoslojeva heksagonalnog bor-nitrida, što u određenoj meri modifikuje njegova elektronska, električna, transportna i optička svojstva [7].

U cilju primene u realnim napravama fosforen se obično izrađuje u formi nanotraka [4]. Kao i svi 2D materijali sa heksagonalnom rešetkom, trake fosforena se mogu fabrikovati tako da imaju karakteristične regularne cik-cak ili foteljaste ivice, koje se razlikuju po elektronskoj strukturi i transportnim svojstvima [8]. Kod traka sa cik-cak ivicama postoje ivična stanja čija je energija u blizini centra procepa i ponašaju se kao metalne, dok trake sa regularnim foteljastim ivicama nemaju stanja u procepu i ponašaju se kao izolatorske. Bez obzira na tip ivica traka, njihove elektronske i transportne osobine se mogu podešavati primenom električnog polja gde u okolini kritične vrednosti polja primenjenog normalno na ravan trake dolazi do karakterističnih prelaza izolator-metal [8].

Ab initio proračuni elektronske strukture višeslojnog fosforena predviđaju da primena naprezanja može dovesti do formiranja Dirakovih konusa [9], što je inherentna karakteristika elektronske strukture topoloških izolatora. U formi masivnog materijala topološki izolatori poseduju energetski procep, dok u materijalu konačnih dimenzija dolazi do pojave karakterističnih stanja lokalizovanih po ivicama ili površinama strukture koja u inverznom prostoru, u vidu Dirakovog konusa, zatvaraju procep i invarijantna su u odnosu na inverziju u vremenu [10]. U ovom radu biće prikazano da se slična svojstva elektronske strukture mogu indukovati u dvoslojnom fosforenu primenom normalnog električnog polja.

II. TEORIJSKI MODEL

Za analizu elektronske strukture nanotraka korišćen je metod jake veze, gde je hamiltonijan dat sa



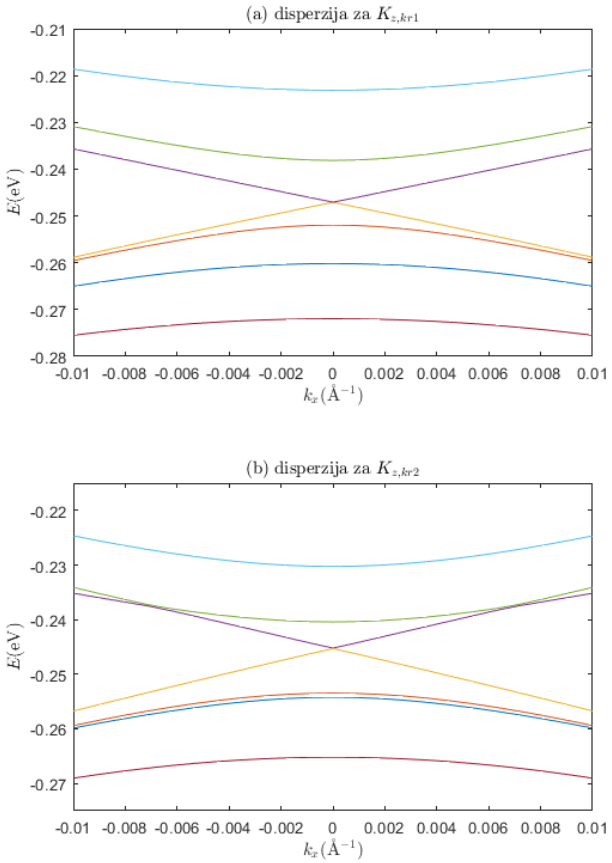
$$= \sum_{i \neq j} t_{i,j} c_i^{\dagger} c_j + \sum_i e \quad _i \mathbf{r}_i . \qquad (1)$$

Vladimir Arsoski – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: vladimir.arsoski@etf.bg.ac.rs), (https://orcid.org/0000-0002-9326-7809)

Milan Tadić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: tadic@etf.bg.ac.rs), (https://orcid.org/0000-0002-9408-7957)

