I. Introduction

ELECTROMAGNETIC (EM) simulation tools have become essential for circuit designers. Across industries and disciplines, simulation modeling solves real-world problems safely and efficiently and provides valuable solutions by giving clear insights into complex systems. It provides an important method of analysis which is easily verified, communicated, and understood. The designers have to be able to simulate and test their designs, and to provide accurate predictions of real-world performance of the design, before the design is fabricated in order to avoid major expenses committed to circuit construction and experimental verification.

Wave digital (WD) approach is based on A. Fettweis WD filter theory [1]-[2]. In recent years, it appears to be universal and has been successfully applied to digital modeling of a wider class of analog circuits (including microwave structures), systems and processes (including electromagnetic signals generation and radiation) [3]-[8].

On the one hand, this paper summarizes the development and applications of wave digital (WD) models for predicting the frequency response of four-port microwave passive circuits such as directional couplers. The advantage of the presented WD models is their ability to account for a wide frequency range very quickly, as well as to model different coupler geometries. Models are developed, built up in MATLAB/Simulink and afterwards validated by a commercial software tool. On the other hand, the agreement between suggested microwave device WD models is investigated.

The present paper is organized as follows. First, in Section II, an overview of WD models based on an equivalent circuit network that have been used to simulate frequency response in different four-port microstrip structures is given. Second, in Section III, WD models based on transmission lines (TLs) for the multiport structures are described. Third, in Section IV, a list of coupler models and their simulated frequency performance is provided and compared. The covered range is from two- or tri-section couplers to tri- and five-section wideband couplers with the defected ground structures (DGS). Finally, concluding remarks are included in Section V.

II. Nutshell of the Equivalent Circuit-Based Wave Digital Models

Over the past years, for the purpose of the application of the WD modeling method, the authors have been generated WD models of different couplers based on their equivalent circuit networks [9]-[12]. All these models have been implemented with an in-house MATLAB algorithm. Simulink environment let one drag-and-drop blocks from its library and predifine modeling elements, connect them and create complex WD models.

The equivalent circuit parameters are not quoted at the beginning, therefore the initial step in the proposed technique is to synthesize the values of inductors and capacitors based on the frequency and the characteristic impedances of the individual coupler branches. The lumped equivalent circuit model for the conventional branch-line coupler is proposed in [13]. During modeling process, i.e. model synthesis, parts of the system representing multiport networks with inductors and capacitors in the equivalent circuit are replaced with their wave digital counterpart. One sub-block in the generated WD counterpart models a specific part of coupler layout; it represents one wave digital element (WDE). The main attention in the papers [11]-[12] is focused on generating so-called basic two-dimensional symmetric and asymmetric WDEs. So, a WD model of the device under consideration is based on basic multi-port WDEs and two-port adaptors for port impedance matching. Therefore, the developed WD model will be completely characterized by its parameters: port resistances and adaptor coefficients.

III. Transmission Line-Based WD Models (Development of New Models)

A transmission line-based wave digital model of the directional coupler is derived from its circuit diagram. A starting point for creation of a WD model of the observed four-port structure is to look on that structure as a connection of several individual arms (transmission lines) as shown in [14]. Interconnection networks are used to interconnect

 ISBN 978-86-7466-930-3

idendified TL segments. So, a TL-based WD model is synthesized by making use of basic wave digital building blocks. The boxes in the WD model contain the arithmetic operations and represent the interconnection network or contain the delay elements corresponding to the TL models.

A. Basic Wave Digital Buiding Blocks

Basic building blocks in the proposed TL-based WD model are unit elements (Fig. 1), circuit elements (like resistor shown in Fig. 2) and interconnection networks (Fig. 3) [5], [15]. Therefore, we describe the wave-flow equivalents to circuit elements and interconnection networks used in WD models.

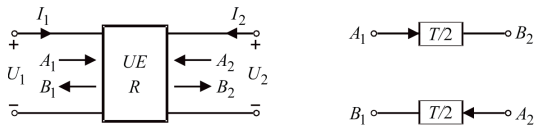

Fig. 1. Unit element and the corresponding wave-flow graph.

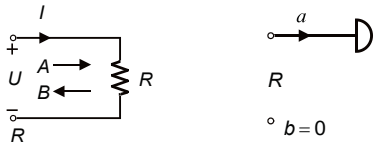

Fig. 2. Wave-flow equivalent for resistor, Zin = R.

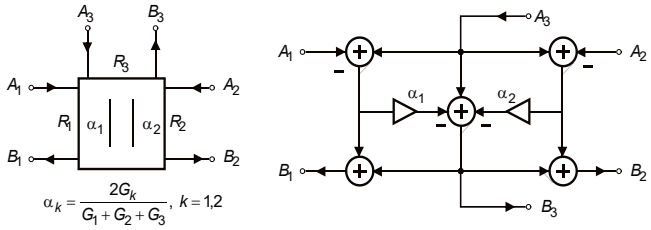

Fig. 3. Interconnection network: Three-port parallel adaptor with port 3 as the dependent port.

IV. List of Coupler Models (Comparison)

One of the most popular passive circuits used for various microwave and millimeter-wave applications is a branch-line directional coupler. In this section, digital models of several coupler structures are presented and discussed. Simple wave digital models are generated and simulated by use of MATLAB/Simulink environment. Also, the commercial Keysight Pathwave Advanced Design System (ADS) simulation software is used to generate ideal TL models of the designed couplers for comparison purposes.

To investigate the validity of the described WD models, comparison of the magnitude performance is given. The results of the illustrated examples in the frequency domain are presented here. The covered example range is from two- and tri-section couplers to tri- and five-section wideband couplers with DGS structures.

B. Case 1: A Single-Band Two-Section Coupler

The simplest coupler structure is composed of four quarter-wavelength transmission lines with different impedances. One such structure, i.e. a symmetric single-band coupler, which circuit diagram is shown in Fig. 4, with characteristic impedance of the main line $Z_1 = Z_0/\sqrt{2}$, and for the branch line $Z_2 = Z_0 = 50\ \Omega$, is observed in [9], [12]. The electrical lengths of the TL segments are $\theta = \pi/2$. The operating frequency is 2.45 GHz. Its model in ADS based on ideal transmission line is shown in [12]. That paper contains also its equivalent circuit-based WD model described in detail.

TL-based WD model is shown in Fig. 5 together with adaptor coefficients putted in Table I. Delays of all TLs are equal because of their equal electrical lengths and amounts to 102 ps. Simulated magnitudes are compared in Fig. 6. The comparison shows a coincidence between the *S*-parameter results obtained by EC-based WDM, TL-based WDM and ideal ADS model.

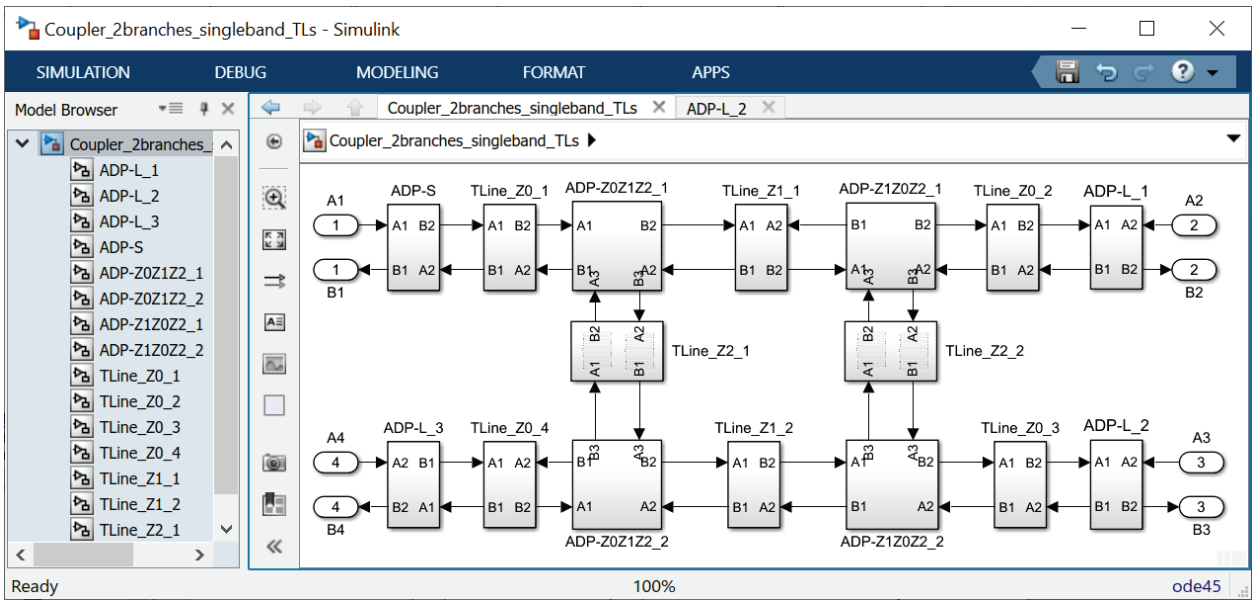

Fig. 5. Simulink model of TL-based WDM of a single-band two-section coupler.

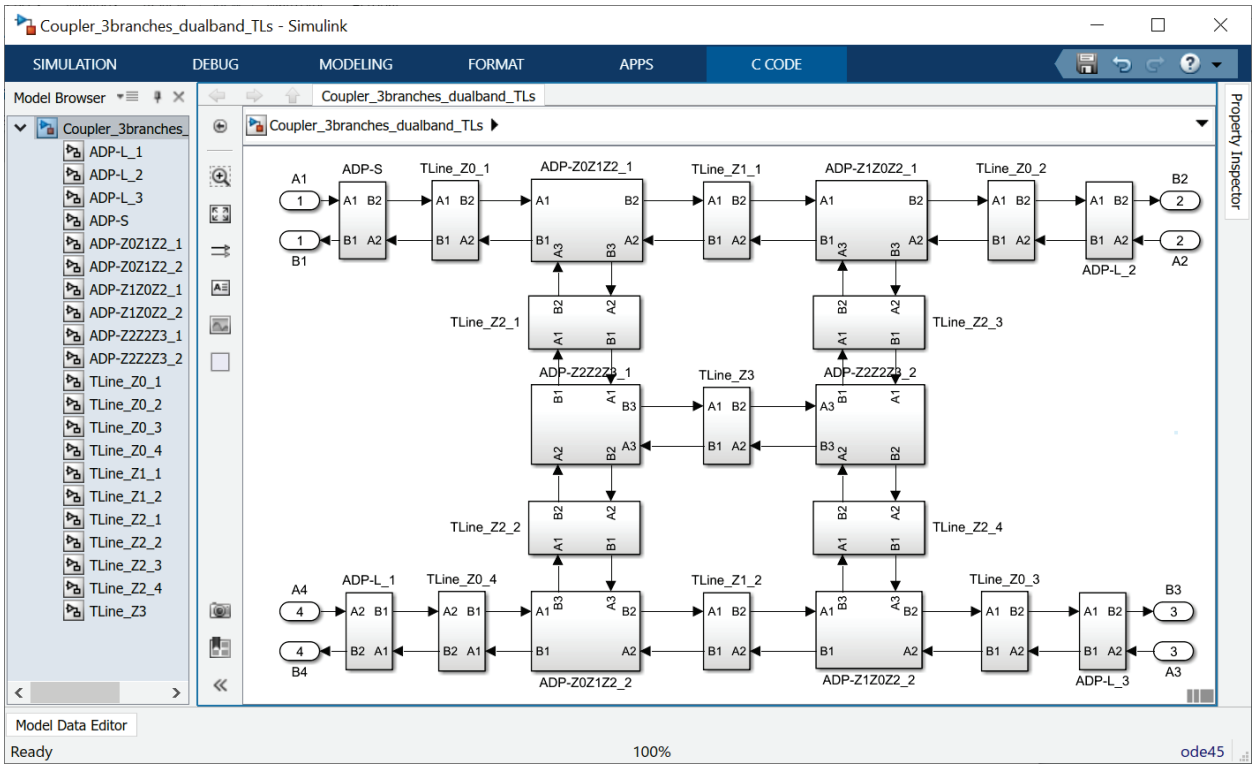

Fig. 8. TL-based WDM of a dual-band tri-section coupler.

C. Case 2: A Dual-Band Tri-Section Coupler

A dual-band branch-line coupler structure with three parallel lines which schematic diagram can be found in Fig. 7 is analyzed in [12]. It is design to operate at 1.0/2.5 GHz. For the characteristic impedance Z_0 set to $50\,\Omega$, the calculated line impedances are $Z_1 = 49.48\,\Omega$, $Z_2 = 79.21\,\Omega$, and $Z_3 = 132.66\,\Omega$ having the power ratio of $3\,\text{dB}$. This example is specific, because of different electrical lengths of transmission lines, $\theta = 51.43^{o}$ and 2θ.

TL-based model of this structure is shown in Fig. 8. The blocks corresponding to individual TLs are assigned as TLine_Z*x* (*x*=0,1,2,3). Delay of the corresponding TLs with the electrical length θ is 143 ps, and for 2θ is 286 ps at the frequency of 1 GHz. Ordering of port signals for used interconnection networks (two- and three-port parallel adaptors) and relations for multiplier coefficients are presented in Table I. Additional adaptor ADP-Z2Z2Z3 has two equal multiplier coefficients $\alpha_1 = \alpha_2 = (2/Z2)/SG$, where $SG = 2/Z2 + 1/Z3$.

 ISBN 978-86-7466-930-3

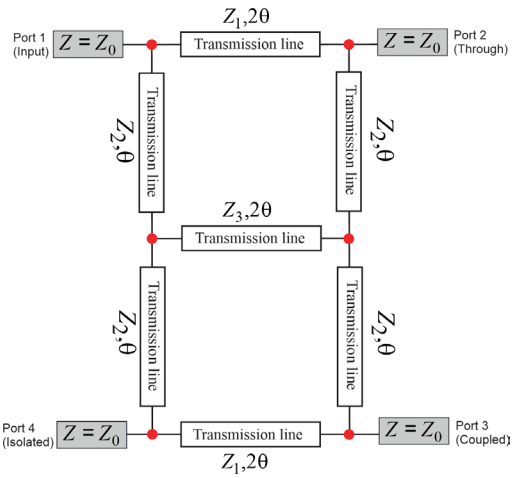

Fig. 7. Circuit diagram of a dual-band tri-section coupler. (Red dots show the locations of three-port parallel adaptors in the WD model).

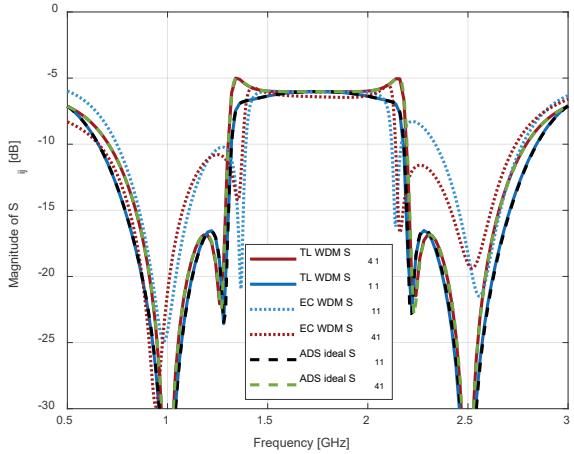

Fig. 9. Comparison of the simulated magnitudes of S_{11} and S_{41} parameters.

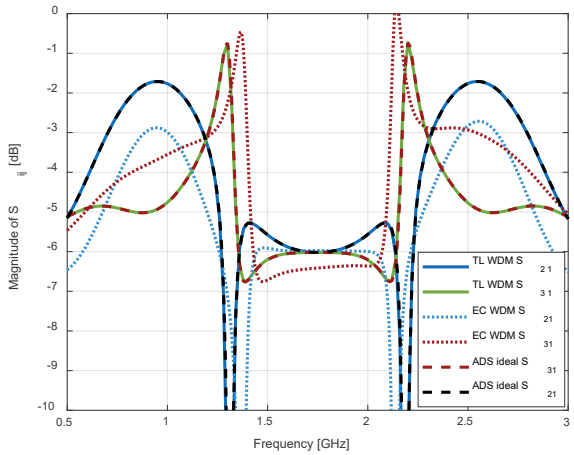

Fig. 10. Comparison of the simulated magnitudes of S_{21} and S_{31} parameters.

Comparison of simulated magnitudes of the *S*-parameters obtained by WD models (EC-based and TL-based) and ADS model are given in Figs. 9 and 10. TL-based model curves from MATLAB and ADS are barely distinguishable. There is a slight disagreement with results from EC-based model.

D. Case 3: A Tri-Section Wideband DGS Coupler

An example of a tri-section wideband branch-line hybrid for operating at center frequency of 2.4 GHz has been design and fabricated by authors in [10]. The characteristic impedances of the stubs are $Z_s = 99.86\Omega$, $Z_{s1} = 41.13\Omega$ and the main line impedance is $Z_1 = 34.74\Omega$. All TLs are $\lambda/4$ long (λ is the wavelength at the operating frequency). Their delays are calculated as 104 ps. Fig. 11 contains layout of DGS coupler and Fig. 12 its circuit diagram.

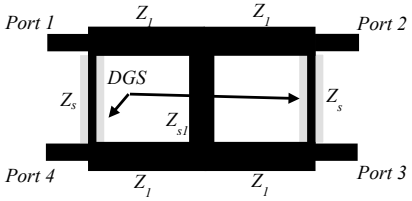

Fig. 11. Layout of a tri-section wideband DGS hybrid designed in [10].

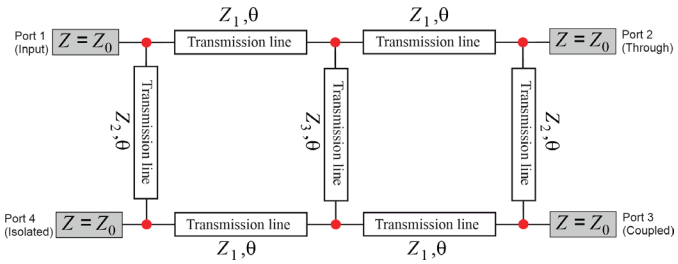

Fig. 12. Circuit diagram of a tri-section wideband DGS hybrid. (Red dots show the locations of three-port parallel adaptors in the WD model).

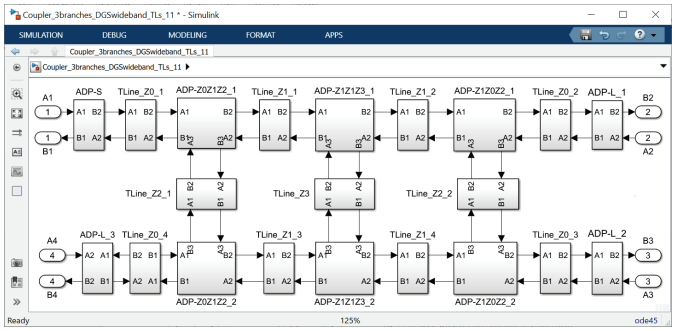

Fig. 13. TL-based WDM of a DGS wideband tri-section coupler.

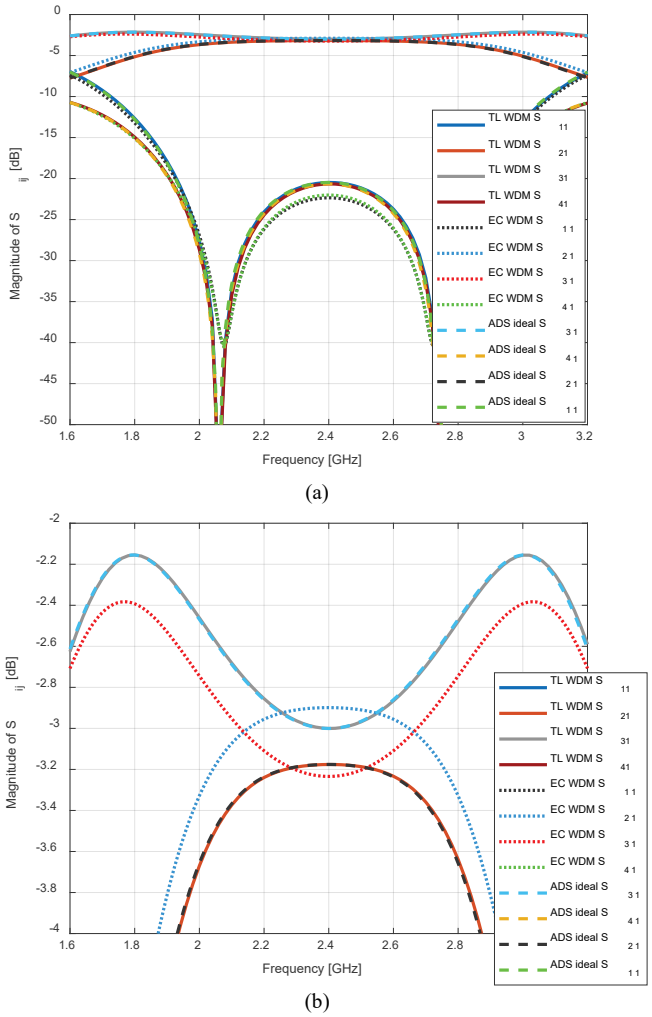

Coefficient relations in three-port parallel adaptors used as interconnection networks in TL-based WDM drawn in Fig. 13 are presented in Table I. Additional adaptor ADP-Z1Z1Z3 has the multiplier coefficients with equal value calculated by relation $\alpha_1 = \alpha_2 = (2/Z1)/SG$, where $SG = 2/Z1 + 1/Z3$.

The simulated magnitude responses of this coupler example are compared in Fig. 14. Slight disagreement between EC-based model and other models is evident. The corresponding equivalent circuit-based model is validated by measurements and full-wave simulation results in [10].

E. Case 4: A Five-Section Wideband DGS Coupler

Different aspects of five-section wideband 3 dB branch-line hybrid with 90° phase difference which operates at center frequency of 2.5 GHz are presented in [11]. The proposed hybrid configuration, shown in Fig. 15, having symmetric nature with defected ground structures is designed and fabricated. The hybrid is also simulated and measured, and its wave digital model based on multimethod technique and an equivalent circuit is created there.

 ISBN 978-86-7466-930-3

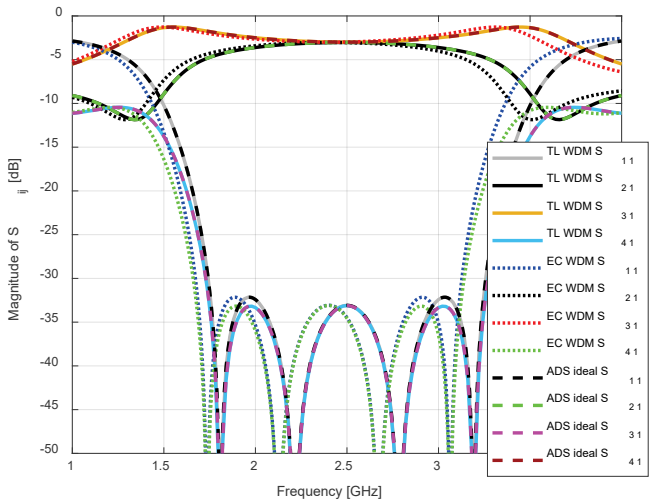

Fig. 18. Simulated magnitude performances of a five-section wideband DGS coupler (differences among TL-based WD, EC-based WD and ADS ideal TL models).

A circuit diagram of the analyzed DGS coupler is presented in Fig. 16. This circuit diagram contains some red dots which show places where three-port parallel adaptors are used in a TL-based WDM given in Fig. 17. Each TL block is presented by 100 UEs corresponding to 100 ps delay, Fig. 17b. Ordering of port signals for three-port adaptors is given in Table II.

Once again, comparison in Fig. 18 confirms matching of TL-based model results from WDM and ADS, and slight non-matching of EC-based model results. The corresponding equivalent circuit-based model is validated by measurments and full-wave simulation results in [11].

V. Conclusion

The paper confirms potential of a WD approach for the simulation of given directional couplers. We have investigated the differences between equivalent circuit-based and transmission line-based WD models of these four-port microwave devices. The simulations demonstrate that the proposed TL-based WD model behaves exactly the same as model generated in ADS by ideal TLs. The differences between EC-based models and abovementioned models are evident except in the case of the simplest coupler design. To conclude, there is progress, but still more to do in this WD modeling approach. The next step is to find a way to include losses in the models in order to get closer to real measurements.

On the other hand, comparing the circuit diagrams with the TL-based WDMs clearly shows their great similarity. Due to the advantages of the nature of generating the TL-based model, this approach can be easily adopted by researchers for simulation purposes of wide range of branch-line couplers. In comparison with the equivalent circuit-based modeling approach a TL-based approach is more intuitive.

Doherty PA Linearization by Injection of the 2nd order Digitally Processed Signals for 5G FBMC modulation

Aleksandar Atanasković[1], Nataša Maleš-Ilić[1], Biljana Stošić[1] and Djuradj Budimir[2]

Abstract – **In this paper, the analysis of the linearization effects of the 2nd order digitally processed signal for the linearization that modulates the 2nd harmonic of the fundamental carrier has been performed on the Doherty power amplifier for C 5G modulation form. In the first method, linearization signals are injected at the input and output of the main Doherty amplifier, whereas in the second method, they are inserted at the outputs of the Doherty main and au iliary amplifiers.**

eywords – **5G, C, Doherty power amplifier, baseband signal, second harmonic, linearization.**

I. INTRODUCTION

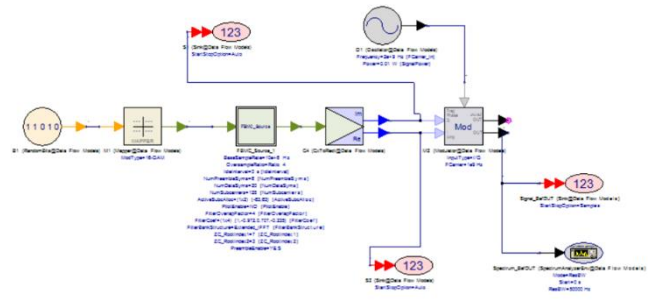
Fifth generation (5G) mobile communication systems represent one of the most important segments of the overall digital transformation of society based on the concept of Industry 4.0. The importance of 5G systems for the global development of the economy and society has been widely recognized, so that the coordinated introduction of 5G mobile networks in many countries has become part of the strategy of complete social and economic development. New technologies such as artificial intelligence (AI) and machine learning, cloud computing, augmented and virtual reality (AR / VR), IoE (Internet of Everything) and IoT (Internet of Things) and billions of connected devices are pushing boundaries and setting new demands on connectivity and mobile communication network performance. 5G mobile networks are expected to provide ultra-fast connectivity with low latency, not only to individual users, but also to a large number of connected facilities, as well as to create an ambient for expansion of technological and business innovations in different industrial sectors (agriculture, energy, trade, health, education, public safety, tourism, media, etc.). The frequency bands provided for 5G systems can be divided into three groups: High band (frequencies from 24 GHz to 60 GHz and above), mid band (which can be divided into two parts, from 1 GHz to 2.6 GHz and from 3.5 GHz to 6 GHz), and low band (below 1 GHz). Each of these bands has comparable advantages and disadvantages. The 5G systems operating in the low band will provide large cells but with a slight improvement in performance compared to 4G systems. In the high band range, all the advantages of the 5G systems in terms of performance compared to 4G systems will be expressed, with transfer speeds from 1 to 3 Gbps and even higher. The disadvantage of high band is shown in the fact that due to the large attenuation of the signal as a result of millimeter wave propagation and potential interference from various obstacles (such as vegetation and buildings) it is necessary to provide very small cells. Mid band spectrum is considered ideal for 5G because it can carry plenty of data while also traveling significant distances.

The most important limitations that existed in previous generations of communication systems with OFDM modulation schemes are loss of spectral efficiency due to the use of cyclic prefix (CP) and needs for fine time and frequency synchronization to ensure the orthogonality of the carriers. To overcome these limitations, several alternative modulation schemes for 5G systems, known as 5G candidates, have been introduced over the past few years, such as filter bank multicarrier (FBMC), universal filtered multi carrier (UFMC), generalized frequency division multiplexing (GFDM) and filtered orthogonal frequency division multiplexing (FOFDM).

The results of Doherty power amplifier (DPA) linearization in simulation by applying a method that uses second-order digital signals processed in the baseband are presented in this paper. After adjusting for the amplitude and phase in the baseband, the second order digital signals modulate the second harmonic of the fundamental carrier and then are injected into the gate and drain (input and output) of the PA transistor [1]. The results obtained by applying this linearization method in simulation or experiments have already been published in [2-4] for single-stage PA and two-way DPA, which operate at a frequency of about 1 GHz and tested for QAM and OFDM modulation schemes. In this paper, we analyzed the behavior of the DPA when source signal is 5G FBMC signal.

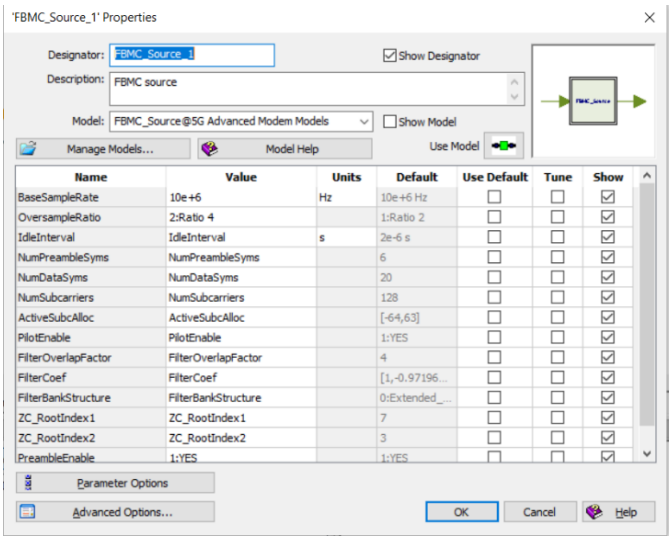
The paper is organized in the following manner: after introduction, the second section is devoted to the 5G FBMC signal, and the results of the linearization are illustrated in the third section. Conclusion and list of used literature are given at the end of paper.

II. 5G FBMC SIGNAL



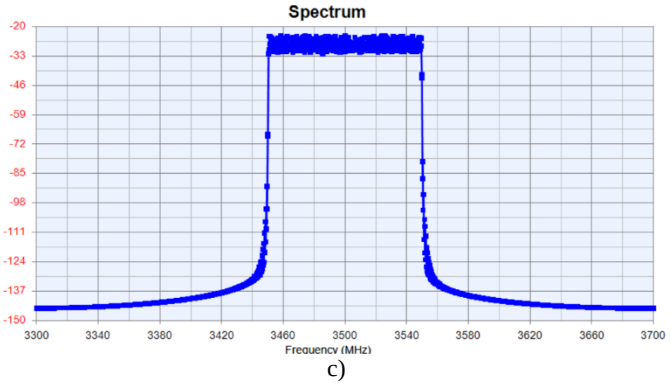
FBMC is a type of multi carrier modulation scheme based on OFDM. It represents an improvement of OFDM with the aim of eliminating certain shortcomings at the cost of increasing the complexity of signal processing. It consists of a set of data that are broadcast through a bank of modulation filters that filter each subcarrier. The prototype of the used filter can be chosen in a suitable way, so that there is very little leakage into the adjacent channels. FBMC has significantly better utilization of channel capacity and can offer higher data throughput in a given bandwidth, which

[1]Aleksandar Atanasković, Nataša Maleš Ilić and Biljana Stošić are with the Faculty of Electronic Engineering, University of Nis, A. Medvedeva 14, Nis, Serbia (e-mails: aleksandar.atanaskovic; natasa.males.ilic; biljana.stosic@elfak.ni.ac.rs)



[2]Djuradj Budimir is with the University of Westminster, 115 New Cavendish Street, London, UK, (e-mail: d.budimir@wmin.ac.uk)

 ISBN 978-86-7466-930-3



means it provides better spectral efficiency. Also, the FBMC has eliminated one of the main disadvantages of OFDM, which is the use of the cyclic prefix (CP) [5]. The cyclic prefix is essentially a copy of part of a transmitted symbol in OFDM that is appended at the beginning of the next symbol. This leads to a reduction in signal speed as well as unnecessary loss of transmitted power.

b)

c)

Fig 1. FBMC signal generation in Keysight SystemVue: a) FBMC transmitter; b) FBMC signal parameters; c) FBMC signal spectrum

FBMC signals for simulation purposes can be created using various software packages (Matlab, Keysight SystemVue, ...) or using general purpose programming languages (Python, C/C++, ...). In this paper, we used Keysight SystemVue to create the appropriate FBMC signal. This software was chosen because it provides a simple interface in which parameters related to the FBMC signal can be easily adjusted, and the impact of changing the appropriate parameters on the FBMC signal itself can be monitored, either in time or in the spectral domain. Figure 1 shows the interface for creating FBMC signals in the SystemVue environment, as well as a set of parameters that control the signal characteristics and signal appearance in the frequency domain.

III. Results

Symmetrical two-way DPA that operates at 5G mid band was designed according to the instructions given in [6]. The DPA was designed by using CGH40010F GAN HEMT transistor. The drain voltage is 28 V, whereas the gate voltage of the main and auxiliary amplifier is -2.8 V, and -5.7 V, respectively. Main characteristics of DPA in simulation at 3.5 GHz are: 12.6 dB gain and 1-dB compression point at 31 dBm output power.

The designed DPA was linearized in ADS simulation using two linearization methods: 1) the first - standard method that leads linearization signals at the gate and drain of the transistor in the main cell of the DPA and 2) the second - modified method, where the linearization signals are put at the drain of the main and auxiliary amplifier transistors in the DPA [7]. The signal used for testing DPA was 5G FBMC signal at carrier frequency 3.5 GHz with useful signal frequency bandwidth of 50 MHz and two output power levels: around 30 dBm (1 dB below 1-dB compression point) and near 24 dBm (roughly 7 dB below 1-dB compression point).

The Figs. 2 and 3 show the output spectrum before and after application of the proposed linearization technique. Summarized results for ACP (Adjacent Channel Power) at ±50 MHz offset over 5 MHz band are presented in Tables I and II. We can observe for 24 dBm output power, that the ACP is improved about 15 dB for both linearization methods, whereas for 30 dBm output power they become better by 5 dB for the 1st method and almost 8 dB for the 2nd method. A slight asymmetry can be noted in results for linearization between lower and upper adjacent channel.

IV. Conclusion

We analyzed the effect of the linearization technique that uses baseband signals of the 2nd order nonlinearity adequately shaped and processed in magnitude and phase in baseband and then modulate the 2nd harmonic of the fundamental useful signal carrier. The linearization signals formed in this way are then inserted at the input and output of the main amplifier of DPA (linearization method 1) as well as at the output of the main and auxiliary amplifier of DPA (linearization method 2). The linearization was performed for the 5G FBMC signal.

It can be concluded that very acceptable improvement in adjacent channels power was achieved by applying the proposed linearization technique. On the bases of the obtained results, it can be noticed that the 2nd method provides slightly better results for higher power then the application of the 1st method.

Planar Archimedean Spiral Antenna Resonant Frequency and Bandwidth Estimation using MLP Neural Network

Zoran Stanković, *Member, IEEE*, Maja Sarevska, Nebojša Dončov, *Senior Member, IEEE*, Ksenija Pešić

***Abstract*— This paper presents a neural model for fast estimation of the resonant frequency and bandwidth of a planar Archimedean spiral antenna based on MultiLayer Perceptron (MLP) network. The input parameters of the model are the number of turns of the spiral, the inner radius of the spiral and the outer radius of the spiral, while the output parameters of the model are resonant frequency, minimum operating frequency and maximum operating frequency of the Archimedean spiral antenna. The proposed neural model was applied in the process of modeling a planar self-complementary Archimedean spiral antenna with two arms.**

***Index Terms*— Archimedean spiral antenna, neural network, neural model.**

I. Introduction

Planar Archimedean spiral antennas, due to their low weight, simplicity of construction, low manufacturing cost and approximately frequency-independent characteristics in a wide frequency range, have significant applications in broadband communication systems (*Ultra-Wide Band* (UWB) communication systems, satellite communication systems, ground penetrating radars, military aircraft radars and other broadband systems) [1],[2].

The classic approach in the analysis of characteristics, modeling and design of such antenna structures is the use of EM simulators based on numerical EM modeling techniques such as Method of Moments (MoM), Finite Element Method (FEM), Transmission Line Matrix (TLM) method, Finite Difference Time Domain (FDTD) and others [3],[4]. The main disadvantages of this approach are the need for strong hardware resources and long computation times.

An alternative approach that can overcome the above problems is the use of artificial neural networks to model planar spiral antennas. For this purpose, a good candidate in the modeling process is the MultiLayer Perceptron (MLP) network [5],[6], which has shown good results in modeling planar antenna structures [7],[8].

As part of the research covered by this paper, the "ASA_design_MT software" was first implemented for the analysis of the characteristics and design of the planar Archimedean spiral antenna with two arms. Then, a neural model of this antenna was developed, which is based on the MLP network and which is presented in this paper. Data generated by ASA_design_MT software was used to develop this model.

II. Planar Archimedean Spiral Antenna

The architecture of the planar Archimedean spiral antenna with two arms is shown in Figure 1. The basic geometric parameters of the antenna are: inner radius of the spiral antenna r_i, outer radius of the spiral antenna r_o, arm width w, space between arms s, and feed point f.

The Archimedean spiral curve is determined by the equation

$$r = a\theta + r_i \tag{1}$$

where r is the radius of curve, a is the growth rate, θ is the winding angle, and r_i is the inner radius of spiral [2]. Accordingly, the outer radius of the spiral is defined in a way

$$r_o = 2\pi t a + r_i \tag{2}$$

where t is the number of spiral turns. Two edge curves of c_1 and c_2 describe one spiral arm as

$$\begin{aligned} c_1 &= a\theta + r_i \\ c_2 &= a\left(\theta + \theta_{off}\right) + r_i \end{aligned} \tag{3}$$

where θ_{off} is the offset angle. The metal (arm) width w and the metallization ratio χ of spiral antenna can then be defined as [2]

$$\begin{aligned} w &= \left|c_1 - c_2\right| = a\theta_{off} \\ \chi &= \frac{w}{w+s} = \frac{\theta_{off}}{\pi} \end{aligned} \tag{4}$$

In this paper, the case where the Archimedean spiral antenna is a self-complementary antenna is considered. This case is obtained when the condition $w = s$ is met. In this case

 ISBN 978-86-7466-930-3

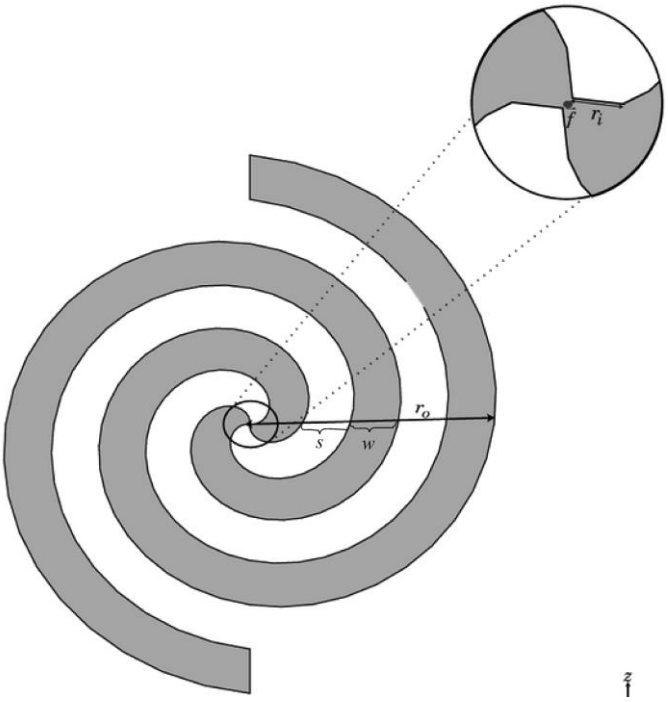

Fig. 1. Architecture of the planar Archimedean spiral antenna with two arms (r_i - inner radius of the spiral antenna, r_o - outer radius of the spiral antenna, w - arm width, s - space between arms, f –feed point).

the metallization ratio, offset angle, growth rate and arm width can be determined by equations

$$\begin{cases} \chi = \dfrac{1}{2} \\ \theta_{off} = \dfrac{\pi}{2} \\ a = \dfrac{2w}{\pi} \\ w = \dfrac{r_o - r_i}{4t} \end{cases} \tag{5}$$

By applying Babinet's principle [1]

$$z_{metal} z_{air} = \frac{\eta_0^2}{4} \tag{6}$$

where η_0 is the characteristic impedance of free space, to an ideal planar self-complementary Archimedean spiral antenna ($r_i \to 0$, $r_o \to \infty$), the input impedance of the antenna can be calculated [1]

$$z_{in} = \frac{\eta_0}{2} \approx 188\,\Omega \tag{7}$$

In this case the antenna has infinite bandwidth and all primary characteristics (input impedance, antenna efficiency) and secondary characteristics of the antenna (radiation characteristics, directivity, polarization) are frequency independent. If the planar self-complementary Archimedean spiral antenna has limited physical dimensions then its bandwidth is wide but limited and its impedance deviates to some extent from 188 Ω. In this case, the approximate theoretical formula for determining the lower bound of bandwidth is [1]

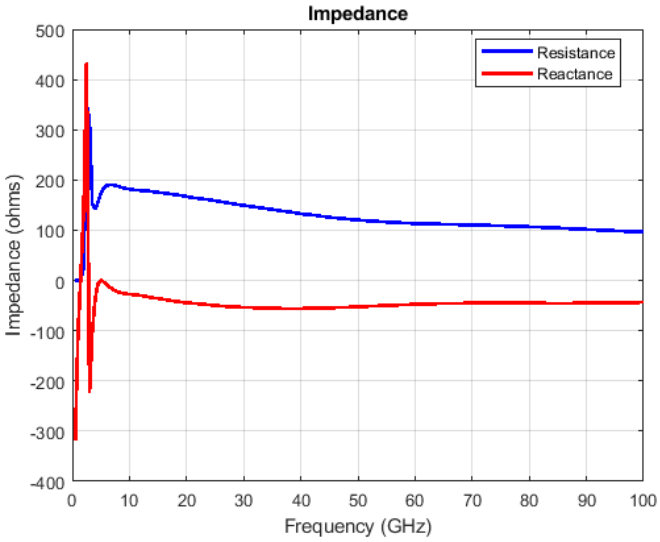

Fig 2. Impedance of the planar self-complementary ASA vs frequency (t = 1, r_i = 2 mm r_o = 2 cm)

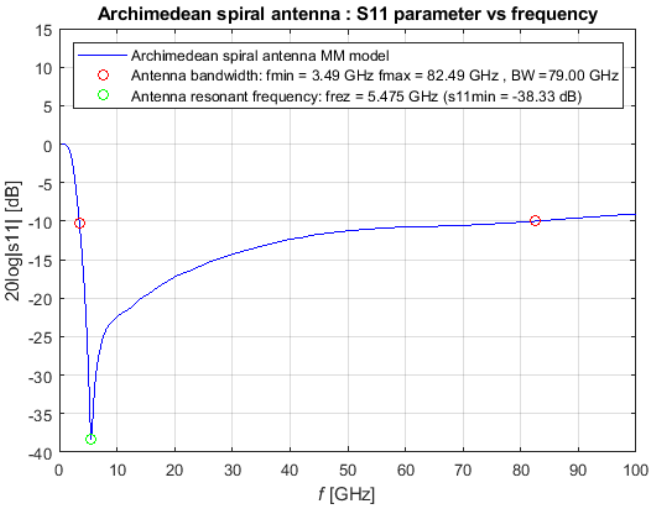

Fig. 3. S_{11} parameters of the planar self-complementary ASA vs frequency (t = 1, r_i = 2 mm r_o = 2 cm)

$$f_{\min} = \frac{c}{2\pi r_o} \tag{8}$$

In practice, the lower bound of bandwidth will be greater than predicted by Eq.8 due to reflections from the end of the arm.

If the antenna does not use a tapered feed region in the spiral center, the upper bound of bandwidth can be determined by the approximate theoretical formula [1]

$$f_{\max} = \frac{c}{2\pi r_i} \tag{9}$$

In practice, the upper bound of bandwidth differs from the theoretical value due to the influence of the real physical geometry of the feed region.

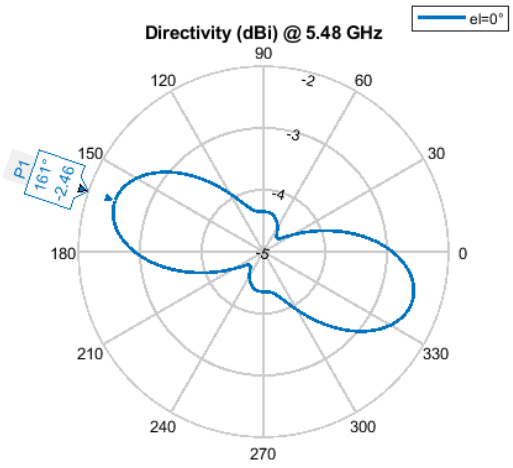

Fig. 4. Directivity of the planar self-complementary ASA in the azimuthal plane at f_r = 5.475 GHz (t = 1, r_i = 2 mm r_o = 2 cm)

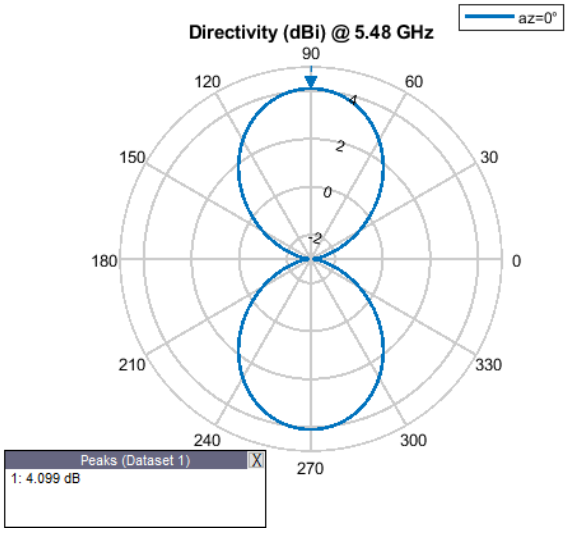

Fig. 5. Directivity of the planar self-complementary ASA in the elevation plane at f_r = 5.475 GHz (t = 1, r_i = 2 mm r_o = 2 cm)

III. EM MODELING OF A PLANAR ASA USING "ASA_DESIGN_MT" SOFTWARE

In order to perform EM analysis and modeling of primary and secondary characteristics of the planar self-complementary Archimedean spiral antenna (ASA), "ASA_design_MT" software was developed. This software is based on Method of Moments (MoM) and is implemented using the MATLAB Antenna toolbox.

Figures 2 and 3 show the impedance and s_{11} parameter as a function of frequency for a planar self-complementary ASA with physical parameters t = 1, r_i = 2 mm and r_o = 2 cm. It can be seen that the antenna at the resonant frequency f_r = 5.475 GHz has a resistance of 188 Ω. As the frequency increases, the impedance takes on a slightly capacitive character, while the resistance slowly decreases compared to 188 Ω.