 ISBN 978-86-7466-930-3

Ovde je $t_{i,j}$ energija skoka između *i*-tog i *j*-tog atoma, $c_i^{\dagger}\left(c_j\right)$ je operator kreacije (anihilacije) elektrona u *i*(*j*)-tom atomskom stanju, $_{\mathbf{i}}$ je vektor spoljašnjeg električnog polja na mestu *i*-tog atoma, $\mathbf{r_i}$ je vektor položaja *i*-tog atoma, a *e* je elementarno naelektrisanje. Referentna tačka za izračunavanje dodatnog potencijala u prisustvu električnog polja je postavljena u koordinatni početak i poklapa se sa centrom nanotrake. Korišćeno je 10 parametara za skokove u okviru jednog monosloja, dok su sa 5 parametara opisani skokovi između monoslojeva. Izabrani skup parametara daje verodostojne rezultate za razmatranu višeslojnu strukturu [11]. Rastojanja između atoma, koja figurišu kroz članove zavisne od položaja atoma, su preuzeta iz reference [8]. Širina trake je određena brojem dimera duž poprečnog preseka trake, dok jediničnu ćeliju sačinjava minimalan skup atoma čijim se periodičnim ponavljanjem reprodukuje nanotraka beskonačne dužine. Za implementaciju trake nominalno beskonačne dužine korišćeni su periodični granični uslovi. Dijagonalizacijom matrice hamiltonijana (1) dobija se skup svojstvenih vrednosti i svojstvenih vektora koji opisuje elektronsku strukturu razmatranog sistema.

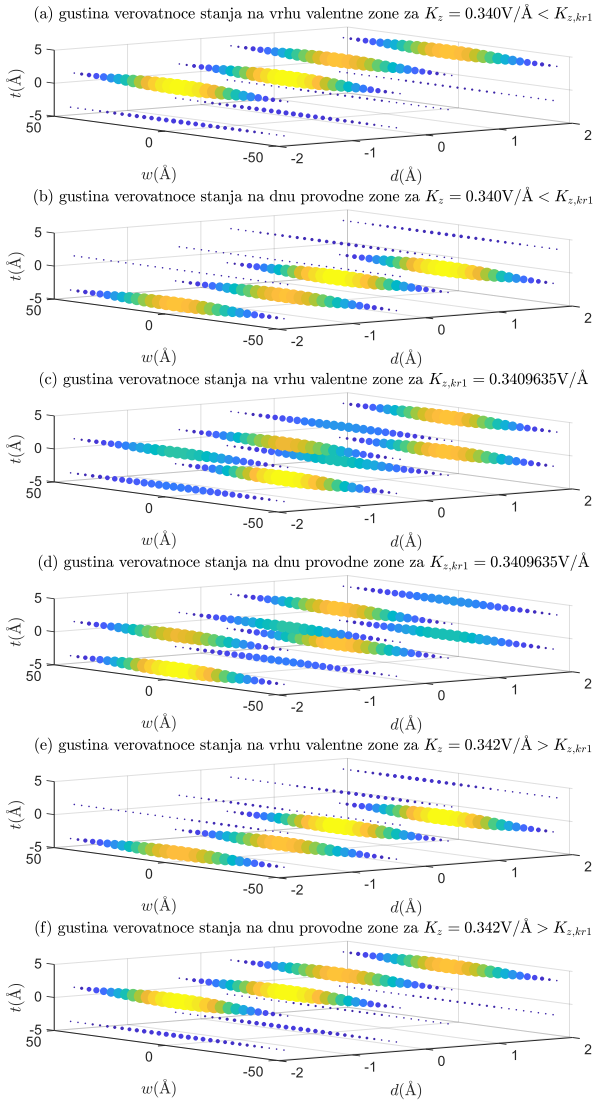


Sl. 1. Razlika svojstvenih vrednosti stanja najniže energije u provodnoj zoni i stanja najviše energije u valentnoj zoni u 0 u funkciji amplitude normalnog električnog polja .

III. REZULTATI I DISKUSIJA

Analizirane su trake sa regularnim foteljastim ivicama debljine dva monosloja fosforena, pri čemu je broj dimera u jednom monosloju duž poprečnog preseka N_d =61 što približno odgovara širini trake od 10 nm. Referentna tačka za potencijal je tačka na sredini između slojeva na polovini širine trake. Osa je usmerena duž trake, osa *y* je paralelna ravni monoslojeva duž poprečnog preseka trake, dok je osa normalna na ravan strukture.

Najpre je analiziran uticaj električnog polja primenjenog normalno na površinu trake na razliku energija stanja na dnu provodne zone i stanja na vrhu valentne zone u tački k = 0. U određenom opsegu amplituda električnog polja ova razlika odgovara širini energetskog procepa koji je direktan. Povećanje amplitude električnog polja dovodi do smanjenja procepa i za određene kritične vrednosti se pojavljuju minimumi, što je prikazano na Sl.1. Može se uočiti da lokalni minimumi procepa imaju veću vrednost što je amplituda kritičnog polja veća.



Sl. 2. Prikaz zavisnosti svojstvenih energija u okolini centra zone u funkciji talasnog vektora k, usmerenog duž trake, za kritičnu vrednost amplitude električnog polja za koju energetski procep ima minimalnu vrednost: (a) najniža kritična vrednost polja $_{,kr1}$ = 0.3409635 V/Å; (b) prvi sledeći (lokalni) minimum $_{,kr2}$ = 0.3439790398 V/Å.

Disperzije u okolini centra zone za najnižu kritičnu vrednost polja $_{,kr1}$ = 0.3409635 V/Å kada procep ima minimalnu širinu $E_{g1,\min}$ = 22.96310 μeV i za prvu sledeću vrednost $_{,kr2}$ = 0.3439791 V/Å kada je vrednost procepa $E_{g2,\min}$ = 92.49116 μeV su prikazane na Sl.2 (a) i (b), redom. U tački k =0 dolazi do antiukrštanja stanja energija najbližih energetskom procepu, takozvanih najnižih stanja u provodnoj i valentnoj zoni. Ukoliko se kao referentan raspored usvoji raspored stanja na disperziji kada polje nije primenjeno, pri prvoj kritičnoj vrednosti polja dolazi do antiukrštanja najnižih stanja u provodnoj i valentnoj zoni za $_{,kr1}$. Za vrednost polja $_{,kr2}$ dolazi do antiukrštanja drugog stanja iz provodne i drugog iz valentne zone pri čemu se tačka antiukrštanja prvog stanja iz provodne i valentne zone pomera iz centra zone

 ISBN 978-86-7466-930-3

većim vrednostima $|k|$, što se lako može uočiti sa Sl.2 (b) (tačka antiukrštanja je za $|k| \cong 0.007\,\text{Å}^{-1}$). Ovaj trend se nastavlja sve do amplitude polja $_{,kr10}$ = 0.447989 V/Å, koja odgovara desetom (krajnjem desnom) lokalnom minimumu na Sl.1, kada procep postaje indirektan. Tada materijal prelazi iz izolatorskog u polumetalno stanje.

Sl. 3. Prikaz gustine verovatnoće stanja: (a) na vrhu valentne zone za polje = 0.340 V/Å < $_{,kr1}$; (b) na dnu provodne zone za polje = 0.340 V/Å < $_{,kr1}$; (c) na vrhu valentne zone za polje $_{,kr1}$ = 0.3409635 V/Å; (d) na dnu provodne zone za polje $_{,kr1}$ = 0.3409653 V/Å; (e) na vrhu valentne zone za polje = 0.342 V/Å > $_{,kr1}$; (f) na dnu provodne zone za polje = 0.342 V/Å > $_{,kr1}$; Na slici osa *w* je postavljena po širini trake, *d* po dužini, dok je *t* normalno na površinu trake.