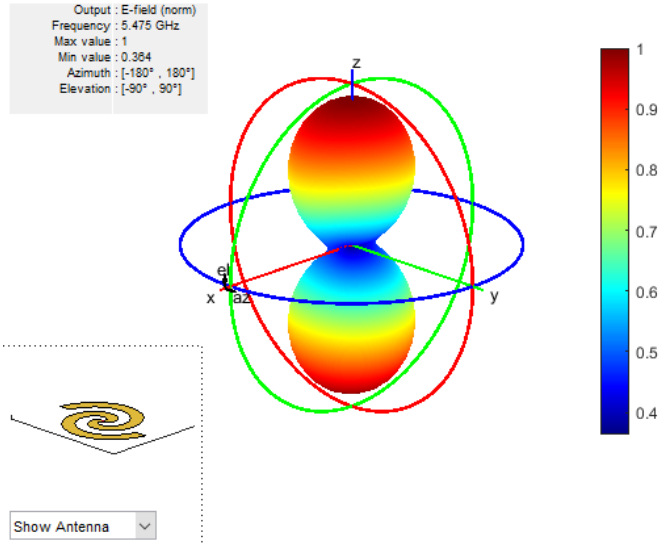

Fig. 6. 3D radiation pattern of the planar self-complementary ASA at f_r = 5.475 GHz (t = 1, r_i = 2 mm r_o = 2 cm)

Figures 4, 5 and 6 show the directivity of the planar self-complementary ASA in the azimuthal plane, the directivity of the planar self-complementary ASA in the elevation plane and the 3D radiation pattern of the planar self-complementary ASA at resonant frequency, respectively.

IV. MLP MODEL OF THE PLANAR SELF-COMPLEMENTARY ASA

The MLP model of the planar self-complementary ASA (MLP_ASA) consists of a single MLP network and its architecture is shown in Figure 7. MLP_ASA models the dependence of lower bound of bandwidth, resonant frequency and upper bound of bandwidth on the following physical parameters: number of spiral turns, inner radius of spiral and outer radius of spiral. Therefore, MLP_ASA can be functionally described by the following expression

$$[f_{\min}\ f_r\ f_{\max}]^T = f_{MLP_ASA}\left([t\ r_i\ r_o]^T\right) \tag{10}$$

MLP networks consist of a single input layer, a single output layer, and multiple hidden layers of neurons. In accordance with Eq. 10, the input layer has three neurons, the output layer has three neurons, while the hidden layers have N_1, N_2,…, N_H neurons respectively, where H is the total number of hidden layers. For MLP network with a specific number of layers and neurons in them, notation was used MLPH-N_1-…-N_i-…-N_H, $1 \le i \le H$.

The outputs of the hidden layers are given by the expression

$$\mathbf{y}_l = F(\mathbf{w}_l \mathbf{y}_{l-1} + \mathbf{b}_l) \quad l = 1, 2, \ldots, H \tag{11}$$

where $\mathbf{y}_0$ represents the output of the input layer and vectors y_l and y_{l-1} represent the output of l-th and (l-1)-th hidden layer, respectively. Weight matrix for connections between neurons in (l-1)-th and l-th layers is denoted by $\mathbf{w}_l$, while biases of l-th hidden layer neurons are represented by vector $\mathbf{b}_l$. Neurons in

 ISBN 978-86-7466-930-3

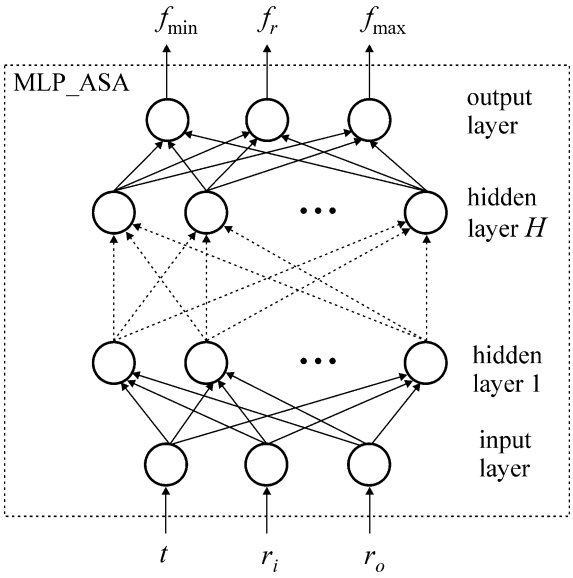

Fig. 7. The MLP neural model of the planar self-complementary Archimedean spiral antenna

hidden layers have the hyperbolic tangent sigmoid activation function $F(\cdot)$ defined by the expression

$$F(u) = \frac{e^{u} - e^{-u}}{e^{u} + e^{-u}} \tag{12}$$

The neurons in the output layer use a linear activation function so that their output is defined in a way

$$\left[f_{\min}\ \ f_r\ \ f_{\max}\right]^T = \mathbf{w}_{H+1}\mathbf{y}_H + \mathbf{b}_{H+1} \tag{13}$$

where $\mathbf{w}_{H+1}$ is a weight matrix for connections between neurons of the last hidden layer and output layer neurons.

During the training of the MLP network, the weight matrices $\mathbf{w}_1$, $\mathbf{w}_2$,…, $\mathbf{w}_H$, $\mathbf{w}_{H+1}$ and bias vectors $\mathbf{b}_1$, $\mathbf{b}_2$,…, $\mathbf{b}_H$, $\mathbf{b}_{H+1}$ are optimized in order to achieve the desired mapping accuracy defined by the expression Eq. 10.

V. Modeling results

Using the "ASA_design_MT" software 1000 samples are generated for training and 300 samples for testing having random distribution.

With the aim to develop a model with better accuracy the training was done for various MLPH-N_1-…-N_i-…-N_H, networks while only networks with two hidden layers were used (H = 2). For the number of neurons in the hidden layer. the values that were used are $6 \le N_1$, $N_2 \le 22$.

The MLP training is done using Levenberg – Marquardt algorithm with given goal mean squared error of training $MSE_{target} = 10^{-4}$ and maximal number of iterations $N_{\max} = 500$. Before training the neural connection weights and biases are initialized with random values in the range [-1 1]. Also input network data are scaled and output data are descaled in the range [-1 1]. After the training each network is tested using test data in order generalization capabilities to be evaluated. For the evaluation of the generalization capabilities of the network and its accuracy the following test metrics are used: mean squared error (RMSE) and Pearson product moment correlation coefficient (r^{PPM}) [6].

The Table I shows the testing results for eight MLP networks that showed best testing results after training. It may be seen that the networks have small RMSE in the lower bandwidth limit and resonant frequency, while in the estimation of the upper bandwidth limit they have much higher RMSE.

For the realization of the MLP model of the planar self-complementary Archimedean spiral antenna MLP2-9-8 is chosen as this network in the testing procedure had largest value for the Pearson product moment correlation coefficient.

TABLE I
TEST RESULTS FOR EIGHT MLP MODELS WITH THE HIGHEST r^{PPM} VALUE

MLP networks	RMSE ($f_{\min}$)	RMSE (f_r)	RMSE ($f_{\max}$)	r^{PPM}
MLP2-9-8	0.1628	0.3345	6.4747	0.9939
MLP2-10-9	0.1537	0.3628	6.4915	0.9938
MLP2-8-8	0.1584	0.3144	6.5339	0.9937
MLP2-8-11	0.1590	0.3980	6.5706	0.9937
MLP2-8-10	0.1606	0.3747	6.6170	0.9936
MLP2-11-10	0.1568	0.3223	6.5715	0.9936
MLP2-12-8	0.1569	0.3174	6.6360	0.9936
MLP2-8-15	0.1622	0.3517	6.6686	0.9935

On Fig.8 the scattering diagram of MLP2-9-8 model output is shown. It may be noticed the good match for the lower bandwidth limit and resonant frequency with the referent values. Also it may be noticed that for the values of the upper bandwidth limit the match is not so good as for the two previously mentioned parameters. This may be explained with fact that EM simulator while training sample generation had difficulty to accurately determine the upper limit of the bandwidth. The reason for that is that for higher frequencies the function of parameter s_{11} almost asymptotically approach the bound of -10 dB so the indetermination of the cross point estimation between that function and the horizontal line s_{11} = -10 dB is very large.

For above explained situation MLP model of the planar self-complementary ASA may be used only for rough estimation of the upper bound of the bandwidth. But this does not decrease the useful application of the proposed model because in real life the detremination of the lower bound of the bandwidth is more important than for the upper boind. The reason for this is that upper bound ftrequency is much higher than the maximal working frequency for emission and reception.

MLP model of the planar self-complementary ASA is implemented on a modest referent hardware platform (Intel Core i3-2350M@2.3 GHz, 4GB RAM). This model, the estimation of the resonant frequency, the minimum operating

 ISBN 978-86-7466-930-3

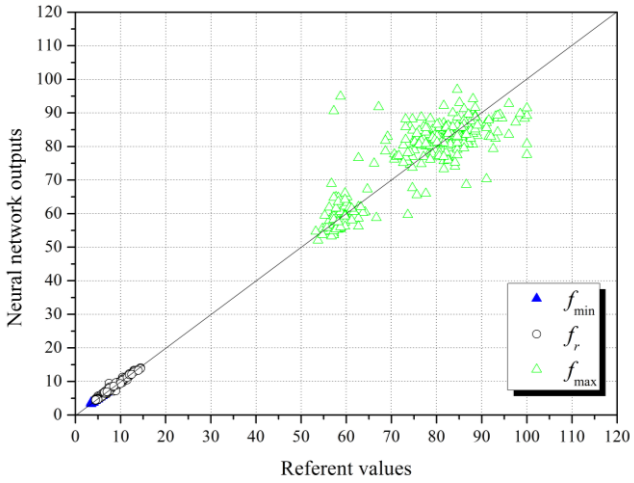

Fig. 8. Scattering diagram for MLP2-9-8 network

frequency and the maximum operating frequency of the antenna, has performed in 300 points defined with testing set for only 0.03 s. This speaks about the high speed of the MLP model.

VI. Conclusion

Today planar spiral antennas attract more and more attention because they are convenient for the application in the modern portable broadband communication devices. The modeling of these antenna structures with the help of EM simulators that are based on MoM techniques presents classical approach in EM characteristics modeling. Because of intensive numerical estimations this kind of EM simulators demand strong hardware platform and estimations itself may last very long, that is main disadvantage of the EM simulator approach. Alternative approach for the spiral antenna modeling is using of artificial neural networks.

This paper presents the MLP model of the planar self-complementary Archimedean spiral antenna that is implemented on a modest hardware platform. MLP model has shown exceptional speed in the estimation of resonant frequency, minimum operating frequency and maximum operating frequency for this antenna structure. Currently developed model supports estimation of the resonant frequency and minimum operation frequency with high accuracy and rough (low accuracy) estimation of high operating frequency for the antenna.

Further investigations will be steered to the increased MLP model accuracy for the planar self-complementary Archimedean spiral antenna in the maximum operating frequency estimation.

Analysis of Feeding Methods for High-Gain Crossed Slot Antenna Arrays

Marija Milijic, *Member, IEEE*, Branka Jokanovic, *Senior Member, IEEE*

***Abstract*— In this paper we present the influence of different feeding methods on performances of the dual polarized antenna array. Antenna array consists of 14 identical crossed slots serially fed by coplanar waveguide (CPW) and positioned at equal distances forming a linear array. Three proposed feeding methods are compared with the ideal case when two antenna sub – arrays are fed by two generators to achieve the highest possible gain. The CPW-T junction, CPW rat-race coupler and modified CPW rat-race coupler are engaged for feeding 2D crossed slots array to analyze its performances for use in 5G and radar applications.**

***Index Terms*—Antenna array; CPW-fed antenna; CPW T-junction; CPW rat-race coupler; crossed slot antenna.**

I. Introduction

FOR operation at millimeter waves, antenna arrays are very attractive candidates considering high-gain and beamforming characteristic. However, the feed network, its necessary part that enables suitable amplitude and phase distributions for a large number of radiating elements in array, increases both design complexity and size of antenna. Otherwise, antennas in printed circuit technology have aroused more and more attention as one of vital components in modern 5G wireless communication system thanks to their planar structure, compact design, inexpensive and uncomplicated manufacture [1]. The printed antennas as elements in an array are usually fed by corporate-feed network, when there are a multiple lines for feeding array elements, or by series-feed network, when elements are fed by a single line. A series-feed network can be easily modeled and cheaply fabricated using simultaneous photolithography for both the radiating elements and the feed network [2,3]. However, a corporate-feed network is widely used to provide desired power splits necessary to synthesize a required radiation pattern or to achieve high side lobe suppression [4,5]. Some research has employed the combination of series and corporate feed methods to obtain the desired antenna characteristics.

There are some considerable losses typical for high operating frequency of mm-waves antennas as free-space path loss and propagation loss due to atmospheric absorption. They are both lower at the frequencies below 28 GHz wherefore the frequencies between 24.25 ï 27.5 GHz are tag as a promising operation bandwidth for the next-generation 5G networks and technologies [6]. Therefore, the antennas proposed in this paper are model and simulated for the center frequency f_c=25.875 GHz calculated as the central value of that band. This is an extension of the research presented in [7,8] that modeled the advanced high-gain rectangular slot antenna arrays fed by CPW feeding line.

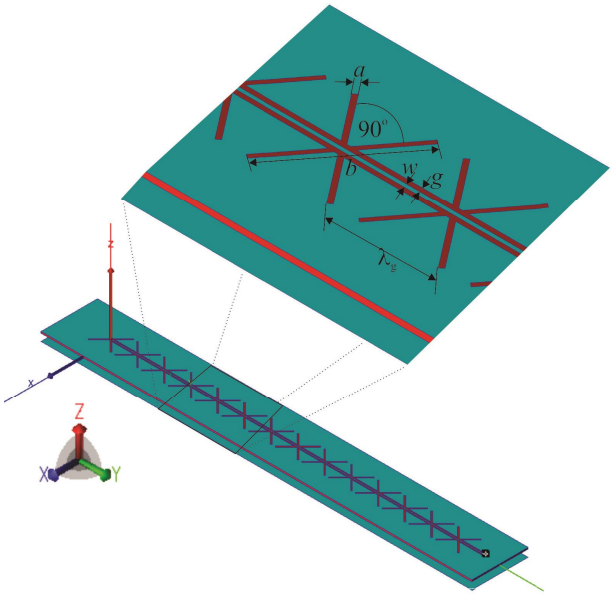

Fig. 1. Linear CPW-fed crossed slot array.

This paper analyzes firstly a linear array of identical 14 crossed slots, positioned symmetrically relative to the CPW feeding line. The crossed slot antennas, whose two rectangular parts are positioned at right angle, are dual polarized antenna with identical radiation patterns for both vertical and horizontal polarization [9]. Further, the linear crossed slot array has replicated forming CPW-fed 2D array. The following types of feeding methods are investigated: feeding by two generators for every sub ï array, CPW ï T junction, CPW rat-race coupler and modified CPW rat-race coupler. The simulated results, especially gain and bandwidth, obtained by WIPL-D Pro CAD [10] software are discussed and compared.

II. Linear CPW-fed crossed slot array

The radiating element in proposed antennas is a crossed slot that consists of two rectangular parts with dimensions *a* x *b* - slot width x slot length, positioned at right angle to each other [9]. The identical fourteen crossed slots are combined to form an array (Fig 1). A series feed is in a form of coplanar

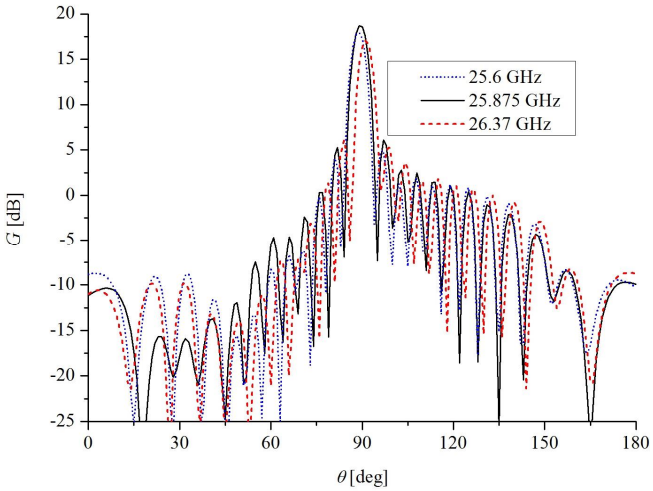

Fig. 2. Radiation patterns in the yOz plane (φ=90°) of the proposed 14 crossed slots antenna array.

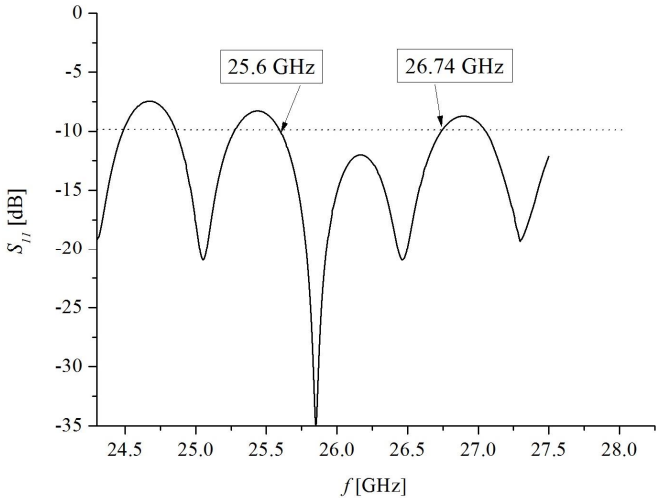

Fig. 3. S_{11} parameter versus frequency of the proposed 14 crossed slots antenna array. S-parameters are normalized to the 120 Ý -impedance of CPW feeding line.

waveguide (CPW) transmission line with strip and gap (w and g) of 0.3 mm and 0.375 mm, respectively resulting in characteristic impedance around 120 q. The slots are positioned symmetrically along to the CPW feeding line at the mutual distance λ_g=9 mm where λ_g is CPW line wavelength at the center frequency f_c. Their dimension a=0.44 mm and b=10.84 mm are optimized at an operating frequency f_c [9]. The proposed antenna design is built on a substrate that has a dielectric constant (e_r) of 2.54 and the dimensions 145 mm x 19 mm x 0.508mm. At the distance λ_0/4 =2.89 mm from the array there is a reflector plate whose dimension are the same as the substrateôs dimensions (λ_0 is the wavelength in vacuum at the center frequency f_c=25.875 GHz). Unlike the microstrip antennas with a backside ground plane, slot antennas require the reflector plane to be at a distance equal to the quarter of the free space wave-length. It should ensure that the antenna radiates only in half the space.

Fig. 2 shows the radiation patterns of the proposed 14 crossed slot antenna array at three frequencies: center f_c, lower (25.6 GHz) and higher (26.37 GHz) edge frequencies. The edge frequencies are determined by the criteria that the maximum gain at an edge frequency does not vary more than 10% of the maximum gain at the center frequency and that its side lobe suppression (SLS) is bigger than 10 dB. The maximum gain of the proposed 14 crossed slots antenna array at the center frequency f_c is 18.7 dBi while it is 18 dBi at the lower and 17 dBi at the higher edge frequency. The antenna has its maximum gain for θ=89° at lower edge frequency, for θ=90° at center frequency f_c and for θ=91° at higher edge frequency. Moreover, its SLS is 12.5 dB at the center frequency while it is 13 dB at the lower and 11 dB at the higher edge frequency. Its S_{11} parameter, normalized to the impedance of CPW feeding line (120 Ý), is depicted in Fig. 3. It is less than -10 dB for the frequency range between 25.6 GHz and 26.74 GHz which is more than range determined by radiation pattern.

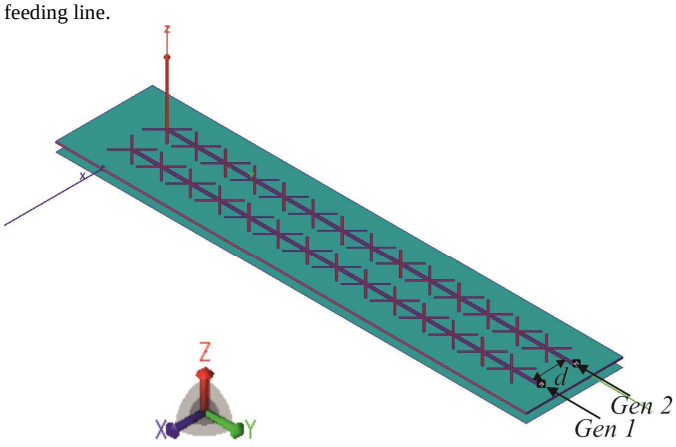

Fig. 4. 2D CPW-fed crossed slot array fed by two independent generators.

III. 2D CPW-FED CROSSED SLOT ARRAY

Two identical linear 14 crossed slot sub ï arrays, presented in previous section, are associated together at the mutual distance d=10.8 mm building a 2D array (Fig. 4). It is situated on the substrate with dimensions 145 mm x 29.8 mm x 0.508 mm while the equal reflector plate is at the distance λ_0/4.

The feed structure, required to enable equal amplitude and phase distribution for both subarrays, must be designed in order to achieve the best radiation and bandwidth properties. Therefore, different feeding techniques are modeled and studied: feeding by two generators for every sub ï array, CPW ï T junction, CPW rat-race coupler and modified CPW rat-race coupler.

A. Feeding by Two Generators

In the first study, the two sub-arrays are fed by two generators placed at the end of CPW lines (Fig. 4). Due to the influence of the mutual coupling between sub-array in x-axis direction, the dimensions of crossed slot antennas are optimized to the different values a=0.53 mm and b=10.78 mm in the respect to the linear array. The radiation patterns of 2D crossed slots antenna fed by two generators is depicted in Fig. 5.

 ISBN 978-86-7466-930-3

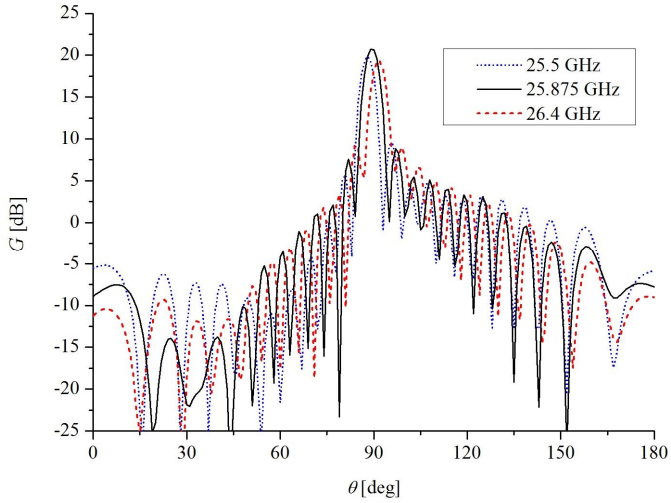

Fig. 5. Radiation patterns in the yOz plane (φ=90°) of the 2D CPW-fed crossed slots array fed by two independent generators.

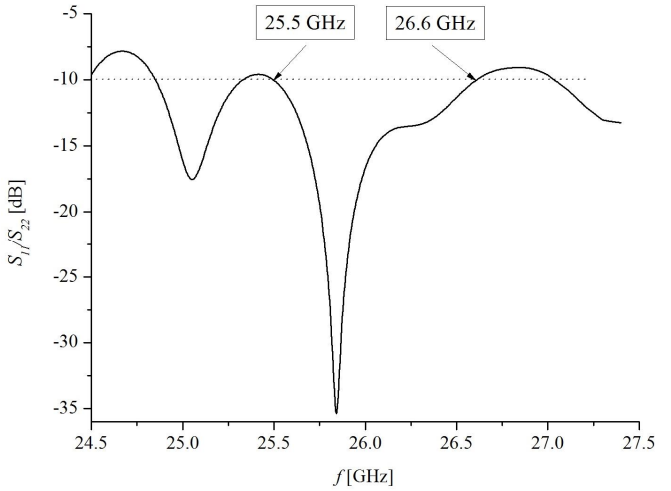

Fig. 6. S_{11} and S_{22} parameter versus frequency of the 2D CPW-fed crossed slots array fed by two generators. S-parameters are normalized to the 120 Ý - impedance of CPW feeding lines.

Because there are two sub-arrays of 14 crossed slots, the gain at the center frequency f_c is 20.7 dBi (θ=90°). At the edge frequencies the gain drops off a bit: it is 19.9 dBi (θ=88°) at lower edge frequency (25.5 GHz) and 19.3 dBi (θ=92°) at higher edge frequency (26.4 GHz). SLS is 12 dB at the center frequency f_c while it falls to 10 dB at the edge frequencies. However, as the previously discussed linear 14 crossed slots antenna, the proposed 2D CPW-fed crossed slots antenna has the bigger range where its S_{11} parameters (Fig. 6), normalized to the 120 Ý -impedance of CPW feeding line, is less than -10 dB (25.5 GHz ï 26.6 GHz) then the range of the satisfying radiation patterns (25.5 GHz ï 26.4 GHz). Besides very good radiation properties of the proposed 2D crossed slots antenna fed by two generators, it is necessary to design the unique feed to enable the uniform amplitude and phase distribution for both arrays and therefore CPW T-junction and CPW race rat couplers are introduced.

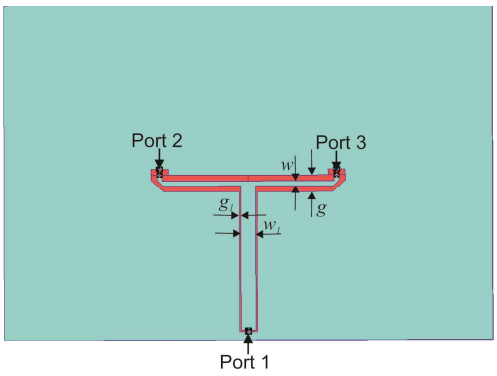

Fig. 7. CPW-T junction.

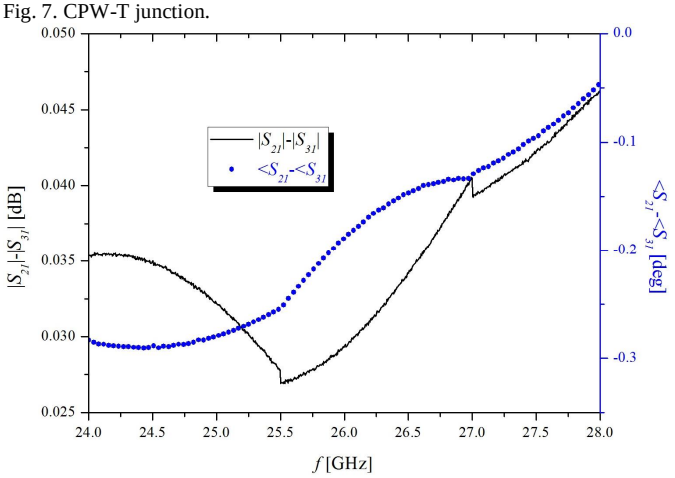

Fig. 8. The difference between insertion losses calculated at ports 2 and 3 of CPW T-junction. S-parameters are normalized to the impedance of CPW feeding line (120 Ý).

B. CPW –T junction

Further, the 2D array is fed by the T junction power divider implemented with coplanar waveguide transmission lines (CPWï T junction). Configuration of the proposed CPW power divider is shown in Fig. 7. The CPW feed line is 60 Ý-CPW line (featuring the strip w_1=0.9 mm and gap g_1=0.1 mm), that enables equal feeding for both sub - arrays dividing power into two 120 Ý CPW feed lines featuring the strip w=0.3 mm and gap g=0.375.

The difference between S-parameters (magnitudes ($|S_{ij}|$) and phases ($\angle S_{ij}$) of S_{21} and S_{31} S scattering (S-) parameters for left and right subarrays) is presented in Fig. 8. Analyzing shown results, it can conclude that proposed CPW T junction provides necessary equal feeding for both subarrays for range between 24-28 GHz. Therefore, CPW T-junction is used to feed the 2D crossed slots array. The whole structure, 2D array and CPW T-junction, is situated on the substrate with dimensions 150 mm x 29.8 mm x 0.508 mm while the equal reflector plate is at the distance $\lambda_0/4$ (Fig. 9).

The Fig. 10 presents the radiation pattern of 2D crossed slots array fed by CPW T-junction. The radiation pattern at the center frequency f_c features with gain of 18.45 dBi at θ=90° and SLS of 12 dB. At the lower edge frequency (25.49 GHz) the gain is 18.16 dBi at θ=88°. At the higher edge frequency (26.45 GHz) the gain is 17.48 dBi at θ=92°. SLS for both edge frequencies is 10 dB. S_{11} parameter is less than -10 dB for the frequency above 25.49 GHz (Fig.11).

C. CPW rat-race coupler

The additional research employs CPW rat-race coupler, with the shape of a ring/circle, to provide required feeding for both sub-arrays. Rat race couplers have been very attractive for use in many applications such as mixers, multipliers, amplifiers, beamformers, etc. [11]. One of its disadvantages is that its big circumference ($3\lambda_g/2$) requests too much space increasing the overall size of antennas.

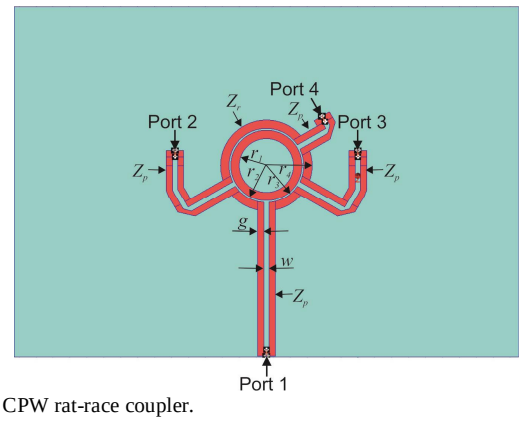

Fig. 12. CPW rat-race coupler.

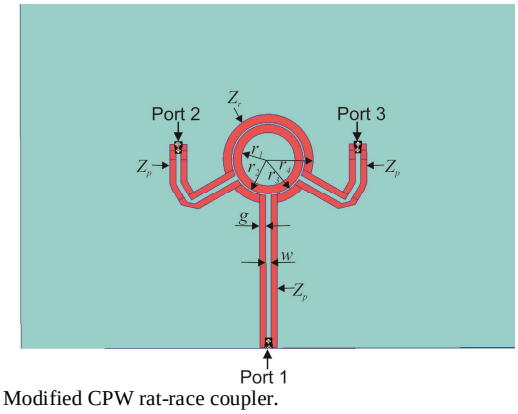

Fig. 13. Modified CPW rat-race coupler.

The proposed CPW rat-race coupler has 4 ports with Z_p=120 q impedance as numbered in Fig. 12, each of which is presented by CPW feed line featuring the strip w=0.3 mm and gap g=0.375. Each port is placed at a distance of one-quarter wavelength (λ_g) away from the other around the one half of the ring. The CPW forming the ring has a impedance Z_r=ã2*Z_p=ã2*120=169.7 q with gap g_r=0.5 mm and strip width w_r=0.105 mm. The CPW rat-race ring features the following radius: r_1=1.6 mm, r_2=2.1 mm, r_3=2.205 mm and r_4=2.705 mm.

An input signal is fed from port 1 resulting in two equal amplitude in-phase signals at ports 2 and 3. Port 4 is isolated in this case. Therefore, ports 2 and 3 are used to feed two identical linear 14 crossed slot sub ï arrays while port 4 is connected to the ground through the impedance of 120 q. Although there are two sub-arrays, we model likewise a modified CPW rat-race that does not contain port 4 (Fig. 13) in order to investigate its role and necessity in rat-race coupler.

The imbalance between S-parameters (magnitudes ($|S_{ij}|$) and phases ($\angle S_{ij}$) of S_{21} and S_{31} S scattering (S-) parameters referring Port 2 and Port 3 of both CPW rat-race coupler and modified CPW rat-race coupler for feeding left and right subarrays) for frequency range from 24 GHz to 28 GHz is presented in Fig. 14. Analyzing shown results, it can see that maximum difference between magnitudes of S_{21} and S_{31} parameters of rat-race coupler with 4 ports is less than 0.5 dB while the maximum variation between their phases is less than 2.5 degrees. Modified rat-race coupler enables equal amplitude in-phase signals at ports 2 and 3 concerning results shown in Fig. 14.

 ISBN 978-86-7466-930-3

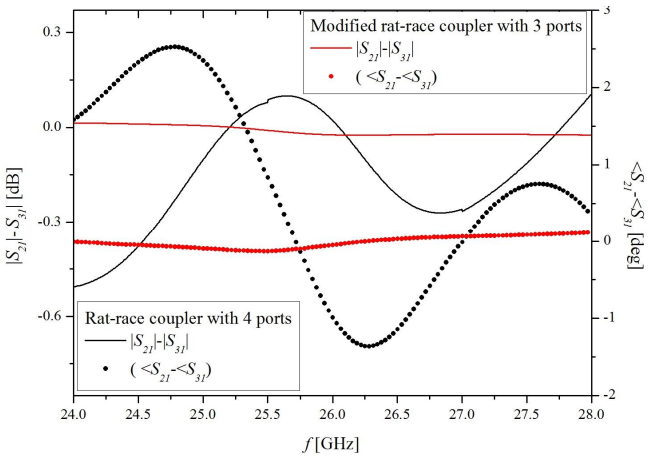

Fig. 14. The difference between insertion losses calculated at ports 2 and 3 of CPW rat-race coupler and of modified CPW rat-race coupler. S-parameters are normalized to the impedance Z_p (120 Ý).

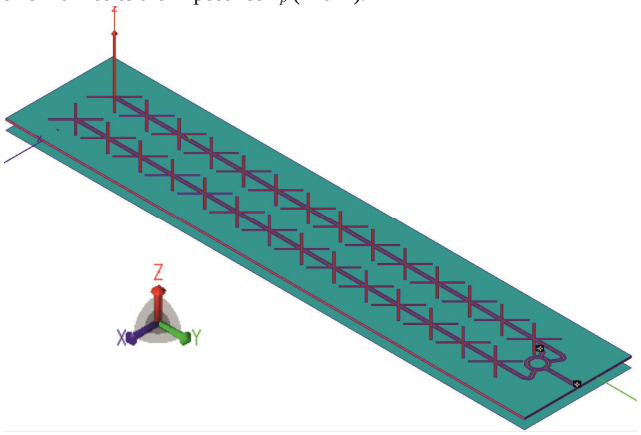

Fig. 15. 2D CPW-fed crossed slot array fed by CPW rat race coupler.

It can be concluded that proposed both CPW rat-race coupler and modified CPW rat-race coupler provide necessary feeding for both subarrays for range between 24-28 GHz. Therefore they are employed to feed 2D crossed slots array (Fig. 15). 2D crossed slots array and CPW rat-race coupler are both situated on the substrate with dimensions 145 mm x 29.8 mm x 0.508mm while the equal reflector plate is at the distance $\lambda_0/4$.

The radiation patterns of 2D CPW-fed crossed slots array fed by CPW rat-race coupler with 4 ports is presented in Fig. 16. The maximum gain at the center frequency f_c is 19.6 dBi at the position θ=90°. At the lower edge frequency 25.6 GHz, the maximum gain is 18.8 dBi at the position θ=89°. At the higher edge frequency 26.8 GHz, the maximum gain is 18.65 dBi at the position θ=93°. SLS is 12.5 dB at the center frequency f_c and 10 dB at the both edge frequencies.

However, the radiation pattern of the 2D CPW-fed crossed slots array fed by modified CPW rat-race coupler with 3 ports has less gain for all considered frequencies (Fig. 17): 18.85 dBi at the center frequency f_c, 18.4 dBi at the lower edge frequency 25.6 GHz and 18.6 dBi at the higher edge frequency 26.6 GHz. The maximum gain spreads from θ=89° for the lower edge frequency 25.6 GHz, through θ=90° for f_c to θ=93° for the higher edge frequency 26.6 GHz. SLS is 12 dB at the center frequency f_c and it drops to 10 dB at the edge frequencies.

TABLE I
THE GAIN AND BANDWIDTH DEFINED BY RADIATION CHARACTERISTICS AND BY S_{11} PARAMETERS OF THE PROPOSED LINEAR AND 2D CPW-FED CROSSED SLOT ARRAYS

Array and feed	Gain [dBi]	Bandwidth by radiation pattern/by S_{11} [GHz]
14 slots	18.7	0.77/1.14
2x14 slots by 2 generators	20.7	0.9/1.1
2x14 slots by CPW T-junction	18.45	0.96/>2.51
2x14 slots by CPW rat-race	19.6	1.2/>2.53
2x14 slots by modified CPW rat-race	18.85	1/>2.45

It is less than -10 dB for frequency above 25.47 GHz for feeding by CPW rat-race and for frequency above 25.55 GHz when the modified CPW rat-race is used. It can notice that 2D CPW-fed crossed slots array fed by CPW rat-race coupler has the biggest frequency range defined by both criteria: by satisfying radiation characteristics and by condition that S_{11}<-10 dB. Also, the latter criterion gives greater frequency range than the former.

Although the single crossed slot antenna is dual polarized [9], the simulated radiation patterns in both X-Z and Y-Z planes for two orthogonal polarizations (vertical and horizontal) of the 2D CPW-fed crossed slots array fed by CPW rat-race coupler are presented in Fig. 19. It can conclude that it is also a dual polarized antenna.

All obtained results of comparison between feeding methods and antenna arrays are shown in Table I.

IV. CONCLUSION

This paper presents the antenna arrays of crossed slot antenna fed by CPW transmission line. The first proposed antenna is a linear array of 14 crossed slots that features with gain of 18.7 dBi at the center frequency f_c. It has the satisfying radiation patterns from the frequency range from 25.6 GHz to 26.37 GHz. Also, its S_{11} parameter is less than -10 dB for the frequencies between 25.6 GHz to 26.74 GHz.

After that we investigate feeding networks for two planar arrays of 14 crossed slots and employ four feeding methods. First method is two generators that enable great gain of 20.7 dBi of the proposed 2D crossed slot array. The gain and SLS have the allowed variation for the frequency range from 25.5 GHz to 26.4 GHz. Moreover, S_{11} parameter stays below -10 dB for the frequencies between 25.5 GHz to 26.6 GHz.

CPW T-junction, CPW rat-race coupler and modified CPW rat-race coupler are proposed. The comparison among the simulated results of investigated three feeding methods gives the advantage to the CPW rat-race coupler. The gain is the greatest when CPW rat-race coupler is used (19.6 dBi). Additionally, the radiation pattern keeps the satisfying gain and SLS values in the largest frequency range when 2D array is fed by CPW rat-race coupler (25.6 GHz - 26.8 GHz). However, S_{11} parameter of 2D array fed by CPW rat-race coupler is less than -10 dB for the similar frequency range above 25.47 GHz as S_{11} parameter of 2D array fed by CPW T-junction and S_{11} parameter of 2D array fed by modified CPW rat-race coupler.

ACKNOWLEDGMENT

This work was supported by the Ministry of Education, Science and Technological Development of the Republic Serbia. The authors would like to thank prof. Natasa Males Ilic and dr. Aleksandar Atanaskovic for their useful suggestions concerning the rat-race coupler modelling.

Cost-Effective Standing Wave Ratio Meter

Ana Đ. Ćupurdija, *Member, IEEE*, and Slobodan V. Savić, *Member, IEEE*

***Abstract*—This paper presents a cost-effective and compact realization of a standing wave ratio (SWR) meter designed with commercially available low-cost components. The SWR meter was tested by measuring voltage standing wave (VSW) and complex impedance with slotted coaxial transmission line, and both results were in good agreement with the simulated circuit results and measurements done on professional equipment - HP SWR meter and vector network analyzer (VNA). The proposed system presents an affordable and precise SWR meter, but also a valuable educational platform for understanding electromagnetic field distribution along transmission lines.**

***Index Terms*—complex impedance; electromagnetic waves; measuring instruments; slotted coaxial transmission line; standing wave ratio.**

I. Introduction

SINCE their discovery, electromagnetic (EM) waves never lost their significance and the functionality of many modern devices would be unimaginable without them. These devices include mobile phones, laptops, wireless devices, radar systems, etc. Bluetooth and the internet would not exist were it not for EM waves. Therefore, today they represent an irreplaceable means for information transmission and a physical phenomenon whose number of applications will only increase in the future [1].

However, when propagating through different mediums (air, water, dielectrics, ionosphere, etc.) or when guided with different guiding-structures (transmission lines or waveguides), EM waves form certain patterns [2] that are not always quite intuitive and can be hard to visualize, even for an experienced RF engineer. An excellent starting point for analyzing this phenomenon is the graphical representation of standing waves along transmission lines (TLs).

To provide a way for students to better understand the concepts of electromagnetic field distribution, we have designed and realized a compact and affordable standing wave ratio (SWR) meter. This prototype, along with slotted coaxial TL, presents a working principle of SWR measurements in a simple and easy-to-understand manner and also provides relatively precise measuring equipment.

The rest of the paper is organized as follows. In the second chapter, the theory of standing waves is briefly introduced, and the requirements for a functional SWR meter are discussed. In the third chapter, starting SWR meter model and its simulation results obtained via TINA simulator [3] are shown. In the fourth chapter, the design and realization of the SWR meter are presented, along with schematics and printed circuit board (PCB) layout. In the fifth chapter, voltage standing wave (VSW) measurements were done for a transmission line closed with different loads, and these results are compared with the results obtained with a professional SWR meter. In the sixth chapter, unknown load impedances are estimated from the SWR measurements and compared to the results obtained with AWR Design Environment [4] and vector network analyzer (VNA) measurements. Finally, in the seventh chapter, conclusions are drawn.

II. Standing Waves Measurement Theory

Two-wire transmission line represents a pair of conductors carrying an EM wave. The theory of EM propagation along TLs is explained in detail in [2, 5].

When exciting a TL with a signal from a generator connected at its one end, voltage and current waves are formed along the TLs axis. In the steady state, when all excitations and all responses are single-frequency signals, on the transmission-line there are, generally, two waves traveling in opposite directions. These waves are progressive (traveling) waves, and their superposition forms the standing wave. The effective (rms) value of the standing wave is a function of the generator's power, the complex impedance of a load which ends TL on the other end, the characteristic impedance of the TL, and it (generally) changes along the TLs axis. When the TL is opened on its other end, all of the incident power is reflected from the open end. When the TL is ended with a lossy load, some of the excited power is dissipated in the load, making the reflected wave have less energy than the incident wave.

The parameter that integrally describes standing wave is SWR, defined as

$$SWR = \frac{U_{\max}}{U_{\min}}, \tag{1}$$

where $U_{\max}$ and $U_{\min}$ are the maximum and the minimum effective value of the VSW along TL's axis, respectively. The standing wave ratio can be in the range $[1, \infty)$. If SWR equals one, the load is matched to the TL, and there is no reflection. If SWR tends to infinity, all the energy of the incident wave is reflected.

One way to measure SWR is to use slotted coaxial TL and measure EM field or voltage along TL's slot with a short probe. The probe should be long enough to detect high enough voltage, and short enough not to (locally disturb) the

 ISBN 978-86-7466-930-3

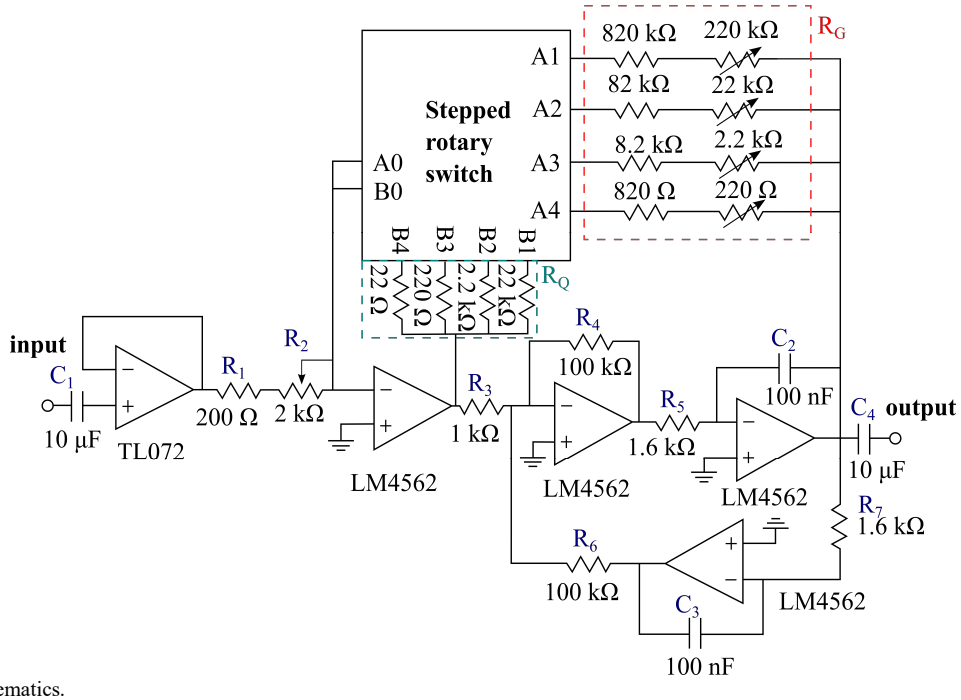

Fig. 1. SWR meter schematics.

EM field. The voltage measured with this probe is proportional to the electric field in the slotted coaxial TL and is connected to the square-law diode detector [6]. This diode is usually a germanium diode, which works in the quadrature region of the I-V (current-voltage) characteristics. Therefore, the signal obtained with this diode detector is proportional to the square of the VSW effective value. This signal is then further processed by the SWR meter. Keeping all of this in mind, we can define SWR meter functionalities and parameters of interest. Also, please note that in the measurement set up that we are using, shown in Fig. 5, incident voltage (field) is modulated with a signal of a fixed, preferably low, frequency (i.e., around 1 kHz), that represents an envelope of the high-frequency signal that form the standing wave. The incident signal is amplitude modulated because when working with an unmodulated signal, the output of the diode detector would be a DC voltage which is generally susceptible to high measurement errors due to the existence of the DC offset in systems. Since the amplitudes of the measured unmodulated signal are relatively small (about 1 mV), even a small DC offset could introduce significant measurement errors. By measuring the effective value of the detected 1 kHz envelope, the effective value of the high-frequency signal could also be measured. Expected values for the signals at the output of the probe are in the range 1-10 mV, so the designed SWR meter should have a significant gain. Based on all of this, we decided to design the SWR meter as an active bandpass filter, with the center frequency around 1 kHz. The proposed design has four gain stages (times 1, 10, 100, and 1000), while also having an option to fine-tune gain to any value in these ranges. Finally, the Q factor of the filter needs to be set accordingly, so the circuit can filter unwanted harmonics and harmonic components, but also not be too selective. The Q factor needs to be independent of the set gain, and the gain and the Q factor of the system should be independent of impedances connected at its input and output.

III. Simulation Results

The main part of the circuit (bandpass active filter) was designed starting from [7] and by using the operational amplifier LM4562. This chip is made by Texas Instruments, so simulation of the circuit was done in their TINA simulator [4]. The schematics used for simulation are shown in Fig. 1, while omitting the stepped rotary switch. This schematic is the main building block for the SWR meter.