Da bi ustanovili koliko je ova struktura slična topološkim izolatorima, izračunate su gustine verovatnoća stanja na dnu provodne i vrhu valentne zone za amplitude električnog polja u okolini prve kritične vrednosti, što je prikazano na Sl.3. Za vrednosti polja koje su manje od $_{,kr1}$ stanja u valentnoj zoni su pretežno lokalizovana na gornjoj površini trake, dok su stanja u provodnoj na donjoj, što se može uočiti na Sl. 3 (a) i (b), redom. Električno polje je normalno na površinu trake i usmereno vertikalno naviše (u smeru *t* ose) tako da potiskuje šupljine na gornju površinu, dok su elektroni potisnuti na donju. Za kritičnu vrednost električnog polja lokalizacija stanja u valentnoj i provodnoj zoni je slična, pri čemu su stanja u različitim zonama lokalizovana na različitim podrešetkama strukture, što je prikazano na Sl. 3 (c) i (d). Ovo je posledica izrazite anizotropije dvoslojnog fosforena i posebno male debljine strukture zbog čega je sprezanje stanja u valentnoj i provodnoj zoni jako čak i pri velikim amplitudama električnog polja koje teži da razdvoji elektrone i šupljine. U slučaju kada je amplituda polja veća od kritične vrednosti, uočava se da su stanja na vrhu valentne zone lokalizovana na donjoj površi, dok su stanja na dnu provodne zone lokalizovana na gornjoj površi (videti Sl.3 (e) i (f)) što je obrnuto od onoga što smo imali na Sl.3 (a) i (b) kada je amplituda polja bila manja od kritične. Ovo je indikacija da je u oblasti antiukrštanja došlo do inverzije zonske strukture, što je ponašanje slično onome koje se sreće kod topoloških izolatora. Inverzija zonske strukture počinje u centru zone i širi se ka ivicama zone sa porastom amplitude električnog polja. Za stanja kod kojih nije došlo do inverzije lokalizacija je takva da su stanja u valentnoj zoni pretežno na atomima na gornjoj površi strukture, dok su stanja u provodnoj zoni dominantno lokalizovana na donjoj, što odgovara efektu koji električno polje ima na šupljine i elektrone.

IV. ZAKLJUČAK

U radu je teorijski razmatrana elektronska struktura dvoslojnih traka od fosforena sa foteljastim ivicama. Utvrđeno je da primenom normalnog električnog polja dolazi do antiukrštanja stanja iz provodne i valentne zone, što je praćeno zonskom inverzijom. Nađene su kritične vrednosti polja za koja je procep između zona minimalan. Za veće kritične vrednosti polja, procep je veći. Za razmatrane kritične vrednosti je nađeno da je u centru zone lokalizacija stanja u različitim zonama energija najbližih ivici procepa bila slična, ali na različitim podrešetkama. Ovo je posledica anizotropije i male debljine strukture. Indukovani efekti su slični onima koji se sreću kod topoloških izolatora. U daljem istraživanju bi trebalo utvrditi kako magnetsko polje u ravni utiče na disperziju, što bi dalo dodatne rezultate koji bi ukazali na topološke efekte.

ZAHVALNICA

Ovaj rad je podržan od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije 451-03-68/2022-14/200103.

ABSTRACT

Tight-binding method is employed for electronic structure analysis in bilayer black phosphorous nanoribbons in presence of electric field. Due to the absence of edge states, there is a large gap in arm-chair nanoribbons in absence of an external field. An application of an electric field perpendicular to the ribbon surface decreases the gap width. At the critical value of the electric field, the gap is almost completely closed due to sharp anti-crossing between the lowest energy conduction band state and the highest energy valence band state. This behavior is characteristic in conventional topological insulators where an inversion of the zone structure is due to strong spin-orbit interaction that is not accounted for in our model. It is found that in thin nanoribbons there is a strong coupling between conduction and valence band states due to anisotropy despite the electrons are holes being pushed to the opposite sides of the slab by an external electric field. Increase of the perpendicular electric field above critical value results in an inversion of higher conduction and valence band states that manifests in characteristic anti-crossings.