The circuit shown in Fig. 1 is excited with an AC generator at 1 kHz. The gain is set with resistors R_1, R_2 and R_G, and is given by the formula

$$G = \frac{R_G}{R_1 + R_2}. \tag{2}$$

The Q factor is set with the resistors R_G and R_Q, given by the formula

$$Q = \frac{R_G}{R_Q}. \tag{3}$$

In the mentioned configuration, without the stepped rotary switch, the Q factor depends on the gain (since they have a common factor of the resistor R_G). This is not a desirable feature, hence, stepped rotary switch was introduced in the PCB design step. The circuit is intended to operate in a single-frequency mode, just like the professional HP SWR

 ISBN 978-86-7466-930-3

meter, which is used for comparison. This central bandpass frequency is set with capacitor C_2 and resistor R_5 (aka C_3 and R_7), given with the formula

$$f_c = \frac{1}{2\pi R_5 C_2} \tag{4}$$

Simulation results are shown in Table I, for four gain configurations. The resistor R_Q was changed along with R_G, so that the Q factor is constant, and is set to be around $Q = 45$. These results confirmed that the designed circuit works as expected, so we proceeded with the board design and fabrication.

TABLE I
GAIN SIMULATION RESULTS

Resistor R_G	1 kΩ	10 kΩ	100 kΩ	1 MΩ
Theoretical gain	1	10	100	1000
Simulated gain	1.13	10.13	100.12	993.76

IV. SWR METER PROTOTYPE

Based on the schematics in Fig. 1, PCB layout was made and is shown in Fig. 2. The purpose of the buffer at the input stage is to make the input impedance of the circuit independent from the gain and Q factor. The output stage of the meter is not buffered. When the output current is below the maximum value stated in the datasheet (26 mA), practically there is no distortion in the output voltage. In order not to exceed the current limit, in the worst case scenario for output voltage of 1 V, the load impedance must be greater than 40 Ω, which is well below input impedances for all commercial multimeters.

The resistor R_2 is a potentiometer, so the gain can be fine-tuned to any value in the predefined ranges. Predefined ranges of 1, 10, 100, and 1000 are set using the stepped rotary switch, with three pins and four positions. This switch changes the resistors used for setting the gain (R_G in Fig. 1). Also, using this switch, the resistors used for setting the Q factor are simultaneously switched when setting the gain, so the Q factor would stay constant when the resistor R_G changes. For the measurements shown in Section V, the Q factor is set around $Q = 45$.

The branches with resistors used for gain setting contain one fixed resistor and one trimmer potentiometer. This way, even with component tolerances, the gain can be fine-tuned to exactly match the predefined values (1, 10, 100, and 1000). The made prototype has its stage for power supply (converting the AC voltage of 230V into ±5 V DC needed for the operational amplifiers) and also has added overcurrent protection, in a form of a fuse.

The final prototype is shown in Figs. 3 and 4, where it can be seen that the final prototype is compact and practical to use. With this design, we satisfied all of our requirements for a functional SWR meter, so we proceeded with the measurements.

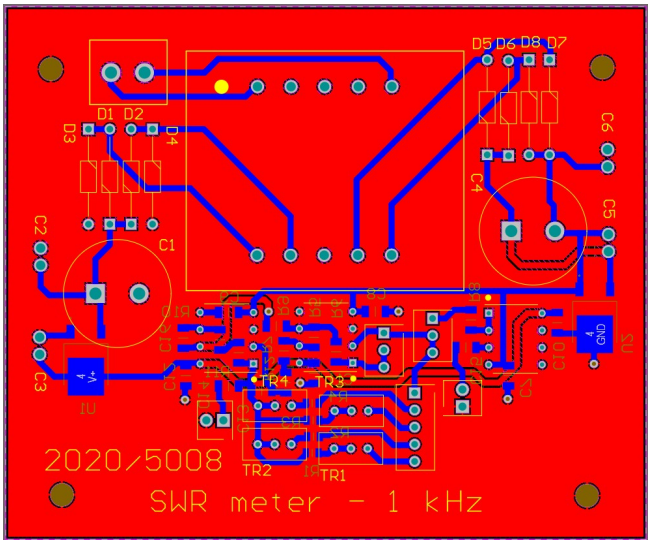

Fig. 2. Printed circuit board layout of the SWR meter.

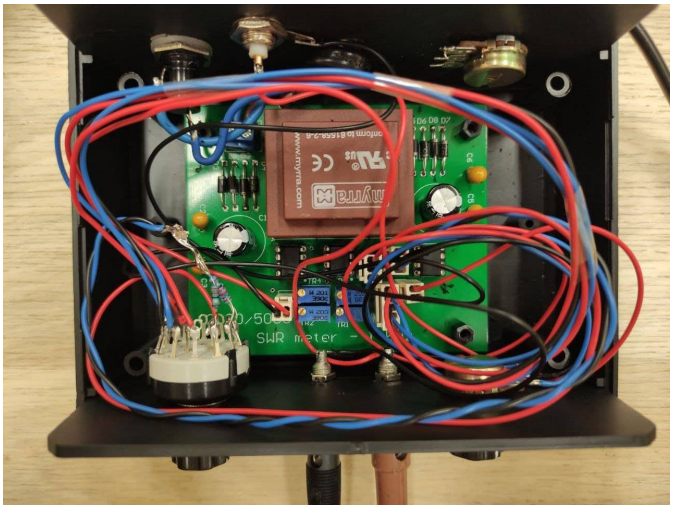

Fig. 3. The prototype of the SWR meter.

V. MEASUREMENTS ON A SLOTTED COAXIAL TRANSMISSION LINE

The first measurement to test the functionality of the SWR meter was made with an oscilloscope, where the input and the output voltages are observed to set the desired gain to 1, 10, 100, and 1000 with trimmer resistors. The effective value of input voltage is set so that the output can be easily visible on the oscilloscope for a given measurement, but also to prevent the operational amplifiers from entering the saturation. The gain was then fine-tuned to the wanted values with trimmer resistors.

After setting the gains to the desired values, measurements on the TL were done. The used TL is a slotted coaxial TL having $Z_c = 50\ \Omega$ characteristic impedance with a probe that could be moved longitudinally along TL's axis. This way the effective value of VSW is measured along TL's axis. The slotted TL we are using has a ruler along its axis, so we will use this ruler for measuring distance along TL's axis. The probe position is controlled with a mechanical knob. The line was excited with a sine wave at 1.4 GHz, modulated with a sine at 900 Hz. This signal was generated by a

 ISBN 978-86-7466-930-3

software-defined radio (SDR) device. The frequency of the envelope at 900 Hz was chosen because, due to the component tolerances, the central frequency of the filter was not exactly 1 kHz. Central frequency was determined by changing the envelope frequency and observing when the maximal gain occurs.

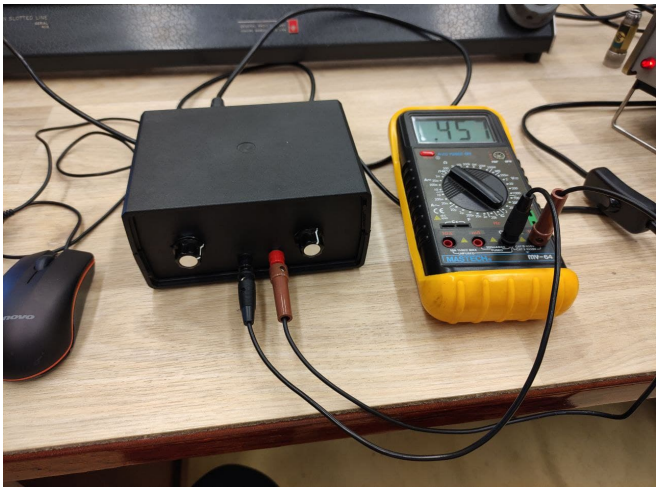

Fig. 4. The prototype of the SWR meter is enclosed in a box and connected to the voltmeter.

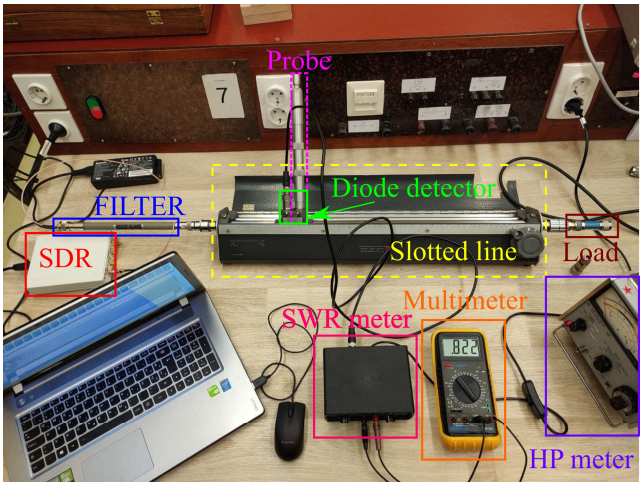

Fig. 5. Complete measurement setup.

To suppress any unwanted signal, at the input of the TL, a coaxial filter was placed, with a cut-off frequency at 2.2 GHz. The effective value of the output voltage of the realized SWR meter is measured with a multimeter, as shown in Figs. 4 and 5. The measurements were done by moving the probe in steps of 5 mm and measuring the VSW effective value in 81 data points. The measurements were done in the distance range from 15 cm to 55 cm at the TL ruler. The same procedure was done when TL was opened at its other end, and when it was terminated with the 6 dB and with the 10 dB loads. These loads are realized as coaxial (6 dB and 10 dB) attenuators, opened at their second end. The SWR meter gain for the measurements is set so that the peak of the VSW corresponds to the effective value of 1 V measured with the multimeter.

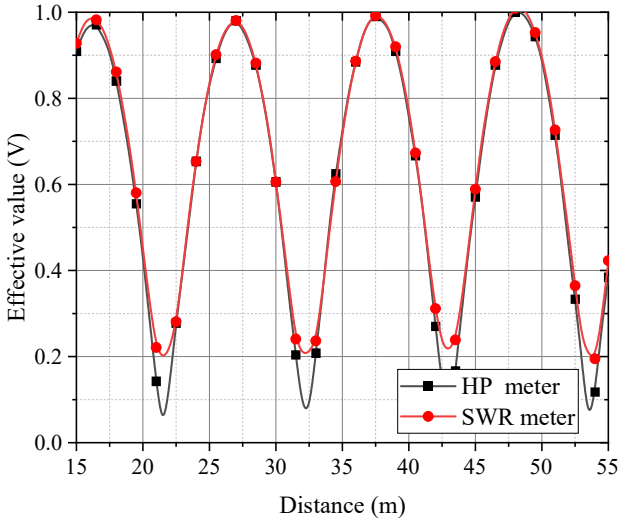

Fig. 6. Comparison of the VSW measurement obtained with designed and professional SWR meter for open-ended transmission line.

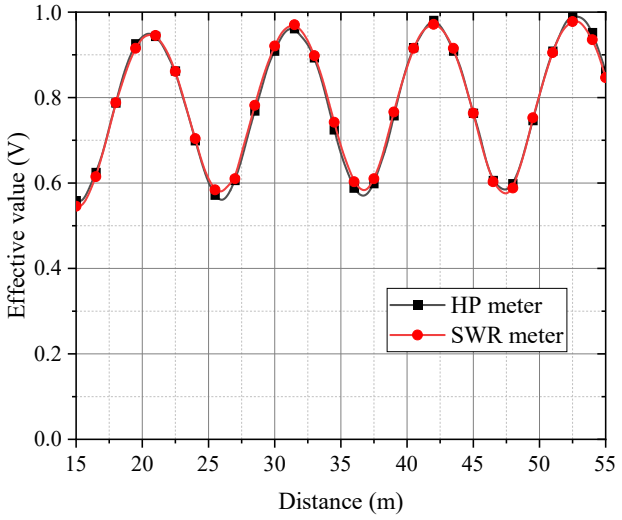

Fig. 7. Comparison of the VSW measurement obtained with designed and professional SWR meter when the transmission line is closed with the 6 dB load.

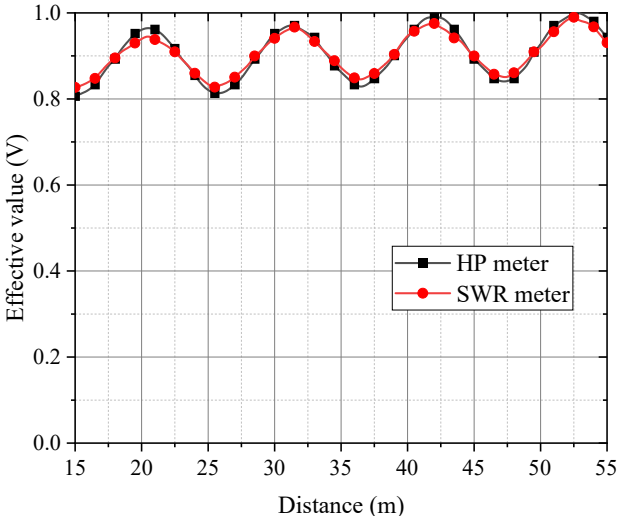

Fig. 8. Comparison of the VSW measurement obtained with designed and professional SWR meter when the transmission line is closed with the 10 dB load.

 ISBN 978-86-7466-930-3

For the obtained results to be double-checked, the same set of measurements was done with the professional Hewlett-Packard 415E SWR meter. The entire measurement setup is shown in Fig. 5. The obtained VSW curves for the case of the unloaded TL are shown in Fig. 6, while the obtained curves for cases of 6 dB and 10 dB loads are shown in Figs. 7 and 8, respectively. In the case of the unloaded line, the proposed SWR meter does not have such deep minimums as the professional one. Additionally, for this case, VSW should be equal to zero at its minimum. This is not being the case in Fig. 6 due to, among other, finite number of measuring points along TL's axis. Nevertheless, these two sets of results are in good agreement, and even better when TL is closed with loads (Figs. 7 and 8).

VI. Load Impedance Calculation

The impedances of used loads (6 dB and 10 dB) are firstly estimated based on the fact that these loads are matched coaxial attenuators opened at their second end. Based on this, a simple model for the calculation of their input impedance is assembled in the AWR Design Environment, as shown in Fig. 9. The load which complex impedance we want to measure, labeled as "LOAD" at Fig. 5, is modeled as two short TLs with ideal (matched) attenuator between them. The same model is used for 10 dB load, with a loss parameter of the ATTEN element from Fig. 9 set to 10 dB. The length of used short TLs is estimated experimentally.

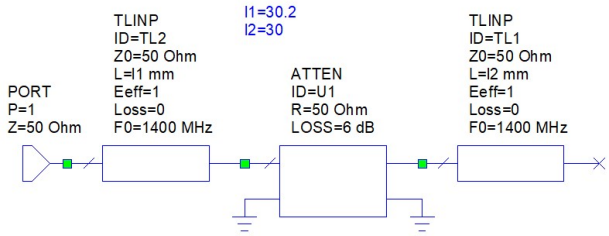

Fig. 9. The simple model of used loads made in the AWR Design Environment.

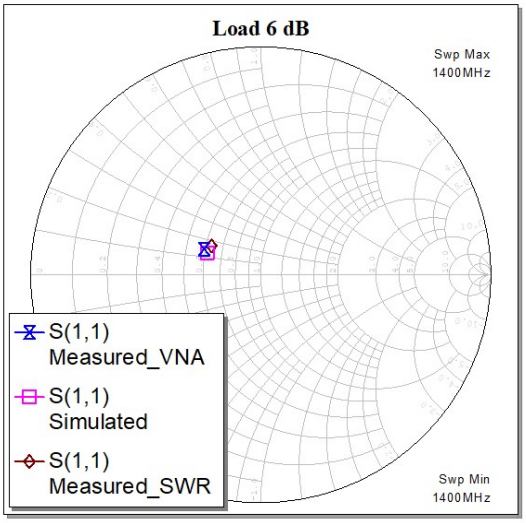

Fig. 10. Smith chart for the 6 dB load.

From the given SWR measurements, using the Smith diagram, load impedances are calculated as described in [5, 8] and compared to the impedances of the loads obtained via simulation and via measurements done on the N5227a Agilent VNA. The results are shown in Figs. 10 and 11 for 6 dB and 10 dB loads, respectively. From these figures, it can be noticed that the obtained results of the load impedances are in excellent agreement for all three sets of results. Therefore, we conclude that the designed SWR meter can be used for the precise determination of unknown impedances.

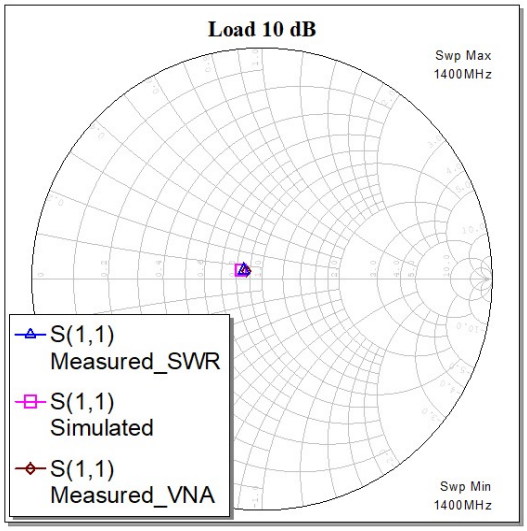

Fig. 11. Smith chart for the 10 dB load.

VII. Conclusion

A compact and affordable prototype for the SWR meter was proposed and realized. Simulation and measurement results are proven to fit well. The realized circuit acts as an active filter with four gain stages (1, 10, 100, and 1000), and the gain can also be fine-tuned to any value in these ranges.

Standing wave ratio measurements were done on a slotted coaxial transmission line for two different loads, and measurements obtained with the designed SWR meter are compared to those obtained with the professional HP SWR. These two sets of measurements are in good agreement. From the measured standing wave curves, load impedances are calculated and they are in excellent agreement with the results obtained with AWR Design Environment and professional VNA.

The realized device can be used to better understand and visualize the EM waves distribution on TLs but also could be a usable piece of equipment for microwave laboratories which is a good alternative to much more expensive professional equipment. Further improvements would include adding a tunable Q factor functionality to the device. This will be part of the authors' further efforts.

Automatizacija određivanja nivoa EM polja radio-difuznih predajnika na osnovu ITU-R P.1546 metode za visine h_1 manje od 10 m

Miloš Radojković, Zlatica Marinković, *Senior Member, IEEE*

***Apstrakt*—U ovom radu predložen je metod za određivanje nivoa EM polja iz preporuke ITU R-1546 za očekivani nivo elektromagnetnog polja koji potiče od radiodifuznih predajnika i visine h_1 manje od 10 metara. Predloženi metod je baziran na primeni veštačkih neuronskih mreža i omogućava efikasno određivanje nivoa polja za frekvencije do 4000MHz i visine h_1 manje od 10 metara. Tačnost metoda prikazana je na primerima krivih koje se odnose na frekvencije i vrednosti h_1 koji nisu korišćene u procesu obučavanja neuronske mreže.**

***Ključne reči*—ITU-R P.1546, nivo elektromagnetnog polja, radio-difuzni predajnik, veštačke neuronske mreže.**

I. Uvod

Radiodifuzne komunikacije su komunikacije tipa tačka-oblast i njihova primena je veoma česta (radio i televizijski predajnici, bazne stanice mobilnih sistema i sl.). Jedan od nezaobilaznih koraka prilikom projektovanja radiodifuznog sistema jeste određivanje zone pokrivanja. Zona pokrivanja predstavlja oblast u kojoj je nivo elektromagnetnog (EM) polja veći od vrednosti definisane zahtevima razmatranog sistema i određen je daljinom od predajnika na kojoj je nivo EM polja veći od zadate vrednosti.

Zona pokrivanja je određena u nekoliko pravaca – azimuta (obično 36 pravaca sa korakom od po 10˚ ili 120 pravaca sa korakom od po 3˚, što zavisi od jačine predajnika). Postoje različite metode za određivanje zone pokrivanja. Najčešće se koristi statistički metod definisan u preporuci ITU-R P.1546 [1]. Preporuka ITU-R P.1546 daje postupak određivanja nivoa polja za zemaljske radio-difuzne servise u frekvencijskom opsegu od 30 MHz do 4000 MHz. Preporuka se bazira na empirijskim krivama (dostupnih i tabelarno) za zavisnost očekivanog nivoa polja od rastojanja za različite vrednosti parametra koji opisuje karakteristike terena. Imajući u vidu da je preporuka data za fiksne vrednosti frekvencija, visine h_1 i daljine d, ukoliko je potrebno izvršiti proračun EM polja za vrednosti koje nisu date u preporuci ITU-R P.1546 potrebno je izvršiti veliki broj interpolacija.

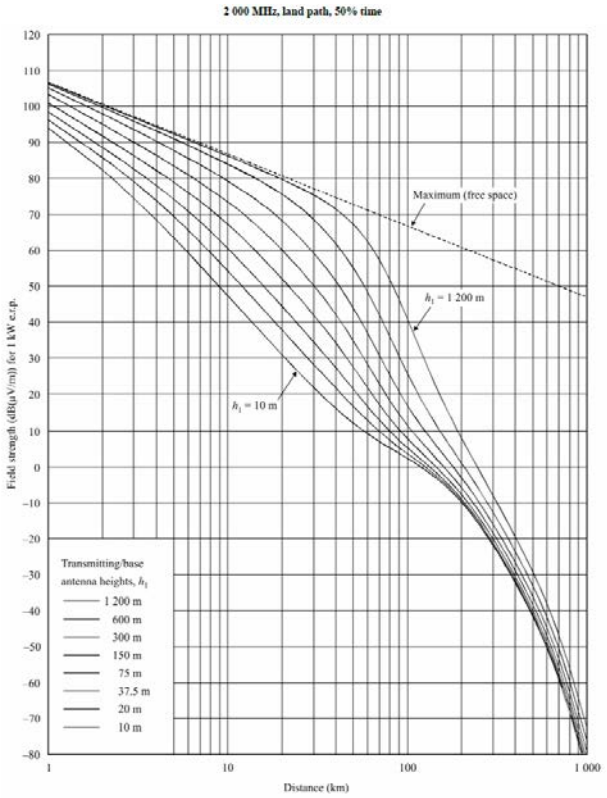
U ovom radu je predložen je metod za očitavanje krivih za očekivani nivo EM polja baziran na veštačkim neuronskim mrežama. Veštačke neuronske mreže su izabrane zahvaljujući njihovim odličnim interpolacionim sposobnostima, zbog čega su i široko primenjene u oblasti mikrotalasa [2]-[11]. Neuronske mreže su već primenjivane za očitavanje krivih za očekivani nivo polja po pomenutoj preporuci i ranijim verzijama [2]-[6], a u ovom radu se po prvi put neuronske mreže primenjuju za očitavanje vrednosti nivoa EM polja za visine h_1 manje od 10 metara.

U Sekciji II najpre je kratko opisan postupak određivanja nivoa polja na osnovu preporuke ITU-R P-1546. Predloženi model za očitavanje krivih za vrednosti h_1 manje od 10 metara objašnjen je u Sekciji III. Dobijeni rezultati primenom razvijenog modela prikazani su u Sekciji IV. Izvedeni zaključci dati su u Sekciji V.

II. Preporuka ITU-R P-1546

Preporuka ITU-R P.1546 se zasniva na familiji krivih koje su date kao očekivane vrednosti intenziteta polja u dBμV/m na visini 10m iznad tla (usvojena prosečna visina prijemne antene za radio-difuzni prijemnik), za signal emitovan predajnikom snage 1 kW izračen pomoću polutalasnog dipola (dobitak 0 dBd), u funkciji rastojanja.

Krive su date posebno za kopno i posebno za more, a u preporuci je opisan i način proračuna u slučaju kombinovanog terena. Za oba tipa sredine date su krive očekvanog intenziteta polja za frekvencije 100 MHz, 600 MHz i 2000 MHz i to za 50%, 10% i 1% vremena i za 50% lokacija u oblasti površine 500×500 m^2. Kao primer na Sl. 1 prikazane su krive za očekivani intenzitet polja na frekvenciji 2000 MHz za kopno. Parametar na krivama je vrednost EM polja u dBμV/m za visine h_1 u rasponu od 10 do 1200 m (diskretne vrednosti 10 m, 20 m, 37.5 m, 75 m, 150 m, 300 m, 600 m i 1200 m) i daljine d do 1000 km. Parametar h_1 je za rastojanja od predajnika veća od 15 km jednak efektivnoj visini terena h_{eff} (visinska razlika između visine centra antene u odnosu na nivo mora i srednje nadmorske visine na rastojanju od 3 km do 15 km od predajnika). Za rastojanja d manja od 15 km, parametar h_1 predstavlja visinsku razliku između visine centra antene u odnosu na nivo mora i srednje nadmorske visine na rastojanju od $0.2d$ do d od predajnika. U slučaju da je poznata samo efektivna visina antene, a ne i detaljne informacije o terenu, za rastojanja do 3 km parametar h_1 je jednak visini antene iznad tla h_a. Za rastojanja veća od 3km za određivanje visine h_1 koristi se sledeći izraz:



$$h_1 = h_a + \frac{(h_{eff} - h_a)(d-3)}{12}. \quad (1)$$

Imajući u vidu da su krive date za diskretne vrednosti h_1, prilikom proračuna neophodno je vršiti interpolaciju za konkretnu vrednost h_1 na sledeći način:

Miloš Radojković – Energoprojekt Entel, Bulevar Mihajla Pupina 12, Beograd 11070, Srbija (e-mail: milosradojkovic89@gmail.com).

Zlatica Marinković - Elektronski fakultet u Nišu, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: zlatica.marinkovic@elfak.ni.ac.rs).

 ISBN 978-86-7466-930-3

Sl. 1. Krive za očekivani intenzitet polja na 2000 MHz za kopno po preporuci ITU-R P-1456.

$$E_o = E_{\inf} + (E_{\sup} - E_{\inf})\frac{\log(h_1 / h_{\inf})}{\log(h_{\sup} / h_{\inf})} \quad (2)$$

gde je: E_{inf} nivo polja za zadato rastojanje očitano sa krive koja se odnosi na prvu manju tabelarnu vrednost visine h_1, h_{inf}, a E_{sup} nivo polja za zadato rastojanje očitano sa krive koja se odnosi na prvu veću tabelarnu vrednost visine h_1, h_{sup}.

Za određivanje nivoa polja na proizvoljnom rastojanju d, (u opsegu od 1km do 1000km) koristi se sledeći izraz

$$E_o = E_{\inf} + (E_{\sup} - E_{\inf})\frac{\log(d / d_{\inf})}{\log(d_{\sup} / d_{\inf})} \quad (3)$$

gde je E_{inf} očitana vrednost polja za d_{inf}, prvu tabuliranu vrednost rastojanja manju od d, E_{sup} očitana vrednost polja za d_{sup}, prvu tabuliranu vrednost rastojanja veću od d.

Dalje, ukoliko se frekvencija za koju se vrši proračun ne poklapa sa jednom od vrednosti 100 MHz, 600 MHz i 2000 MHz, potrebno je izvršiti interpolaciju:

$$E_o = E_{\inf} + (E_{\sup} - E_{\inf})\frac{\log(f / f_{\inf})}{\log(f_{\sup} / f_{\inf})} \quad (4)$$

gde su: f_{inf} prva tabulirana vrednost frekvencije manje od f (100 MHz ako je f < 600 MHz, u ostalim slučajevima 600 MHz), f_{sup} prva tabulirana vrednost frekvencije veće od f (600 MHz ako je f < 600 MHz, u ostalim slučajevima 2000 MHz), E_{inf} očitana vrednost polja za f_{inf} i E_{sup} očitana vrednost polja za f_{sup}.

Kao što se može primetiti sa Sl.1, minimalna vrednost h_1 za koje su date vrednosti EM polja je 10 m. Vrednosti EM polja za visine između 0 m i 10 m nisu tabulirane i jednačina (2) se ne može koristiti za proračun nivoa EM polja. Za proračun nivoa EM polja za vrednosti h_1 u opsegu od 0 do 10 m koristi se sledeći izraz:

$$E[dB\mu V/m] = E_{zero} + 0.1h_1(E_{10} - E_{zero}) \quad (5)$$

gde su:

$$E_{zero}[dB\mu V/m] = E_{10} + 0.5(C_{1020} + C_{h1neg10}), \quad (5a)$$

$$C_{1020}[dB] = E_{10} + E_{20}\ \text{dB} \quad (5b)$$

$C_{h1neg10}$ je korekcija C_{h1} u dB izračunata korišćenjem sledećeg izraza:

$$C_{h1} = 6.03 - J(v)\ \text{dB} \quad (6)$$

gde je

$$J(v) = \left[6.9 + 20\log\left(\sqrt{(v-0.1)^2 + 1} + v - 0.1\right)\right], v > -0.7806 \quad (6a)$$

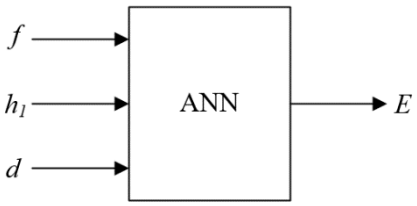
$$v = K_v \Theta_{eff\,2} \quad (6b)$$

$$\Theta_{eff\,2} = \arctan(-h_1 / 9000) \quad (6c)$$

a K_v konstanta koja ima sledeće vrednosti:

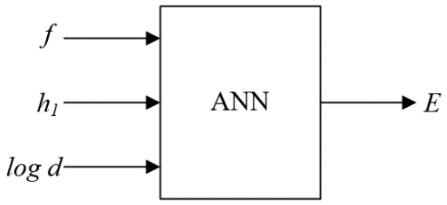
K_v = 1.35 za 100 MHz,
K_v = 3.31 za 600 MHz,
K_v = 6.00 za 2000 MHz.

$E_{10} + E_{20}$ je jačina polja u dBμV/m izračunata prema jednačini (2) za traženu daljinu d i visine h_1 = 10 m i h_2 = 20 m.



Preporuka ITU-R P.1546 se može koristiti za sisteme koji rade u opsegu od 30 MHz do 4000 MHz i gde visina h_1 ne prelazi 3000 m.

U realnim primerima se u najvećem broju slučajeva, sve tri veličine (parametar h_1, rastojanje i frekvencija) razlikuju od tabuliranih vrednosti, pa je potrebno vršiti višestruke interpolacije, posebno ako je visina h_1 manja od 10 metara. U sledećoj sekciji je predložen efikasni metod zasnovan na primeni veštačkih neuronskih mreža koji omogućava određivanje EM polja za zadatu daljinu i vrednosti h_1 u opsegu 0≤ h_1≤10 m.



III. PREDLOŽENI METOD

U ovom radu predložena su dva metoda za određivanje nivoa EM polja za visine h_1 manje od 10 metara primenom veštačkih neuronskih mreža. Na Sl. 2 prikazan je neuronski model kojim se na osnovu frekvencije f, visine h_1 i daljine d određuje nivo polja, odnosno koji modeluje zavisnost $E=f(f,h_1,d)$. Kako je na krivama za očekivani nivo polja u preporuci ITU-R P.1546 rastojanje prikazano na logaritamskoj skali razmatran je i model prikazan na Sl. 3 , koji kao ulaze ima frekvenciju f, visinu h_1 i daljinu u d predstavljenu u logaritamskom formatu i nivo polja kao izlaz $E=f(f,h_1,\log d)$.

 ISBN 978-86-7466-930-3

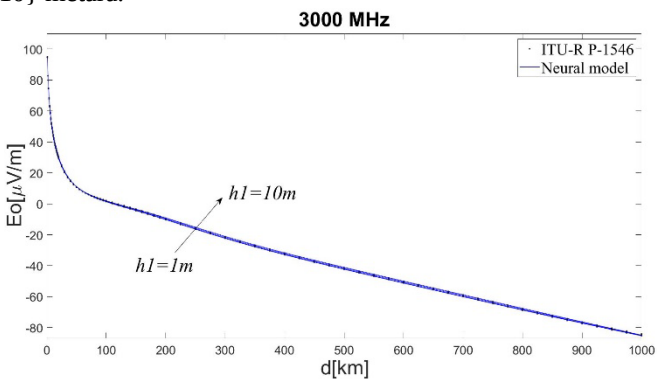
Sl. 2. Neuronski model za određivanje nivoa EM polja $E=f(f, h_1, d)$

Sl. 3. Neuronski model za određivanje nivoa EM polja sa log d na ulazu $E=f(f, h_1, log\ d)$

Modeli predstavljaju višeslojne neuronske mreže, koje se sastoje od osnovnih jedinica, neurona, grupisanih u slojeve (ulazni sloj, jedan ili više skrivenih slojeva i izlazni sloj). Broj ulaznih neurona je određen brojem ulaznih parametara, u konkretnom slučaju tri, a broj izlaznih neurona odgovara broju izlaznih parametara, u konkretnom slučaju jedan. Broj neurona u skrivenim slojevima nije moguće unapred odrediti, već se taj broj određuje u postupku učenja mreže. Neuronska mreža uči zavisnost između ulazno-izlaznih parametara primenom optimizacionih procedura, kojima se vrši optimizacija parametara mreže (težine veza između neurona i pragovi aktivacionih funkcija neurona), sa ciljem da odziv mreže bude što je moguće bliži željenoj zavisnosti između ulazno-izlaznih parametara.

Uspešno obučena mreža sposobna je da da korektan odziv ne samo za kombinacije ulaznih veličina koje su korišćene tokom procesa učenja mreže, već i za bilo koje vrednosti ulaznih veličina koje nisu korišćene tokom učenja ali su u opsegu veličina u kome su i trening vrednosti. Treba napomenuti da je model razvijen za ceo skup frekvencija na koje se može primeniti preporuka ITU-R P.1546, tj. frekvencije u opsegu od 30 MHz od 4000MHz.

IV. Rezultati



Podaci za obučavanje neuronskih mreža prikazanih na Sl.2 i Sl.3 se odnose na 40 različitih frekvencija u opsegu od 100 MHz do 4000 MHz i korakom frekvencije od 100 MHz. U cilju provere da li broj i distribucija trening uzoraka u pogledu izabranih vrednosti h_1 utiče bitno na tačnost mreže razmatrana su dva dva skupa podataka koji se odnose na h_1={1, 3, 5, 7, 9 i 10}m i (trening skup 1) i h_1={1, 3, 6, 9, 10}m (trening skup 2). Svi podaci potrebni za obučavanje i testiranje mreže generisani su korišcenjem izraza (3), (4), (5-5b) i (6-6c). Tokom razvoja modela, veći broj mreža sa jednim ulaznim slojem, dva skrivena sloja i jednim izlaznim slojem je obučeno i testirano. U skrivenom sloju, korisćen je različit broj neurona kako bi se pronašao model sa što boljom tačnošću.

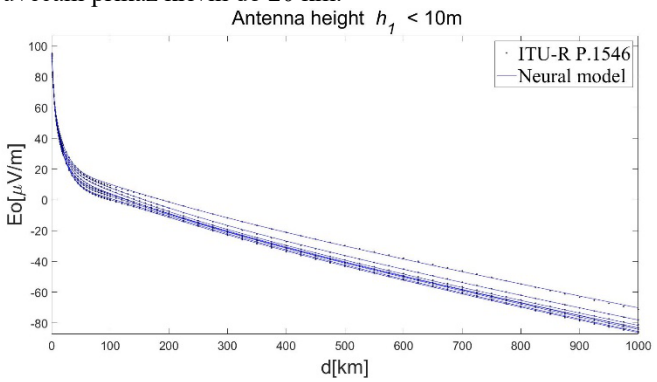
U ovom slučaju korišćene su neuronske mreže kod kojih skriveni neuroni imaju sigmoidnu transfer funkciju, a izlazni neuroni linearnu transfer funkciju. Ulazni neuroni imaju bafersku funkciju, pa je njihova funkcija jedinična linearna funkcija. Za obučavanje mreža primenjen je *Levenberg-Maquardt* algoritam [2]. Tačnost odziva mreže testirana je poređenjem odziva mreže i referentnih vrednosti. Takođe, vođeno je računa da ne dođe do preučenja mreže van referentnih tačaka, tj. da mreža ima dobru generalizaciju. Generalizacija se može proveravati testiranjem mreže za ulazne vrednosti koje nisu korišćene u toku učenja. Kako je u cilju što boljeg učenja mreže iskorišćen ceo skup referentnih podataka iz preporuke, provera da li je došlo do preučenosti vršena je vizuelno, tj. proverom odziva mreže kada su ulazne veličine menjane sa korakom koji je manji od koraka promene referentnih vrednosti kao i proračunom srednje greške (ATE - *Average Test Error*), maksimalne greške (WTE - *Worst Case Error*) i korelacionog koeficijenta *r*. Mreža je obučena i generisan u programskom paketu Matlab.

Nakon testiranja razvijenih modela, izabrani su najbolji modeli za oba predložena modela u slučaju obučavanja sa dva izabrana trening skupa. Za testiranje generalizacije korišćen je test skup koji se odnosi na vrednosti koje nisu korišćenje tokom obuke, a odnosi se na vrednosti frekvencije i visine koje su u opsegu veličina kao i vrednosti korišćene tokom obučavanja (f=150MHz, h_1=2m; f=450MHz, h_1=4m; f=850MHz, h_1=6m; f=1450MHz, h_1=8m; f=1850MHz, h_1=2m; f=2350MHz, h_1=4m; f=3350MHz, h_1=6m; f=3850MHz, h_1=8m).

Rezultati testiranja najboljih modela prikazani su u Tabeli I. Može se uočiti da su srednje greške u svim razmatranim slučajevima manje od 0.15%, dok je maksimalna greška manja od 1.5%. Korelacioni koeficijent je veoma blizu jedinici, što takođe potvrđuje visoku tačnost modelovanja.

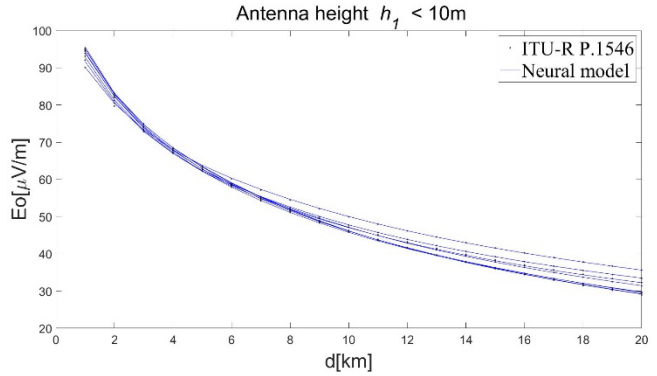
Kao najbolji model za određivanje rastojanja za zadati nivo EM polja izabrana je mreža prikazana na Sl. 3 - $E=f(f, h_1, log\ d)$, sa dva skrivena sloja (10 neurona u prvom sloju i 12 neurona u drugom sloju i za koju su korišćeni podaci za obučavanje koji se odnose na visine {1, 3, 5, 7, 9, 10} metara.

Sl. 4. Poređenje vrednosti EM polja generisanih pomoću razvijenog neuronskog modela i referentnih vrednosti iz preporuke ITU-R P1546.



Na Sl. 4 se može videti tačnost modela. Prikazane su krive za nivo polja generisane pomoću neuronske mreže (linije) za parametar visine h_1={1, 3, 5, 7, 9, 10} metara i referentne vrednosti određene preporukom (prikazane simbolima).

Može se uočiti da odziv mreže tj. vrednosti generisane pomoću neuronskog modela veoma dobro prate referentne vrednosti što potvrđuje da je postignuta zadovoljavajuća tačnost modelovanja.



Kao dodatna ilustracija tačnosti modela $E=f(f, h_1, log\ d)$, na Sl. 5 prikazane su krive koje se odnose na test skup. Sa

 ISBN 978-86-7466-930-3

Sl.5 se može primetiti da su vrednosti generisane pomoću neuronskog modela veoma blizu referentnim vrednostima prema preporuci ITU-R P1546. Kako bi se bolje prikazali rezultati krive za daljine do 20 km, na Sl. 6 se može videti uvećani prikaz krivih do 20 km.

Sl. 5. Poređenje vrednosti EM polja generisanih pomoću razvijenog neuronskog modela i referentnih vrednosti iz preporuke ITU-R P1546 za vrednosti koje nisu korišćene u obučavanju mreže

Sl. 6. Poređenje vrednosti EM polja generisanih pomoću razvijenog neuronskog modela i referentnih vrednosti iz preporuke ITU-R P1546 za vrednosti koje nisu korišćene u obučavanju mreže (daljina do 20 km)

V. ZAKLJUČAK

Kao što se može videti u Sekciji II, ukoliko se određuje nivo EM polja za vrednosti parametara h_1, *f* i *d*, potrebno je izvršiti veliki broj interpolacija. Predloženi metod baziran na neuronskoj mreži omogućava automatizaciju procesa intepolacija i trenutnog izračunavanja EM polja nalaženjem odziva neuronske mreže. Kako se svaka neuronska mreža može opisati pomoću skupa jednačina baziranih na linearnim i eksponencijalnim funkcijama, izračunavanje EM polja pomoću razvijene neuronske mreže nije kompleksno, a može se vršiti u bilo kom programskom okruženju.

Prikazani metod određivanja EM polja može biti korišćen kao efikasan alat za određivanje zone pokrivanja predajnika korišćenjem statističke metode definisane preporukom ITU-R P.1546. Cilj budućih istraživanja je da se razvije neuronski model za inverzno očitavanje krivih za visine h_1 manje od 10 m.

ZAHVALNICA

Istraživanja prikazana u ovom radu podržana su od strane Ministarstva prosvete, nauke i tehnološkog razvoja.

ABSTRACT

In this paper a method for determination of EM field level, according to ITU-R P.1546 recommendation for EM filed level originated form broadcast transmitters with height h_1 less than 10 meters is proposed. Proposed method is based on the applications of artificial neural networks and enables efficient determination EM field level for frequencies up to 4000 MHz and height h_1 less than 10 meters. Accuracy of the method is illustrated by an example of curves realated to several frequencies and h_1 not used for the training of neural network.

Automatization of calculation the EM field strength according to the ITU-R P.1546 method for height parmeter *h*1 smaller than 10 meters

TLM modelovanje deformacija savijanja antene u biomedicinskim aplikacijama

Jugoslav Joković, *Member, IEEE*, Tijana Dimitrijević, *Member, IEEE*, Aleksandar Atanasković, *Member, IEEE*, and Nebojša Donšov, *Senior Member, IEEE*

***Sadržaj* — Prikazane su mogućnosti cilindričnog TLM numeričkog modela za analizu uticaja deformacije savijanja na parametre antene postavljene na ljudsko telo, koja se koristi u biomedicinskim aplikacijama. Kreiran je model pravougaone *patch* antene omotane oko dela cilindra koji može da se koristi za predstavljanje ljudskog tela (torzo, noga ili ruka) i istovremeno za modelovanje dielektričnih svojstava slojeva ljudskog tela. Ilustrovani su problemi u pogledu tačnosti i ograničenja kada se deformacija antene modeluje korišćenjem numeričkih metoda zasnovanih na pravougaonoj mreži. Prednosti cilindričnog TLM metoda kao tačne i efikasne alternative u odnosu na pravougaoni TLM pristup istaknute su kroz analizu uticaja deformacije savijanja na rezonantnu frekvenciju antene.**

***Ključne reči*—Deformacije antene, tekstilne antene, TLM metod.**

I. UVOD

Brojne tehnike rešavanja problema biomedicinskog inženjeringa (*Biomedical Engineering, BME*) našle su korisne primene u biologiji i medicini što je dovelo do razvoja mnogih naprednih BME uređaja, koji se generalno mogu klasifikovati kao uređaji za dijagnostiku ili tretman [1,2]. Jedna od ključnih komponenti mnogih BME uređaja je antena koja se može postaviti blizu, unutar ili na ljudskom telu [3] ili ugraditi u ljudsko telo direktno ili kroz kapsulu koja putuje kroz telo [4]. Postavljanjem antene na odeću ili direktno preko torza formira se bežični sistem za detekciju i komunikaciju za veze prenosa na telu ili van tela [5]. Tako postavljena jedna ili više antena koristi se npr. za dijagnostiku pomoću magnetne rezonantne slike (*Magnetic Resonance Imaging,* MRI) i mikrotalasne slike (*Microwave Imaging,* MI) [2,6] ili za lečenje hipertermijom [7]. Dizajn većine ovih antena suočava se sa fizičkim ograničenjima kao što su veličina, snaga i bezbednosna ograničenja, što sveukupno može uticati na efikasnost samog BME uređaja.

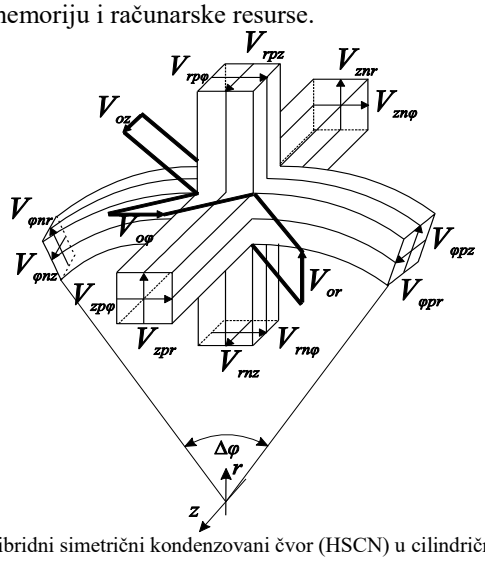
Za antene postavljene na različite delove ljudskog tela, bilo na ljudsku kožu ili odeću (npr. tekstilne antene), postoje i drugi izazovi u njihovom dizajnu, kao što je neposredna blizina ljudskog tela koja, zavisno od tipa antene, može dovesti do razdešavanja parametara antene, odnosno promene impedanse i smanjenja pojačanja i efikasnosti antene [8,9]. Takođe, promene držanja i pokreti ljudskog tela u svakodnevnim aktivnostima izazivaju brojne deformacije kao što su istezanje, uvijanje, savijanje, gužvanje ili češće kombinacija dve ili više ovih deformacija. Kao rezultat deformisane geometrije, mnogi parametri antene se takođe menjaju kao što su rezonantna frekvencija, pojačanje, dijagram zračenja i polarizacija [9].