I. UVOD

Već više decenija elektronske naprave zasnovane na silicijumu dominiraju u izradi elektronskih naprava. Trendovi minijaturizacije elektronskih naprava doveli su silicijum do granice kada kvantnomehanički efekti, koji dominiraju pri malim dimenzijama strukture, bitno utiču na funkcionisanje naprave. Kao alternativa su se pojavili materijali izrađeni od jednog ili više monoslojeva poluprovodničkog krustala, poznati kao dvodimenzioni (2D) materijali, koji usled malih dimenzija pokazuju poboljšana elektronska, transportna, električna, termička i optička svojstva u odnosu na masivne materijale od kojih su dobijeni. Kao posebno interesantan materijal, zbog velike potencijalne primene, izdvaja se monosloj grafita poznat kao grafen [1]. Uspešna fabrikacija ovog materijala pokrenula je eru razvoja post-silicijumske elektronike koja obećava veliki napredak u domenu elektronskih naprava [2]. Prvobitna fabrikacija grafena zasnivala se na metodi mehaničke eksfolijacije pomoću dvostruko-lepljive trake [3]. Ovako dobijeni uzorci su imali mnogo defekata, bili su relativno malih dimenzija i obično su se sastojali od više monoslojeva grafita, te metoda nije bila reproduktivna. Usledile su tehnike eksfolijacije u tečnoj fazi organskih rastvarača, jonskih tečnosti, rastvora surfaktanata i mnogih rastvarača koji su imali sličan površinski napon kao i grafen [4]. Vremenom se kao dominantna metoda izdvojila sonifikacija [5]. Ultrazvuk se prostire kroz tečnu fazu do grafena gde dovodi do naizmenične promene pritiska, što uzrokuje sabijanje i razvlačenje veza između slojeva atoma. Prilikom razdvajanja monoslojeva u međuprostoru se stvaraju mikromehurići, koji postepeno narastaju i pucaju pri dostizanju kritične veličine, što dovodi do generacije snažnih udarnih talasa. Dalje se centrifugiranjem mogu razdvojiti supernatant i dobijeni grafenski proizvod. Iako zahteva veliku količinu energije i ima malu efikasnost, ova metoda se koristi jer se njome uspešno mogu proizvesti monoslojevi [6]. Kao efikasna metoda za dobijanje grafenskih nanotraka pokazala se tehnika zasecanja i razvijanja ugljeničnih nanotuba. Veličina dobijenih traka zavisi od dijametra i dužine nanotube, dok tip ivica određuje pravac zasecanja nanotrake [7]. Kao efikasna metoda za formiranje slojeva grafena velike površine i sa malo defekata pokazala se tehnika heteroepitaksije, gde se narastanje vrši na supstratu koji ima sličnu kristalnu strukturu kao i grafen [8]. Posebno interesantan supstrat je silicijum karbid (SiC) na kojem je kontrolisanim postupkom moguće narasti jedan monosloj ukoliko se narastanje vrši na površini orijentacije (0001) [9]. Fabrikovane površine grafena se dalje mogu obrađivati radi postizanja željene morfologije.

Kao glavni nedostatak grafena kod primene u tranzistorima navodi se zanemarljiva vrednost energetskog procepa koja otežava njegovu primenu u tranzistorima sa efektom polja. Procep od nekoliko desetina meV može se dobiti oblikovanjem grafena u formu traka malih dimenzija [10] ili slaganjem više slojeva grafena (stekovanjem) na različite načine [11], što nije sasvim dovoljno za veliki broj savremenih primena.

Poznato je da proizvoljno mala periodična perturbacija masivnog dielektričnog materijala dovodi do pojave zabranjenog opsega učestanosti za prostiranje svetlosti u materijalu, što odgovara nastanku fotonskog procepa [12]. Periodične perturbacije imaju sličan efekat i na elektronsku strukturu poluprovodnika. Pokazano je da se specifičnim periodičnim uvijanjem grafena može neznatno otvoriti energetski procep [13]. Ideja je da se pomoću periodičnih

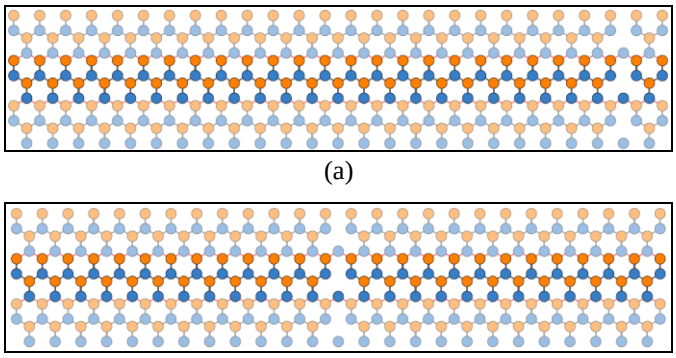
defekata formiranih u grafenu kontroliše veličina energetskog procepa.

Inherentan tip defekta u grafenu predstavljaju upražnjena mesta u rešetki, takozvane vakancije, koje imaju slučajan raspored u strukturi. Površinska koncentracija ovih defekata zavisi od primenjenih tehnika fabrikacije, a najmanja je kod novijih tehnike fabrikacije [7-9]. Utvrđeno je da defekti ovog tipa u izvesnoj meri utiču na elektronska i magnetska svojstva grafenskih nanotraka [14, 15]. Primenom tehnike koja koristi visokoenergetske jone ili elektrone moguće je precizno ukloniti pojedine atome iz rešetke, što otvara mogućnost za preciznu kontrolu položaja defekata [16], a samim tim i kontrolu veličine procepa u strukturama od grafena.