U literaturi dominantno je razmatran uticaj deformacije cilindričnog savijanja na performanse uglavnom štampanih tekstilnih antena, kako numerički tako i eksperimentalno [10]. Takođe, treba uzeti u obzir da je ljudsko telo neplanarna struktura i da je za rad na različitim delovima tela potrebna antena različitih oblika. Da bi se odgovorilo na ove izazove, različite vrste anatomskih modela ljudskog tela ili njegovih delova se obično koriste u eksperimentalnim merenjima kako bi se uračunalo prisustvo telesnih tkiva. Mogu biti različite geometrijske složenosti uključujući jednoslojne i višeslojne strukture kao što je troslojni fantomski model (koža, masno tkivo, mišići) napravljen korišćenjem gelova i/ili tečnosti. Ipak, da bi se obezbedio potpuno konforman BME uređaj koji se može neprimetno i neinvazivno integrisati sa ljudskim telom koje karakterišu krivolinijske površine i dinamički pokreti, elektromagnetni (EM) kompjuterski alati za simulaciju igraju vitalnu ulogu u celokupnom dizajnu antene za BME aplikacije. Ovi alati, obično zasnovani na nekim od dostupnih diferencijalnih ili integralnih numeričkih tehnika punog talasa, kao što su FDTD [11], MoM [12], FEM [13], TLM [14], itd, treba da budu u stanju da precizno uzmu u obzir disperziju, gubitke i u nekim slučajevima anizotropna tkiva ljudskog tela. Istovremeno, trebalo bi da budu u stanju da precizno generišu geometrijske modele antena koje su ili deformisane usled držanja i kretanja odeće na telu ili su jednostavno konformne sa nekim zakrivljenim delovima ljudskog tela kao što su ruke i noge. Većina ovih alata je zasnovana na konstruktivnoj geometriji čvrstog materijala (npr. korišćenje *Boole*-ovih geometrijskih operacija) i diskretizaciji pravougaone mreže, odnosno modelovanog prostora, što znači da su u stanju da realizuju jednostavnije deformacije i/ili da koriste veoma finu stepeničastu aproksimaciju za predstavljanje takve deformisane geometrije antene odnosno geometriju antene koja prati krivolinijski oblik dela tela. U slučaju diferencijalnih numeričkih tehnika u vremenskom domenu ovaj pristup može dovesti do veoma malog vremenskog koraka i prekomernog vremena rada, a takođe u nekim slučajevima može proizvesti tzv. parazitne efekte koji su štetni za EM simulacije.

Jugoslav Joković, Tijana Dimitrijević, Aleksandar Atanasković, Nebojša Dončov – Elektronski fakultet, Univerzitet u Nišu, Aleksandra Medvedeva 14, 18000 Niš, Srbija (e-mail: jugoslav.jokovic@elfak.ni.ac.rs, tijana.dimitrijevic@elfak.ni.ac.rs, aleksandar.atanaskovic@elfak.ni.ac.rs, nebojsa.doncov@elfak.ni.ac.rs).

 ISBN 978-86-7466-930-3

Kada EM problemi uključuju mnogo složenije geometrije, onda bi se upotreba tetraedarske mreže mogla pojaviti kao optimalnije rešenje. Kompjuterski grafički metodi (npr. *Green coordinates* [15]) nedavno su predloženi da bi se prevazišla ograničenja klasičnih komercijalnih EM alata zasnovanih na *Boole*-ovoj geometriji [16,17]. Ovi geometrijski generatori mogu omogućiti manipulaciju oblika antene pod proizvoljnom deformacijom u kombinaciji sa odgovarajućom numeričkom metodom i tetraedarskom mrežom da bi se minimizirale greške diskretizacije i predstavljaju moćan alat za konformni dizajn BME uređaja. Alternativa ovom naprednom rešenju u pogledu predstavljanja geometrije, ali i dalje skupom u pogledu memorije i vremena rada, može biti implementacija odabrane numeričke tehnike u koordinatnom sistemu koji je u skladu sa razmatranom deformisanom geometrijom antene. U slučaju savijanja antene, cilindrična diskretna mreža je savršeno prikladna da precizno opiše ovu deformaciju i da eliminiše greške diskretizacije koje dovode do mnogo brže i efikasnije simulacije u poređenju sa bilo kojom od pravougaonih ili tetraedarskih mreža. Pored toga, svaka promena ugla savijanja jednostavno se može implementirati u istoj cilindričnoj mreži omogućavajući da se isključi uticaj različitih veličina mreže (a samim tim i drugačije postavljenih napajanja i izlaznih tačaka zbog podešavanja mreže), Na taj način omogućena je konzistentna analiza uticaja različitih uglova savijanja antene na performanse.



U ovom radu, cilindrični TLM pristup je primenjen na modelovanje deformacije savijanja antene postavljene na ljudsko telo. Ilustrovane su prednosti ovog pristupa, koji istovremeno obezbeđuje precizno modelovanje geometrije antene i dielektričnih slojeva tela i efikasnu analizu efekta savijanja pod različitim uglovima, u odnosu na slučaj kada se koristi pravougaona TLM metoda. Postizanje tačnosti fizičkog modela antene omogućilo je analizu uticaja savijanja na performanse antene u prisustvu mišićnog tkiva. Objašnjen je TLM metod sa kompaktnim modelom žice u cilindričnom koordinatnom sistemu kroz definisanje TLM žičanog čvora duž radijalnog pravca, koji je potreban za modelovanje koaksijalnog napajanja, kao i postupak modifikacije granica u radijalnom i ugaonom pravcu koji omogućava veću efikasnost simulatora u konkretnom slučaju. Glavna pitanja za realizaciju TLM modela antene odnose se na opis EM svojstava medijuma sa radijalno postavljenim slojevima zajedno sa proširenjem modelovane oblasti, pružajući mogućnost definisanja spoljnih granica u ugaonom i radijalnom pravcu. Simulirani rezultati dobijeni TLM modelima savijanja antene u prisustvu tkiva i numeričke analize dati su za različite uglove savijenja antene.

II. TLM METODOLOGIJA

TLM predstavlja numerički metod koji pripada grupi diferencijalnih metoda pogodnih za rešavanje EM problema u vremenskom domenu [14]. Zasnovan je na ekvivalencijama između Maksvelovih jednačina i prostiranjanja napona i struja duž vodova. Mreža međusobno povezanih čvorova koristi se za modelovanje prostiranja EM talasa uzimajući u obzir diskontinuitete i interakciju sa različitim svojstvima materijala. Tradicionalno, TLM metod je razvijen u Dekartovom koordinatnom sistemu, ali za strukture koje sadrže samo kružne/cilindrične površine, pogodniji je i efikasniji TLM metod zasnovan na cilindričnoj mreži. Hibridni simetrični kondenzovani čvor (*Hybrid Symetrical Condensed Node*, HSCN) koji predstavlja ćeliju u ortogonalnoj polarnoj mreži predstavljen je na Sl.1.a. Takva mreža ćelija se koristi za opisivanje EM osobina medijuma, preko odgovarajućih karakterističnih impedansi i admitansi povezanih vodova i stabova [18]. Iterativni postupak TLM algoritma sastoji se od dve glavne procedure poznate kao rasejanje i povezivanje [14]. Prilagođene su ortogonalnoj polarnoj mreži i dodatno modifikovane da bi se uzela u obzir pobuda, granice i nehomogena sredina i gubici [18,19].

Adaptacija i implementacija kompaktnog žičanog modela na cilindričnu mrežu [18] omogućila je modelovanje žičanih segmenata postavljenih duž radijalnog pravca. S obzirom da su za susedne čvorove razlikuju impedanse vodova i stabova ugrađenih u postojeću mrežu ćelija da bi se uzela u obzir žica, razvijen je i implementiran u postojeći softver baziran na TLM-u u cilindričnoj mreži dodatni postupak povezivanja za segmente žice u radijalnom pravcu [18, 19].

Pored relevantnog prikaza geometrije i EM svojstava nehomogenog medijuma, u slučaju takozvanih otvorenih problema kao što je *patch* antena, potrebno je dodati i odgovarajuće proširenje modelovane strukture, kako bi se uključila okoline antena. Primena cilindrične mreže je u ranijim radovima pretpostavljala da je okolina razmatrane strukture, koja čini modelovani prostor sa definisanim spoljnim granicama, potpuno cilindričnog oblika. Dakle, simulacije su zahtevale definisanje granica bez ikakvih graničnih uslova definisanih duž ugaonog pravca, gde je razmena impulsa obezbeđena povezivanjem poslednjeg i prvog čvora u ugaonom pravcu. Kada je ugao savijanja mali što se najčešće dešava u praksi prilikom razmatranja deformacija, modelovana *patch* antena je smeštena daleko od centra cilindričnog koordinatnog sistema, pa u tom slučaju upotreba celog cilindra kao modelovanog prostora koristi veliku memoriju i računarske resurse.

Sl. 1. Hibridni simetrični kondenzovani čvor (HSCN) u cilindričnoj mreži

 ISBN 978-86-7466-930-3

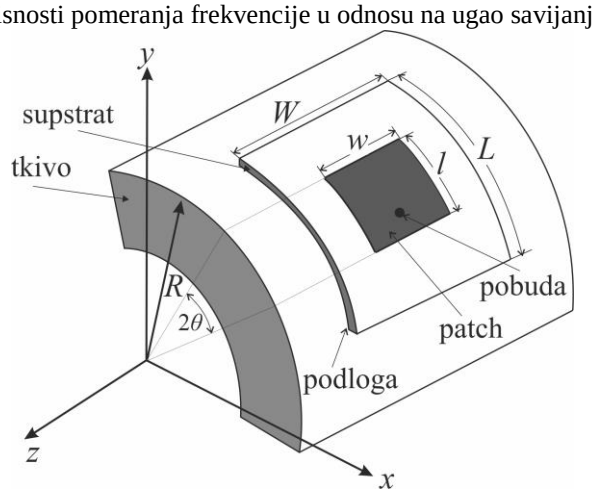
Iz tog razloga, TLM algoritam je prilagođen da omogući postavljanje graničnih uslova duž ugaonih pravaca. Dodatna poboljšanja se postižu omogućavanjem mogućnosti definisanja graničnog stanja na unutrašnjoj površini modelovanog prostora duž radijalnog pravca, umesto definisanja centralnog čvora. Ortogonalna polarna mreža u tom slučaju je bazirana na diskretizaciji prostora predstavljenu unutar isečka cilindra.

Generalno, TLM metod omogućava da se opiše tri tipa granica: električni zid, magnetni zid i zid koji apsorbuje. U slučaju modelovanja antene, električni zid se koristi za modelovanje metalne podloge i zračeće površine, dok su spoljašnje granice proširenog regiona opisane kao apsorbujuće sa koeficijentom refleksije voda na kraju prostora ρ_{ij} [22]:

$$\rho_{ij} = \frac{(1+\rho_w)-\hat{Z}_{ij}(1-\rho_w)}{(1+\rho_w)+\hat{Z}_{ij}(1-\rho_w)}. \qquad (1)$$

gde je ρ_w koeficijent refleksije zida, a Z_{ij} je normalizovana impedansa odgovarajuće linije.

Kao rezultat definisanja modelovanog prostora kao dela cilindra zajedno sa graničnim uslovima, značajno je smanjen potreban broj TLM ćelija što dovodi do veće efikasnosti i uštede vremena i memorije. Prednosti ovog pristupa bile bi posebno uočljive u slučajevima kada je zakrivljenost odnosno savijanje mala, kada se zahteva veliki poluprečnik cilindrične površine, a samim tim i znatno veći broj ćelija ako se modelovana oblast predstavlja kao ceo cilindar. Dodatno, na ovaj način, uz dovoljno velike vrednosti poluprečnika cilindra u odnosu na dimenzije antene, moguće je modelovati pravougaone strukture u cilindričnoj mreži. Promenom samo poluprečnika cilindra moguće je kreirati modele sa različitim uglovima savijanja, koristeći mrežu iste rezolucije, i analizirati uticaj deformacije savijanja na performanse antene, nezavisno od drugih parametara modela koji se menjaju kada se primenjuje aproksimacija, kao što su površina zračeće površine, debljina supstrata, položaj napajanja itd.



III. Rezultati i analiza

TLM solver je korišćen za analizu uticaja savijanja na performanse *patch* antene kada se postavi na ljudsko telo. U razmatranom slučaju, deo mišićnog tkiva se nalazi ispod antene. *Patch* antena dimenzija $w \times l = (50 \times 39.5)\text{mm}^2$, postavljena na podlogu i uzemljenu ravan dimenzija $W \times L = (100 \times 100)\text{mm}^2$ i savijena preko dela cilindra koji predstavlja mišićno tkivo, šematski je prikazana na Sl.2. Antena je realizovana na podlozi debljine h=2mm sa supstratom relativne permitivnosti ε_r^s=2.1, dok je sloj mišićnog tkiva debljine d=35mm predstavljen relativnom permitivnošću ε_r^m=52.67-j13 [23]. U TLM modelu, zračeni *patch* i uzemljena ravan su predstavljeni kao savršeni električni provodnici, a antena se napaja preko koaksijalnog napajanja koji povezuje uzemljenu ravan i *patch*, što je opisano preko kompaktne žičanog modela. Položaj koaksijalne pobude je optimizovan za postizanje prilagođenja impedanse između generatora i antene, tako da se nalazi se na l_f=11.5mm od ivice *patch-a*. Radna frekvencija dizajnirane antene iznosi f=2.45GHz.

Opisivanje problema sa odgovarajućom mrežom, u smislu veličine ćelije i sinhrinizacije, veoma je važno kako bi se obezbedila konvergencija rezultata. Za razliku od stepeničaste aproksimacije koja se mora koristiti u pravougaonoj TLM mreži za opisivanje zakrivljenih granica, tačno modelovanje kružnih granica je jednostavno u cilindričnoj TLM mreži, sa dimenzijama ćelija određenim maksimalnom frekvencijom od interesa [14]. Kao rezultat, zakrivljene granice se mogu precizno modelovati pomoću cilindrične mreže bez obzira na rezoluciju mreže, dok pravougaona mreža mora biti dovoljno fina da bi se postigla bolja tačnost. Da bi se ovo dokazalo, razmatrani model antene je kreiran i korišćenjem pravougaonog TLM rešavača. Izvedene su simulacije za ravnu antenu, ali i za savijenu antenu da bi se ispitao uticaj deformacije savijanja na rezonantnu frekvenciju antene. Razmatrana su dva ugla savijanja, 2θ = 25 i 50 stepeni. Simulirani rezultati, koji predstavljaju koeficijent refleksije, kada se veličina TLM ćelije od 1.0mm primeni za modelovanje antene, dobijeni cilindričnim i pravougaonim modelom, respektivno, prikazani su na Sl.3. i 4.

Kod modelovanja ravne antene može se uočiti slaganje rezultata dobijenih primenom cilindrične mreže rezolucije 1.0mm sa odgovarajućim rezultatima primene pravougaone mreže (crna linija na Sl. 3. i 4). Praktično, u slučaju modela antene u cilindričnoj mreži, ravna antena je modelovana primenom veoma malog ugla savijanja, 2θ = 0.1 stepen, što je ekvivalentno poluprečniku cilindra koji zadovoljava uslov da je mnogo veći od dimenzija antene $R>>l$ (oko 500 puta), pa se može smatrati ravnom. Primenljivost cilindrične mreže na modelovane strukture bez zakrivljenosti potvrđena je dobijenom vrednošću rezonantne frekvencije od 2.444 MHz, sa odstupanjem od 1% u odnosu na vrednost od 2.473 MHz dobijenu primenom pravougaone mreže.

Sa druge strane, rezultati dobijeni pomoću cilindričnog TLM-a i pravougaonog TLM-a, sa veličinom ćelije od 1.0mm primenjenom za modelovanje antene, pokazuju značajnu razliku u pomeranju frekvencije usled savijanja antene postavljene na mišićno tkivo. Praktično, modelovanjem cilindričnim pristupom se može primetiti da veći ugao savijanja dovodi do pomeranja rezonantne frekvencije ka višim vrednostima, dok istovremeno rezultati modelovanja pravougaonom mrežom pokazuju smanjenje frekvencije u odnosu na ravan slučaj, zajedno sa nedoslednošću u pogledu zavisnosti pomeranja frekvencije u odnosu na ugao savijanja.

Sl.2. Pravougaona antena savijena preko dela tkiva

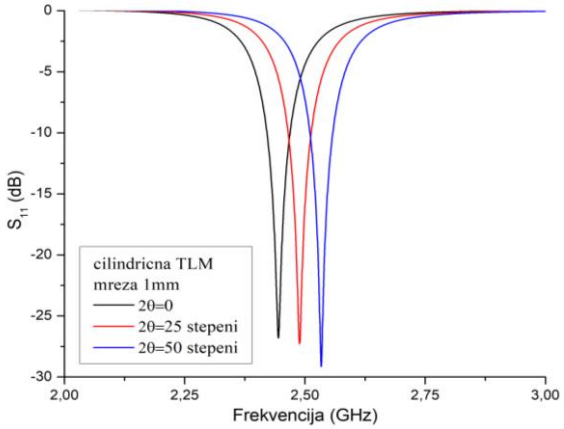
 ISBN 978-86-7466-930-3

Nekonzistentnost rezultata dobijenih primenom pravougaonog modela može se objasniti činjenicom da pravougaona mreža rezolucije od 1.0mm model u slučaju savijene antene uvodi grubu aproksimaciju zakrivljene površine zračenja koja utiče na njenu rezonantnu frekvenciju. Shodno tome, neophodno je koristiti finiju mrežu koja bi smanjila grešku stepeničaste aproksimacije i obezbedila tačne rezultate. Da bi se ilustrovao uticaj rezolucije mreže pravougaoni TLM model antene je definisan mrežom veličine ćelije 0.1mm. Simulirana rezonantna frekvencija dobijena ovom pravougaonom mrežom, prikazana na Sl.5, pokazuje da se, sa povećanjem ugla savijanja, povećava i rezonantna frekvencija, slično kao što je slučaj kada se koristi cilindrična TLM mreža.

Dakle, kada se ista veličina ćelije koristi u pravougaonoj i cilindričnoj mreži (1.0mm) ponašanje rezonantne frekvencije je drugačije. Iz tog razloga, potrebna je finija pravougaona mreža (0.1mm) koja obezbeđuje konzistentnost rezultata u pogledu pomeranja frekvencije, slično onima koje daje cilindrična mreža (1.0mm). Parametri cilindrične TLM mreže – veličina ćelije i broj ćelija, prikazani su u Tabeli 1. Rezolucija mreže je podešena da ispuni zahteve vremenske sinhronizacije [14].

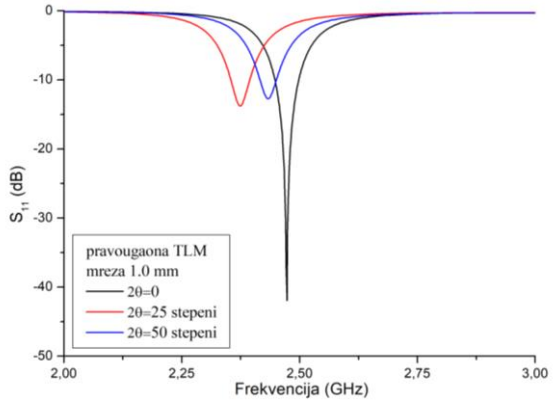
Prikazani rezultati dobijeni na osnovu mreže od 1.0mm potvrdili su da se cilindrični model može koristiti u analizi deformacija savijanja, dok pravougaona mreža te rezolucije nije adekvatna, odnosno da se zahteva finija rezolucija. Međutim, kada se koristi pravougaona mreža od 0.1mm koja obezbeđuje konvergenciju rezultata, povećanje broja ćelija iznosi oko 1000 puta, što dokazuje jake prednosti cilindrične mreže u ovom slučaju.

IV. Zaključak



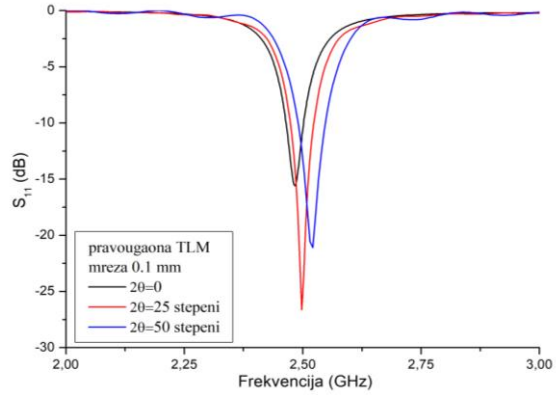
U ovom radu je TLM metod prilagođen ortogonalnoj polarnoj mreži korišćen za analizu deformacije savijanja *patch* antene postavljene na ljudsko telo - podešavanjem dimenzija modela, rezolucije mreže, odgovarajućeg proširenja regiona modelovanja i optimizacije položaja koaksijalnog napajanja, obezbeđeno je da efekat deformacije na parametre antene bude nezavisan od numeričkih grešaka.

Pristup je modifikovan kako bi se omogućilo korišćenje graničnih uslova duž radijalnog i ugaonog pravca koji dovode do značajnog smanjenja modelovane oblasti, a time i do smanjenja korišćenja memorije i vremena potrebnog za simulaciju. Prikazani rezultati pokazuju prednosti modela kreiranog u cilindričnoj TLM mreži, koja istovremeno obezbeđuje precizno modelovanje geometrije antene i dielektričnih svojstava supstrata i tkiva.



Prikazani numerički rezultati su pokazali da je TLM metod zasnovan na cilindričnoj mreži pogodniji i precizniji za modelovanje antene koja je deformisana savijanjem, u odnosu na pravougaoni TLM model. Glavne prednosti cilindričnog TLM metode su konformno modelovanje zakrivljenih površina, sa preciznošću koja se postiže manjim brojem ćelija, i dodatno fleksibilnost modelovanja realnog savijanja za različite uglove, bez promene parametara mreže.

TABELA I
PARAMETRI CILINDRIČNE MREŽE



Osa	Medijum	Rezolucija	Broj čvorova

	vazduh	1.449 mm	

Sl.3. Zavisnost S_{11} parametra antene na mišićnom tkivu od ugla savijanja dobijen primenom cilindrične TLM mreže rezolucije 1.0mm

Sl.4. Zavisnost S_{11} parametra antene na mišićnom tkivu od ugla savijanja dobijen primenom pravougaone TLM mreže rezolucije 1.0mm

Sl.5. Zavisnost S_{11} parametra antene na mišićnom tkivu od ugla savijanja dobijen primenom pravougaone TLM mreže rezolucije 0.1mm

 ISBN 978-86-7466-930-3

Mogućnosti definisanja različitih dielektričnih slojeva u radijalnom pravcu takođe omogućavaju precizno modelovanje antene omotane oko cilindra kako bi se oponašalo ljudsko tkivo predstavljeno u simulacijama kao standardni višeslojni model (koža, masno tkivo, mišićno tkivo i kosti). Iz navedenih razloga, TLM cilindrični solver se može efikasno koristiti za sprovođenje parametarske studije za karakterizaciju deformacije savijanja antene u režimu rada na telu koji se odnosi na promenu rezonantne frekvencije, širinu opsega i promenu tzv. povratnih gubitaka, odnosno S_{11} parametra.

ABSTRACT

The possibilities of the cylindrical TLM numerical model used for the analysis of the influence of bending deformation on the parameters of the antenna placed on the human body, which is used in biomedical applications, are presented. A model of a rectangular patch antenna wrapped around a part of a cylinder was created in order to represent the human body (torso, leg or arm) and at the same time to model the dielectric properties of the layers of the human body. The problems in terms of accuracy and limitations when antenna deformation is modeled using numerical methods based on a rectangular grid are illustrated. The advantages of the cylindrical TLM method as an accurate and efficient alternative in relation to the rectangular TLM approach are highlighted through the analysis of the influence of bending deformation on the resonant frequency of the antenna.

Sintering and Phase Transition of the $ZnTiO_3$ Nano Powder Dilatometric Data Deconvolution

Nebojša Labus, Smilja Marković, Maria Vesna Nikolić, Milena Rosić, Srđan D. Matijašević

***Abstract*— intering and phase transition are often superimposed at dimensional change diagram recorded during heating. Phase transition inetic is thus hard to deconvolute due to the superposition of the sintering and phase transition dimensional change phenomena.**

etastabile perovs ite phase nTi has transition to stabile spinel n2Ti 4which occurs at 45ºC with high inetic rate. ano powder with 4 nm particle diameter was pressed unia ially at 2 Pa pressure without binder to form compact that will be consequently sintered. Dimensional change during heating was monitored using dilatometric thermo-mechanical analyzer T A model T volution. ever s rule was used to calculate amount of the emerging phase during phase transition.

The compacted specimens were treated on the non-isothermal schedule up to 1 5 ºC. intering phenomenon of the nTi nanopowder compact was also recorded up to ºCwith isothermal holding of 25 minutes where phase transition was avoided due to lower temperature and isothermal holding. econd run heating of the obtained sintered specimens were recorded with the heating schedule of non-isothermal heating up to 1 5 ºC.

inetic of the phase transition was obtained from dilatograms recorded during sintering and from bul on the second run heating. urthermore, phase transition inetics was obtained by subsequent data subtraction of the sintering curves without phase transition from the dilatation sintering curves containing phase transition.

In such a manner comple inetics of phenomena such as sintering, linear e pansion and phase transition recorded as dimensional change during heating brings the recognition of their mutual interconnected relations. Also application of these mathematical operations on dilatometric data leads to the established procedure for the sintering and phase transition data treatment.

I. INTRODUCTION

In the following work phase transition represents change from $ZnTiO_3$ to Zn_2TiO_4. Phase transition investigated here encounters following phases on phase diagram ZnO-TiO_2: Zn_2TiO_4 (zinc orthotitanate) which has an inverse cubic spinel structure ($Fd\bar{3}m$) and it is stable from room temperature to its melting (liquid) temperature. $ZnTiO_3$ (zinc metatitanate) has a hexagonal ilmenite structure ($R\bar{3}$), a variant of the corundum structure where the cations are ordered into two non-equivalent oxygen sites. Zinc metatitanate is stable from room temperature to 945.8ºC. $Zn_2Ti_3O_8$ was first determined by Yamaguchi et al. [1] as a low temperature form of $ZnTiO_3$ having a defect cubic spinel structure with ordered cation vacancies leading to degradation of the space group symmetry from $Fd\bar{3}m$ to $P4_332$.

Phase transition belongs to second order phase transition. Since it is changed from metastabile to stabile phase, it has very fast kinetic rate, comparing, for example, to anatas - rutile phase transition [2]. Phase transitions are observed usually with the means that are enabling record of the property that comes with the emerging phase. Here volume change caused by structure change is registered as linear dilatation in a function of rising temperature. This leads to a possibility of phase transition kinetics observation.

Sintering phenomenon represents densification of the powder compacted in desired form during heating. Sintering dimensional change can during heating encompass phase transition dilatataion. Also specific influence of the nano powder during sintering is influencing phase transition kinetics. It is often compared to bulk polycrystalline kinetics of the same transition. This work intention is to use dilatometry as a tool for observing phase transition and sintering phenomena indicating their interdependent mutual relations.

II. METHOD

Experiment is set to record phase transition from $ZnTiO_3$ bulk specimen and $ZnTiO_3$ nano powder during sintering. $ZnTiO_3$ nanopowder, Aldrich [CAS 112036-43-0] was used. Two specimens are used for this purpose. Specimen 1 and specimen 2, respectively. Dilatometric thermo-mechanical analyzer TMA model SETSYS Evolution device was used. Specimens were compacted at 200 MPa uniaxially with both sided actions. Transmission electron microscopy of the nano powder $ZnTiO_3$ was performed on JEOL JEM 1400 plus microscope at 120kV and 150k enlargement.

Specimen 1 is heated to 1150ºC non isothermally (1st run)

 ISBN 978-86-7466-930-3

and phase transition during sintering is recorded using dilatometric oven. Without extracting it from dilatometric device specimen is heated again to 1150ºC, using same temperature schedule. (2nd run).

Specimen 2 is heated non-isothermally to 900ºC and then held 25 minutes at that temperature isothermally (1st run) and thus sintering of the $ZnTiO_3$ nanopowder is recorded. It is expected and confirmed that phase transition is absent. Same specimen 2, without extraction from the dilatometric device, is than heated again, but now to 1150ºC non-isothermally with previously used thermal schedule (2nd run). Obtained curve contains phase transition of $ZnTiO_3$ to Zn_2TiO_4 recorded from bulk specimen. All diagrams have been recorded on three heating rates - 20, 10 and 5ºC/min rate.

Stage of cooling is recorded as well with 20ºC/min rate. It is important to note that during cooling no intensive dimensional change is present. This implies that phase transition is irreversible.

III. Results and Discussion

Nano dimensional powder sintering process assumes different mechanisms of mass transport compared to micro dimensional powder sintering. Transmission electron micrograph on Fig. 1 represents powders dimensional and morphology introspection. Powder particles are dimension bellow 40 nm, what is declared by the producer.

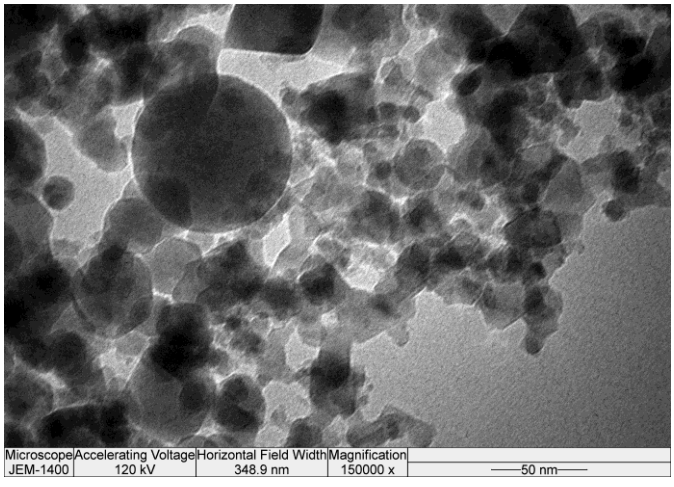

Fig. 1. TEM images of the nanopowder $ZnTiO_3$.

At Fig. 2 temperature experimental setup with whole interval dilatation curves and temperature programs are presented. Sintering phenomenon reaches 18% shrinkage while bulk specimen dimension change is represented with 3% shrinkage event. Phase transition record is marked with red square for bulk specimen and blue square for the powder sintering specimen.

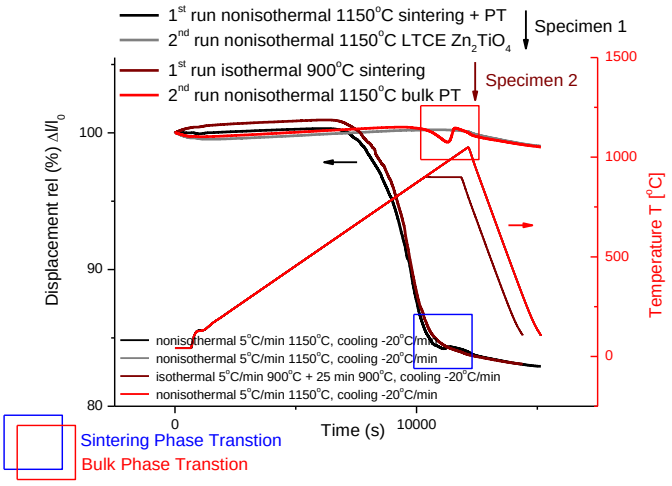

Fig. 2. Dilatometric curves and temperature programs for two specimens and four runs for the 20ºC/min speed, containing phase transition dilatation for bulk and powder specimen. Experimental setup.

Metastabile perovskite phase $ZnTiO_3$ reforms to stabile spinel Zn_2TiO_4 at 950ºC with high kinetic rate. The phase transition dimensional change diagram is consisted of sintering shrinkage and phase transition here on named as sintering. Obtained non-isothermally sintered specimens at were then second run treated with same schedule. Sintering phenomenon of the $ZnTiO_3$ nano-powder compact was also recorded up to 900ºC with isothermal holding of 25 minutes. Here phase transition was avoided with lower temperature and isothermal holding. Second run heating, of isothermally obtained specimens at 900ºC, was recorded with non-isothermal heating schedule to 1050ºC. This has led to the dilatometric curve record of the $ZnTiO_3$ phase transition in polycrystalline bulk specimen, now recorded without sintering, here on named - bulk.

All before mentioned was recorded for three different heating rates - 5ºC/min, 10ºC/min and 20ºC/min. It is presented all together and critical points are circled, red for the phase transition from bulk specimen, and blue circle for phase transition from powder during sintering Fig 3.

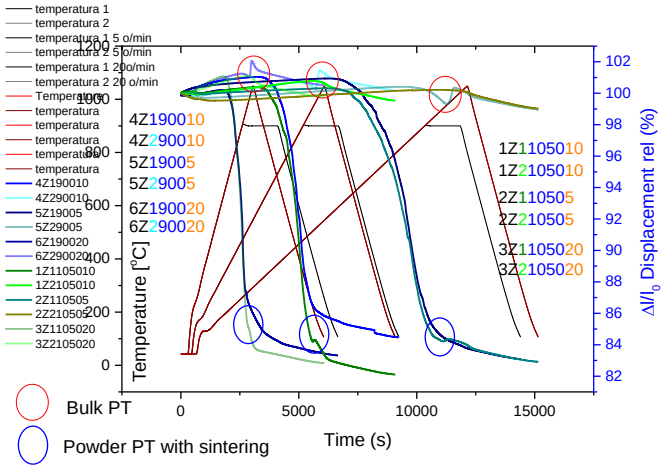

Fig. 3. Dilatometric curves, right axes and temperature programs left axes, heating rates 5, 10 and 20ºC/min.

 ISBN 978-86-7466-930-3

It is worth to emphasize that on the presented diagrams phase transition during sintering 20°C/min rate is not well distinguished, and also those final densities for 10°C/min and 20°C/min for non-isothermal sintering and isothermal are significantly different.

Extraction of the observed region with phase transition has been done in the 800°C to 1100°C, Fig. 4. Interval of the shrinkage curve heated isothermally is extracted as well. Heating rates 5, 10 and 20°C/min.

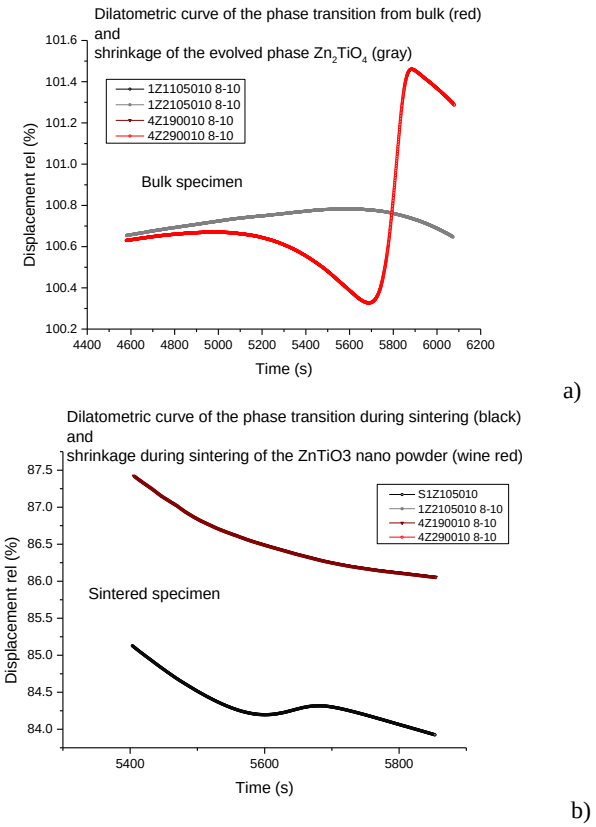

Fig 4. Dilatometric curves of phase transition $ZnTiO_3$ to Zn_2TiO_4 extracted phase transition interval a) observed in a bulk specimen (red), thermal expansion of the Zn_2TiO_4 phase (gray). b) Dilatometric curves of the phase transition and sintering (black), and sintering phenomenon without phase transition (wine red).

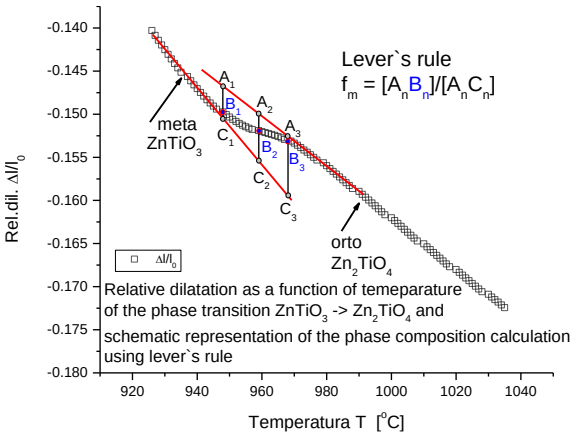

Fig 5. Relative dilatation as a function of temperature of the phase transition $ZnTiO_3$ -> Zn_2TiO_4 and schematic representation of the phase composition calculation using lever`s rule

Lever law is used in a XRD determination of the solvus curves - solid solubility curve on a phase diagram. It assumes that phases are in equilibrium during phase transition at each temperature. It also supposes that weight fraction of the observed phase amount varies linearly with composition from 0 to 1 [3].

At the dilatogram diagram, linearity, even with the sintering curve included, represents linear thermal expansion of the starting phase and can be fitted with linear function. Intensive deflexion from linearity is caused by phase transition dilatation. When phase transition is finished new phase again reaches linearity. Dimensional difference is caused by phase interchange and it is proportional to phase composition during phase transition. So, the distances AB, AC have to be determined and their relation AB/AC suites phase composition during phase transition, f=AB/AC, Fig 5. It is obvious that three sets of data are formed by the series made for each experimental point. Linear C data set, linear A data set and experimental set of curve B. All data sets have to posses same number of points since the subtraction ought to be performed. A and C sets have to be constructed. B is experimental dilatation. Than A minus B values make one column of Y. Similarly, A minus C forms second Column of Y and finally ratio AB/AC, third. AB/AC column plot in a function of temperature or time, represents kinetic curve of the phase transition.

 ISBN 978-86-7466-930-3

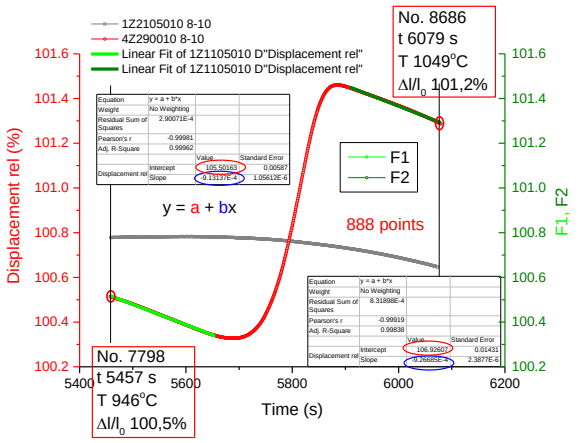

Fig 6. Linear fitting and interpolation of the inserted linear functions

At Fig. 6, phase transition curve was fitted in the linear regions before and after phase transition, light green and olive green portions of the red curve. Linear parameters of the line denoted as y= ax + b, where a is slope and b represents intercept. Number of points on the dilatometric curve in the observed interval is pointed out, it equals 888 points. Functions F1 and F2 are inserted to the graph with the interpolation of the linear functions points to the number of points that are resembling experimental dilatometric curve.

Procedure steps using Origin software after interval extraction consists of:

1. Detecting characteristic values of points and labeling them as starting and end point - No., t seconds, Temperature T, displacement shrinkage %
2. Determent of the number of points that interval consists of, here 888 points.
3. Determent of the interval that represents straight line on the begging and end of the graph that you want to fit linear. Origin software - Data, -> Mark data range, or Data selector, markers left and right positioned on the graph by cursor, Enter.
4. Linear fit of the beginning, left part, of the red curve and of the end, right part - linear fit tool – Analysis, -> Fitting -> Linear fit. Determent Y=a+bX relation from data sheet. Slope a and intercept b.
5. Adding a function graph F1 and F2 consisted of straight lines. The function insertion uses a and b parameters determined for left and right part of dilatometric curve, here light green and olive green parts. Graph -> Add Function Graph -> F2(x) = 3,31697-0,00254 * x where (example) 3,31697 is intercept b and 0,00254 is slope a parameter. -> Add. Number of points will be set to 100. Auto X range and Display curve – checked.-> Apply
6. Interpolation of the number of points on the F1 and F2 to experimental number, here 888. F1 select -> workbook -> Name of the data set image of F1, F1-C2 Enter. Graph of FuncCopy will be plot. Select function you want to Interpolate. Go to Workbook button. -> Workbook , C2-Y column Sheet 1, Analysis-> Mathematics -> Interpolate/Extrapolate -> Open dialog -> Input C2 Y, method Linear, Number of points determined at 2 (888). Decheck Auto, X minimum enter the left minimal value determined at 1. here (5457 s), Decheck Auto, X maximum same procedure now X maximum here (8686 s), Output new sheet, -> Ok.
7. Organize workbook of the experimental data with interpolated values columns and subtract columns AB and AC, and AB/AC according to the levers rule. Plot the function AB/AC as a function of time or temperature that represents phase composition.

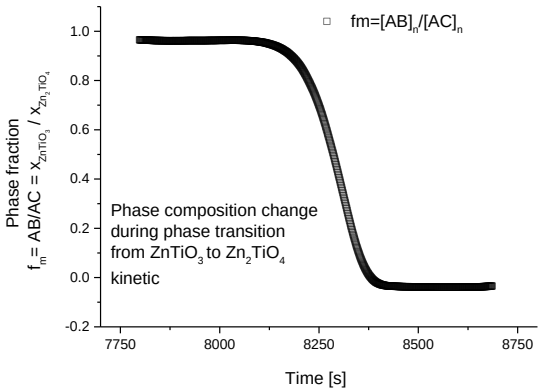

Fig 7. Dilatometric curve that represents phase composition change during phase transition from $ZnTiO_3$ to Zn_2TiO_4.

Sigmoidal curve obtained by the described procedure is presented at Fig 7. It represents disappearing of starting phase $ZnTiO_3$ and appearance of the evolving phase Zn_2TiO_4. This curve allows us to observe and, furthermore, even to discuss the kinetic of the phase transition.

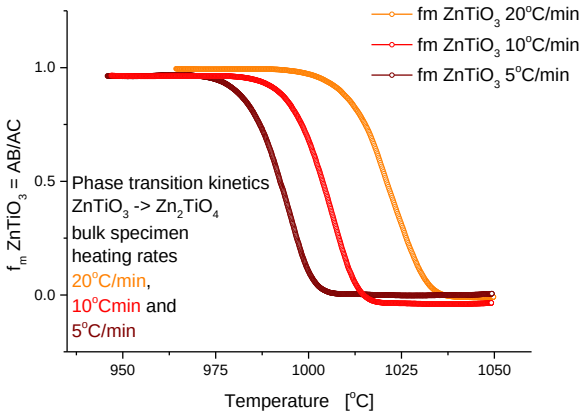

Fig 8. Phase transition kinetic from bulk specimen, three heating rates: 20°C/min 10°C/min and 5°C/min.

Phase transition from bulk specimen as a function of temperature, three heating rates, 20 10 and 5 °C/min, orange 20°C/min, red 10°C/min and wine 5°C/min represented at Fig. 8. Since the temperature is a linear function of the time, due to non isothermal heating schedule, temperature scale is used. Change of the phase composition represents phase transition

 ISBN 978-86-7466-930-3

kinetic. Note that temperature of the curve center is the point with highest rate of phase transition. If the temperature of the phase transition observed, with higher heating rate, temperature of the phase transition is higher - 20ºC/min 1021ºC, 10ºC/min 1004ºC, 5ºC/min 993ºC. It is as well higher than expected 945ºC for the phase diagram of $ZnTiO_3$ [4]. Nano-dimensions are introducing difference, as well as composition, since it is $ZnTiO_3$ pure.

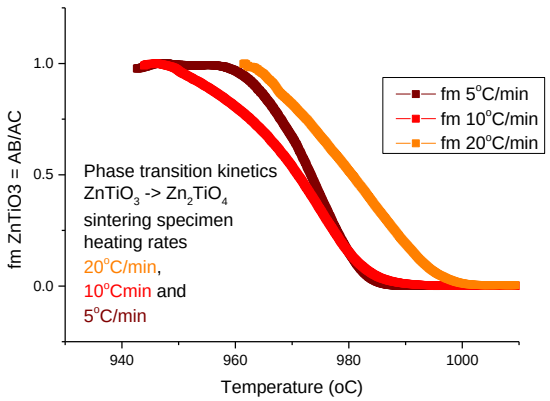

Fig 9. Phase transition kinetic from powder sintered specimen, three heating rates: 20 ºC/min 10ºC/min and 5ºC/min.

It is obvious that curves at Fig. 9 for the phase transition kinetic for the sintered specimen do not resemble heating rate rise trend. Also, the shape is more irregular mutually for the different heating rates and also different regarding the bulk specimen curves.

Mathematical procedures enabling comparison of the data were necessary since data obtained by levers rule are different in their appearance due to physical phenomena they include. First, all values must be positive. Then, second, to compare them they must be in the zero to one values interval. Third, if the function is monotonically increasing than it should be converted to monotonically decreasing due to the convention that we observe disappearing phase.

Minimal value for the every set of data was determined by applying column statistic tool. Determined value is than added to all values in the column what has led to all values of the function are positive

1. fm > 0

Maximal value for the every set of data was determined by applying column statistic tool. Determined maxima value is used to divide all values with, what has led to the norming boundary condition - all values are inside of [0,1] set

2. fm [0,1]

Column values were finally inverted by subtracting them from 1. Parent phase disappearance shape is thus established. Function is presented as monotonically decreasing when this trend is absent due to final sintering stage influence.

3. fm = 1- [col]

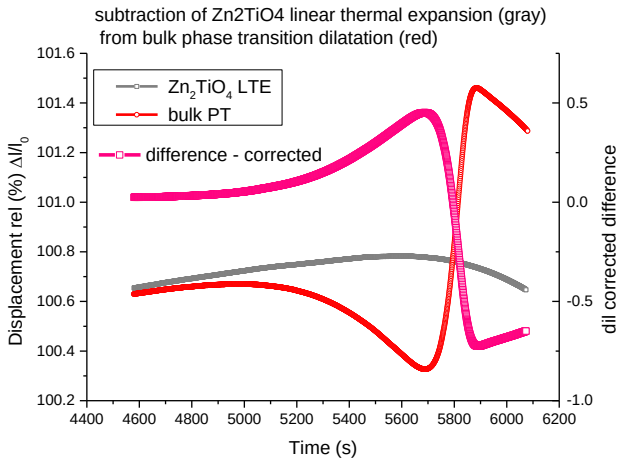

Fig 10. Correction by subtraction for the bulk specimen.

Dilatometric curves should be corrected mainly for the dilatation of the carrier system and pushing rod material enlargement. In the device with two samples, in the differential dilatometry, this procedure is done during the experiment. Here, we have decided to subtract linear dilatation of the Zn_2TiO_4 bulk sample, from phase transition recorded from bulk.

Specimen that was heated to 1050ºC passed through phase transition Fig. 10, (red). Specimen was second time heated to the same temperature and this second curve represents linear thermal expansion of the evolved phase Zn_2TiO_4 (gray). This set of values will be subtracted from curve with phase transition obtained from bulk specimen (red). Pink curve represents difference – corrected curve (pink). Number of points that are going to be subtracted is often equal, and if it is not - interpolation to the number of points present in the experimental phase transition curve is performed.

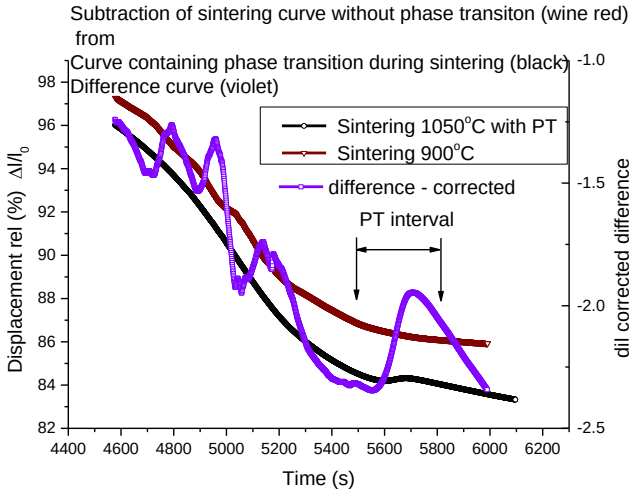

Fig 11. Correction by subtraction for the powder -sintered.

Correction by subtraction of sintering curve 900ºC without phase transition (wine red) from sintering curve 1050ºC that is containing phase transition during sintering (black) is performed, figure 11. Difference corrected curve is obtained (violet). Large interval was presented to show that difference

 ISBN 978-86-7466-930-3

curve (violet) consists of irregularities, Fig. 11. Observed Phase Transition interval (PT interval) was extracted. The absence of stability for the resulting curve origins from sintering phenomenon when nano-powder is used. High shrinkage rates and overall large shrinkage is present due to rearrangement of highly agglomerated powder and also from intensive recrystallization and grain growth. It should be mentioned that sintering curve at 900ºC was obtained by combination of non-isothermal and isothermal temperature program sequence. Yet, correction calculation was performed.

From the difference corrected curve, by the levers rule usage, the kinetic phase transition curves for bulk and sintering specimens are obtained, Fig. 12.

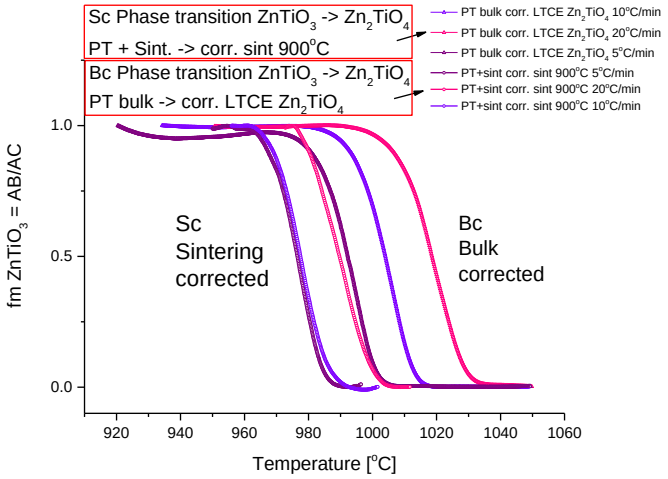

Fig 12. Phase transition kinetics comparison: Corrected curves for phase transition from Bulk and Sintered specimens.

At fig.12, obtained corrected curves for Bulk and Sintering are presented separately from experimental curves at fig. 9 and 10. Pink, violet and purple colors are subscribed to 20, 10 and 5ºC/min heating rate, respectively. Sintering corrected curves does not follow heating rate sequence. This fact is expected since experimental curves are distributed in the same manner. Sintering corrected specimens' curves for heating rates 10ºC/min and 5ºC/min are close each other. Bulk corrected curves are well distributed following the rise of the heating rate parameter.

It is interesting to make a phase transition kinetics comparison: Bulk vs. Sintered and also Experimental vs. Corrected, Fig. 13. All curves are presented together. Good match of the bulk curves between experimental and corrected is visible. Sintered are showing deviations between experimental and corrected. Deviation is in the position of the curve, as well as in the shape. This implies great influence of sintering phenomenon on the phase transition, thermodynamically as well as kinetically. Temperature scale disproportion implies activation energy difference, while curve shape implies kinetic difference.

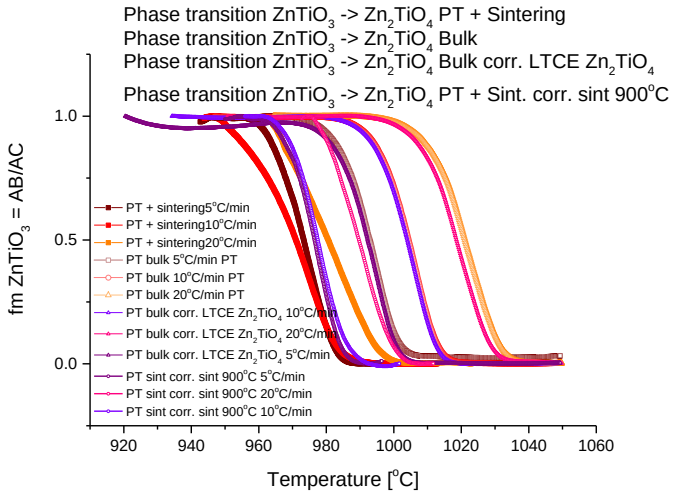

Fig 13. Phase transition kinetics comparison: Bulk and Sintered, Experimental vs. Corrected.

Although the previous comparison has led to some of the conclusions we have presented, quantitative comparison needs fitting function and overlapping measure determination of the constructed function with experimental curve. We have chosen Sigmoid shape - Boltzmann fitting function. Formula of the fitting function is given in the equation (1). Boltzmann fitting function has two constant values for the y = A1 and A2. Maximal rate represents X0, and ((A1+A2)/2), set of values. Shape of the curve, on the Fig. 14, gives good resemblance comparing to other offered functions in the Origin software package [6]. Although shape represents rise of the emerging phase, constants A1 and A2 enable as well diminishing shape. Fitting function resembles Johnson-Mehl-Avrami-Kolmogorov (JMAK) expression for the model of the kinetics for the isothermal phase transformations [5]. Their phenomenological model is often used for crystallization process and solid phase transition kinetic description.

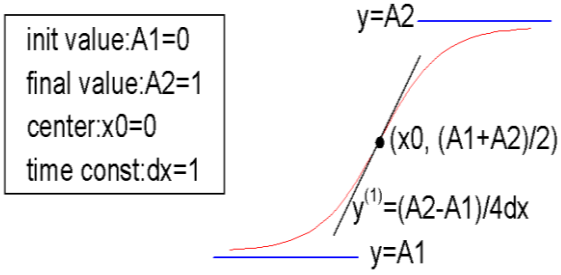

Fig 14. Sigmoid shape - Boltzmann fitting function for phase transition kinetic process.

$$y = \frac{A_1 - A_2}{1 + e^{(x - x_0)/dx}} + A_2 \qquad (1)$$

 ISBN 978-86-7466-930-3

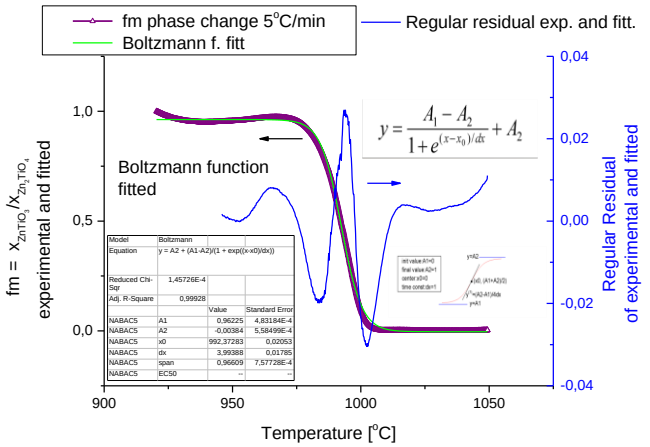

Fig 15. Phase transition curve, Boltzmann fitting function – Bulk, corrected, 5°C/min.

.

Example of the fitting function is presented on Fig 15. Fitting function (light green thin) for the experimental set of data (purple bold). Regular residual curve quantifies resemblance (blue, right axes). Table inserted represents fitting function parameters listed in a report data sheet of the fitting procedure. Residuals are the measure of discrepancy with the experimental curve and they also are listed in a report data sheet.

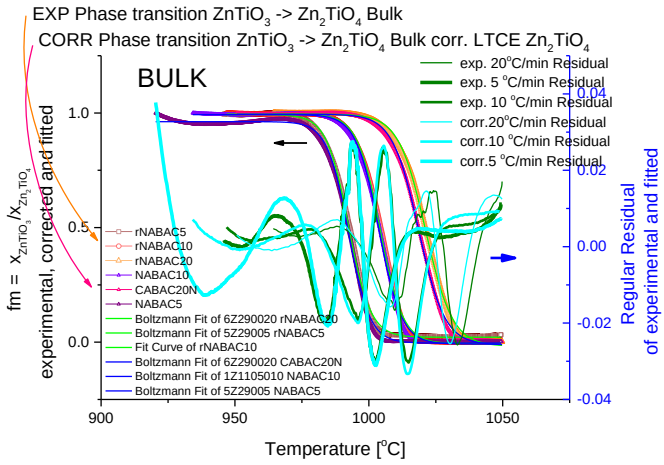

Fig 16. Bulk phase transition curve, 5, 10, 20°C/min, experimental and corrected, Boltzmann function fitted – Residuals

Curves presented at Fig. 16 of experimental and corrected curves are bold with symbols in the colors previously used. Fitted function is green thin line for experimental and blue thin line for corrected curves, all on left axes. It is visible that residuals (cyan and olive, thickness refers to a heating rate, right axe) for the experimental and corrected curves are mutually resembling, Fig. 16. This implies that corrected curves are following fitting equation just as good as experimental. Only 20°C /min are somewhat shifted. This can be subscribed to the fact that at larger heating rates stress - strain relation is not negligible.

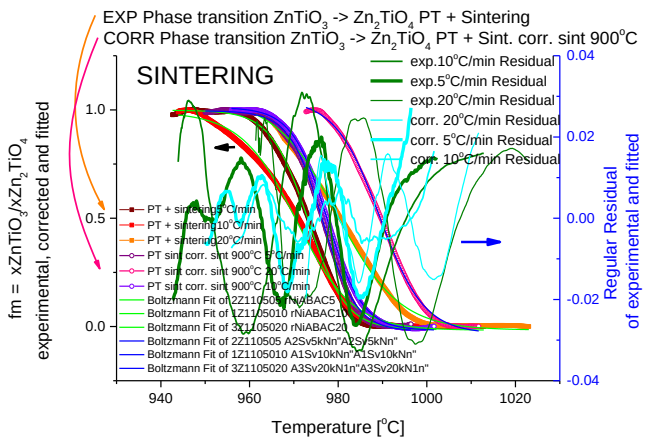

Fig 17. Sintering phase transition curve, 5, 10, 20°C/min, experimental and corrected, Boltzmann function fitted – Residuals

Same procedure of fitting for experimental and corrected curves with Boltzmann function is performed at sintering phase transition curve, Fig. 17, left axes. Residual functions for experimental (olive) and corrected (cyan) are showing intensive difference for the corrected and experimental, right axes. If the fitted functions are observed for experimental (green thin) and corrected (blue thin), it is obvious that shape of the curve that represents phase transition with correction is showing more resemblance with the sigmoid shape. Thus, the made correction is more reasonable.

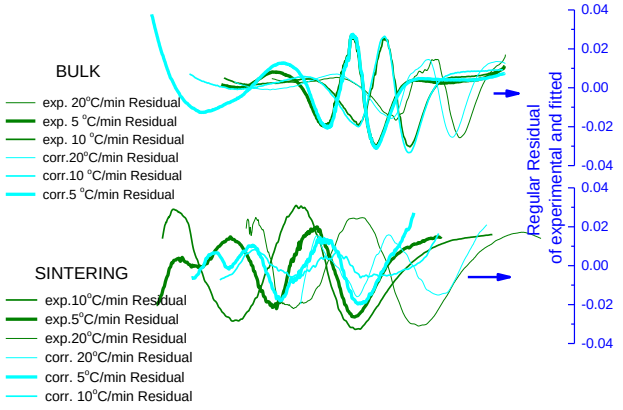

Fig 18. Fitting function Residuals comparison Boltzmann function fitted – Residuals, Sintering phase transition curve, 5, 10, 20°C/min, experimental and corrected, Bulk phase transition curve, 5, 10, 20°C/min, experimental and corrected.

Fitting function Residuals comparison experimental and corrected – Bulk and Sintered brings a reason that if we are comparing just residuals, Fig. 18, the conclusion drawn is that the sintering correction brings large misfit comparing to the bulk. The misfit is for the sintering residuals, as well for the different heating rates presented with different thickness of the line. Experimental curves misfit for the sintering residuals are significant (Sintering, olive, different thickness).

 ISBN 978-86-7466-930-3

IV. Conclusion

Physical differentiation of the sintering shrinkage and Phase transition phenomena dilatation has been compared with mathematical data manipulation of the sintering curve and phase transition subtraction. It is found that data manipulation procedure does not give the reliable results.

Although a thorough procedure for the phase transition kinetic data achieving from the dilatometric data and fitting procedure with sigmoidal function has been established.

Study of the effect of microstructure and magnetic texture on major hysteresis loop phenomenology using OOMMF

Mehrija Hasičić, Aphrodite Ktena and Jasna Hivziefendic

***Abstract*— This paper presents a study of the effect of microstructure and magnetic te ture on the hysteresis loop through quasi-static micromagnetic simulations using the open-source software . esults show that microstructure and magnetic te ture parameters can be used to control the coercivity. The anisotropy constant is the parameter mainly controlling the coercivity. The increase in the volume fraction of hard inclusions in a soft matri typically leads to higher coercivity. In the case of randomly oriented inclusions, the calculated coercivity is lower than that for the homogeneous soft case which is e plained through the prominent anisotropy energy density compared to the much wea er e change energy density. The results will be used to correlate simulation parameters with magnetic parameters obtained from major hysteresis loop measurements.**

***Index Terms*—micromagnetic calculation, microscopic modeling, energy minimization, magnetic properties, hysteresis loop,**

I. Introduction

MAGNETIC materials have played a significant part in the formation of modern civilization and continue to do so in the advancement of industrial and scientific development. Their applications range from the compass, which was the first known application, to power generation and transmission, electronic appliances, analogue and digital data storage, medical appliances such as magnetic resonance imaging (MRI), magnetic therapy, and drug delivery, sensors and actuators, scientific instruments, and so on [1].

Electrical steel, in particular, is a material that is widely used in construction, shipping and other modes of transportation, automobiles, electrical equipment and appliances, and other metallic products. Reducing waste and saving energy is a highly discussed and investigated topic. Increasing efficiency and lifecycle of the electrical machines would be beneficial for both topics.

Stresses are the result of both thermomechanical treatments during the manufacturing of the materials and fatigue during the lifetime of a steel structure. They are difficult to avoid however, they should be monitored and treated if and when possible [2]. Increased stress levels are known to contribute to losses [3], [4].

The study of the effects contributing to losses as well as the effect of stress on the magnetization process is necessary for the optimization of magnetic materials used in the above applications. Several physical or phenomenological models of magnetization have been developed to assist in the design of new materials or contribute to the control of magnetization driven processes. These models can be grouped into phenomenological [5]–[8], microscopic [9]–[12], atomistic [13], [14] and multiscale [15]–[18].

The modeling of the magnetization process consists in determining the relationship between the magnetization state of a material and external stimuli, such as externally applied fields, mechanical loads, or heating. The major hysteresis loop M(H) of a material, where M represents magnetization of the material and H is applied field, yields the macroscopic parameters typically used to classify a given material, such as the saturation magnetization, remanence, coercive field, energy product, for specific excitation conditions. Losses are also obtained from the major hysteresis loop measurement since they depend on the area of the loop. The M(H) curve is the result of magnetization processes at the atomistic, domain and macroscopic level, which in turn depend on the underlying microstructure. Changes in temperature, frequency of the applied field or stress levels affect the M(H) characteristic. The modeling of stress dependent magnetization processes is a challenging task due to the highly nonlinear dependence of the magnetization on external stimuli which is further complicated by the magneto-elastic coupling.

The stress-strain characteristic for any given material consists of an elastic region, where the stress is proportional to the strain and the proportionality constant is the Young's modulus, and a plastic region. The microstructure in plastically deformed materials consists of finer grains, hence longer grain boundaries acting as pinning centers, anisotropy dispersion, and magnetically hardened regions which considerably affect the magnetization response.

The long-term goal of our work is to develop a modeling approach that links stress-induced microstructural changes to the macroscopic parameters obtained from hysteresis loop or magnetic Barkhausen noise measurements [4], [12]. Towards this goal, in this paper, we report on the quasi-static micromagnetic modeling of the effect of microstructure on the major hysteresis loop phenomenology using the open source OOMMF software to minimize the free energy equation of material [12], [19].

The proposed methodology is presented in the following section which is followed by simulation results and their

discussion. The last section summarizes the main conclusions and presents the roadmap of our future work.

II. Methodology

In micromagnetic modeling, the minimization of the energy equation reflects the balance between long range and short-range interactions and their interplay with external stimuli, such as a magnetic field. Short range interactions have a localized effect and are determined by the competition between the exchange and anisotropy energy terms which reflect the effect of the chemical composition and the crystalline structure of the material. The long-range interactions are represented by the magnetostatic energy term which summarizes the magnetic fields experienced by a given elementary volume inside the material, as the former emanate from all the remaining volumes in it. This term depends on the current magnetic state of the material, which incorporates the effect of previous states as well, and is responsible for the hysteresis property observed in magnetic materials.

The effect of stress on the magnetization process was introduced through various microstructural configurations as well as through the parameters of anisotropy constant, exchange energy coefficient, and magnetic saturation which control the anisotropy, exchange and mangnetostatic energy terms, respectively.

More details on micromagnetic calculations with OOMMF are given in [12] where the effect of simulation parameters on the major hysteresis loop phenomenology was studied. More specifically, we discussed the effect of discretization and cell size as well as the effect of magnetic parameters, such as the exchange and anisortopy constants and the orientation of the easy axis, on the major hysteresis loop.

In this work, we report on the effect of changes in microstructure through the introduction of hard magnetic inclusions in a soft matrix combined with changes in the direction of anisotropy, i.e. in the magnetic texture. The parameters used in the simulations to define different types of materials are the anisotropy coefficient K_1, the exchange enrgy coeffiecient A_{ex} and the magnetic saturation M_s. The parameter values used in the simulation results shown here are summarized in Table I. They correspond to three different types of materials: Material 1 is homogeneous with parameters corresponding to a soft magnetic material, while Materials 2 and 3 have inclusions of hard material in the soft magnetic matrix. The inclusions of Material 3 are harder than those of Material 2 with parameters corrseponding to those of a rare earth magnet.

TABLE I
MAGNETIC PROPERTIES OF MATERIALS

aterial	Type of material	Parameters		
		K_1 $[kJ/m^3]$	A_{ex} $[kJ/m]$	M_s $[kA/m]$
Material 1	Soft	48	21	1700
Material 2	Hard	520	21	1400
Material 3	Hard	4500	21	1280

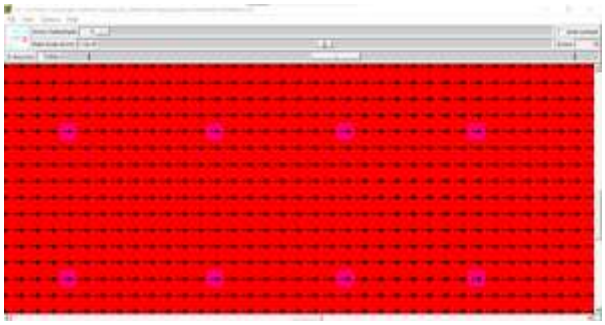

Fig. 1. shows the magnetization plot of a soft matrix with hard inclusions.

The simulated material is of rectangular shape discretized along the x (length), y (width) and z (thickenss) direction in cubic cells of side *a*. The size of the cubic cells is a user defined variable which has to be chosen so that it is smaller than the magnetocrystalline exchange length for hard magnetic materials and magnetostatic exchange length for soft magnetic materials, as presented in [12]. Fig. 1 shows the initial state of the magnetization vector for every cell in the xy plane for a given z-value. The plot is zoomed in 35x so that it is easier to see the hard inclusions (in purple) which are of a size of one cell. The pattern continues throughout the sample in the xy plane. Simulations have been carried out for two cases, where hard inclusions are either cylindrical structures throughout the z layer, or one spherical cell in the middle z layer. Table II summarizes the texture and type of inclusions for the simulations shown here.

The applied field in all simulations is 1100 mT along the x-axis.

TABLE II
PROPERTIES OF HARD INCLUSIONS IN THE SOFT MATRIX USED IN THE SIMULATIONS

	ard inclusions	Anisotropy direction	Type of inclusions
1	Material 2	randomized	cylindrical
2	Material 2	[1 0 0]	cylindrical
3	Material 2	[0 1 0]	cylindrical
4	Material 2	[0 0 1]	cylindrical
5	Material 2	[1 1 0]	cylindrical
6	Material 2	[0 1 1]	cylindrical
7	Material 2	[1 0 1]	cylindrical
8	Material 2	[1 1 1]	cylindrical
9	Material 2	[1 0 0]	spherical
10	Material 2	[0 1 0]	spherical
11	Material 2	[0 0 1]	spherical
12	Material 2	[1 1 0]	spherical
13	Material 2	[0 1 1]	spherical
14	Material 2	[1 0 1]	spherical
15	Material 2	[1 1 1]	spherical
16	Material 3	[1 0 0]	cylindrical
17	Material 3	randomized	cylindrical

III. Results

The base case used for comparison corresponds to a homogeneous magnetic material where all cells have the parameters of Material 1 and the anisotropy, saturation magnetization and the applied field are all along the x-axis or [1 0 0].

 ISBN 978-86-7466-930-3

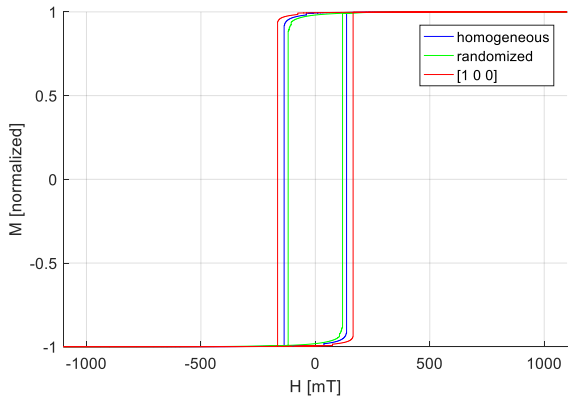

Fig. 2. Simulated hysteresis loops of a homogeneous magnetic material (blue) versus a material with cylindrical hard inclusions, extending throughout the z layer, with randomized anisotropy (green), and with the anisotropy oriented along the [1 0 0] (red) parallel to the applied field

First, we examine the effect of the anisotropy direction of hard magnetic inclusions of Material 2. In Fig. 2, the simulated hysteresis loop of the homogeneous case is compared against those of materials with cylindrical hard inclusions with anisotropy along the same direction as that of the soft matrix and the applied field, i.e. along [1 0 0], and with randomized anisotropy orientations. When the hard inclusions are aligned with the soft matrix, the coercivity increases as it is expected (red line). However, when the anisotropy of the inclusions is randomly dispersed, the material presents a softer response (green line). To better understand these results, we examine the energy plots for the two cases shown in Fig. 3.

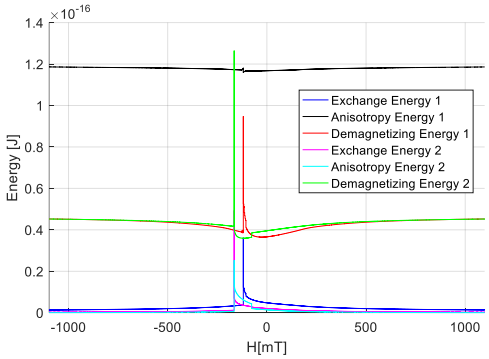

Fig. 3. Energy plots for materials with hard inclusions with randomized anisotropy (case 1) and anisotropy aligned with the anisotropy of the soft matrix (case 2)

The peak in the computed energy terms is observed around coercivity which is higher for the material with the hard inclusions along the same direction of the applied field (case 2). When the anisotropy is randomized (case 1), the anisotropy energy term is the most prominent and does not vary much with the field (black line). Exchange energy on the other hand is lower (blue line) even though the exchange constant used is the same in both cases. The exchange energy between two neighboring magnetic dipoles depends on the angle between their magnetization vectors, i.e. the larger the angle, the smaller the exchange energy. When the anisotropy is randomized and there is no predominant preferred direction, the resistance of a given magnetic volume to the forced change in magnetization is lower and the magnetization rotation towards the effective field experienced by the given volume is facilitated.

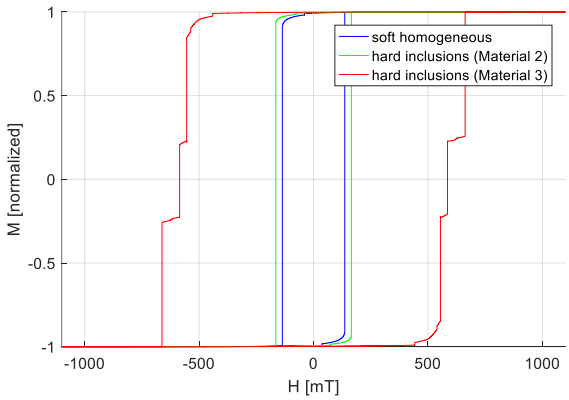

Fig. 4. Calculated hysteresis loops for the soft homogeneous case (blue) versus hard inclusions of Material 2 (green) and Material 3 (red)

The next step was to investigate the effect of magnetic hardness of the inclusions by carrying out simulations with inclusions of Material 2 and Material 3 (Fig. 4). The anisotropy and initial magnetization of hard inclusions in both samples is along [1 0 0]. The coercivity for the cases shown in Fig. 4 increases six-fold as the anisotropy constant of the inclusions increases almost ten-fold. Observed results are consistent with major hysteresis loop characteristics of harder magnetic materials. The step-like response of the loop corresponding to Material 3 (red line) is an artefact of the OOMMF calculation.

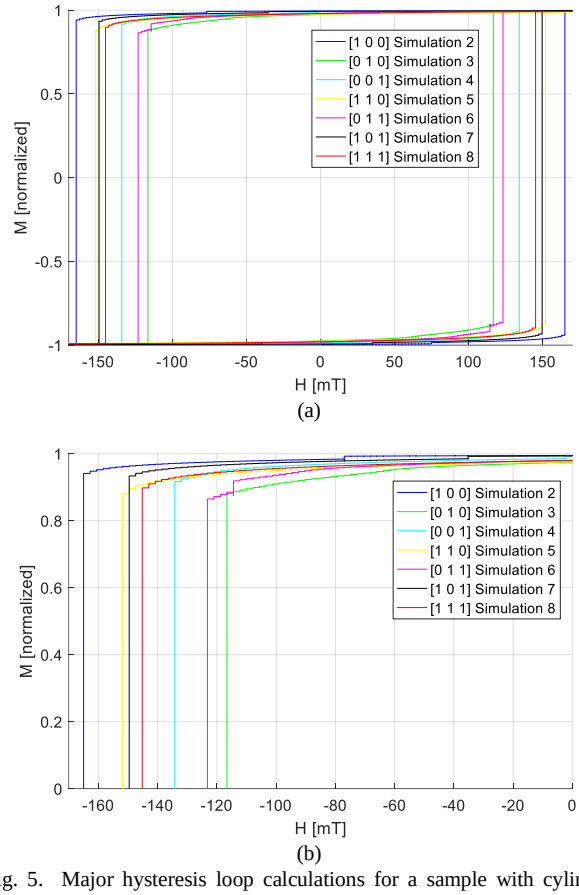

Fig. 5. Major hysteresis loop calculations for a sample with cylindrical hard inclusions of Material 2 throughout the z layer with the anisotropy lying along different directions (a) full loop (b) second quadrant

In Fig. 5 we present the effect of magnetic texture on the major hysteresis loop phenomenology of a sample with hard inclusions of Material 2. The details of each simulation are given in Table 2. The anisotropy direction is varied from

 ISBN 978-86-7466-930-3

easy axis (x-axis) (#2) through various in-plane (#3 and #5) and out-of-plane (#4, #6, #7 and #8) directions.

Hard axis loops (#3 and #6) are narrower, as expected. The lowest coercivity is observed when the anisotropy is along y-axis [0 1 0] in-plane and along [0 1 1] direction, out of the plane, respectively. The case with the anisotropy pointing out of plane along [0 0 1] (#4) yields a higher coercivity than the previous cases. The widest loops are obtained when the anisotropy of the hard inclusions is along [1 0 0], collinear with the applied field, or has an x-component [1 1 0], [1 0 1] and [1 1 1] (#2, #5, #7 and #8).

The effect of distribution of hard cells along the z layer is investigated next, by arranging the hard inclusions only in one z layer, the middle one. The results are presented in Fig. 6.

Distributing the hard inclusions in only one z layer, while keeping the pattern along the xy plane presented in Fig. 1 consequently, means a decrease in the volume fraction of hard inclusions. Therefore, we observe that the widest major hysteresis loop presented in Fig. 6 is narrower than the widest major hysteresis loop presented in Fig. 5. The discussion of Fig. 5 is valid for Fig. 6 as well. The only different trend observed is that when the hard inclusions' anisotropy is along [0 1 0], the observed coercivity is 10 mT higher than in the case of cylindrical inclusions.

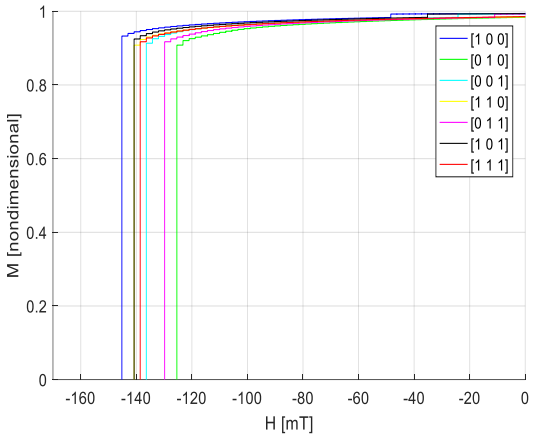

Fig. 6. Major hysteresis loop calculations for a sample with spherical hard inclusions of Material 2 in the middle z layer, with the anisotropy lying along different directions

The presented calculations demonstrate the effect of microstructure and magnetic texture on the observed phenomenology of the hysteresis loop. Experimental evidence has shown that both are affected in plastically deformed material [4], [20]. In our future work, simulations will be based on experimental measurements and the OOMMF software will be used to link microstructural parameters to macroscopic magnetic parameters obtained from a major hysteresis loop measurement, such as the differential permeability and coercivity which have a well-established dependence on residual stresses in a magnetic material.

The limitations of the OOMMF software, observed mainly in the approach to saturation in the third quadrant, need to be further examined and ensure that they do not affect the validity of our conclusions.

IV. Conclusion

The effect of microstructure and magnetic texture on the hysteresis loop has been studied through quasi-static micromagnetic simulations using the open-source software OOMMF. Microstructure was varied through cubic or columnar inclusions of different magnetic parameters inside a soft matrix. Magnetic texture was varied through the anisotropy orientation of the inclusions. Coercivity varies considerably with both microstructure and texture. When the hard inclusions have randomized anisotropy, lower coercivity is observed, even compared to the homogeneous case calculation. This is explained through the interplay between the different energy density terms, where the anisotropy energy density is predominant, and the exchange energy is reduced.

Future work will be focused on the correlation between simulation parameters and magnetic parameters obtained from measured loops at various residual stress levels on electrical sheet laminates.

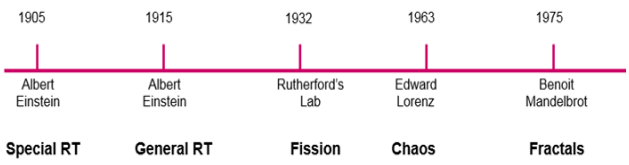
Primeri primene fraktalne analize za karakterizaciju novih materijala

Sanja Aleksić, Branislav Ranđelović, Aleksandar Pantić, Neda Stanojević, *Member, IEEE,* Dušan Milošević

***A stra t*— ovom radu je dat pregled novih metoda za pri upljanje, obradu i analizu materijala oji se oriste ili su u fazi istraživanja za primenu u savremenim uređajima za široku ili specifičnu, namensku proizvodnju. Razvoj biofizike, ele torhemije, napreda u proizvodnji alternativnih izvora energije, biomole ulima, ali i svim ostalim oblastima nau e, ukratko je objašnjen vezom između nanotehnologije, kao intrdiscplinarne nauke budućnosti i novih matematičkih metoda i pristupa koji omogućavaju analizu zrna, pora i njihovih sraničnih delova i interakcija. Dobijeni rezultati imaju za cilj da se električne, fizičke i hemijske osobine materijala povežu sa njihovim izlaznim parametrima (temperatura, gustina, električna i magnetna provodnost...) i da se, u s ladu sa tim, dođe do novih ili uvedu korekcije u postojeće metematičke i fizičke teorije i jednačine, da bi se dobili što relaniji iu precizniji rezultati za karakterizaciju uređaja u kojima se koriste. Jedan od elementarnih uslova za unapređivanje karakteristika matrijala je optimizacija procesa sinterovanja i ele tro-fizičkih osobina materijala, što je, takođe, analizirano u ovom radu.**

***Ključne reči*— anotehnologije; fra talna analiza; obnovljivi izvori energije; materijali za ele troni u.**

I. Uvod



Sve novije i, doskora, čak i nezamislivo nepoznate potrebe modernog čoveka u svim sferama života, primoravaju nas da budemo kreativni i gradimo nove koncepte bezbedne i stabilne arhitekture, medicine, informacionih i telekomunikacionih elemenata - objekata i sistema za prenos informacija na što veće daljine sa što manje gubitaka, sredstava za transport i prevoz robe i putnika, unapređenja poljoprivrede u cilju dobijanja što većih količina zdrave i jeftinije hrane, itd. Činjenica da su bukvalno sve oblasti života i rada, koje bi ljudima trebalo da donose dobrobiti, u intenzivnoj fazi razvoja, podrazumeva da je osnovni preduslov za to obezbeđivanje tehničkih i tehnoloških uslova za proizvodnju i korišćenje ogromnih količina, najpre toplotne i električne, a zatim i svih ostalih vidova energije. Naravno, sve nove tehnologije bi, takođe, morale zadovoljavati što veći broj kriterijuma koji su okosnica borbe savremenog sveta za očuvanje životne sredine.

Nanotehnologije, nova naučna disciplina koja uključuje, pre svega, fundamentalne nauke kao što su, fizika, hemija, biologija, nauka o materijalima, ali i veliki broj inženjerskih grana (elektronika, građevinarstvo, mašinstvo), obećavaju da će u budućnosti biti vrlo bitan faktor razvoja i proizvodnje novih generacija uređaja za upotrebu u svim sferama života savremenog društva sa visokim stepenom minijaturizacije i integracije, a minimumom utroška energije [1-6].

Razvoj tehnika i tehnologija je nezamisliv i beskoristan ukoliko ne postoje novi načini za korišćenje već postojećih ili pronalaženje načina za proizvodnju i upotrebu novih, modernih materijala, koji bi od strane fizike, hemije i biologije mogli biti proučavani na neki način drugačiji od klasičnog. Prilagođavanje metodologija je neophodno s obzirom da se radi o objektima čije su dimenzije reda veličine nekoliko (ili nekoliko desetina) nanometara, tj. dimenzijama koje teže veličini jednog atoma, molekula ili njihovih klastera [1].

Osim gore pomenutih tehnika i tehnologija, čiji je razvoj uzročno-posledično povezan sa razvojem i upotrebom novih materijala, neophodno je razvijati i naučne metode priključpljanja, obrade i analize dobijenih rezultata eksperimentalnih merenja ili simulacija, koji služe za karakterizaciju njihovih fizičkih, hemijskih ili električnih osobina.

U ovom radu će biti dat osvrt na jedan noviji matematički pristup, koji se razlikuje od konvencionalne Euklidove geometrije i predstavlja pionirske pokušaje uvođenja drugačijeg načina razmišljanja primenjenog na zrnastu strukturu materijala, koji je poznat kao fraktalna analiza.

Sl. 1. Periodi važnih otkrića tokom XX veka.

Na Sl. 1 se vidi da je do otkrića "fraktala" došlo mnogo kasnije nego što je to bio slučaj sa prethodnim važnim

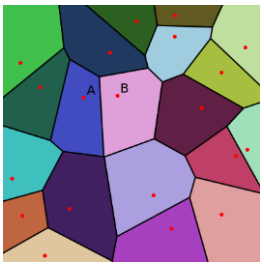
saznanjima koja su pomogla čovečanstvu na putu otkrivanja velikih tajni prirode.

Jedan fenomen, veoma intrigantan za ljudsku socijalnu inteligenciju, je činjenica da isti atomi predstavljaju osnovne gradivne elemente i nosioci su istih procesa i u živoj i u neživoj prirodi. Osnova tih procesa i pojava je, ustvari, kretanje elektrona, samostalno ili unutar atoma ili molekula. Potreba za razumevanjem "trenutka" koji pravi razliku između materije koja je živa i one koja to nije, zahteva interdisciplinarni pristup molekularne biologije i ostalih grana nauke i inženjerstva. Naime, molekularna biologija, kao nauka o životu, proučava različite procese u živim organizmima na molekularnom nivou. To znači da se ona bavi i kretanjem elektrona u biomolekulima, pa je neophodna saradnja sa molekularnom bioelektronikom, jer se kretanje elektrona zasniva na istim principima u živim organizmima, kao i u svim ostalim oblicima materije. Zbog toga je jedini ispavan pristup proučavati ga kao zajedničko svojstvo jednog fundamentalnog procesa [2].

Dosadašnji razvoj nauke i tehnologije ne omogućava nam da pratimo kretanje i proučavamo pojedine elektrone, kao nosioce elementarnog naelektrisanja i energije (električne, toplotne, mehaničke…). U ovom trenutku je moguće posmatranje i opisivanje kretanja molekula metodama koje nudi kvantna fizika. Naravno, sve vreme imamo u vidu da svaki molekul nosi klaster elektrona koji se kreće zajedeno sa njim, ali se i svaki electron ponaosob kreće unutar samih atoma koji čine molekule, i čiji su osnovni elementi građe. Zato činjenica da, unutar molekula koji su delovi biosistema, postoje atomi i elektroni koji "nisu svesni" da li su delovi žive ili nežive prirode, je veoma važna, jer izdvaja molekul kao značajan integrativni faktor između njih.

Zbog svega toga će na ovom mestu biti ukratko objašnjene osnove fraktalne analize, kao jedne od novijih matematičkih metoda, koja se danas sa velikim uspehom, naročito uzimajući u obzir ograničenja Euklidove geometrije, koriste za karakterizaciju materijala na nivou nanometra. Korisnost njene primene u materijalima koji su zanimljivi sa stanovošta fizičke elektronike biće prezentovana na nekoliko, od velikog broja primera, ali bez ograničenja da se identična analiza ne može proširiti univerzalnim principima od objekata nanodimenzija do otkrivanja tajni kosmosa, jer sve to, sagledano objektivnim očima van našeg egocentričnog referentnog sistema, doprinosi i spoznaji uzroka, načina i razloga postojanja nas samih u univerzuma čiji smo sastavni deo.



Zbog toga će u ovom radu ukratko biti opisane osnove na kojima se bazira ideja fraktalne matematike, metode koje se primenjuju u zavisnosti od toga o kojoj vrsti problema i sferi ljudkog života se radi i primeri vezani za fizičku elektroniku, alternativne izvore energije, materijale za energetiku i telekomunikacione uređaje...

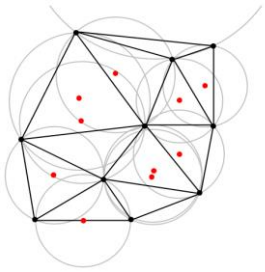
II. Osnovne postavke fraktalne teorije

U cilju približavanja koncepta novog načina razmišljanja i njegove primene u pomenutim naučnim istraživanjima vezanim za razvoj elektronskih komponenata, prvenstveno u sferi primene u novim, alternativnim izvorima energije i telekomunikacionim sistemima, počećemo kratkom rekapitulacijom analize $BaTiO_3$, koja, kao što je već rečeno, predstavlja pionirska istraživanja u ovoj grani nauke.

Pokazano je da su kod $BaTiO_3$, čiji prah ima zrnastu, granularnu strukturu, oblasti prostora oko granica pojedinačnih zrna odgovorne za skoro sve procese koji određuju fenomene i osobine različitih materijala. Naime, pojave opisane kao, veoma specifične karakteristike elektroprovodnosti, dielektrične, feroelektrične, feromagnetne, poluprovodničke i brojne druge, zajedno definišu bazične električne osobine u čitavoj zapremini materijala. To znači da se pomenuti procesi odigravaju u slojevima koji se mogu opisati kao ljuske Minkovskog, i da se mogu ponavljati i na isti način prostirati po čitavoj zapremini posmatranog uzorka.

Zato je pogodna polazna tačka za opisivanje ćelijskih struktura kao što je kristalni perovskit i slični materijali Voronojeva teselacija (mozaički raspored geometrijskih figura u prostoru koje se ne preklapaju, ali "komuniciraju" graničnim oblastima bez praznina između njih), jer termin *tessella* potiče od latinske reči tessella, što znači ravan kamenčić ili parče keramike ili stakla za pravljenje mozaika. Ovakav koncept je primenljiv i na zrna i na pore, i efikasan je alat za prognozu projektovanih mikrostrukturnih svojstava i mikrostrukturne karakterizacije materijala (Sl.2).

Sl. 2. Primer Voronoevog dijagrama.



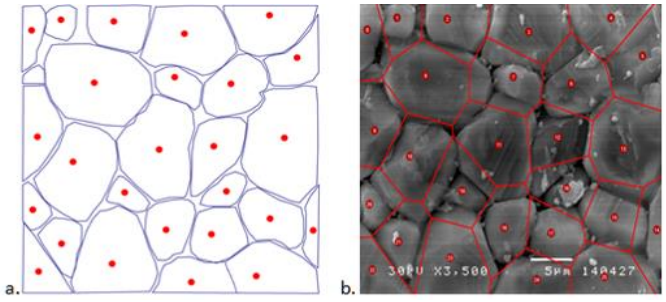
Voronojevi dijagrami imaju mnogo mogućnosti za primenuu, prvenstveno u predviđanju ili simulaciji interakcija između susednih struktura. Na primer, modeliranje bioloških ćelijskih struktura, modeliranje obrazaca rasta u šumama, procena mineralnih rezervi za rudarenje, mapiranje najbližeg aerodroma avione koji bi trebalo da slete u hitnim sliučajevima, itd [6].

Da bi se formirala Voronojeva teselacija, potrebno je posmatrati skup tačaka u ravni, jer je to najlakše zamisliti, naročito u euklidskoj metrici. Za svaku tačku je moguće odabrati oblast u okolini koji je bliži toj tački od bilo koje druge tačke u datom skupu. Na taj način svaka oblast formira ćeliju koja odgovara toj tački. Unija svih skupova takvih ćelija pokriva oblast prostora koji se posmatra u datoj ravni. Ta unija skupova predstavlja Voronojevu teselaciju.

Usko povezan pojam sa Voronojevom teselacijom je Deloneova triangulacija. Za dati skup tačaka u nekom matematičkom prostoru, Deloneova triangulacija se formira povezivanjem tačaka i stvaranjem trouglova sa uslovom da za

 ISBN 978-86-7466-930-3

bilo koju tačku ne postoji ni jedna druga tačka u opisanoj kružnici odgovarajućeg trougla (Sl.3).



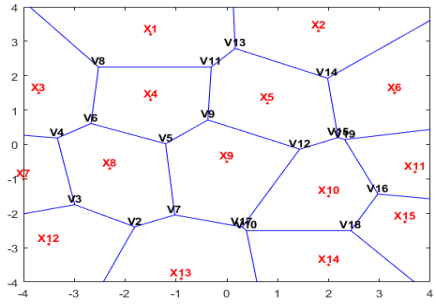
Sl. 3. Primer Deloneove triangulaciju sa tačkama (crvenim) koje predstavljaju centre odgovarajućih opisanih krugova Deloneovih trouglova.

Bazirajući se na osnovnim postavkama koje smo pomenuli, Voronojev dijagram je, najpre, definisan kao ravan ili deo ravni ili teselacije (*S*), pri čemu je ispunjen uslov da je skup $=\{ _1, _2, _3, _4 ...\}$ i da je njihova unija skup *S*, a presek između bilo koje dve ćelije prazan skup. Osim toga, ovakva teselacija je izomorfizam sa konačnim skupom tačaka $Z=\{ _1, _2, _3, ... _n\}$ iz skupa *S* na način prikazan na Sl.4 i 5:

Sl. 4. Izomorfni skup tačaka odabrane ravni ili teselacije *S*.

Sl. 5. Poligonalna aproksimacija konture zrna

Voronojeva ćelija $_i$, koja je generisana oko tačke $_i$, sadrži sve tačke iz *S* i zadovoljava jednačinu:



$$\rho(, _i) < \rho(, _j), \text{ za } j \neq i, \quad (1)$$

pri čemu je ρ Euklidovo rastojanje:

$$\rho(, y) = \sqrt{(_1 - _2)^2 + (y_1 - y_2)^2} \quad (2)$$

za tačku čije su koordinate:

$$= (_1, _2),\ y = (y_1, y_2). \quad (3)$$

Sl. 6. Primer Voronojevog dijagrama za datu distribuciju tačaka sa jednom pokretnom generišućom tačkom.

Na Sl.6 je dat primer Voronojevog dijagrama za datu distribuciju tačaka sa jednom pokretnom generišućom tačkom.

Algoritam za generisanje planarnih Voronojevih dijagrama može biti direktan i indirektan. Prva grupa algoritama generiše Voronojeve ćelije počevši od, a priori, datih tačaka generisanja. Indirektni algoritmi prvo generišu Deloneov trougao koji potom proizvodi Voronojeve ćelije. Triangulisana nepravilna mreža (TIN) je geometrijska struktura podataka koja se koristi, npr. u Geografskim informacionim sistemima (GIS) za 3D modeliranje reljefa (Sl.3). Osnovna karakteristika TIN strukture je korišćenje većeg broja tačaka na mestima gde je prikazan niži nivo detalja. Generalno, kad je set tačaka definisan, mora biti uspostavljena optimalna veza između tačaka trouglova korišćenjem Delaunai triangulacije (DT).

Ovakve polazne geometrijske i matematičke postavke su se pokazale kao izuzetno efikasan alat za prognozu projektovanih mikrostrukturnih svojstava i mikrostrukturne karakterizacije materijala čije su jedinice građe zrna i pore. Naime, čist euklidski pristup ne daje dovoljno verodostojnu reprodukciju oblika zrna i pora, pa pretpostavka fraktalne geometrije, bazirana na Voronojevom modelu daje rezultate mnogo bliže realnom formiranju mikrostrukturnih konstituenata – granica zrna i pora. Zato ovakav mikrostrukturni pristup rekonstrukcije i prognoze daje i realnije vrednosti elektrofizičkih parametara i svojstava, čime se pomeraju granice unutar fraktalne mikroelekotrnike i stvaraju novi pristupi koji vode ka minijaturizaciji i integraciji višeg nivoa (Sl.4). Diektna implikacija svega toga se vidi u reviziji i korekcijama osnovih fiziko - hemijskih i eletrkofizičkih zakona i jednačina (Cobbleov, Heivangov i intergranularni model za određivanje kapacitivnosti kondenzatora, Curie – Veisov zakon, visina Šotkijeve barijere, dielektrična i magnetna susceptibilnost materijala, električna otpornost...)