II. Implementacija modela

Modelovanje elektronske strukture grafenskih nanotraka zasnovan je na metodi jake veze. Teorijske osnove razmatranog modela mogu se naći u [17]. Za implementaciju modela je korišćena biblioteka PyBinding 0.9.5 [18] koja je napravljena u programskom jeziku Python. U radu je korišćena aproksimacija koja razmatra skokove samo na najbliže susede. Svi parametri koji figurišu u modelu su preuzeti iz [19].

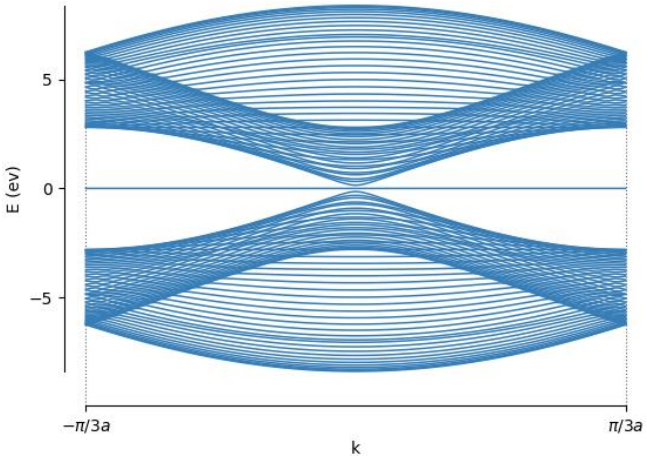


U zavisnosti od pravca zasecanja sloja grafena, nanotrake mogu imati različite ivice, ali se najčešće razmatraju trake sa cik-cak i foteljastim ivicama [20]. U ovom radu su analizirane trake sa foteljastim ivicama pošto, za razliku od traka sa cik-cak ivicama, kod njih ne postoje ivična stanja. Razmatrane su isključivo trake sa periodičnim defektima u vidu jedne vakancije, pri čemu se u prvoj aproksimaciji usvaja da nije došlo do ismene položaja atoma u okolini upražnjenog mesta u rešetki [21]. Kada nedostaje više susednih ugljenikovih atoma u sloju grafena može doći do građenja novih veza i međusobnog vezivanja nesusednih atoma [22].

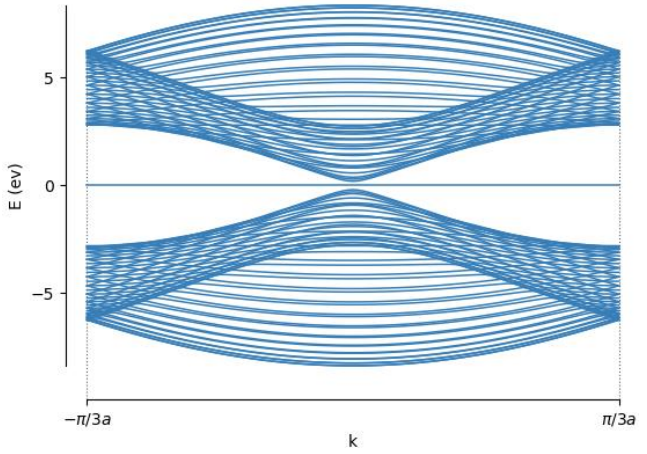
Sl. 1. Izgled elementarne ćelije čijim se ponavljanjem u prostoru reprodukuje traka sa foteljastim ivicama proizvoljne širine [17,18].

III. Rezultati i diskusija

Pri analizi nanotraka korišćena je elementarna ćelija prikazana na Sl.1. Atomi različite boje pripadaju različitim podrešetkama. Periodičnim ponavljanjem elementarne ćelije u pravcu vektora $\mathbf{a}_1$ može se reprodukovati nanotraka sa foteljastim ivicama proizvoljne širine. Minimalna širina trake odgovara dužini vektora $\mathbf{a}_2$. Uvođenje periodičnih graničnih uslova u ovom pravcu ekvivalentno je formiranju trake nominalno beskonačne dužine. Usvojeno je da je minimalno rastojanje defekata $w_{\min}=|\mathbf{a}_2|$. Analiziran je slučaj gde se defekti mogu periodično ponavljati duž trake u pravcu vektora $\mathbf{a}_2$ tako da im je međusobno rastojanje $w = mw_{\min}$, gde je m prirodan broj. Rastojanje defekata w ujedno predstavlja dužinu elementarne ćelije koja gradi traku beskonačne dužine.