 ISBN 978-86-7466-930-3

Veću fleksibilnost po pitanju rekonstrukcije strukturnih jedinica (zrna i pora) i njihovih međusobnih odnosa sa konačnim ciljem predviđanja osobina mikrostrukture tokom procesa minijaturizacije obezeđuje Kantorov pristup, razvijen kao metod fraktalne analize, koji omogućava modeliranje fraktalne površine modelirane kao skup fraktalnih krivih.

Kantorov ternarni skup C je kreiran iterativnim brisanjem otvorene srednje trećine iz skupa linearnih segmenata. Neka je I interval $[0,1]$. Brisanjem otvorene srednje trećine $[1/3,2/3]$ iz intervala $[0,1]$, ostaju dva segmenta linije $[0,1/3]\cup[2/3,1]$. Zatim se briše otvorena srednja trećina svakog od segmenata, posle čega ostaju četiri linearna segmenta $[0,1/9]\cup[2/9,1/3]\cup[2/3,7/9]\cup[8/9,1]$. Ovaj proces se nastavlja do beskonačnosti. Na bilo kojoj n-toj iteraciji, ovakav skup je moguće pokriti uvođenjem 2^n intervala prečnika $1/2^n$. Procena gornje granice α - dimenzionalne Hausdorfove dimenzije C za pokrivanje intervala širine (prečnika) $w_a(1)$ se dobija iz:

$$\sum_{k=1}^{2^n}\left(w_a\left(\frac{1}{3^n}\right)\right)^{\alpha}=\frac{2^n\left(w_a(1)\right)^{\alpha}}{3^{n\alpha}}, \qquad (4)$$

Za dobijenu vrednost gornje granice broja iteracija skupa neophodno je prodiskutovati moguća rešenja. Iz (4) je jasno da će za $n\to\infty$ ovaj razlomak biti konačan i različit od nule ukoliko je $\alpha=\ln 2/\ln 3$, što znači da je $\alpha=\ln 2/\ln 3$ tražena vrednost gornje granice iteracije. Iz principa raspodele mase moguće je zaključiti da je ovo i donja granica iteracije datog skupa. Dakle, Kantorova dimenzija C je kartezijanski proizvod sa samim sobom, što znači da mora biti posmatran kao deo vektorskog proizvoda vektor-tenzor [1-6].

Na identičan način je moguće obuhvatiti 4^n krugova dijametra $2^{0.5}/3^n$. U tom slučaju će procenjena gornja granica α - dimenzionalne Hausdorfove dimenzije C za pokrivanje intervala širine (prečnika) $w_a(\sqrt{2})$:

$$\sum_{k=1}^{4^n}\left(w_a\left(\frac{\sqrt{2}}{3^n}\right)\right)^{\alpha}=\frac{4^n\left(w_a\left(\sqrt{2}\right)\right)^{\alpha}}{3^{n\alpha}}, \qquad (5)$$

biti konačna i različita od nule kada $n\to\infty$ za $\alpha=\ln 4/\ln 3$, tako da Kantorov prah ima fraktalnu dimenziju $\alpha=\frac{\ln 2^2}{\ln 3}=\frac{2\ln 2}{\ln 3}$. Isto bi važilo za bilo koji kompaktan skup tačaka na jedičnom intervalu.

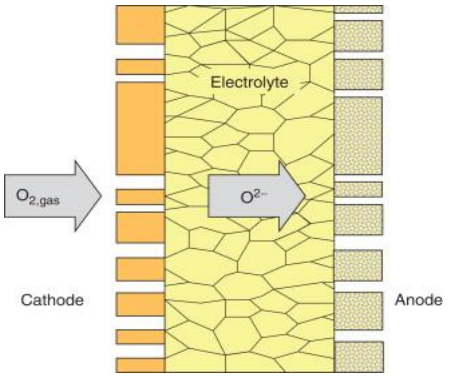
III. PRIMERI PRIMENE FRAKTALNOG RAČUNA ZA IZRAČUNAVANJE ILI KOREKCIJU NEKIH FIZIČKIH PARAMETARA

Na postavkama datim u prethodnom delu ovog rada u najkraćim mogućim crtama, razvijen je veliki broj matematičkih metoda, koje se primenjuju u svim sferama života i u svetovima u opsegu dimenzija od nanočestica do svemirskih objekata ili njihovih skupova.

A. Brauno o kretanje

Za oblast kojom se bavi fizička elektronika i fizika savremenih materijala za elektroniku veliki izazov je mogućnost predviđanja i modelovanja Braunovog kretanja elektrona u kristalnim materijalima. Sa druge strane, osnove Braunovog kretanja bi trebalo da budu iste i u biomolekulima. Povezivanje biofizičkih i sistema kondenzovane materije je od velikog značaja zbog potrebe za novim pristupom u mikroelektronskim biouređajima, biokompjuterima ili biočipovima. S obzirom na to da su submikronske čestice živog i neživog sistema identične, moguće je uspostaviti dvoznačno korespodentnu vezu ova dva sistema čestica čije je integrativno svojstvo biomimetička korelacija zasnovana na sličnostima fraktalne prirode Braunovog kretanja.

U jednom od istraživanja koja je sprovela grupa naučnika, dobijeni su eksperimentalni rezultati kretanja bakterija pod uticajem energetskih impulsa, kao što je muzika. Da bi bilo moguće definisati odnos između biofizičkih i fizičkih sistema čestica, uvođenjem matematičke analitičke forme i primenom karakterizacije fraktalne prirode Braunovskog kretanja fraktalnom interpolacijom, bilo je potrebno imati i eksperimentalne rezultate praćenja kretanja nekih biomolekula. Ova napredna istraživanja uključuju i proučavanja fizičkih sistema čestica u čvrstom stanju kao deo neorganskih sistema.



Dimenzije i obrasci kretanja bakterija i virusa ukazuju na biomimetiče sličnosti sa kretanjem čestica kondenzovane materije. Obrasci kretanja bakterija pokazuju stohastičke, a samim tim i nepredvidive karakteristike, jer se ovi mikroorganizmi suaraju kako međusobno, tako i sa okolnim molekulima, naglo menjaju pravce kretanja, kreću se rotaciono ili u cik-cak linijama, što je osnovna karakteristika Braunovog kretanja. Putanja i brzina njihovog kretanja su specifične za svaku bakterisku vrstu, ali im je zajedničko to što na sve njih značajno utiču faktori okoline (temperatura, osvetljenost, "hranljive materije", energetski impulsi...). Budući pravci istraživanja moraju uključiti stvaranje matemtičkih analitičkih jednačina, generisanje 3D interpolacionih dijagrama, kao i dizajniranje 3D fraktalnog interpolacioog dijagrama kretanja bakterija i biomolekula primenom metoda fraktalne interpolacije.

B. Materijali a alternati ne i ore energije

Sa porastom svetske energetske krize, istraživanja novih, obnovljivih i alternativnih izvora energije su u porastu. Fokus je na istraživačkim oblastima, ponekad od manjeg značaja u aplikacijama, gde su različite metode sinteze i optimizacija svojstava mikrostrukture izvršile značajno poboljšanje elektrofizičkih svojstava izlaznih materijala i komponenti. Ovo je posebno značajno za veću energetsku efikasnost u proizvodnji električne energije, pa je velika potreba za poboljšanjem performansi baterije i sistemi baterija, gorivnih ćelija, uređaja za eksploataciju energije vodonika, tj. za poboljšanjem kapaciteta rezervoara za tako proizvedenu

 ISBN 978-86-7466-930-3

energiju, što je jedno od najvažnijih razvojnih pitanja u energetskoj sferi. Imajući u vidu postignute rezultate u oblasti elektrohemijskih izvora energije, posebno razvoja elektrolita, istraženi su doprinosi pojedinih elemenata ili matrijala primenom fraktalne analize prirode materijala. Elektrohemija se bavi proučavanjem hemijskih reakcija koje se odigravaju na granici između elektroda (čvrsti metali ili poluprovodnici) i elelektrolita, odnosno jonskog provodnika, preko kojih se vrši razmena naelektrisanja između elektroda i elektrolita. Sa tačke gledišta fizike i energetike, to znači da se, ustvari, traži veza između električne energije i hemijskih reakcija. Pri tome, elektrokatalliza ima sve veći značaj u gorivim ćelijama, jer uključuje supstance koje povećavaju brzinu hemijskih reakcija, posebno na površinama umetnutih elektroda, naročito kada se koriste mešoviti jonsko-elektronski provodljivi oksidi. Tipični primeri su elektrode u gorivim ćelijama sa čvrstim oksidom (SOFC) ili membrane za izdvajanje kiseonika iz okolnog vazduha. Kako je za inkorporaciju kiseonika neophodno formiranje jona kiseonika, u sistemu moraju postojati slobodni elektroni, a to je moguće ili povezivanjem elektroda ili, još bolje, korišćenjem mešavine poluprovodnika i metala u čvrstom stanju (MIEC), kao što su oksidi sa perovskitnom kristalnom strukturom. Jedan od primere takve analize je istraživanje uticaja parametara mikrostrukture u oblasti elektrohemije (npr. uticaj koncentracije Ho2O3 (od 0,01 tež% do 1 tež%) i temperature sinterovanja (od 1320°C do 1380°C), kao parametara konsolidacije. Samim tim su otvorena vrata fraktalizacije elektrohemijske funkcije i u osnovnim termodinamičkim parametrima je uvedena fraktalna korekcija. Sa velikim interesovanjem se istražuje i zavisnost fraktalne dimenzije od koncentracije aditiva [1-6].

Sl. 7. Jedinična ćelija koja se sastoji od dve elektorde rzdvojene elektorlitom.

Mnogobrojna novija proučavanja alternativnih izvora energije danas su u fokusu većine projekata iz obasti energetike. Kako se svet suočava sa ozbiljnim energetskim izazovima, razvoj i implementacija tehnologija obnovljivih izvora energije postaju sve važniji. U ovom trenutku se, u tu svrhu, koriste svi raspoloživi izvori alternativne, kao i izvori energije bazirani na fosilnim gorivima. Međutim, najintenzivnije se proučavaju načini korišćenja energije Sunca. Procesi tokom kojih dolazi do pretaranja “energije” Sunca u neki drugi oblik energije (prvenstveno hemijsku) su mnogobrojni i mogu biti fotokatalitički, fotoelektrohemijski, procesi fotosinteze... Na osnovu njih se razvijaju i odgovarajuće tehnologije, poznate kao tehnologije solarnih ćelija (fotonaponske i fototermalne). Iz navedenih referenci se jasno vidi da suštinu rešenja dela problema predstavlja upotreba materijla kao što je TiO_2, ZnO, CoS i da se svi oni nanose u što tanjim (nanoslojevima, kao nanoprevlake za nanonožice...).

C. Feromagnetni i elektromagnetni materijali

Međutim, bez informatičke revolucije, bez mogućnosti prenosa informacija između nano-i makroobjekata, ništa od ovoga ne bi bilo moguće. Telekomunikacioni uređaji, tj. uređaji i oprema za obradu, prenos i prijem signala korišćenjem žičanih, radio, optičkih i dugih elektromagnetskih urežaja, takođe zahtevaju minijaturizaciju i optimizaciju brzine prenosa informacija, sa što manjim utroškom i gubicima sopstvene energije.

Za sve, gore navedene, primene i potrebe, neophodno je obezbediti rekonstrukciju i projektovanje strukturne jedinice (zrna i pore), da bi se postigla što viša minijaturizacija morfologije. Elektomagnetni, feroelektrični i srodni magnetni materijali se sve više koriste za ovakve pametne i multifunkcionalne namene. U tom smislu su zanimljiva istraživanja posvećena feroelektričnim materijalima, posebno jednofaznim kristalnim materijalima u tehnologiji tankog filma. Materijali sa strukturom perovskita imaju pravilan atomski red, tako da u tim mrežama postoje varijacije i promene koje se kao šabloni ponavljaju i prave domene atoma sa pravilnim promenama u određenom pravcu u materijalu, kao i polarizaciju u datoj tački. Difuzioni fazni prelaz utiče na feromagnetna svojstva materijala, jer se pod uticajem temperature javljaju mikrostukturne promene u vidu promene rasporeda atoma i pojave faznih prelaza u mikro i nano skali. Zbog toga se menja i Kirijeva temperatura i trenutak početka polarizacije. Ovakvi fazni prelazi su dominantni kada čvrsti rastvor dobije homogenu strukturu. U ovoj fazi za analizu različitih površina zrna i pora, i definisanje njihovih geometrijskih karakteristika nije dovoljno koristiti euklidsku geometriju. Zato se skoro uvek uključuje elektronska mikroskopija, koja omogućava posmatranje objekata sa nekoliko nivoa uvećanja. Najzastupljeniji u eksperimentalnim prosedurama u električnom i magnetnom smislu su $BaTiO_3$ i NZT ($Nd(Zn0.5Ti0.5)O_3$) materijali, dobijeni tokom standardnih metoda u kojima se odigravaju rekacije za dobijanje čvrstog stanja.

U ovim procesima je veoma bitno poznavanje morfologije keramičkih zrna, jer se realne međuzrnaste kontaktne površine, kao izrazito nepravilni oblici, mogu optisati na adekvatan način samo korišćenjem fraktalnih modela. Model intergranularnog kapaciteta omogućava izračunavanje veličine zrna određivanjem vrednosti fraktalne dimenzije korišćenjem fraktalne korekcije. Pri tome je naročito važna uloga dielektrične i magnetne konstante materijala, čije vrednosti je moguće korigovati na osnovu fraktalne prirode intergranularne morfologije, a koja dovodi do korekcije u

 ISBN 978-86-7466-930-3

Heyvangovom modelu i Curie – Veissovom zakonu.

Neka početna istraživanja inergranularnih kontakata $BaTiO_3$ keramike pokazuju da ona mogu imati jako veliki uticaj na električna i magnetna svojstva u celoj zapremini materijala. Intergranularni kontakti se formiraju tokom procesa sinterovanja. Tokom sinterovanja, dve čestice praha formiraju kontakt, dok međuatomske sile počinju da formiraju vrat čestice u kontaktnoj oblasti, što uzrokuje povećanje gustine materijala. Glabni mehanizam za povećanje gustine je smanjenje slobodne površinske energije sistema. U daljem procesu sinterovanja vrat počinje da raste. Kontrola tog procesa se vrši različitim difuzionim mehanizmima (rešetkasta difuzija, difuzija na granici zrna...), čije su brzine određene ukupnim fluksom atoma koji dolaze do vrata.

Karakterizacija datih procesa se može raditi simulacijom rasta vrata u vremenskom domenu, kombinovanjem rezultata za vrednosti kontaktnih površina sa kinetikom firmiranja tri ili više kontaktnih površina ili modelom tri ili više zrna, koji omogućavaju uspostavljanje ekvivalentnog modela klastera takvih zrna. To znači da se uzorak $BaTiO_3$ keramike može modelovati u električnom smislu kao impedansa koja sadrži dva kondenzatora, kalem i otpornik. Kako se uzorak keramike sastoji od velikog broja zrna organizovanih u klastere različitih veličina, moglo bi se pretpostaviti da svaki klaster, pa čak inergranularni kontakt unutar klastera, pokazuje slično ponašanje. Dominantni doprinos ekvivalentnoj impedansi u širokom grekventnom opsegu dolazi od kapacitivnosti, pa se svaki i ntergranularni kontakt može posmatrati kao intergranularni mikrokkondenzator. Na osnovu ovih razmatranja mogu biti formirani ekvivalentni električni modeli tri ili četiri klastera zrna, zasnovani na računarskom modeliranju i simulacijama [1-6].

IV. Zaključak

Primena fraktalne analize na fundamentalno kretanje virusa, bakterija, ali i atoma, molekula, klastera i elektrona u svim strukturama poznato kao Braunovo kretanje je jedna od osnovnih ideja koja bi povezal aživu i neživu prirodu. Ali, i sve oblasti inženjerskih nauka, sa posebnim osvrtom na fizičku elekotrniku, nauku o materijalima i savremenim materijalima u oblasti altrnativnih izvora energije i telekomunikacija je u povoju. POvezivanje nanotehnologija sa biomimetikom i korekcijom svih ostalih do sada poznatih fizičkih i hemijskih jardnačina klasičnim matematičkim aparatom bi trebalo korigovati uzimanjem u obziru parametara spoljašnje sredine i njihovog uticaja na ponašanje gradivnih elemenata živog i ili neživog mikrosveta.

Zahvalnica

Zahvalnost za otvaranje vrata za ulazak u oblast primene fraktalne analize u granama nauka koje su obuhvatile čitav spektar osnovnih, ali i preimenjenih nauka obuhvaćenih pojmom Nanotehnologije, sa strane svih potpisnika ovog rada upućena je profesoru doktoru Vojislavu Mitiću sa Elektronskog fakulteta u NIšu, koji je jednan od idejnih tvoraca ovog koncepta i sigurno čovek bez čije upornosti i istrajnosti, sagorevanja i vizije, mnogo toga ne bi bilo započeto.

Abstract

This paper provides an overview of new methods for collecting, processing and analyzing materials that are used or are in the research phase for use in modern devices for wide or specific, dedicated production. The development of biophysics, electrochemistry, progress in the production of alternative energy sources, biomolecules, but also all other fields of science, is briefly explained by the connection under nanotechnology, as an interdisciplinary science of the future and new mathematical methods and approaches that allow analysis of grains, pores and their interactions. The aim of obtained results is to connect the electrical, physical and chemical properties of materials with their output parameters (temperature, density, electrical and magnetic conductivity ...) and, accordingly, to reach new ones or introduce corrections to existing mathematical ones and physical theories and equations, in order to obtain as realistic and accurate results as possible for the characterization of the devices in which they are used. One of the elementary conditions for improving the characteristics of the material is the optimization of the sintering process and the electro-physical properties of the material, which is also analyzed in this paper.

Mikrostrukturna i dielktrična karakterizacija PLZT keramike

Vesna Paunović, *Member, IEEE*, Miloš Marjanović, *Member, IEEE,* Zoran Prijić, *Member, IEEE*

***Apstrakt* –PLZT keramika spada u jednu od veoma značajnih grupa funkcionalnih materijala koji čine osnovu za proizvodnju velikog broja elektronskih uređaja. Mikrostruktura i dielektrična svojstva keramike zavise od pripreme praha i uslova termičke obrade. PLZT prahovi, korišćeni u radu su pripremljeni na dva različita načina, modifikovanom Pechini metodom, primenom metode polimernog prekursora (PMM) i parcijalnom oksalatnom metodom (B). Proces sinterovanja, uključujući toplo presovanje, izveden je na 1100°C. Mikrostruktura i fazni sastav su istraživani SEM i EDS analizom, dok su promena dielektrične konstante i dielektričnih gubitaka merene u frekventnom opsegu od 1 kHz do 20 kHz, i u temperaturnom intervalu od 25 do 180°C. Kod ispitivanih uzoraka primećena je značajna razlika u mikrostrukturi i dielektričnim svojstvima u zavisnosti od porekla praha i postupka sinterovanja. Mikrostruktura PLZT(PMM) uzoraka, otkriva prisustvo tri različita regiona u uzorcima u pogledu oblika, veličine i sastava zrna. Keramika dobijena oksalatnim postupkom odlikuje se kuboidnim zrnima duž granice izduženih zrna kao i poliedarskim zrnima.**

Ključne reči – PLZT keramika, dielektrična konstanta, dielektrični gubici.

I. Uvod

PLZT keramika se zbog svojih piezoelektričnih i feroelektričnih svojstava široko koristi za niz aplikacija u električnim uređajima. U zavisnosti od koncentracije dopanta La i odnosa Zr/Ti, mogu se dobiti poboljšana piezoelektrična i poboljšana mehanička svojstva kao i poboljšana optička stabilnost keramike [1-4]. Osobine PLZT keramike su u korelaciji sa efektima na granici zrna, a samim tim i sa mikrostrukturom koja se razvija tokom procesa sinterovanja. Otuda je sinteza visoko čistog i ultrafinog praha, sa dobrom hemijskom stabilnošću, od prvenstvenog značaja za proizvodnju keramike specifičnog dizajna. PLZT keramika se tradicionalno dobija konvencionalnim postupkom sinterovanja koristeći čiste oksidne prahove kao polazne materijale. Ova metoda zahteva visoku temperaturu kalcinacije, a aglomeracija čestica praha doprinosi neujednačenoj mikrostrukturi keramike. Zbog toga su razvijeni novi niskotemperaturni prahovi na bazi neorganskog i/ili organometalnog prekursora u cilju dobijanja homogene i finozrnaste keramike [5-7]. Brojne tehnike za proizvodnju PLZT keramičkih prahova zasnivaju se na upotrebi alkoksida, acetata, citrata i oksalata rastvora La, Ti, Zr i Pb koje uključuju koprecipitaciju i sol gel proces. Najpoznatiji procesi su Pechini proces i oksalatni procesi koji omogućavaju preciznu stehiometriju materijala [7,8].

Takođe, za dobijanje keramičkog praha nano veličine koristi se mehanohemijska tehnika. Karakteristika ove tehnike je da se reakcija čvrstog stanja pojačava mehaničkom energijom umesto toplotnom energijom. Pokazalo se da se mehanički dobijeni prahovi bolje sinteruju od prahova dobijenih konvencionalnom reakcijom čvrstog stanja.

Svrha ovog istraživanja je uporedno ispitivanje mikrostrukturnih i dielektričnih svojstava PLZT keramike dobijene dvema različitim metodama pripreme praha. Praškovi su pripremljeni modifikovanom Pechini metodom i parcijalnim oksalatnim postupkom. Uticaj tehnike pripreme na dielektričnu konstantu i dielektrične gubitke keramike je ispitivan u frekventnom opsegu od 1 kHz do 20 kHz i temperaturnom intervalu od 25 do 180°C.

II. Eksperimentalni deo

Za pripremu PLZT keramičkih prahova su korišćene dve različite tehnike a) modifikovani Pechini proces, odnosno metod polimernog prekursora (PMM) i b) parcijalni oksalat metod (B).

U metodi polimernog prekursora organometalni kompleks se dobija počev od La, Ti, Zr-citrata i Pb-acetata, a nakon termičke obrade i kalcinacije prah se melje i presuje u pelete. Prekursor korišćen za pripremu PLZT praha parcijalnom oksalatnom metodom, sastojao se od rastvora Ti-Zr citrata, olova i lantan oksalata. Posle termičke obrade u tri koraka i kalcinacije, prah je takođe mleven i presovan u pelete. Jedna grupa peleta je sinterovana na 1100°C u trajanju od 2 sata konvencionalnim postupkom sinterovanja, a druga grupa peleta je toplo presovana na pritisku od 40 MPa a zatim sinterovana na istoj temperaturi u istom vremenskom intervalu. Da bi se smanjio gubitak PbO tokom sinterovanja, sinterovanje je vršeno u atmosferi kiseonika. Dijagrami toka dobijanja PLZT keramike PMM i B metodom dati su na slikama 1 i 2.

Mikrostruktura PLZT keramike, dobijene različitim poreklom praha i postupcima sinterovanja, ispitana je skenirajućim elektronskim mikroskopom, JSM 5300, JEOL, Japan, opremljenim EDS sistemom (Energy Dispersive

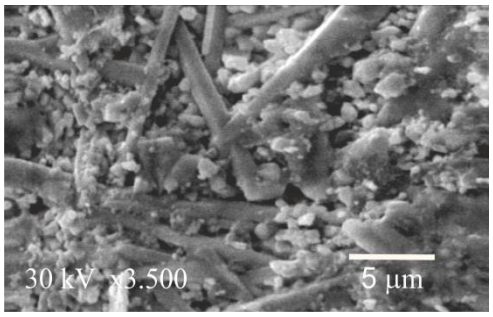
III. Rezultati i diskusija

A. *Mikrostrukturna svojstva*



PLZT keramika korišćena u ovom radu pripremljena je prema hemijskoj formuli $Pb_{0.905}La_{0.095}(Zr_{0.65}Ti_{0.35})_{0.976}O_3$ sa viškom PbO. Uloga viška PbO, koji podstiče sinterovanje u tečnoj fazi, je veoma važna u početnoj i srednjoj fazi sinterovanja. Isparavanje PbO u završnoj fazi sinterovanja je korisno za formiranje defekata rešetke koji pojačavaju difuziju atoma, pri čemu se povećava gustina uzoraka. Modifikovana Pechini tehnika, ima prednost zato što se kalcinacija prahova odvija na temperaturama nižim od onih koje se zahtevaju konvencionalnim metodama, pri čemu se na ovaj način postiže dobra stehiometrija prahova.

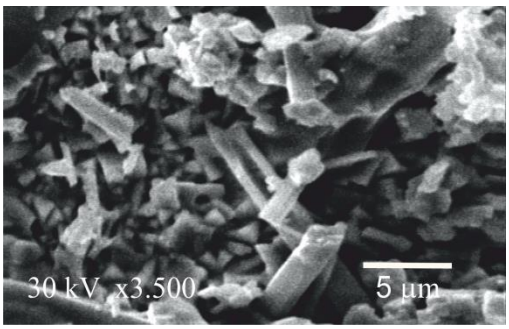
Za obe primenjene metode sinteze praha je karakteristično da se konačno formiranje faza završava nakon kalcinacije na temperaturi od 700°C, pri čemu dobijeni prahovi pokazuju prisustvo samo čiste PLZT faze. U svim sinterovanim uzorcima, bez obzira dali su dobijeni toplim presovanjem ili konvencionalnim sinterovanjem, postiže se visok stepen sinterovane gustine koja se kreće do 94% teorijske gustine.

Mikrostrukture PLZT keramike, dobijene od prahova pripremljenih metodom polimernih prekursora (PMM), i sinterovanih na 1100°C, prikazane su na slici 3. Zbog submikronske veličine čestica kao i prisustva visoke reaktivnosti praha, primećena je neujednačena mikrostruktura uzoraka, za oba postupka sinterovanja (toplo presovanje i konvencionalni postupak sinterovanja).

a)

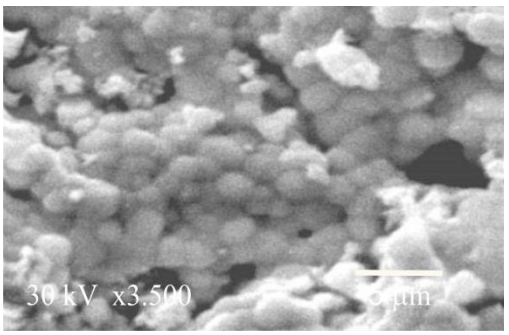
b)

Sl. 3 SEM mikrostruktura PLZT keramike dobijene Pechini metodom a) toplo presovana i b) konvencionalni postipak siterovanja.



U mikrostrukturi ovih uzoraka, razlikuju se tri različita regiona: prvi, sa nasumično orijentisanim izduženim zrnima koja imaju visok aspekt odnos širine i dužine, drugi sa tankim stubastim zrnima i treći region se uglavnom sastojao od svernih zrna. Mikrostruktura je pokazala da su početni prahovi

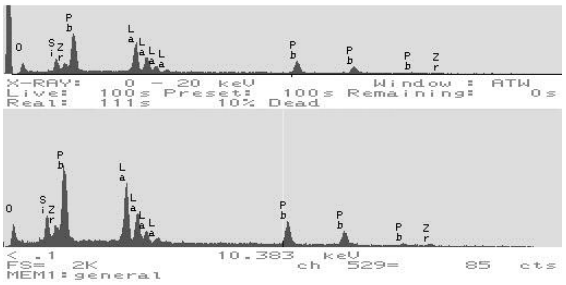
 ISBN 978-86-7466-930-3



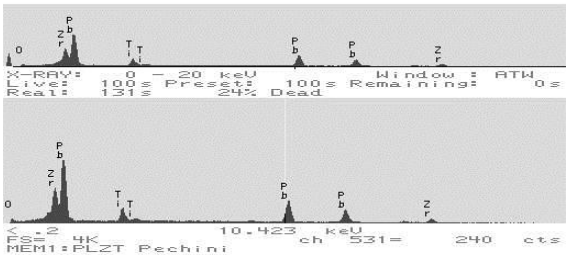
submikronske veličine čestica, pripremljeni Pechini postupkom, izazvali preterani rast zrna tokom sinterovanja. Veličina zrna kod uzoraka PLZT keramike dobijenih PMM metodom kretala se od 2-4 μm u sitnozrnim regionima do 10 μm kod izduženih zrna.

Mikrostruktura PLZT keramike dobijene parcijalnim oksalatnim postupkom se znatno razlikuje od one dobijene PMM metodom (sl.4). Mikrostruktura uzorka dobijenog oksalatnom metodom i toplim presovanjem otkriva prisustvo kuboidnih zrna duž granice izduženih zrna. Takođe su prisutna i zrna igličastog oblika i poliedarska zrna. Prosečna veličina kubičastih zrna je manja od 5 μm.

Mikrostruktura keramičkih uzoraka dobijenih oksalatnom metodom i konvencionalnim postupkom sinterovanja je ujednačena po celom uzorku, a veličina i oblik zrna su skoro identični (sl.4b). Zrna su sfernog oblika sa prosečnom veličinom oko 1-2 μm. Međutim, primećeno je prisustvo malih pora, manjih od 1μm, unutar i između zrna.



a)



b)

Sl. 4 SEM mikrostruktura PLZT keramike dobijene oksalatnim postupkom a) toplo presovana i b) konvencionalna metoda.

Neuniformnost mikrostrukture, posebno na ivici uzoraka, određena je EDS spektrima. Sastav dugih, izduženih zrna u uzorcima PLZT (PMM) i PLZT (B) je prilično različit. EDS spektar za PLZT (PMM) uzorak, ukazuje da su izdužena zrna, bogata Pb i La fazom (sl.5a). Odnos Pb/Zr u izduženim zrnima je relativno veći u poređenju sa drugim regionom. S obzirom na malu koncentraciju La, manju od 1 tež.%, La se ne može detektovati energetsko disperzivnom spektroskopijom osim ako nije prisutna nehomogena distribucija i segregacija La. Odgovarajući EDS spektar uzet iz regiona sa izduženim zrnima u PLZT (B) keramici (Sl.5b) jasno pokazuje prisustvo novoformiranih faza bogatih Pb i Zr sa tragovima La.

a)

b)

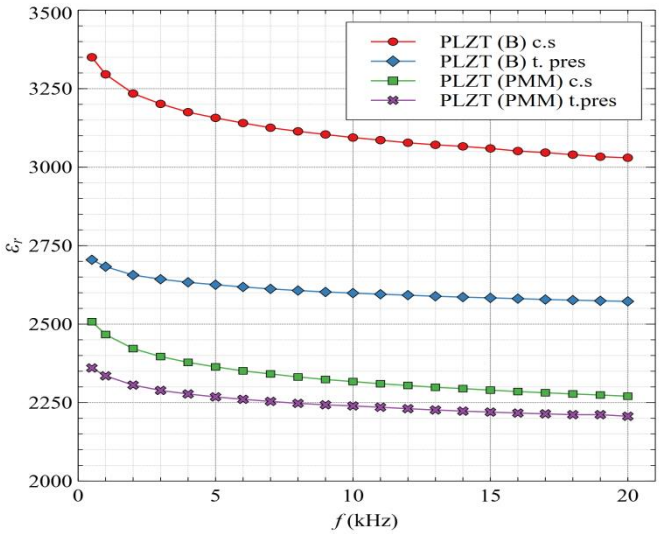
Sl.5 EDS spektar PLZT keramike dobijene a) Pechini metodom i b) oksalatnom metodom.

B. Električna svojstva

Uticaj načina pripreme praha i dobijene mikrostrukture na dielektrične osobine ispitivan je preko promene zavisnosti dielektrične konstante i tangensa ugla gubitaka od frekvencije i temperature.

Zavisnost dielektrične konstante PLZT keramike, dobijene različitim tehnikama, u funkciji frekvencije data je na slici 6.

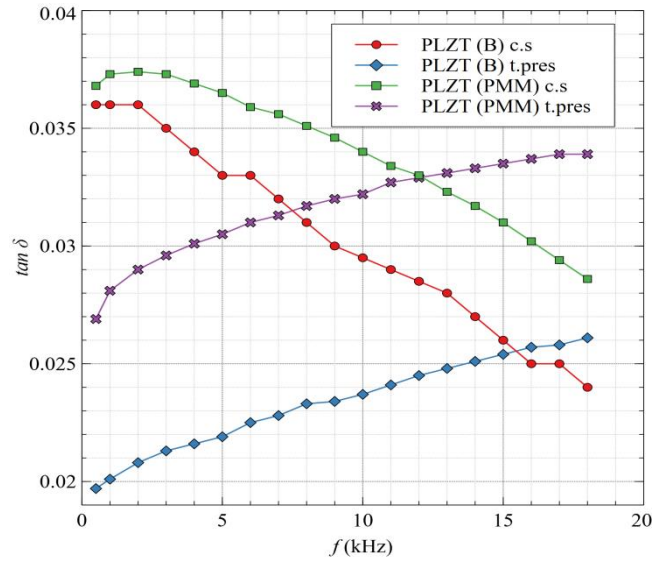
Frekventni opseg za sve ispitivane uzorke kretao se od 1 kHz do 20 kHz.



Za sve sinterovane uzorke je karakteristična visoka vrednost dielektrične konstante na nižim frekvencijama. Sa povećanjem frekvencije uočeno je sporo monotono smanjenje njene vrednosti do frekvencije od 10kHz, kad je promena postala skoro konstantna.

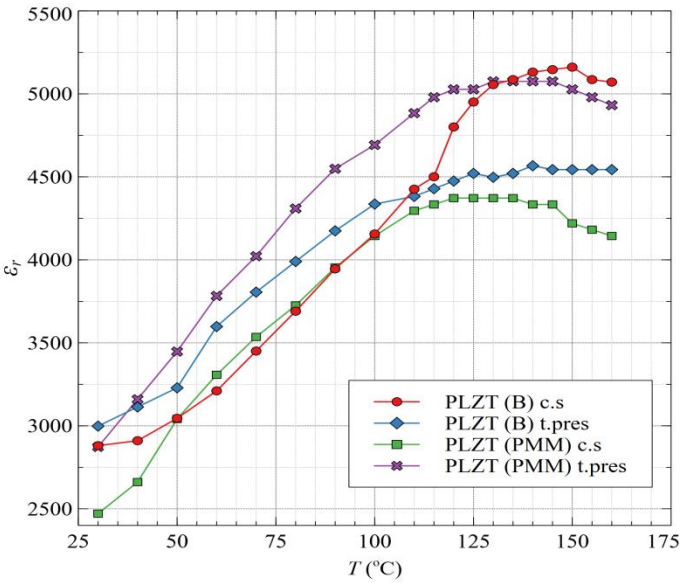
Takođe vrednost dielektrične konstante je veća u uzorcima dobijenim konvencionalnim postupkom sinterovanja (uzorci su označeni kao c.s) u poređenju sa toplo presovanim PLZT uzorcima.

Razlika u dielektričnim konstantama može biti direktno povezana sa varijacijama u mikrostrukturi, veličini i sastavu zrna.



Različita veličina i oblik zrna u toplo presovanoj keramici primećena u PLZT (PMM) i PLZT (B) doprinosi nižoj dielektričnoj permitivnosti. U uzorcima dobijenim konvencionalnim sinterovanjem karakteristična je uniformnija mikrostruktura što ima za posledicu više vrednosti dielektrične konstante i izraženiju promenu ε_r sa frekvencijom.

 ISBN 978-86-7466-930-3



Sl. 6. Zavisnost dielektrične konstante PLZT keramike od frekvencije.

Najviša vrednost dielektrične konstante na 1kHz, ε_r = 3400, je izmerena za PLZT keramiku dobijenu oksalatnim postupkom kovencionalnim sinterovanjem. Najnižu vrednost pokazuje PLZT (PMM) toplo presovana keramika (ε_r = 2400).

Sl. 7. Zavisnost *tan δ* od frekvencije za PLZT keramiku.

Na osnovu merenja dielektričnih gubitaka u frekventnom opsegu od 1 kHz do 20 kHz, prikazanih na slici 7, može se zaključiti da su dielektrični gubici za sve uzorke veoma mali i kreću se od 0.018 do 0.037. Najveća vrednost od 0.037 na 1kHz i značajna promena *tanδ* u odnosu na frekvenciju, od 0.037 do 0.023 na 20 kHz, pokazuju PLZT (B) uzorci dobijeni konvencionalnim sinterovanjem. Neuobičajena frekventna zavisnost *tanδ*, odnosno povećanje *tanδ* sa frekvencijom, primećena je u toplo presovanim PLZT uzorcima. Za razliku od dielektrične konstante, koja pokazuje male promene u frekventnom opsegu i postaje konstantna na frekvenciji većoj od 10 kHz, dielektrični gubici na sobnoj temperaturi uglavnom opadaju sa frekvencijom. Bez obzira na male razlike u *tanδ*, odgovor tangens gubitaka na kompozicionu i mikrostrukturnu uniformnost je osetljiviji i selektivniji u poređenju sa dielektričnom konstantom.

Sl. 8. Zavisnost dielektrične konstante PLZT keramike od temperature.

Uticaj načina pripreme praha i mikrostrukture na dielektrično ponašanje PLZT keramike može se proceniti pomoću krivih zavisnost dielektrične konstante od temperature. Promena dielektrične konstante sa temperaturom za PLZT keramiku prikazana je na sl.8. Za sve ispitivane uzorke karakterističan je porast dielektrične konstante. Maksimum dostižu na temperaturi od 130-140°C a zatim dolazi do smanjenja vrednosti ε_r. Za obe metode sinteze praha promene su izraženije kod uzoraka dobijenih konvencionalnim sinterovanjem. Najveća promena vrednosti dielektrične konstante (od 2800 do 5160) primećena je kod PLZT (B) uzoraka koji su dobijeni konvencionalnim postupkom za koje je karakteristična sitnozrna i uniformna mikrostruktura. To se može videti iz odnosa maksimalne vrednosti dielektrične konstante i dielektrične konstante na sobnoj temperaturi tj. $\varepsilon_{rmax}/\varepsilon_{rmin,}$ (Tabela I).
Vrednosti dielektrične konstante i dielektričnih gubitaka kao i odnos $\varepsilon_{rmax}/\varepsilon_{rmin}$ date su u tabeli I.

IV. ZAKLJUČAK

U radu su ispitivani efekti pripreme praha i postupka sinterovanja na mikrostrukturne karakteristike PLZT keramike dobijene modifikovanom Pechini metodom i parcijalnim oksalatnim postupkom. Mikrostruktura PLZT(PMM) uzoraka sinterovanih na 1100°C, otkriva prisustvo tri različita regiona u uzorcima u pogledu oblika, veličine i sastava zrna. Izdužena zrna sastoje se od faza bogatih Pb i La, a odnos Pb/Zr je relativno veći u poređenju sa drugim regionom u uzorku. Odgovarajući EDS spektar izduženih zrna u PLZT keramici, dobijenoj oksalatnim postupkom, otkriva prisustvo faza bogatih Pb i Zr sa tragom La. Mikrostruktura PLZT (B) uzoraka primenom konvencionalnog postupka sinterovanja bila je ujednačena u svim uzorcima, a veličina i oblik zrna su bili skoro identični. Dielektrična konstanta na sobnoj temperaturi svih ispitivanih uzoraka kreće se u rasponu od 2400 do 3400 i viša je kod uzoraka dobijenih konvencionalnim postupkom sinterovanja. Dielektrična konstanta ne varira sa frekvencijom iznad 10 kHz. Generalno, dielektrični gubici su veoma mali i kreću se u opsegu od 0.018 do 0.037 na 1 kHz. Frekventna osetljivost $tan\delta$ je otkrivena u svim ispitivanim uzorcima. Sporo povećanje tanδ sa frekvencijom se detektuje u toplo presovanim PLZT(Nb) i PLZT(B), u poređenju sa drugim uzorcima koji pokazuju smanjenje dielektričnih gubitaka sa frekvencijom. Najveću promenu ε_r sa temperaturom pokazuju PLZT (B) uzorci dobijeni konvencionalnim postupkom.

ZAHVALNICA

Ovaj rad je podržalo Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije (Ev. br. 451-03-68/2022-14/200102).

PLZT ceramics belongs to one of the very important groups of functional materials that form the basis for the production of a large number of electronic devices. The microstructure and dielectric properties of ceramics depend on the powder preparation and heat treatment conditions. PLZT powders used in this work were prepared in two different ways, modified by the Pechini method, using the polymer precursor method (PMM) and the partial oxalate method (B). The sintering process, including hot pressing, was performed at a temperature of 1100°C. The microstructure and phase composition were investigated by SEM and EDS analysis, while the change of dielectric constant and dielectric losses were measured in the frequency range from 1 kHz to 20 kHz, and in the temperature range from 25 to 180°C. A significant difference in microstructure and dielectric properties depending on the origin of the powder and the sintering process was observed in the tested samples. The microstructure of PLZT (PMM) samples reveals the presence of three different regions in the samples in terms of grain shape, size and composition. Ceramics obtained by the oxalate process are characterized by cuboid grains along the border of elongated grains as well as polyhedral grains.

Microstructural and dielectric characterization of PLZT ceramics

I. UVOD

Feroelektrici su materijali koji se tokom poslednjih decenija puno koriste i imaju veliki dijapazon primene. Barijum titanat ($BaTiO_3$) je jedan od najčešće ispitivanih perovskitnih materijala. Veliki broj elektronskih komponenata izrađen je na bazi $BaTiO_3$ keramike poput PTC termistora, piezoelektričnih senzora, višeslojnih kondenzatora, memorija itd. [1, 2]. Karakteristike feroelektrične keramike jako zavise od koncentracije i tipa primesa. Da li će $BaTiO_3$ keramika imati dielektrična ili poluprovodna svojstva zavisi od dopanata koji mogu zauzeti mesta Ba^{2+} ili Ti^{4+} jona u perovskitnoj strukturi [3, 4]. Mesto ugradnje zavisi od radijusa jona dopanata.

Donorske primese mogu biti trovalentni joni Sb koji zauzimaju mesta Ba^{2+} ili petovalentni joni Sb koji zauzimaju mesta Ti^{4+} jona. Rastvorljivost Sb u kristalnoj rešetki $BaTiO_3$ zavisi od koncentracije dopanata i temperature sinterovanja.

Temperatura sinterovanja utiče na mikrostrukturne karakteristike koje takođe određuju svojstva keramike. Za primenu dopirane $BaTiO_3$ keramike, kao kondenzatorskog materijala, treba ostvariti dobru gustinu, visoku vrednost dielektrične konstante i nizak faktor gubitaka. Za ostvarivanje ovakvih svojstava potrebna je uniformna mikrostruktura i dobra raspodela primesa i aditiva [5-8]. Jedna od najznačajnih osobina $BaTiO_3$ keramike je njena visoka vrednost dielektrične konstante (ε_r) na sobnoj temperaturi.

U ovom radu analiziran je uticaj koncentracije primesa i temperature sinterovanja na mikrostrukturna i električna svojstva Sb dopirane $BaTiO_3$ keramike. Skenirajućim elektronskim mikroskopom (SEM) vršeno je ispitivanje mikrostrukturnih karakteristika. Dielektrična konstanta i specifična električna otpornost uzoraka određene su u frekventnom intervalu od 100 Hz do 1 MHz.

II. EKSPERIMENTALNA PROCEDURA

U ovom radu proučavani su uzorci $BaTiO_3$ keramike dopirane sa 0,1, 0,5, 1,0, 2,0 i 5,0 at% Sb. Ispitivani uzorci dobijeni su metodom sinterovanja u čvrstoj fazi polazeći od čistih oksidnih prahova $BaTiO_3$ i Sb_2O_3. Nakon mešanja prahova u izopropil alkoholu, izvršeno je njihovo sušenje i presovanje u pelete pri pritisku od 120 MPa. Uzorci su zatim sinterovani u atmosferi vazduha na temperaturama 1290 °C, 1320 °C i 1350 °C.

Ispitivanje mikrostrukture obavljeno je SEM mikroskopijom, JEOL, SEM-5300. Nanošenje srebrne paste na uzorke izvršeno je pre merenja njihovih električnih karakteristika.

Za analiziranje promene dielektrične konstante (ε_r) i specifične električne otpornosti (ρ) sa frekvencijom, korišćene su vrednosti izmerenih kapacitivnosti i otpornosti uzoraka. Merenja ispitivanih uzoraka izvršena su u frekventnom opsegu od 100 Hz do 1 MHz korišćenjem LCR-metra Agilent 4284A [9].

III. REZULTATI I DISKUSIJA

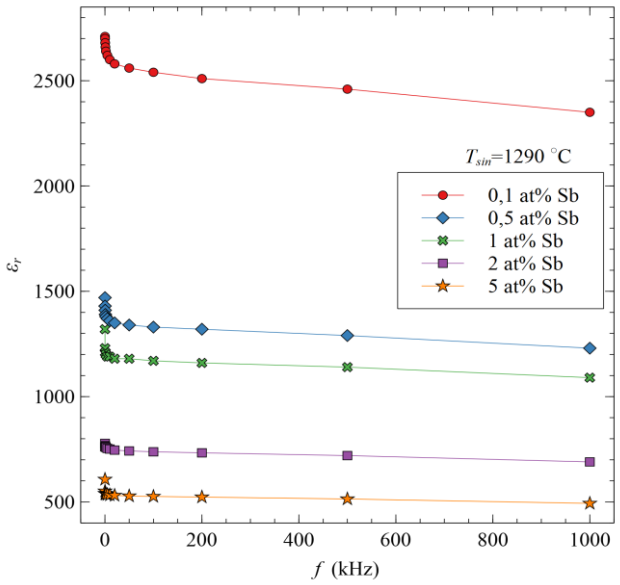
A. Mikrostrukturna ispiti anja

Relativna gustina uzoraka $BaTiO_3$ keramike dopirane sa Sb_2O_3 kretala se od 82 do 95% od teorijske gustine (TG). Sa povećanjem temperature sinterovanja raste gustina uzorka, međutim sa povećanjem koncentracije primesa dolazi do njenog smanjivanja.

Uzorke dopirane sa 0,1 i 0,5 at% Sb karakteriše homogena i sitnozrna mikrostruktura sa uniformnom raspodelom dopanata. Veličina zrna kretala se od 0,5 do 2,0 μm. Sa povećanjem tempearture raste i veličina zrna i ona se za uzorke sinterovane na 1350 °C kretala od 1,0 do 5,0 μm. Kod uzoraka dopiranih sa 5,0 at% Sb veličina zrna kretala se od 1,0 do 2,0 μm za uzorke sinterovane na 1290 °C, i od 1,0 do 4,0 μm za uzorke sinterovane na 1350 °C. Pri povećanju koncentracije primesa primećuje se smanjenje srednje veličine zrna (Sl. 1).