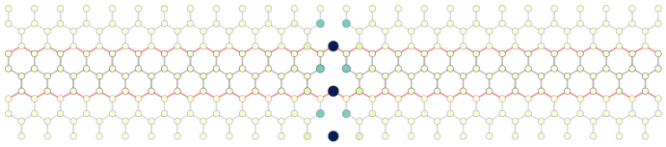
Sl. 2. Jedinična ćelija nanotrake kod koje je rastojanje vakancija $d_{\min}$ za položaj defekta: (a) najbliže ivici trake, (b) na sredini trake [17].



Analizirane su trake sa foteljastim ivicama širine 6.149 nm. U slučaju najmanjeg rastojanja između defekata duž trake, jediničnu ćeliju nanotrake sačinjava 50 C-C dimera i jedan ugljenikov atom. U slučaju trake bez defekta broj dimera bi bio 51. U nedavnim istraživanjima je ustanovljeno da grafenske nanotrake, čija se elementrarna ćelija sastoji od $3N$ nizova dimera, gde je N prirodan broj, mogu da imaju veće energetske procepe i bolje optička svojstva nego trake čije elementrarne ćelije broje $3N$+1 i $3N$+2 dimera [23,24]. Nanotrake kod kojih su defekti periodično raspoređeni na rastojanju w sastoje se od $51\cdot w$ dimera umanjeno za jedan ugljenikov atom, te približno zadovoljavaju navedeni uslov.

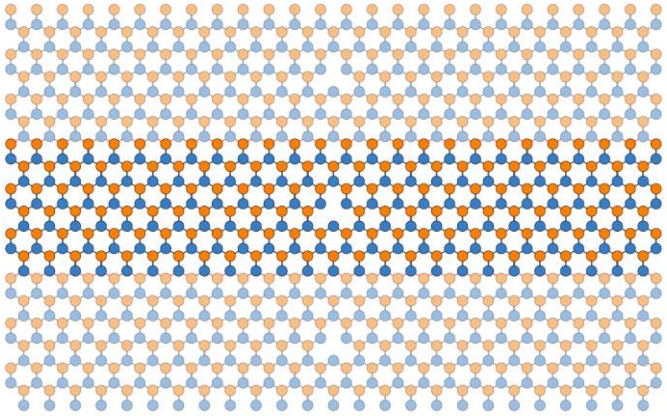
Najpre su analizirane trake kod kojih je rastojanje defekata $d_{\min}$. Položaj vakancije je pomeran po širini trake i menjan je od položaja najbližeg ivici trake (videti Sl. 2(a)) do položaja na sredini trake (videti Sl. 2(b)). Ustanovljeno je da se razlika energija dna provodne i vrha valentne zone povećavala od vrednosti 0.206 eV za slučaj kada je defekt lociran najbliže ivici trake, do vrednosti 0.395 eV za slučaj centralnog defekta, što je veće od vrednosti koja se dobija za traku iste širine bez vakancija [17]. Disperzione relacije za traku sa ivičnim i centralnim defektom su prikazane na Sl. 3(a) i (b), redom. Na obe disperzije se može uočiti pojava ravnih zona u centru energetskog procepa. Ova stanja su slična ivičnim stanjima koja se pojavljuju u nanotrakama sa cik-cak ivicama [17].

 ISBN 978-86-7466-930-3



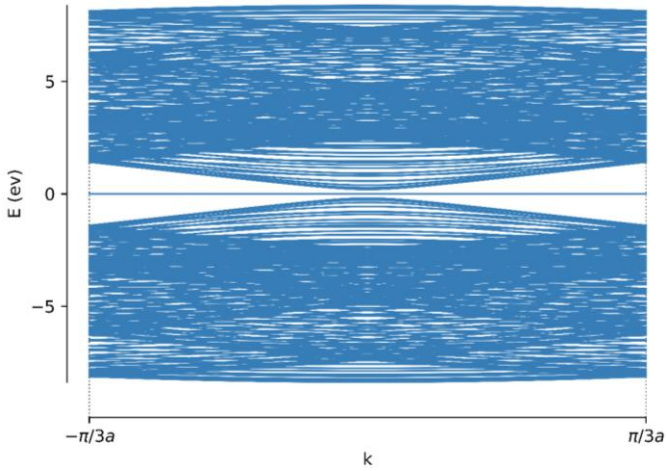
(a)

(b)



Sl. 3. Disperzione relacije za nanotrake kod kojih je rastojanje vakancija $d_{\min}$ za položaj defekta: (a) najbliže ivici trake, (b) na sredini trake [17].