Sl. 1. SEM mikrostruktura Sb dopirane $BaTiO_3$ keramike a) 0,1 at% Sb i c) 5,0 at% Sb (T_{sin}=1290 °C) i b) 0,1 at% Sb i d) 5,0 at% Sb (T_{sin}=1350 °C).

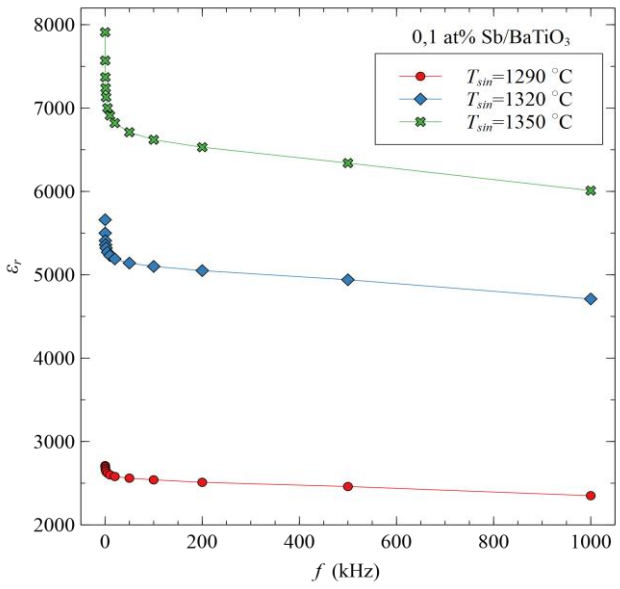
Za razliku od niže dopiranih uzoraka kod uzoraka sa 5,0 at% Sb primećena je mala segregacija Sb koja nije uticala na karakteristike dopirane keramike.



B. Električne karakteristike

S obzirom da su uzorci presovani u pelete debljine d, a na njih nanesena srebrna pasta poluprečnika r, za izmerene vrednosti kapacitivnosti C ispitivanih uzoraka, dielektrična konstatna ε_r je određena korišćenjem formule:

$$\varepsilon_r = C \cdot \frac{d}{\varepsilon_0 \cdot S} = C \cdot \frac{d}{\varepsilon_0 \cdot r^2 \pi}. \qquad (1)$$



Uticaj koncentracije primesa i mikrostrukture na vrednost dielektrične konstatne analiziran je na osnovu promene dielektrične konstatne sa frekvencijom.

Promena dielektrične konstante sa frekvencijom, uzoraka dopiranih različitim koncentracijama Sb pri temperaturi sinterovanja T_{sin}=1290 °C je prikazana na Sl. 2. Jasno se uočava da dielektrična konstanta merenih uzoraka opada ukoliko koncentracija primesa raste. Pri najnižoj koncentraciji primesa od 0,1 at% Sb zabeležena je najviša vrednost dielektrične konstante ε_r=2710, dok za najveću koncentraciju dopiranja od 5,0 at% Sb njena vrednost iznosi ε_r=607.

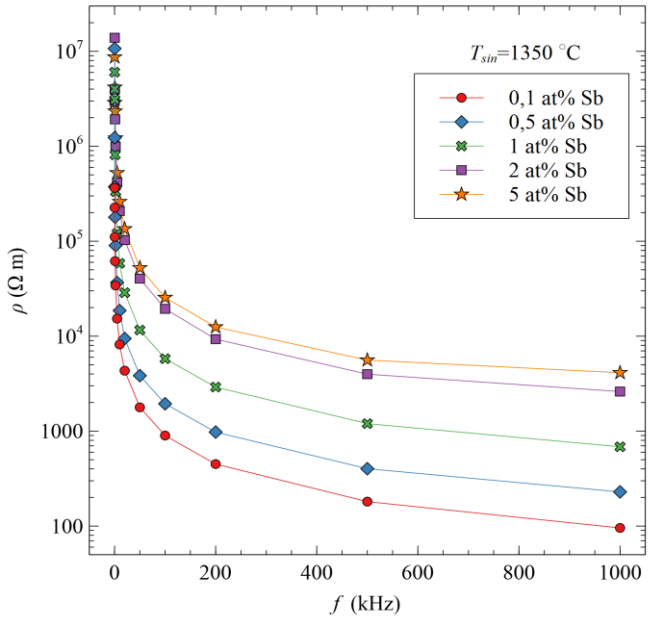
Sl. 2. Zavisnost dielektrične konstante od frekvencije Sb/$BaTiO_3$ uzoraka sinterovanih na temperaturi T_{sin}=1290 °C za različite koncentracije dopanata.

Takođe se primećuje da je vrednost dielektrične konstante viša pri nižim frekvencijama, ali sa porastom frekvencije opada i postaje skoro pa konstantna za frekvencije iznad 5 kHz.

Sl. 3. Zavisnost dielektrične konstante od frekvencije, uzoraka dopiranih sa 0,1 at% Sb za različite temperature sinterovanja.

 ISBN 978-86-7466-930-3

Analiziranjem uzoraka dopiranih istom koncentracijom primesa, ali sinterovanim pri različitim temperaturama, vidno je da pri porastu temperature sinterovanja raste i vrednost dielektrične konstante. Na Sl. 3 je prikazana zavisnost dielektrične konstante od frekvencije, uzoraka dopiranih sa 0,1 at% Sb i sinterovanih na tri različite temperature.

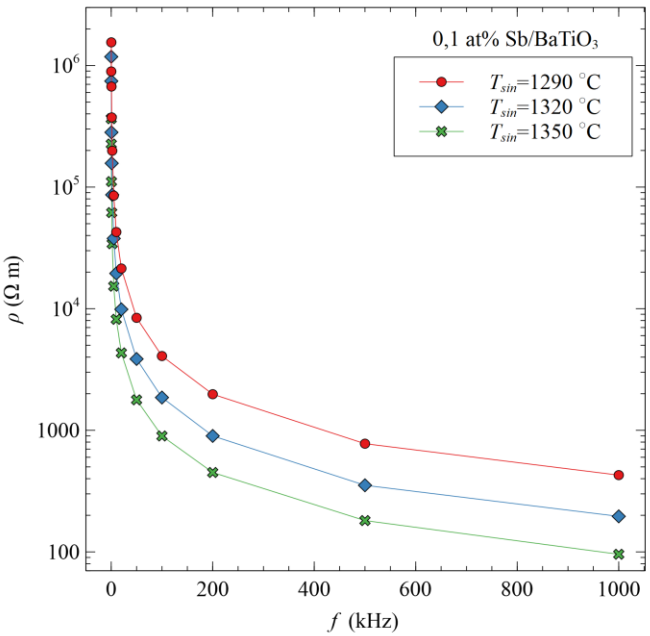


Za uzorak sinterovan na temperaturi T_{sin}=1290 °C, dielektrična konstanta ima najmanju vrednost i iznosi ε_r=2710, dok je pri najvišoj temperaturi sinterovanja njena vrednost maksimalna i iznosi ε_r=7910. Ove vrednosti dielektrične konstante su logične i očekivane, jer keramici sa najvećom gustinom i homogenom mikrostrukturom odgovara i najviša vrednost dielektrične konstante.

Sem zavisnosti dielektrične konstante od frekvencije, analizirana je i promena specifične električne otpornosti sa frekvencijom.

Već je navedeno da su uzorci presovani u pelete debljine d, a na njih nanesena srebrna pasta poluprečnika r, pa je za izmerene vrednosti otpornosti ispitivanih uzoraka, specifična električna otpornost ρ određena korišćenjem formule:

$$\rho = \cdot\frac{S}{l} = \cdot\frac{r^2\pi}{d}. \qquad (2)$$



Promena specifične otpornosti sa frekvencijom, kod uzoraka sinterovanih na istoj temperaturi, ali dopiranih različitim koncentracijama primesa, prikazana je na Sl. 4.

Sl. 4. Zavisnost specifične električne otpornosti od frekvencije Sb/$BaTiO_3$ uzoraka sinterovanih na temperaturi T_{sin}=1350 °C za različite koncentracije primesa.

Pri koncentraciji aditiva od 0,1 at% Sb, uzorak ima najnižu vrednost specifične otpornosti i ona iznosi ρ=3,65·10^5 Ωm, dok je za koncentraciju od 2,0 at% Sb zabeležena najviša vrednost specifične otpornosti ρ=1,39·10^7 Ωm. Očigledna je i tendencija opadanja specifične električne otpornosti sa povećanjem frekvencije, pa su samim tim najviše vrednosti ρ zabeležene pri nižim frekvencijama.

Ukoliko se posmatraju uzorci sa istom koncentracijom dopiranja ali sinterovani pri različitim temperaturama, uočava se da će sa porastom temperature sinterovanja specifična otpornost imati niže vrednosti (Sl. 5). Za uzorke dopirane sa 0,1 at% Sb, najviša vrednost specifične otpornosti zabeležena je kod uzorka sinterovanog na temperaturi od T_{sin}=1290 °C i iznosi ρ=1,55·10^6 Ωm, dok za T_{sin}=1350 °C uzorak ima najmanju vrednost specifične otpornosti ρ=3,65·10^5 Ωm. Primećuje se da specifična otpornost opada sa povećanjem frekvencije, ali na frekvencijama iznad 500 kHz postaje skoro konstantna.

Sl. 5. Zavisnost specifične električne otpornosti od frekvencije 0,1 at% Sb/$BaTiO_3$ uzoraka sinterovanih na različitim temperaturama.

Opseg vrednosti specifične električne otpornosti za sve ispitivane uzorke je od 10^5 do 10^7 Ωm. Ovi uzorci su dobri izolatori. Uzrok tome je sitnozrna mikrostruktura i velika površina granice zrna, što je naročito izraženo kod uzoraka sa većom koncentracijom aditiva, kod koje su izolaciona svojstva granice zrna uporediva sa veličinom zrna pa je i specifična otpornost kod njih veća.

IV. Zaključak

U ovom radu ispitivana je Sb_2O_3 dopirana $BaTiO_3$ keramika. Rezultati ispitivanja odnose se na mikrostrukturu i promenu dielektričnih karakteristika uzoraka. Uzorci sa manjom koncentracijom primesa imaju karakterističnu homogenu mikrostrukturu i veličinu zrna koja se kreće u opsegu od 0,5 do 2,0 μm, dok se za više koncentracije aditiva vrednosti veličine zrna kreću od 1,0 do 4,0 μm.

 ISBN 978-86-7466-930-3

Najviša vrednost dielektrične konstante, na sobnoj temperaturi, zabeležena je za najnižu koncentraciju primesa. Uočava se i da sa porastom frekvencije vrednost dielektrične konstante opada. Sa povećanjem temperature sinterovanja dielektrična konstanta uzoraka takođe raste tako da je najviša vrednost izmerena za uzorke sinterovane na 1350 °C.

Što se tiče specifične električne otpornosti, ona opada sa povećanjem temperature sinterovanja, pa se najviša vrednost beleži pri najnižoj temperaturi od 1290 °C. Najniža vrednost specifične otpornosti, pri istoj temperaturi sinterovanja, odgovara uzorku sa najnižom koncentracijom primesa.

ABSTRACT

In this paper, the microstructural and dielectric characteristics of $BaTiO_3$ ceramics doped with antimony ($Sb/BaTiO_3$) were investigated. Dopanate concentrations, Sb, ranged from 0.1 to 5.0 at%. The conventional solid-phase sintering method for 2 h at temperatures of 1290 °C, 1320 °C and 1350 °C was used to obtain samples.

SEM analysis of $Sb/BaTiO_3$ doped ceramics showed that for samples doped with a lower concentration of additives (0.1 and 0.5 at%) is characteristic fine-grained and uniform microstructure with grain size from 0.5 μm to 2.0 μm. In samples doped with a higher concentration of additives (1.0 and 5.0 at%), the characteristic grain size ranged from 1.0 μm to 4.0 μm.

Measurement of electrical characteristics was performed at room temperature in the frequency range from 100 Hz to 1 MHz. In the sample doped with 0.1 at% Sb and sintered at 1290 °C, the highest value of the dielectric constant ε_r=2710 was measured in relation to the samples doped with higher impurity concentrations. The sample doped with the same concentration (0.1 at% Sb), but sintered at a temperature of 1350 °C, has a higher value of the dielectric constant of ε_r=7910.

In addition to the dependence of the dielectric constant on frequency, the change in specific electrical resistance with frequency was also analyzed. Samples sintered at the highest temperature have the lowest value of specific resistance, and with increasing frequency, it decreases. At the same sintering temperature, and with increasing impurity concentration, the resistance increases.

lectrical characteristics of antimony doped aTi ceramics

Осетљивост магнетоимпедансног елемента CoFeSiB аморфне жице

Јелена Орељ, Небојша Митровић

Апстракт—У овом раду је презентовано испитивање осетљивости магнетоимпедансног (МИ) елемента код жице аморфне легуре CoFeSiB у опсегу фреквенција 2 M ÷ 5 M ma ≈ 4 3 A m . При 1 M , МИ-однос је 45 , док је при вишим фреквенцијама евидентиран максимум криве ΔZ Z који одговара пољу магнетне анизотропије k. Повећање радних фреквенција праћено је порастом поља магнетне анизотропије k чиме се повећава и мерни опсег магнетног сензора базираног на примени испитиваног МИ елемента. Истовремено је евидентирана и промена осетљивости МИ елемента која при 4 M и 5 M достиже највеће вредности од око 0,4 % / A m.

Кључне речи—МИ ефекат, е аморфна жица, МИ елемент, осетљивост МИ елемента

I. Увод

ПОСТИЗАЊЕ оптималних функционалних карактеристика електричних уређаја израђених од феромагнетних легура је могуће тек након детаљног истраживања електричних и магнетних својстава материјала. Један од најинтересантнијих феномена који се може искористити за магнетне сензоре је магнетоимпедансни (МИ) ефекат уочен код аморфних или нанокристалних магнетно меких трака, жица или танких филмовима. Овај ефекат, примећен најпре код аморфних FeCoSiB жица [1], омогућио је интензиван развој сензора на бази МИ-елемената, који су данас у широкој примени код електронских компаса, ГПС навигација, сензора ротације, система безбедности, биомагнетних мерења и др.

У сензорској употреби су углавном две геометријске форме: цилиндрична (жице [2-4]) и планарна (траке, филмови [5-7]). Аморфне жице се могу користити у верзији са заштитним стакленим омотачем [8] или без омотача [9]. Високе вредности магнетне пермеабилности су неопходно својство при избору материјала за МИ елементе, те су легуре на бази кобалта са тог становишта у предности у односу на легуре на бази гвожђа. За разлику од легура на бази кобалта које имају изванредне магнетно-меке перформансе са потпуно аморфном структуром, легуре на бази гвожђа постижу своје одличне карактеристике након оптималних термомагнетних или термомеханичких третмана (током којих се формира нанокристална структура дистрибуирана у аморфној матрици).

Релативна промена импедансе ΔZ/Z у одговарајућем фреквентном опсегу може достићи и више стотина процената (*енг.* **G**iant agneto **I**mpedance (GMI) effect - велики МИ ефекат): 506 % CoFeNiMoBSi @ 8 kA/m [10], 1200 % CoFeBSi @ 15 kA/m [11], што аморфним жицама ових легура омогућава широке могућности примене [12-13].

МИ ефекат је директно повезан са феноменом скин ефекта код феромагнетних материјала. Наиме, порекло магнетоимпедансног ефекта везано је за промене у динамици процеса магнетизације. Те промене утичу на магнетну пермеабилност, а самим тим и на дубину продирања наизменичне струје кроз магнетни проводник са повећањем фреквенције [14]. Познато је да добри проводници са великом пермеабилношћу показују велики МИ ефекат. Поред тога, за наизменичну побуду високе фреквенције (реда од 1 MHz до 1 GHz) модификација дубине продирања (скин ефекта) и магнетне пермеабилности има јаку зависност од фреквенције примењене побуде, као и од спољашњег статичког магнетног поља. Услед вихорних струја ток наелектрисања је потиснут ка површини узорка, што доводи до повећања импедансе, док се примењеним магнетним пољем то потискивање модулише, односно мења се ефективна површина попречног пресека кроз коју протиче наелектрисање – струја, при одређеној константној фреквенцији побуде. Дакле, велика пермеабилност и висока фреквенција смањују дубину продирања, док се примењеним пољем она повећава.

На дубини продирања δ_m

$$\delta_m = \sqrt{\frac{\rho}{\pi \cdot \mu \cdot f}} \qquad (1),$$

код магнетно меких материјала са ниским вредностима специфичне електричне отпорности $\boldsymbol{\rho}$, високим вредностима магнетне пермеабилности $\boldsymbol{\mu}$ а при релативно високим фреквенцијама , амплитуда вектора густине струје опадне на 1/e своје вредности уз површину узорка [15]. Промене и осталих напред наведених физичких својстава ($\boldsymbol{\rho}$, $\boldsymbol{\mu}$) ће резултовати у изменама расподеле тока наелектрисања по попречном пресеку жице и утицати на измену импедансе. Фреквенција при којој дубина продирања постаје мања од полупречника жице (δ_m < a) се назива критична фреквенција [16, 17], тако да се при даљем повећању учестаности запажају феномени МИ-ефекта.

Промена импедансе показује временски зависну природу простирања магнетног поља у проводнику одговарајуће магнетне пермеабилности, на чему су засноване могућности детекције магнетног поља ниског интензитета. Осетљивости великог МИ ефекта у аморфним жицама [18], тракама [19] и вишеслојним филмовима [20] на релативно вишим фреквенцијама (f > 1 MHz) могу достићи изузетно високе вредности, од чак неколико стотина % / Oe (1 Oe = $10^3/4\pi$ A/m).

 ISBN 978-86-7466-930-3

Велика осетљивост комплексне импедансе аморфне жице, , на примењено dc магнетно поље, ***ext***, кључна је за развој бројних магнетних сензора високих перформанси. Високе вредности осетљивости оваквих сензора се захтевају у многим инжењерским и индустријским применама.

На слици 1. је приказана принципијелна шема мерења магнетоимпедансе аморфне жице у спољашњем dc магнетном пољу генерисаном системом 1Д-Хелмхолцових калемова.

Сл. 1. Шема експеримента мерења магнетоипедансе аморфне жице.

Спољашње лонгитудинално dc магнетно поље ***ext*** и циркуларно ac магнетно поље ***ac*** (индуковано протоком наизменичне струје $_{ac}(t)=I_{cc}\cdot\sin(2\pi f\cdot t)$) утичу на промену магнетне пермабилности $\boldsymbol{\mu}$, тако да је импеданса феромагнетног проводника функција три експериментална параметра = (*f*, ***ext***, $\boldsymbol{I_{cc}}$).

Импеданса је количник тренутних вредности наизменичног напона $\mathcal{V}_{ac}$ и наизменичне струје $_{ac}$, а код узорка цилиндричног проводника полупречника ***a*** [21]:

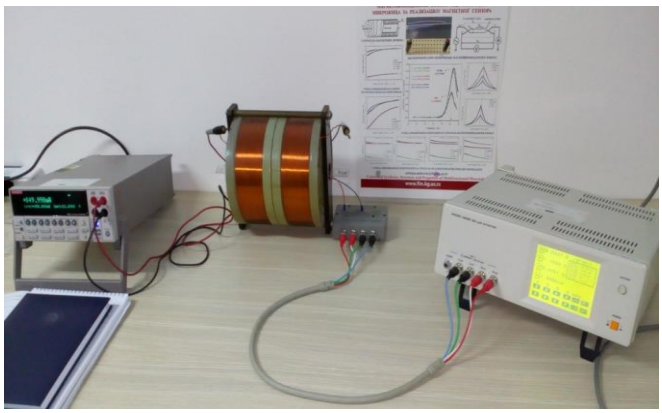
$$Z = \quad + j \quad = \frac{1}{2}\cdot \quad _{dc}\cdot(ka)\cdot\frac{_0(ka)}{_1(ka)} \qquad (2),$$

где су ***dc*** електрични отпор; и реални и имагинарни део импедансе и Беселове функције нултог и првог реда прве врсте, = (1+)/$\boldsymbol{\delta_m}$; ^{2} = -1.

Магнето–импедансни однос се углавном дефинише као релативна промена импедансе узорка са променом спољашњег dc магнетног поља (***ext***):

$$\Delta Z/Z\ (\%) = 100\ \% \times \quad Z \quad - Z \quad _{max} \quad Z \quad _{max} \qquad (3),$$

где је ***max*** импеданса при максималном магнетном пољу. Узорак се најчешће позиционира лонгитудално (у правцу магнетног поља), тј. у центру система 1Д-Хелмхолцових калемова где је постигнута скоро потпуна хомогеност магнетног поља. Ради анализе могућности примене спроводи се прорачун тзв. сопствене осетљивости МИ-елемента η који је дефинисан једначином [22, 23]:



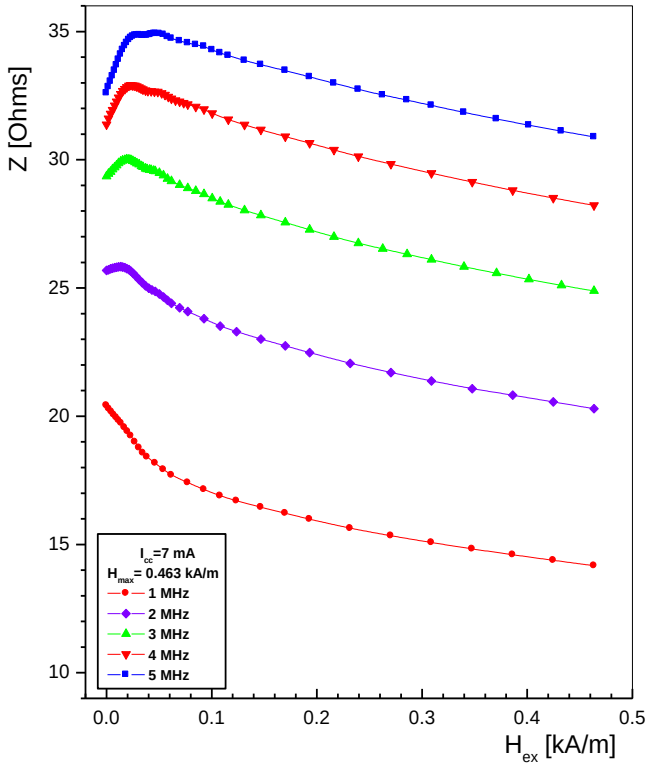
$$\eta = (\partial\,(\Delta Z/Z) / \partial\, H_{ext}) \qquad (4).$$

У овом раду су приказана високофреквентна истраживања f ∈ [1 MHz, 5 MHz] осетљивости МИ-елемента аморфне жице легуре CoFeSiB пречника око 100 μm с циљем процене атрактивности њене примене у сензорици. Ранија истраживања су показала да појава МИ-ефекта започиње на око 5 kHz, а регистровани МИ-однос износи чак 344 % при радној фреквенцији од 950 kHz (@ H_{max}=7,72 kA/m) [24]).

II. Експериментални део

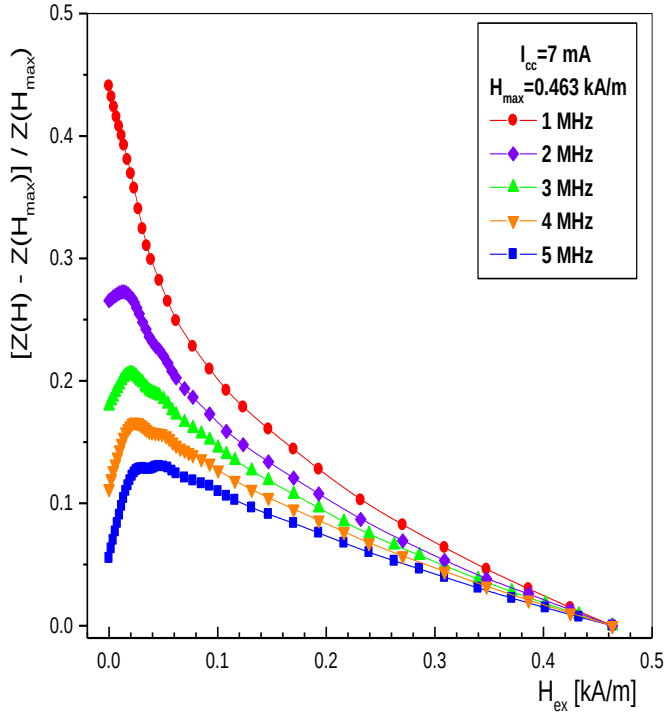
Предмет истраживања је МИ-елемент од CoFeSiB аморфне жице пречника од 100 μm, добијене технологијом брзог хлађења растопа у ротирајућем слоју воде на унутрашњој површини ротирајућег диска (in rotating water melt-spinning [25, 26]).

Мерење магнетоимпедансе је изведено у хомогеном магнетом пољу генерисаном помоћу 1Д-Хелмхоцових калемова при лонгитудиналној оријентацији МИ-елемента. Импеданса испитиваних узорака жица дужине 17 mm, мерена је по методи четири тачке помоћу инструмента LCR Hi-TESTER HIOKI 3532-50, у фреквентном опсегу од 1 MHz до 5 MHz. Током наших експеримената амплитуда струје I_{cc} је одржавана константном и износила је 7 mA тако да је интензитет циркуларног ac магнетног поља h_{ac} на површини узорка аморфне CoFeBSi жице пречника 2a = 100 μm достигао вредност $H_{ac}=I_{cc}/2\pi a=22.3$ A/m. На слици 2. је приказана експериментална поставка мерења магнетоимпедансе узорака жица у систему 1Д-Хелмхоцових калемова.



Сл. 2. Експериментална поставка мерења магнетоимпедансе по методи четири тачке
C i-TESTE I I 3532-50, f ∈ 1 M , 5 M .

III. Резултати и дискусија

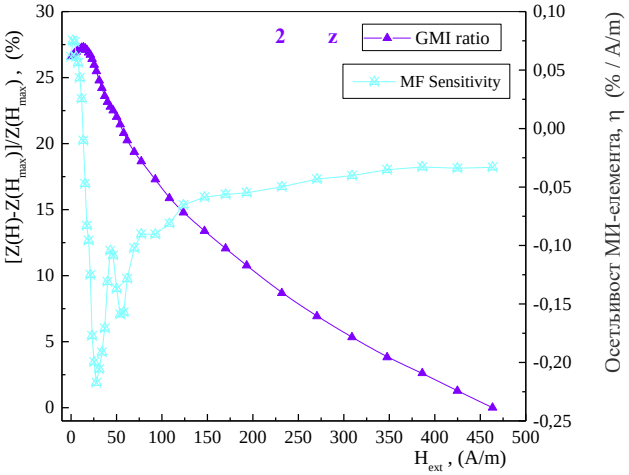


На слици 3. је приказана промена импедансе Z услед примене спољашњег магнетног поља (@ $H_{max}\approx 463$ A/m) при различитим вредностима фреквенције f ∈ [1 MHz, 5 MHz]. Облик зависности импедансе од спољашњег једносмерног магнетног поља *Z e*) се значајно мења, па се из облика криве са константним смањењем импедансе на 1 MHz, при даљем повећању фреквенције региструје максимум који одговара пољу магнетне анизотропије H_k. Уочљив је и померај позиције максималне вредности импедансе при повећању фреквенције, тј. повећање поља магнетне анизотропије H_k. Ово померање максимума импедансе при повећању фреквенције ка вишим вредностима магнетног поља је резултат доминантног учешћа механизма ротације вектора магнетизације током процеса циркуларног магнећења жице (кретање зидова магнетних домена је блокирано) [27]. Порастом поља магнетне анизотропије H_k се повећава и мерни опсег магнетног сензора базираног на примени испитиваног МИ елемента.

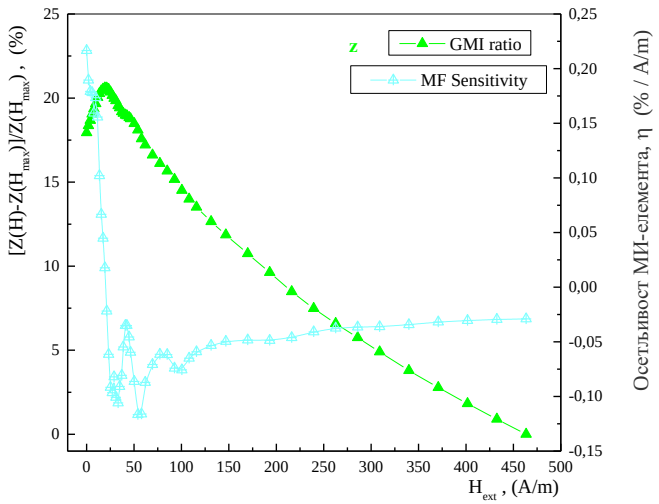
 ISBN 978-86-7466-930-3

Сл. 3 Промене импедансе Z од спољашњег dc магнетног поља H_e при повећању фреквенције f ∈ 1 M , 5 M H_{ma} ≈ 4 3 A m .

На слици 4. је приказана зависност МИ-односа услед примене спољашњег магнетног поља (@ $H_{max} \approx 463$ A/m) при различитим вредностима радне фреквенције $f \in [1\,\text{MHz},\ 5\,\text{MHz}]$.



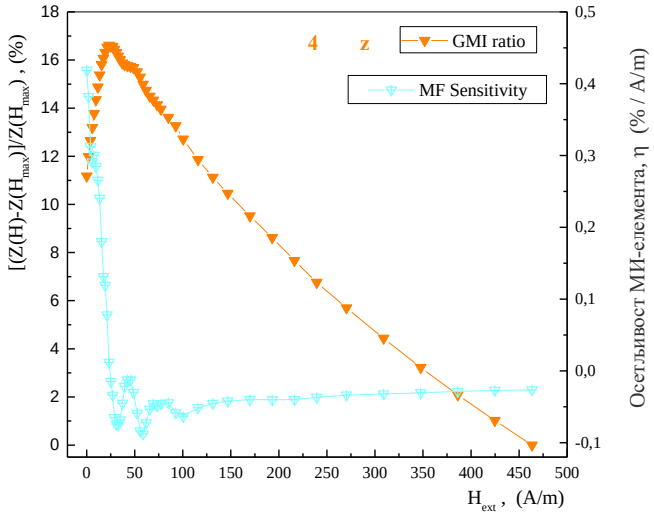
Сл. 4. Зависност МИ-односа од спољашњег dc магнетног поља H_e при фреквенцијама f ∈ 1 M , 5 M H_{ma} ≈ 4 3 A m .



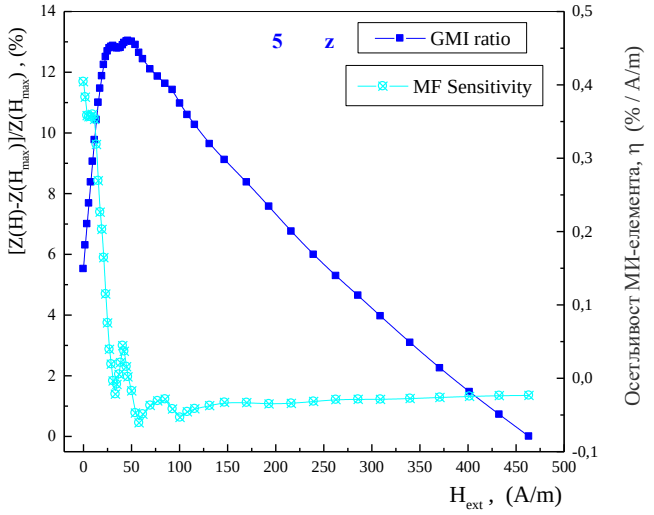
Највеће вредности МИ-односа су регистроване на фреквенцији од 1 MHz (око 45 % при $H_{ex} = 0$), док се при даљем повећању фреквенције уочава константно смањење МИ-односа.

На сликама 5-8. паралелно су приказане зависности МИ-односа ΔZ/Z и сопствене осетљивости МИ-елемента η (једначина (4)) од спољашњег dc магнетног поља H_{ext} (@ $H_{max} \approx 463$ A/m) при радним фреквенцијама f ∈ [2 MHz, 5 MHz]. Евидентирано је константно повећање осетљивости при порасту радне фреквенције. На фреквенцији од 2 MHz осетљивост је најнижа и износи око 0,07 % / A/m док при највећим испитиваним фреквенцијама од 4 MHz и 5 MHz достиже вредности од око 0,4 % / A/m.

При анализи приказаних резултата потребно је нагласити да су овде приказане осетљивости појединачног сензорског МИ-елемента, док је коначна осетљивост самог МИ-сензора дефинисана одабраним електричним колом при изради магнетног сензора (Колпицов осцилатор [28], CMOS IC мултивибратор [29, 30] са резолуцијом мерења магнетне индукције од око 1 pT).



Сл. 5. Упоредни приказ зависности МИ-односа и осетљивости МИ-елемента од спољашњег dc магнетног поља H_e H_t при фреквенцији f 2 M H_{ma} ≈ 4 3 A m .



Сл. . Упоредни приказ зависности МИ-односа и осетљивости МИ-елемента од спољашњег dc магнетног поља H_e H_t при фреквенцији f 3 M H_{ma} ≈ 4 3 A m .

 ISBN 978-86-7466-930-3

Сл. . Упоредни приказ зависности МИ-односа и осетљивости МИ-елемента од спољашњег dc магнетног поља e t при фреквенцији f 4 M ma ≈4 3A m .

Сл. . Упоредни приказ зависности МИ-односа и осетљивости МИ-елемента од спољашњег dc магнетног поља e t при фреквенцији f 5 M ma ≈4 3A m .

IV. Закључак

Испитивања МИ-ефекта код аморфне жице легуре CoFeSiB у фреквентном опсегу f ∈ [1 MHz, 5 MHz] показују константно повећање импедансе узорка жице. Прорачун МИ-односа је показао да се највеће вредности добијају при фреквенцији од 1 MHz (ma ≈4 3A m је око 45 %), а затим се МИ-однос смањује. При фреквенцијама изнад 1 MHz је регистрован максимум импедансе који одговара пољу магнетне анизотропије H_k. Повећање поља магнетне анизотропије H_k при повећању фреквенције је резултат доминантног учешћа механизма ротације вектора магнетизације током процеса магнећења. Пораст фреквенције праћен је и повећањем осетљивости МИ-елемента, које при фреквенцијама од 4 MHz и 5 MHz достижу вредности од око 0,4 % / A/m.

ABSTRACT

This paper presents an examination of magnetoimpedance MI-effect sensitivity of CoFeSiB wires in the frequency range of 2 MHz ÷ 5 MHz. An MI-ratio with a maximum of about 45 % was obtained at 1 MHz @ $H_{max} \approx 463$ A/m. The increase in operating frequencies is followed by an increase of magnetic anisotropy field H_k. The highest sensitivity values of the MI-element of about 0.4 % / A/m were attained at frequencies of 4 MHz and 5 MHz. Consequently, the investigated CoFeSiB wires are perspective as magnetic field sensing MI-elements.

The stability and Quality Control of Instruments for Measurement of Ambient Dose Equivalent Rate

Jelena Krneta Nikolić*, Marija Janković, Milica Rajačić, Ivana Vukanac, Dragana Todorović and Nataša Sarap

***Abstract* — Dosimeters for ambient dose equivalent rate monitoring used in Radiation and Environmental Protection Department in the Institute for Nuclear Sciences Vinča, are made inhouse and they are readily exploited in the field work. Due to this and due to the nature of the measurement itself, quality control of these instruments is readily performed, at least 2 times per year. The control is performed using a ^{60}Co closed point source with the original protective lead casing and an absorber placed over it in order to mimic the real measurement dose levels. Mean value of the ratio of the first 10 consecutive measurements and the activity of the source on the day of the measurement is declared as a baseline value, while the standard deviation of these 10 values was used to establish the limits of acceptance. According to the analysis of the first two years of the quality control, it can be concluded that all three types of instruments show satisfactory stability.**

***Index Terms* — ambient dose equivalent rate monitors; quality control; measurement stability; dosimetry**

I. Introduction

Measurement of ambient dose equivalent rate is a measurement method readily used in Radiation and Environmental Protection Department in the Institute for Nuclear Sciences Vinča. This method is accredited with the Accreditation Body of Republic of Serbia under the Standard 17025/2017 [1]. In that sense, it has to comply with the Quality control management system of the Department. Quality control should be planned activity, described in the quality control documentation, performed in a systematic manner, recorded and reviewed. Planning should identify and define type and frequency of quality control, acceptance limits, actions if those limits are exceeded and periodic review of results.

Dosimeters for ambient dose equivalent rate monitoring used in Radiation and Environmental Protection Department in the Institute for Nuclear Sciences Vinča, are made inhouse and they are readily exploited in the field work. Due to this and due to the nature of the measurement itself, it is decided that the quality controll has to be performed at least 2 times per year. As a result of these periodic quality controll measurements, Shewhart control charts, which span over a period of 2 years from mid 2020 to mid 2022, are revised in terms of the stabiity of the instruments' performance. In this paper, the analysis of these Shewhart control charts is presented for 3 types of dosimeters used in Radiation and Environmental Protection Department.

II. Main Results and Discussion

In the Radiation and Environmental Protection Department of the Institute for Nuclear Sciences Vinča, following types of instruments are readily used and controlled: MOKO-100, RMK 10/RMK-10P and RADEX RDI (total of 10 instruments).

Many of investigated ambient monitors have indication directly in Sv/h, but other instruments have indication in counts per second (cps) and the values in terms of ambient dose equivalent need to be calculated based on the calibration [2]. Also the ones that have an indication in μSvh-1 have to be calibrated and the calibration coefficient established. The calibration is performed in the Secondary Standards Calibration Laboratory in the Radiation and Environmental Protection Department by using the sources with the defined radiation quality, angle of incidence and dose rate. Calibration coefficient is then defined as the ratio of the refrence value and the indication of the instrument. The calibration coefficient with the appropriate measurement uncertainty is stated in a Calibration certificate [3,4].

The quality controll of the instruments is performed every 3 – 6 months, depndent on the availability of the instrument at each particular moment.

The controll is perfomend using a ^{60}Co closed point source, product number 9031-OL-591/09 with activity of 732.9 kBq on 01.08.2011, produced by Czech Metrology Institute. The source was kept in the original protective lead casing and an absorber was placed over it. Absorber is a 12 high cylinder made of polystyrene, which provides that the

 ISBN 978-86-7466-930-3

dose rate originating from the source is not too high. This source and setup were chosen because the dose rate corresponds to the conditions occurring in routine dosimetry measurements. The measurement method was validated by comparing the results of a measurement of the same ^{60}Co closed point source using investigated instruments and other types of instrument that are already in the Quality Management System.

For establishing the baseline, a set of 10 consecutive measurements was performed with each investigated instrument. Since the quality control measurements should be performed over a long period of time, it has to be taken into account that the activity of the source will decrease. Logically, the measured values will decrease also. This is why it was chosen that, instead of a direct result obtained by the instrument, a ratio between the measurement result and the activity of the source on the date of measurement should be used as a value to be regarded.

Mean value of the ratio of the first 10 measurements and the activity of the source on the day of the measurement is declared as a baseline value, while the standard deviation of these 10 values was used to establish the limits of acceptance. As it is usual, the limits of acceptance were set on ±2σ, the warning interval was set to be between ±2σ and ±3σ, while the results that exceed the limits of ±3σ should be regarded as not satisfactory.

A. Results and Discussion

The quality control of the instruments was perfomed 6 times for most of the instruments in the period from mid 2020 to mid 2022. The procedure included performing of 5 consecutive measurements, applying the calibration factor to the mean value and calcuating the ratio between the mean value of 5 measured ambient dose equivalent dose rates and the activity of the source at the day of the measurement. For each instrument, a Shewhart control chart was made and the stability of the measurement results in time was followed. In Table 1, the range of quality control measurement for all instruments is presented along with the baseline ratio expressed in %. As it was said before, the baseline value was obtained by performing 10 consecutive measurements at the beginning of the quality control period.

As it can be seen from the Table 1, all instruments showed results that do not differ significantly from the baseline. In all Shewart charts, the limit of ±2σ was not exceeded. Since the measurement uncertainty of the results obrtained by the ambient dose equivalent rate monitors can be up to 30% [3, 5], the ranges can be considered as a relatively narrow. The difference between the maximum and minimum ratio obtained during the quality control measurements was below 15% for all controlled monitors. This means that the limits of acceptance for the stability and reproducibility of the measurements are more strict than the measurement uncertainty of any single measurement, showing the satisfactory stability of the repeated quality control measurements.

TABLE I
RANGE AND OF THE OBTAINED MEASURED DOSE [μSVH-1]/ SOURCE CTIVITY [BQ] AND BASELINE - MEAN VALUE OF FOR THE FIRST 10 MEASUREMENTS

Instrument	**Range Measured dose/source activity [%]**	**Mean value of Measured dose/source activity ratio for the first 10 measurements [%]**

RADEX RDI1706 s/No. 0711259A711570	0.943-1.028	0.98

Figures 1, 2 and 3 show unified Shewards charts for the three different types of ambient dose equivalent rate monitors. In order to present different instruments on the same chart, the baseline was established as the mean value of all single baselines of each instrument. The limits were established using the standard deviation of the baselines of individual instruments. In this way, the limits of acceptance have become even more narrow, giving the very strict criterion for the stability of measurements. Here we can observe the behaviour of different types of monitors. All tree types showed satisfactory stability of the ambient dose equivalent rate/source activity ratio, since in no case was the limit of ±2σ exceeded. RMK type of monitors showed the gratest stability of the measurement while MOKO 100 and RADEX showed wider spread of the results. This however does not mean that there is an advantage of one type of instrument over the other, since the period of the quality control, as well as the number of performed measurements is not equal for all types and not large enough for more in depth analysis. Also, for MOKO 100 instrumets, the limits of acceptance are very narrow, more so than for other two types of instruments. However, since the quality control measurements are performed in the controlled environment, using the radioactve source of the defined geometry, setting stict limits of acceptance is not unwaranted. The stability of the measurement in the controlled situation can be

 ISBN 978-86-7466-930-3

considered as a good predictor of the stability in the real measurement circumstances.

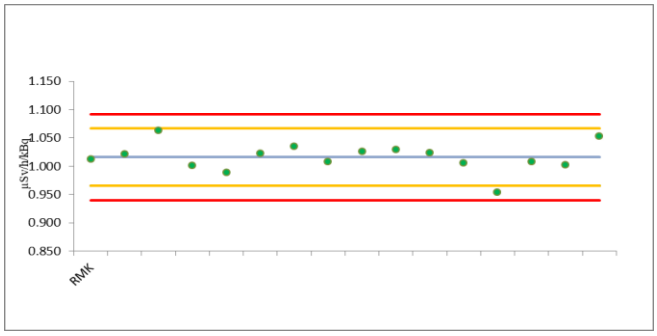

Fig. 1. Unified Sheward chart for 3 RMK 10 type of ambient dose equivalent rate monitors

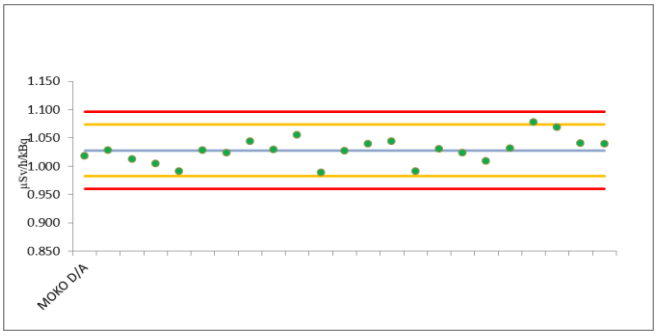

Fig. 2. Unified Sheward chart for 4 MOKO 100 type of ambient dose equivalent rate monitors

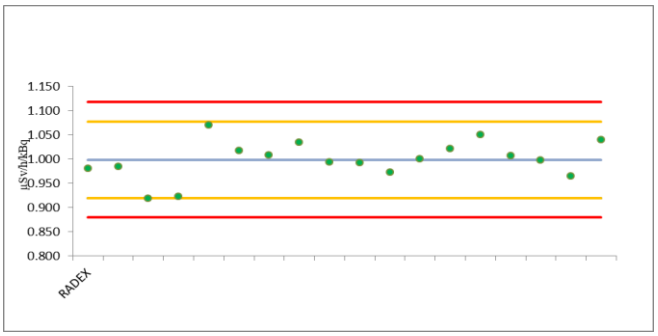

Fig. 2. Unified Sheward chart for 3 RADEX type of ambient dose equivalent rate monitors

III. Conclusion

In this paper we presented the analysis of the quality control measurements and stability of the measurement for 3 types of ambient dose equivalent rate monitors (10 monitors in total) readily used in Radiation and Environmental Protection Department. The period of quality control was from the mid 2020 to mid 2022. All 10 investigated instrument were periodically controlled and Sheward charts readily analyzed in order to assertain the stability of the performance. According to the analysis of the first two years of the quality controll, it can be concluded that all three types of instruments shhow satisfactory stability. Analysing the performance of individual monitors, it can be seen that the difference from the baseline is less than 15% and that the limits of acceptance were never exceeded. Looking at the unified Sheward charts, it can be consluded that neither type of monitor can be singled out as a more or less stable during this period. Since the quality control of these monitors is a mandatory part of the accredited method of measurement, this kind of analysis and controll will be continued in the future, giving more useful data and more opportunities for improvement.

Measurement Using Liquid Scintillation Spectrometer-Quality Control

Marija Janković, Nataša Sarap, Jelena Krneta Nikolić, Milica Rajačić, Dragana Todorović, Ivana Vukanac

***Abstract*—Liquid scintillation spectrometers (LSC) are used for radionuclide activity concentration measurements. This paper presents quality control measurements for Quantulus 1220 LSC, which is used for tritium activity determination. The quality control is verified on a monthly basis with two tritium standards. Based on these measurements two different efficiencies were calculated. Paper also presents the results obtained for tritium activity concentration in water sample within intercomparison, which are performed in Radiation and Environmental Protection Department, Vinča Institute of Nuclear Sciences. Intercomparison was organized by International Atomic Energy Agency in 2021.**

***Index Terms*—liquid scintillation spectrometer, quality control, tritium.**

I. Introduction

Liquid scintillation spectrometer is widely used for determination of low radioactivity. It can be used for detection alpha and beta radiation, Cerenkov radiation, X-rays, Auger electrons, luminescence and gamma radiation. The main advantages of using liquid scintillation spectrometer are rapidity, sensitivity, low detection limits in measurement of low energy beta emitters, such as tritium. Radioactive isotope of hydrogen, tritium ^{3}H, has low beta energy with maximum of 18 keV. Whether of natural or anthropogenic, this radionuclide is mobile in the environment, especially in water, and in biological systems. Tritium exists in three chemical forms: tritiated water (HTO), gaseous tritium (HT) an organically bound tritium (OBT). Naturally occurred tritium, produced in the upper atmosphere is oxidized to tritiated water [1,2]. Anthropogenic source of tritium are nuclear tests (between 1945. and 1963.) and nuclear facilities.

In order to determine the activity concentrations of radionuclides, optimization of detector measurement conditions should be performed. One of the basic parameters is determining efficiency. In the case of internal quality control, a periodic check of the characteristics of the detector is carried out according to the quality control plan. External quality control enables participation in intercomparisons, participation in PT schemes.