U cilju boljeg uvida u prirodu ravnih zona ispitana je prostorna lokalizacija stanja. Lokalna gustina stanja u centru zone za slučaj trake sa vakancijom na sredini je grafički prikazana na Sl. 4. Uočava se da postoji dominantna lokalizacija na atomima duž linije defekta i njima najbližim susedima, što je slično lokalizaciji koja postoji duž ivica cik-cak nanotraka.



Sl. 4. Lokalna gustina stanja u k=0 u traci sa vakancijom na sredini trake [16]. Granice jedinične ćelije trake su markirane crvenom bojom. Veći poluprečnik kružnice i tamnija boja odgovara jačoj lokalizaciji na markiranoj poziciji u rešetki.

Kako bi razmotrili uticaj periode ponavljanja defekta na elektronsku strukturu, razmotrili smo slučaj nanotrake sa jednom vakancijom na sredini trake i međusobnim rastojanjem defekata koje iznosi $3d_{\min}$. Na Sl. 5.(a) i (b) su date skica kristalne strukture i disperzija za ove nanotrake, redom. Disperzija izgleda slično onoj za traku sa manjim međusobnim rastojanjem vakancija, pri čemu je broj stanja veći zbog većeg broja atoma koji čine jediničnu ćeliju. Razlika energija stanja na dnu provodne i vrhu valentne zone iznosi 0.3952 eV, što se neznatno razlikuje od vrednosti koju smo imali kada je prostorna perioda ponavljanja defekta tri puta manja.

(a)

(b)

Sl. 5. Prikaz (a) jedinične ćelije i (b) disperzione relacije u nanotraci kod koje je rastojanje vakancija $3d_{\min}$, a položaj defekta na sredini trake [17].

IV. Zaključak

U radu je sprovedena teorijska analiza mogućnosti inženjeringa energetskog procepa u grafenskim nanotrakama sa foteljastim ivicama. Analizirane su nanotrake nominalno beskonačne dužine u kojima postoje defekti tipa upražnjenog mesta u rešetki. Ustanovljeno je da položaj defekta u odnosu na ivicu trake bitno utiče na razliku energija stanja na dnu provodne i vrhu valentine zone. Sa druge strane, izmena prostorne periode ponavljanja defekta duž trake nije imala značajnijeg uticaja na procep. Na disperzionoj relaciji je uočeno da uvođenje defekta dovodi do pojave ravnih zona unutar procepa koje karakterišu stanja dominantno lokalizovana duž linije defekta. Interesantno bi bilo razmotriti slučajeve defekata koji nastaju kada se ugljenikov atom zameni drugim atomom, slučaj više vakancija unutar jedinične

 ISBN 978-86-7466-930-3

ćelije trake, kao i slučaj nasumičnog rasporeda defekata u traci konačnih dimenzija što je posledica nesavršenosti tehnika za fabrikaciju.

ABSTRACT

For more than a decade, materials that consist of one or more monolayers of crystal have been explored because of their superior electronic and transport properties in comparison to their bulk counterparts. An especially interesting material is graphene which was the first manufactured twodimensional material. For many practical applications relatively large energy gap is a necessary. But it is not the case in graphene. Various techniques were developed to tune the gap, but they are almost not employed in current electronic technology. In this paper, we introduce a method for bandgap tunning by inserting periodic defects in a graphene nanostructure. We analyze the influence of a single vacancy defect that periodically repeats along the nanoribbon. It is shown that periodic defects might have a significant influence on the energy difference between states at the bottom of the conduction band and the top of the valence band in nanoribbons with armchair edges. It, in turn, affects the electronic and transport properties of graphene nanoribbons. Moreover, the presence of a periodic defect results in the appearance of specific defect states with the flat band dispersion.