This paper presents the evaluation of the efficiency of liquid scintillation spectrometer for tritium measurement and analysis of control charts. Radiation and Environmental Protection Department, Vinča Institute of Nuclear Sciences participated in intercomparsion for tritium measurement in water sample and this paper also presents the obtained results.

II. The Method

Measurement for the purpose of tritium activity determination in water samples are performed on liquid scintillation spectrometer Quantulus 1220. Methods for tritium determination, ASTM D 4107-08 standard method [3] and validated method [4], are accredited with the Accreditation Body of Republic of Serbia according to standard 17025.

Because of low energy of tritium, samples must be distillated to prevent the detection of other beta emitters with higher energy that could mask the tritium spectrum. One of the advantages of LSC technique is 4π geometry (Figure 1.).

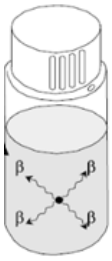

Fig. 1. 4π counting geometry [5]

Spectrometer before any measurement must be calibrated according to the calibration plan. According to the quality control plan, the efficiency check of the detector is done on a monthly basis. The value of the detector efficiency is included in the calculation for determining the activity of tritium.

 ISBN 978-86-7466-930-3

Monthly counting efficiency is determined according to method ASTM D 4107-08 Standard Test Method for Tritium in Drinking Water. Quality control is carried out with reference standard tritium solution ^{3}H 9031-OL-548/13 Czech Metrology Institute Type: ER X with activity 5.060 MBq on day 1.10.2013. and PerkinElmer Unquenched Toluene Standard 6008500 with activity 4890 Bq on day 18.11.2015. which have traceability to the BIPM.

Counting efficiency of the spectrometer, ε, is calculated using the following equation:

$$\varepsilon = \frac{R_{ST} - R_b}{A_{ST}} \qquad (1)$$

where R_{ST} is standard count rate (cps), R_b is background count rate (cps) and A_{ST} is standard activity (Bq).

Measurement uncertainty for efficiency is presented through the following equation:

$$u(\varepsilon) = \sqrt{\frac{\frac{R_{ST}}{t_{ST}} + \frac{R_b}{t_b}}{A_{ST}^2} + \varepsilon^2 \left(\frac{u(A_{ST})}{A_{ST}} \right)^2} \qquad (2)$$

where t_{ST} is standard measuring time (s), t_b is background measuring time (s).

III. Main Results

As already mentioned, according to the quality control plan, the efficiency check of the detector is done on a monthly basis, before measurement of samples.

For efficiency determination two standards are used. In addition to the standard, the background is also measured. Beside the standard from Czech Metrology Institute, for background, dead water (*DW* - tritium free water) from Miami is used, and beside the standard from PerkinElmer Background PerkinElmer is used. The first standard and *DW* are mix with 12 ml scintillation cocktail ULTIMA GOLD LLT in relation 8:12 in 20 ml polyethylene vial. Measurement time for the first standard is 300 s, and for the *DW* is 18000 s, for the second standard and for the background from PerkinElmer measurement time is 1200 s.

Figures 2. and 3. are present control chart for the efficiencies using two different standards. As a reference value, the internal calibration value is taken. Upper and lower control limits are $\pm 3\,\sigma$.

Since the LSC Quantulus 1220 has one detector and 60 positions for measurements, changing the position for the standard and for the background does not change the count rate of standard and background used in efficiency determining.

For the tritium spectrum, standard and background count rates were evaluated between channels 1 and 250 for the first standard, and for the second standard and background count rates were evaluated between channels 1 and 350.

Based on the calculated counting efficiency, the sensitivity of the instrument, *figure of merit* (*FOM*) can be calculated via following equation:

$$FOM = \frac{\varepsilon^2}{R_b} \qquad (3)$$

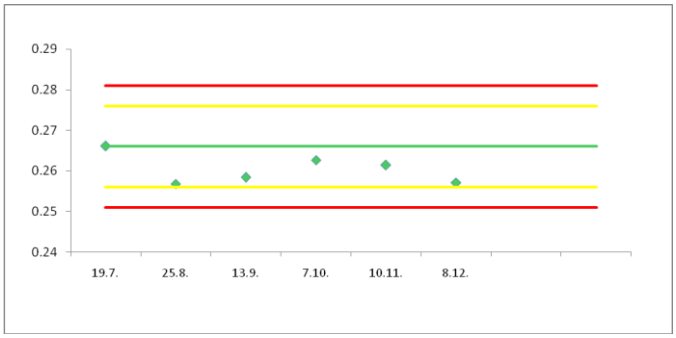

Fig. 2. Control chart for the efficiency for the standard from Czech Metrology Institute for the second half of 2021.

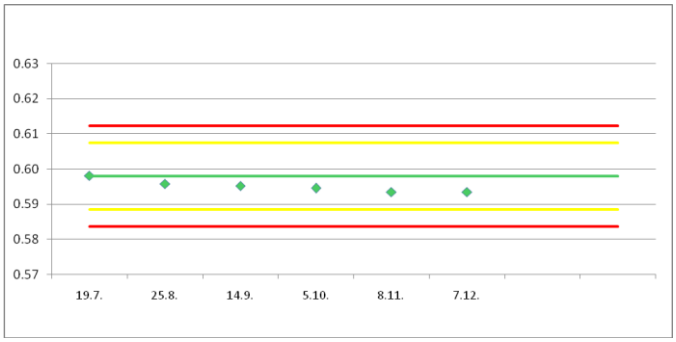

Fig. 3. Control chart for the efficiency for the standard from PerkinElmer for the second half of 2021.

Based on the results obtained for the efficiency check on monthly basis, the limits of acceptance, which is set on $\pm 2\,\sigma$, were not exceeded, observing control charts for both standards.

Using the determining efficiencies, *FOM* can be calculated based on the equation (3). For calculated efficiency for the first standard (26,6 %) and for determined background count rate (2,1 cpm), *FOM* is 337. For the second standard, for calculated efficiency for the first standard (59,8 %) and for determined background count rate (9,66 cpm), *FOM* is 370.

Radiation and Environmental Protection Department, Vinča Institute of Nuclear Sciences, National Institute of the Republic of Serbia, University of Belgrade, participated in intercopmarison ALMERA Proficiency test IAEA-TEL-2021-04. One of the required analyzes was tritium determination in water sample. For sample preparation, ASTM D 4107-08 standard method was used. The method involves preliminary distillation. An aliquot of 8 ml distillated sample is mix with 12 ml scintillation cocktail ULTIMA GOLD LLT in polyethylene vial (volume of vial is 20 ml).

Table I. presents intercomparison results. The final score is A (accepted).

 ISBN 978-86-7466-930-3

TABLE I
INTERCOMPARISON EVALUATION PT IAEA-TEL-2021-03

Sample	Reference value	Reported value	Z-score evaluation
Water	1653.6 ± 98.2	1641 ± 32	A

IV. CONCLUSION

In order to use a Liquid scintillation spectrometer to measure tritium, an analysis of control charts was performed using two tritium standards. Counting efficiencies were calculated and these values were taken as a baseline value. Monthly determination of efficiency, in accordance with the quality control plan, shows stability of the instrument. Results of intercomparison for tritium measurement in water sample show excellent values, using LSC Quantulus 1220 and accredited method.

E-Waste Glass in Radionuclide Immobilization

Tatjana Miljojčić, Ivana Jelić, Marija Šljivić-Ivanović and Slavko Dimović

Abstract — **Comprehensive needs for environmental protection are imposed by the prerogative of preserving natural resources, i.e. efficient usage of materials and energy. Therefore, there is an urgent need for different waste materials recycling or reusing. owever, advances in new technologies in the electronics industry are leading to the problem of disposing of different types of -waste, often discarded even before its usual time. This research represents an overview of -waste glass utilization, li e cathode ray tubes (C T) from old computer monitors and T screens, in mortar matrices for radionuclide immobilization. Due to its properties, mortar is used for liquid radioactive waste (W) solidification. arge quantities of cement, aggregates, and water are used annually for mortar and concrete manufacture. Also, cement production requires the consumption of large amounts of energy, i.e. the use of non-renewable fossil fuels. evertheless, mi ing waste materials with mortar effectively reduces the amount of cement consumption. Aspects of this paper relate to a review of recent developments regarding the use of -waste in cementitious materials. mphasis was placed on their physico-mechanical properties to evaluate the possibility of C T usage in mortar matri for W immobilization.**

***Index Terms* — cathode-ray tubes; liquid radioactive waste; solidification**.

I. INTRODUCTION

Modernization and advancement of technology contribute to the rapid change that applies in big part to electrical devices [1]. This reflects upon the need for innovative technologies, which are more aesthetically pleasing, easier to handle, and especially devices that consume less energy [2]. Improvement in the electronic industry led to a massive problem with different types of E-waste which is often disposed of before their usual time.

In addition to the need for energy efficiency, that the technological leap brings, there is also the need for environmental preservation, especially the development of a "circular economy", which implies the efficient use of materials. As technology advances, the amount of waste increases significantly, and the depletion of natural resources becomes irreplaceable [3]. There is a pressing need for recycling or reuse of various waste materials, and the development of sustainable alternative methods to manage hazardous waste. Collected data last few years from the waste electrical and electronic equipment (WEEE) collection and pretreatment market states that roughly 50,000-150,000 million tons/year of cathode-ray tube glass (CRTs) are collected in Europe only, and this quantity is not expected to decrease in coming years. The widespread use of liquid crystal displays (LCDs), light-emitting diode (LED), and plasma display panels that replaced CRTs are dramatically progressing, producing a million units of waste (Fig. 1).

Fig. 1. E-waste

The environmental problems concerning disposing of CRTs arise because of the high lead (Pb) content stored in the glass, panel section, and funnel. This landfilling non-eco-friendly aspect triggered the call for a solution since the presence of lead in CRT glass means that common disposal methods are not the option. [4].

On the other hand, concrete is the second most widely used material worldwide, right after water. To produce mortar and concrete, large quantities of aggregates are used annually, including cement, water, and other resources. Mixing recycled and waste materials with concrete can reduce the amounts of spent natural raw materials, i.e. these materials could be used as a replacement for cement or aggregates [5]. Combinations

 ISBN 978-86-7466-930-3

and mixtures used as aggregates contain about 70 to 80 % of concrete by volume, with around 25 to 35 % of total aggregates produced globally being used in concrete. Therefore, the demand for adequate materials is considerably increasing. Global consumption of aggregates exceeds 40 billion tons annually [6]. The result is disrupted biodiversity and the ecosystem, soil erosion, and depletion of natural resources. The most widely used is sand, which extraction rate is higher than the rate of its replenishment [7]. Reduction of natural raw materials utilization is possible if waste or already recycled materials are used. There is a large selection of waste materials that can serve as a replacement for most aggregates in concrete, one of which is glass waste [8]. This material has a wide application and is convenient for processing, and on the other hand, there is a lot of this waste kind.

Aggregate partial replacement with CRT glass has many advantages [9]. Numerous studies have confirmed that this waste glass also behaves like a pozzolanic material. It has positive effects on the mechanical properties, and it is stated that it can replace cement-mortar in some cases, due to inefficiency in cement production with high energy demands, and great consumption of natural, non-renewable materials.

There are many investigations that dealt with the recycling of waste glass, including CRT waste, in construction materials. Consequently, the need for new information and research in this area has increased in order to incorporate good practices, develop environmental awareness and find new solutions [10]. On the other hand, the same procedure of mixing E-waste glass and construction materials could be applied in the immobilization of liquid radioactive waste (LRW), which can be a good step toward finding more environmentally friendly solutions. Mortar-matrix is able to trap harmful substances and is known as an excellent matrix for radionuclide immobilization.

The aim of this research paper was to look at the possibility of using CRT glass to see the potential benefits that may arise from it, including the immobilization of LRW. This paper is related to the systematic research of literature and works dating back to a few years ago, and deals with the research of the properties of cement mortar and concrete mixed with waste-based CRT glass. The emphasis is on their phisico-mechanical properties and durability, as well as compression, density, consistency, alkali-silica reaction, and the possibility of LWR immobilization.

II. Immobilization of Liquid Radioactive Waste in Mortar Matrix

There is a great need for proper disposal and immobilization of radioactive waste since this type of waste cannot be destroyed. On an annual basis, a lot of nuclear waste is generated from nuclear power plants, as well as other waste raw materials that are contaminated, such as technological or medical waste. This waste can be found in liquid, solid, and gas forms. Material that is considered a radioactive waste implies the one containing (or contaminated with) radionuclides in such concentrations that the level of radioactivity is higher than the values specified by the competent authorities, without having a use-value. Conditioning of radioactive waste materials implies transformation into forms suitable for later manipulation. These are technological operations of immobilizing these materials into stable, insoluble forms using matrix materials (cement, bitumen, plastic, and glass).

Many years of experimenting proved that this kind of waste is best immobilized by solidification. Theoretical and experimental tests showed that the leaching rate of radionuclides from the solidified matrix was satisfactory. This approach gives a great variety of methods and interpretations of results. However, there have not been investigations dealing with the utilization of CRT waste in mortar matrix for radionuclides immobilization. Hence, there were many comprehensive types of research on the immobilization of heavy metals and radionuclides in mortar matrices [11].

Binder construction materials and demolition debris have proven to be very successful in various studies where it has been investigated how these materials would behave as immobilizers of hazardous, radioactive, and toxic waste. Global economic urbanization contributed to finding more effective technologies that could efficiently manage and solve the environmental issues regarding radioactive waste.

Due to the properties of mortar as a material, which is appreciated for capturing various types of waste materials because of its structure, numerous studies indicate the benefits of mixing cementitious materials and LRW in order to immobilize radionuclides. There is a rising demand for more energy-efficient methods and materials which, in this case, would completely or partially replace the natural raw materials used for its production.

Recently, extensive studies have been carried out on the use of waste products and mortar mixtures. However, there are not many of them dealing with the utilization of CRT glass as a possible replacement for the mortar itself as the solidifier of LRW. It is assumed that the aim of future investigations will be a determination of whether the CRT glass mortar-based matrices satisfy the physical and mechanical properties, instead of the classic mortar. Furthermore, immobilization, storage, and disposal of LWR are expensive, so there is a rising demand for the development of low-cost sorbents [12].

Cement-based materials and other concrete binders require a significant amount of energy and raw materials for their production, and they result in a notable amount of greenhouse gasses and CO_2 emissions into the atmosphere. On behalf of that, many studies have turned to find an adequate replacement for conventional aggregates that are used and suitable binders, for the purpose of radioactive waste solidification.

III. Recycling of CRT, Materials Used, Methodology of Work, and Test Methods

CRT glass should be recycled properly to maximize

 ISBN 978-86-7466-930-3

environmental safety [13]. When it comes to recycling CRT glass there are two options: closed-loop recycling and open-loop recycling (Fig. 2).

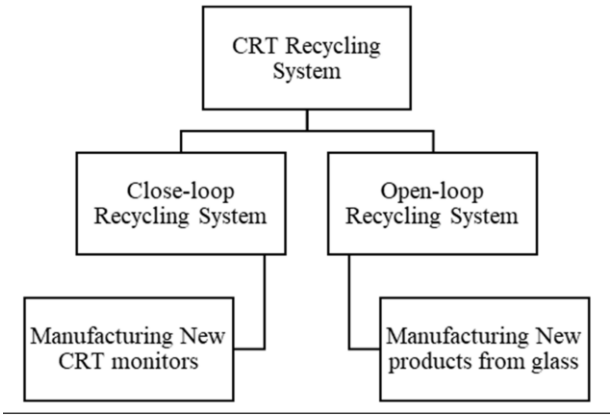

Fig. 2 Recycling system of CRT, redrawn from [3].

The first type of recycling refers to the recycling of old CRT screens in order to obtain new screens, but this method is outdated, new technologies have replaced the need for such screens. The second type of recycling is quite applicable, but the production process is more demanding. It consists of the use of these waste glasses in the form of obtaining new finished products. These species are far more cost-effective, and also have environmental value. Such products include construction materials, which are characterized by low water absorption properties and high silica content, making them an adequate substitute for sand and pozzolan in concrete [14].

CRT monitor consists of three main parts: front panel glass, funnel glass, and the electron gun. There are monochrome CRT (black and white) and color CRT screens (Fig. 3.).

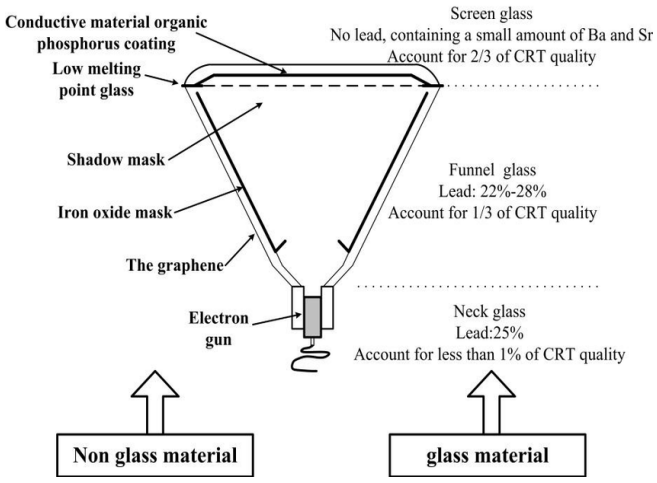

Fig. 3 Composition of a CRT monitor

Consequently, all kinds of chemical compositions are found in CRT glass, hence the main component of CRT is silica. When it comes to recycling and separation of CRTs, the external parts, plastic casing, and metallic parts are removed from TV sets and monitors. The panel and funnel glass are separated by laser cutting. In the recycling procedure of the panel, glass involves the removal of fluorescent powder and using a mechanical crusher to break it into smaller particle sizes.

A. Test methods workability, durability, consistency, compression, AS reaction

There are a lot of investigations where it was estimated the share of ground CRT glass as a fine aggregate in various percentages. For instance, one study focused on using CRT glass 100% instead of sand [5]. Treated and non-treated CRTs were used. Authors reported that the mixture of mortar and non-treated CRT glass produced a higher slump flow than the mixture of mortar and river sand (over 165%), but if treated CRT was used, it decreased slump flow.

Other research [10] found that if used different replacement levels of CRT (0%, 25%, 50%, and 75%) would get different flow speeds and consistency. CRT glass has a smooth surface and is impermeable in nature. Other studies [11,12], as well, showed that the consistency of these mixes is decreased if there is less percentage of CRT. What is evident is that if a higher percentage of CRT glass is used, a more homogeneous mixture is obtained, with less segregation (Fig. 4.).

Fig. 4. Particles of CRT glass

However, it was proven that an increase of CRT in mortar or cement decreases workability and has an important impact on a slump. Consequential is the method of crushing glass, as well as the size of particles and textures, which later has a great influence on mixing with building materials [13].

One research [14] found when CRT glass quantity was increased by replacement of 0 to 75% that caused an increase in the wet density of mortar and cement from 2176 to 2408 kg/m^3. Nevertheless, this was expected, hence density of river sand is lower (2620 kg/m^3) than the density of CRT glass (3042 kg/m^3). Same researchers reported similar results in another study [15], where it was found that the wet density of concrete increased from 2914 to 2992 kg/m^3 after replacing 75% of sand with CRT. Other scientists [16,17] also reported an increase in the wet density of concrete when replacing

 ISBN 978-86-7466-930-3

limestone sand with CRT. In one study [18] sand in the mortar was replaced with treated CRT and non-treated CRT glass at levels of 0%, 25%, 50%, and 75% also. With the increase in substitution level, wet density also increased. The only difference was that non-treated CRT glass in mortar had a higher density, while treated CRT had a lower density. The incorporation of CRT glass into mortar and concrete has led to an increase in density, because of the higher density of CRT glass itself compared to river sand. Higher density in this case is desirable and can be used specifically for concrete used in radiation protection, but not so much for structural concrete.

Researchers came to the conclusion [5] that mortar with non-treated and treated CRT glass has a higher compressive strength compared to a mortar with river sand. The compressive strength of mortar that was mixed with non-treated CRT glass was 41% higher than mortar that was mixed with river sand only. This examination was concluded on the 28th day of the experiment, due to the high probability of improvement in the particle packing. In the same research, they found that mixtures of mortar and CRT glass have higher grades of flexural strength, especially if non-treated CRT glass was used. [19]

Some studies [11] found that while increasing levels of CRT in mortar, there has been a decrease in flexural and compressive strength both, but only in early curing stages. It was speculated that it was probably because of the weaker bond in the cement paste, while during the later curing stages there was a chemical reaction between calcium hydroxide and CRT glass, as a pozzolanic material, and there was a smaller decrease in strength.

When it comes to combining CRT glass with concrete, there has been one investigation [11] that indicated that compressive strength and splitting tensile strength are reduced during the early curing time. In that experiment, they replaced river sand with 100% of non-treated CRT glass. Another study figured that lead, which is located in CRT, is responsible for cement dehydration, and after a longer period of curing, compressive and splitting tensile strengths are increasing. Furthermore, a recent study [20] investigated that strength reduction is also responsible less effective bonding area between cement and CRT glass, because of the smooth surface of the glass.

Regarding water absorption tests, some studies [21,22] found that when sand was replaced with 100% of treated CRT glass in concrete, it was found that usage of this waste material was responsible for the water absorption decrease. This was somewhat expected since CRT glass has lower absorption than sand. Another study [22] found that there was a reduction of permeability when adding CRT glass to concrete, which was more obvious when adding a higher water binding ratio. It was observed that 15% reduction in absorption when aggregate was replaced with 100% of CRT glass. Other authors [23,24] also reported that an increase in the quantity of CRT glass led to a further absorption decrease in cement mortar and concrete, the smaller particle size led to a further decrease in water absorption, also.

Many studies reported that utilization of CRT glass as a fine aggregate increased expansion in cement and mortar mixture, due to the alkali-silica reaction (ASR). During mortar mixtures testing without CRT glass as a fine aggregate, researchers reported an insignificant increase in expansion after 14 days, while mortar mixtures that did contain CRT glass continued to expand. Authors mentioned that utilization of fly ash led to a decrease in expansion, due to the pozzolanic reaction which reduced alkali content [25]. Also, when combining results with treated and non-treated glass, there was noticed that treated glass also led to expansion due to ASR. Other researchers reported that surface treatment of CRT glass can reduce ASR, with or without other fine aggregates. Scientists found that treating the CRT glass with nitrilotriacetic acid effectively reduced the expansion caused by ASR, unlike mortars that contained non-treated CRTs [26].

Combining the fly ash with a mixture of CRT glass is also an adequate method. Either way, cement mortar has exceptional potential to encapsulate hazardous waste in its matrix. The authors also suggested the utilization of additional pozzolanic materials (metakaolin, fly ash, etc.) which are responsible for the denser microstructure of the material, hence it reduces expansion due to ASR [27].

IV. Conclusion

The aim of this paper was the review the investigations related to CRT waste management and its utilization in mortar matrices.

Improvement in the electronic industry led to a massive problem with different types of E-waste which is often disposed of before their usual time. Collected data last few years from the waste electrical and electronic equipment (WEEE) collection and pretreatment market states that roughly 50,000-150,000 million tons/year of cathode-ray tube glass (CRTs) are collected in Europe only, and this quantity is not expected to decrease in coming years. The widespread use of liquid crystal displays (LCDs), light-emitting diode (LED), and plasma display panels that replaced CRTs) are dramatically progressing, producing a million units of waste.

In order to produce mortar and concrete, large quantities of aggregates are used annually, including cement, water, and other resources. Mixing recycled and waste materials with concrete can reduce the amounts of spent natural and raw materials, i.e. these materials could be used as a replacement for cement or other aggregates. There are many investigations that dealt with the recycling of waste glass, including CRT waste, in construction materials.

Many studies reported that the utilization of CRT glass in the mortar was beneficiary to its physico-mechanical properties such as density, water absorption, workability, permeability, compressive, flexural, and splitting tensile strength.

The final result would be that CRT waste glass could partially replace cement-mortar as a suitable waste immobilizer, but more investigations are needed.

***Sažetak*—Rad je eksperimentalnog karaktera. Formiran je model elektronskog generatora za injektovanje energije u plazmu fuzionog reaktora. Snimanjem nejonizujućeg polja u okolini ovakvog generatora utvrđeno je da je to polje izuzetno velike brzine porasta. Na mestu maksimalnog intenziteta tog polja nejonizujućeg zračenja eksperimentisano je sa komercijalnim odvodnicima prenapona i fleksibilnim modelom odvodnika prenapona. Ustanovljeno je da komercijalni odvodnici prenapona imaju efikasnost oko 20%. Za efikasnost fleksibilnog modela ustanovljeno je da je efikasnost nešto manja od 40% (i da se postiže primenom radioaktivnog zračenja alfa čestica). Pošto nijedna od tih efikasnosti ne garantuje pouzdani rad GFSA zaključeno je da bitna elektronika u blizini fuzionog generatora mora biti zaštićena. Međutim, pošto se ta zaštita može sprovesti samo kod fuzionog reaktora ostaje činjenica da je okolina takvog reaktora izuzetno kontaminirana nejonizujućim zračenjem. Komercijalni odvodnici napona su izolovani za ispitivanje pošto je zaštita elektronskih sklopova od brzih prenapona kritična tačka za funkcionisanje savremene elektronike.**

***Ključne reči*—elektromagnetna kontaminacija životne sredine, GFSA, fuzioni reaktor, brzo elektromagnetno polje**

I. UVOD

Rastuća potreba za energijom dovodi do potrebe uvođenja u primenu novih energetskih postrojenja. Ta nova energetska rešenja svakako ne trebaju biti zasnovana na fosilnom gorivu. Više razloga je za to. Dva osnovna su što se rezerve kvalitetnog fosilnog goriva smanjuju i što upotreba fosilnog goriva značajno doprinosi kontaminaciji životne sredine [1]–[3]. Takozvani zeleni (alternativni) izvori energije su problematični pošto proizvode električnu energiju po znatno većoj ceni, a nisu ni potpuno bez uticaja na okolinu. Pored toga, što je i najvažnije, takvi izvori su male snage i nisu u stanju da proizvedu energije tokom radnog veka ni koliko je uloženo u njihovu proizvodnju [4], [5]. Kao rešenje ovog problema nameću se nuklearni reaktori. Nuklearni reaktori, termalni ili brzi, kao gorivo troše uranijum (prirodan ili obogaćeni) pri čemu se energija dobija procesom fisije. Nuklearni reaktori su usled mogućnosti akcidenata sa dugoročnim posledicama veoma nepopularni u većini zemalja [6]–[8]. Međutim, pošto ni rezerve uranijuma nisu velike i pošto je,realno, veliki problem vezan za odlaganje istrošenog goriva fisionih reaktora, definitivno rešenje energetskog problema čovečanstva je u fuzionim reaktorima [9], [10].

Sa aspekta ekologije dobijanja energija na osnovu reakcije fuzije je skoro u potpunosti zelena energija pošto ne proizvodi nikakav radioaktivni otpad koji bi mogao kontaminirati prirodnu sredinu. Nuklearna reakcija fuzije ima u deeksitacionom procesu pojavu gama zračenja. Ovo gama zračenje može da se eliminiše zaštitom dela fuzionog reaktora olovnim pločama. Međutim, mehanizam zagrevanja plazme injektovanjem energije u nju elektronskim snopovima snage TW, širine desetak ns i brzine porasta ns (i manje) izaziva izuzetno nepoželjnu elektromagnentnu kontaminaciju životne sredine. Prvi pokušaj da se ovo izbegne je bio projekat injektovanja energije u plazmu visokoenergetskim laserskim zračenjem. Pokazalo se da u jednom trenutku, pre postizanja praga reakcije fuzije, dolazi do usijavanja plazme. Takva usijana plazma se ponaša kao ogledalo koje odbija elektromagnetne zrake, tj. laserske zrake i sprečava injektovanje energije u plazmu i prelaz energetskog praga za proces fuzije. Elektromagnetno polje koje nastaje prilikom injektovanja elektronskog snopa (opisanih karakteristika) u plazmu ugrožava, u prvom redu, tehnosferu a preko nje i sve ostale aspekte savremenog načina življenja. Naime, u odnosu na tako brza elektromagnetna polja zaštita od prenapona (takozvana koordinacija izolacije na niskonaponskom nivou) postaje neefikasna [11], [12].

Minijaturizacija elektronskih komponenti u velikoj meri smanjuje njihovu otpornost na prenaponske pojave. Prenaponske pojave usled jako brzih elektromagnetnih polja indukuju se u svim (pa i najkraćim) žičanim strukturama. Za izuzetno brze prenaponske pojave prenaponska zaštita nije dovoljno efikasna pa prenaponske pojave mogu izazvati

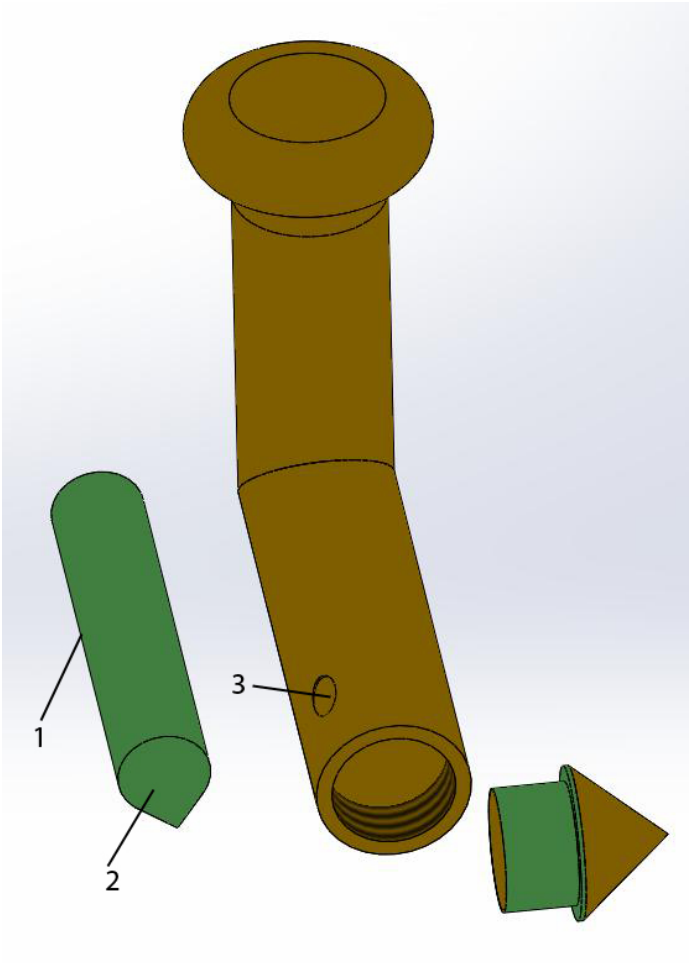
 ISBN 978-86-7466-930-3

oštećenje elektronskih elemenata, sklopova i čitavih uređaja. Pored oštećenja elektronskih komponenti tranzijentni prenaponi mogu prouzrokovati i prolazne poremećaje u funkcionisanju uređaja [13], [14]. Efekti uništenja uglavnom su vezani za poluprovodničke komponente, premda oštećenja izolacije mogu biti i na drugim komponentama. Potrebno je napomenuti da su uništenja elektronskih komponenti spregnutih sa antenama česta pojava.

Elementi prenaponske zaštite mogu se generalno podeliti na nelinearne i linearne. U nelinearne elemente prenaponske zaštite spadaju gasni odvodnici prenapona, varistori i odvodne diode. U linearne elemente prenaponske zaštite spadaju različite vrste filtera. Cilj ovog rada je da se proveri efikasnost gasnog odvodnika prenapona (GFSA – najčešće korišćenog nelinearnog elementa) za koordinaciju izolacije na niskonaponskom nivou polja zračenja elektronskog generatora.

A. FUZIONI REAKTOR (eksperimentalna postrojenja)

Fuzioni reaktori se zasnivaju na činjenici da je energija veze po nukleonu jezgra ^{4}He maksimalna. To omogućuje da se fizičkim procesom fuzije jezgara deuterijuma i tricijuma dobije jezgro helijuma i oslobodi znatan iznos energije u vidu nukleona i gama zračenja [15], [16].

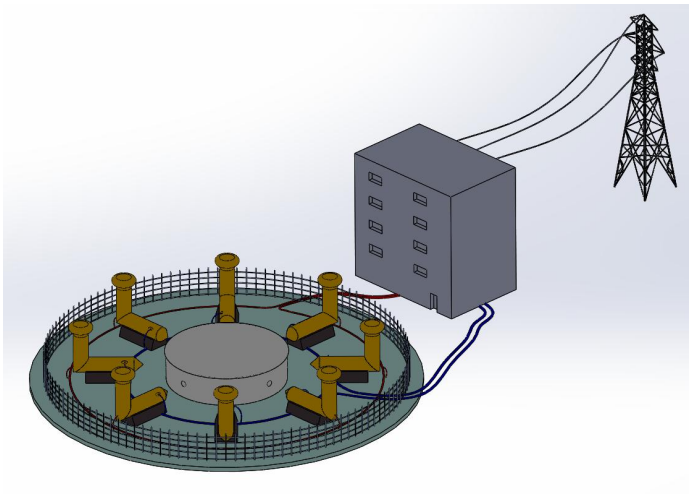


Kod procesa fuzije postoje dva problema:

1) Egzotermni proces sa visokim energetskim pragom.
2) Slobodna dužina puta čestice u procesu fuzije je jako velika

Prvi problem se rešava tako da se gasovima koji treba da ostvare fuziju dovodi energija dok ne dođu u plazma stanje na temperaturi iznad praga energije za fuziju. Pošto se pokazalo da injektovanje energije u plazmu laserskim putem nije efikasno usled refleksije laserskog snopa od površine usijane plazme prešlo se na injektovanje energije u plazmu elektronskim snopovima. Drugi problem se rešava što se plazma čestica u procesu fuzije nalazi u izuzetno jakom magnetnom polju. Time se ostvaruje rotacija čestica oko vektora magnetne indukcije i mogućnost prelaska srednje slobodne dužine puta za proces fuzije na malom prostoru. Ovo jednostavno rešenje je razlog što se fuzioni reaktori još ne koriste u komercijalne svrhe je pošto potrošnja energije na održavanje tog magnetnog polja veća od energije koja se dobija procesom fuzije.

Na prvi pogled ovaj princip rada omogućuje dobijanje čiste energije bez ikakvog hemijskog ili radioaktivnog materijala koji treba odlagati pod posebnim uslovima. Međutim, postoji kontaminacija elektromagnetnim i nukleonskim zračenjem. Komponentu gama zračenja u nukleone iz te kontaminacije je lako ukloniti odgovarajućom zaštitom prostora u kome nastaje fuzija. Pitanje eliminisanja nejonizujuće komponente elektromagnetnog zračenja je malo teže rešiti. Ova komponenta nastaje u generatoru elektronskih impulsa i tehnički se ne isplati rešiti je olovom (i drugim) zaštitnim zidovima. Iz tog razloga ova komponenta elektromagnetnog zračenja obrazuje elektromagnetno polje u široj okolini elektronskog generatora koje znatno ugrožava funkcionisanje savremenih tehničkih uređaja [17], [18].

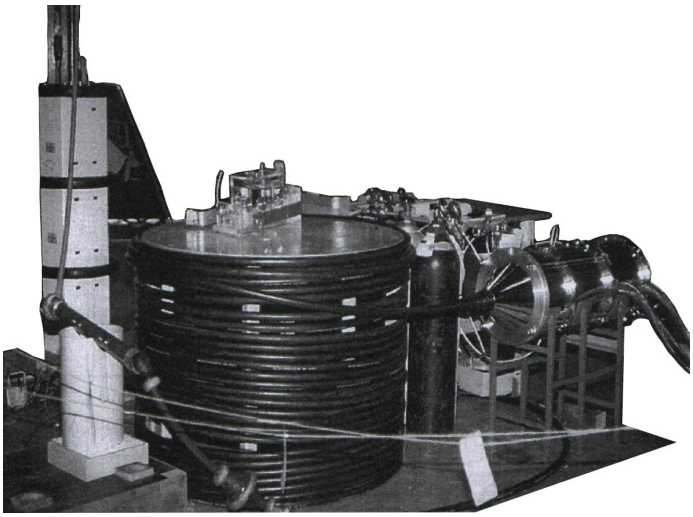


Elektronski generator generiše impulse snage TW i širine 1 ns. Da bi se takvi impulsi dobili elektronski generator je dvodelan. Sastoji se od vertikalnog i horizontalnog dela. Vertikalni deo je standardni Marksov generator potopljen u izolaciono ulje i podešen najčešće da daje impulse atmosferskog oblika 1.2/50 μs. Horizontalni deo se sastoji iz kondenzatora i provodnika za formiranje željenog impulsnog oblika. Interesantno je da su i provodnici i dielektrici kondenzatora u horizontalnom delu često od istog materijala, dejonizovane vode [19], [20]. Na horizontalnom delu se nalazi i naponska sonda za praćenje naponskog oblika impulsa elektron a, slika 1.

Slika 1: Elektronski generator: 1- kolo za oblikovanje impulsa; 2- 50 Ω talasovodni prilagodni otpor; 3- pozicija za postavljanje merno-upravljačke sonde

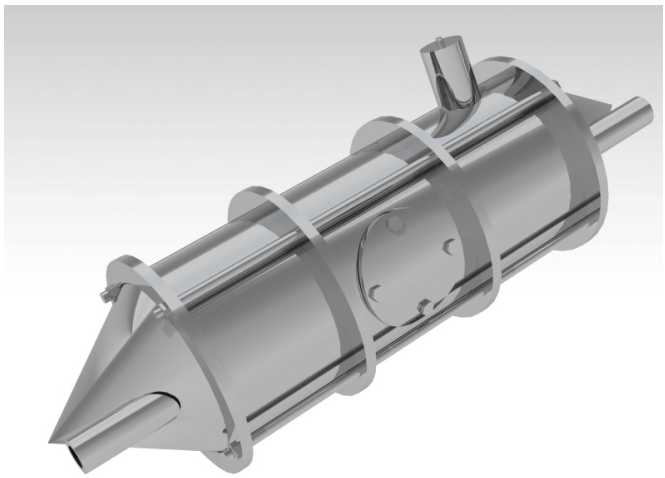
Sonda za praćenje naponskog impulsa je potrebna za sinhronizaciju rada oko deset elektronskih generatora koji trebaju da istovremeno generišu impulse uz minimalni džiter. Na slici 2 je prikazan izgled jednog fuzionog reaktora sa osam elektronskih generatora.

 ISBN 978-86-7466-930-3



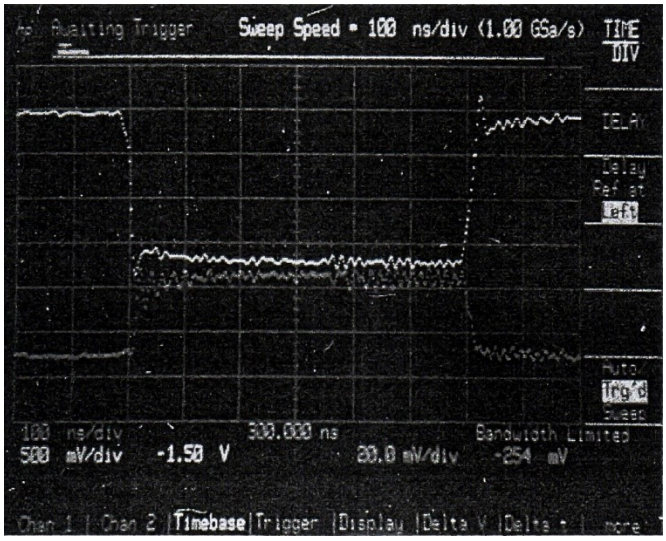
Slika 2: Principijelna šema fuzionog reaktora sa 8 elektronskih generatora

Pošto je elektronski impuls širine oko 5 ns i visine do 10 TW njegova brzina porasta je u nanosekundnoj (odnosno subnanosekundnoj) oblasti. Impulsi takve brzine porasta indukuju u žičanim strukturama elektrotehničkih komponenti izuzetno brze prenapone koji mogu da prođu kroz prenaponsku zaštitu i unište štićene komponente (što se posebno odnosi na savremena višeslojna elektronska kola čiji su izolacioni slojevi izuzetno tanki i probijaju ih naponi reda veličine mV i μV) [21], [22]. Ta neželjena pojava se dešava u oblasti više kilometara udaljenoj od fuzionog reaktora.



II. EKSPERIMENT

Za eksperiment je korišćen model horizontalnog dela elektronskog generatora napajan kablovskim generatorom, slika 3.



Slika 3: Kablovski generator za generisanje impulsa strmine porasta oko 1 ns

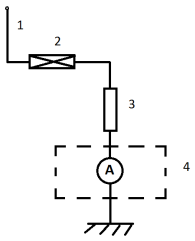
Model horizontalnog dela je bio sa ugrađenom brzom kapacitivnom sondom, slika 4. Kablovski generator generisao je naponski impuls pravougaonog oblika sa sledećim karakteristikama: 1- temena vrednost pravougaonog impulsa je 50 kV; 2- trajanje temenske vrednosti naponskog impulsa je 600 ns; 3- vreme čela i začelja pravougaonog impulsa je 1-3 ns.

Slika 4: Model horizontalnog dela elektronskog generatora sa ugrađenom brzom kapacitivnom sondom

Na slici 5 je prikazan odziv brze kapacitivne sonde modela horizontalnog dela elektronskog generatora na impuls kablovskog generatora. Kablovski generator je okidan troelektrodnim iskrištem izolovanim smešom gasova SF_6-N_2 [23]–[29].

Slika 5: Odziv brze kapacitivne sonde na impuls kablovskog generatora

Elektromagnetno polje u okolini horizontalnog dela elektronskog generatora snimano je instrumentom Narda, slika 6.

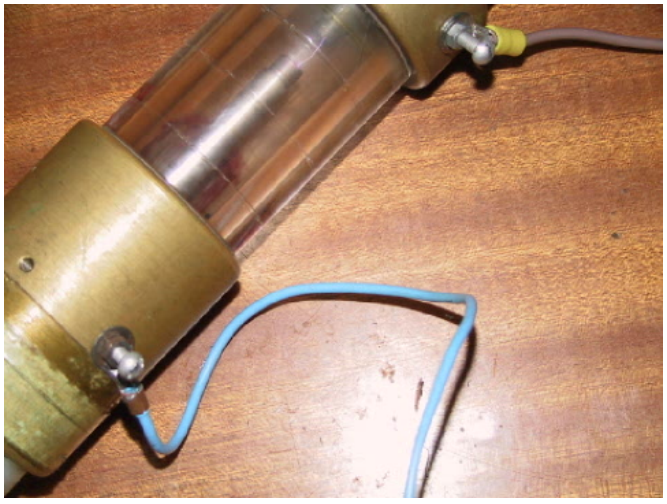


Na mesto maksimalne vrednosti električnog polja postavljen je gasni odvodnik prenapona, prema šemi na slici 7. Provera prorade gasnog odvodnik vršena je merenjem napona na otpor-

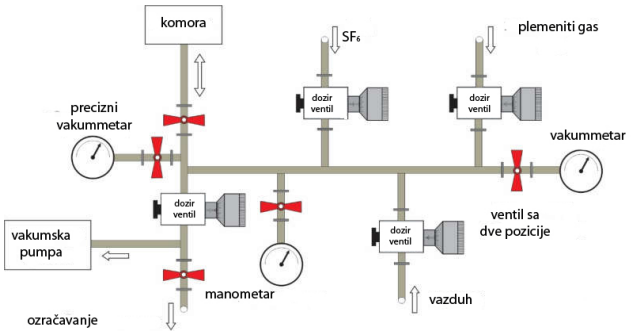
 ISBN 978-86-7466-930-3

Slika 6: Polje nejonizujućeg elektromagnetnog zračenja nastalo okidanjem modela fuzionog generatora na udaljenosti 1 km od eksperimentalnog postrojenja

niku R (100 MΩ). Napon je meren digitalnim osciloskopom (1 GHz) smeštenim u zaštitnu kabinu zaštite 100 dB [30], [31].



Slika 7: Eksperimentalna šema: 1- antena; 2- gasni odvodnik prenapona; 3- otpor uzemljenja; 4- kabina za zaštitu od elektromagnetnog talasa većeg od 100dB



Korišćeni su komercijalni gasni odvodnici i fleksibilni model. Fleksibilni model je prikazan na slici 8. Kod fleksibilnog modela gasnog odvodnika prenapona bilo je moguće menjati oblik elektroda, materijal elektroda, izolacioni gas i međuelektrodno rastojanje.

Korišćene su standardne cilindrične elektrode, tj. elektrode sa šupljinom ispunjenom radioaktivnim izvorom ^{241}Am. Pritisak gasa u fleksibilnom modelu se mogao menjati. Korišćeni gas je bio He. Kolo za punjenje i podešavanje pritiska u fleksibilnoj komori prikazano je na slici 7. Radna tačka fleksibilne komore postavljena je na isti radni napon kao što je bila vrednost radnog napona komercijalnih odvodnika prenapona [32]–[35].

Merenja su vršena pod dobro kontrolisanim laboratorijskim

Slika 8: Fleksibilni model gasnog odvodnika prenapona

Slika 9: Gasno kolo za punjenje gasnog odvodnika prenapona

uslovima. Pošto je merena komplementarna veličina (prorada GFSA – ne prorada GFSA) merna nesigurnost tipA i tipB su bile nula [36]–[38].

III. REZULTATI I DISKUSIJA

U tabeli I dati su rezultati ispitivanja efikasnosti odvođenja indukovanih prenapona nastalih okidanjem modela elektronskog generatora. Rezultati u tabeli 1 su dati za tri tipa komercijalnih GFSA različitih proizvođača i istog nominalnog napona.

Tabela I: Eksperimentalno dobijene vrednosti verovatnoće efikasnosti komercijalnih GFSA; p je verovatnoća da GFSA reaguje na prenaponski talas; 1-p je verovatnoća da GFSA ne reaguje na prenaponski talas.

	p	**1-p**
tipA	18	82
tipB	16	84
tipC	23	77

Poređenjem impulsnih karakteristika komercijalnih GFSA i modela GFSA se pokazalo da model GFSA ima brži odziv na prenapone. Odziv modela GFSA je bio najbrži u

 ISBN 978-86-7466-930-3

slučaju da je korišćena kombinacija efekta šuplje katode i primene radioaktivnog izvora jonizujućeg alfa zračenja ^{241}Am.

Takođe je brzi odziv bio i kada je korišćen samo ili efekat šuplje katode ili efekat jonizujućeg alfa zračenja. Objašnjenje za povećanje brzine odziva primenom efekata šuplje katode i jonizujućeg zračenja je u povećanju broja slobodnih elektrona (potencijalno inicijalnih) u međuelektrodnom prostoru GFSA. Međutim, GFSA koji bi bio konstruisan uz primenu ovih efekata ne bi garantovao efikasnu zaštitu elektronskih sklopova i elektronskih komponenti. To se vidi iz tabele II u kojoj su dati rezultati ispitivanja efikasnosti odvođenja indukovanih prenapona nastalih okidanjem modela elektronskog generatora.

Tabela II: Eksperimentalno dobijene vrednosti verovatnoće efikasnosti modela GFSA; model 1 je efekat šuplje katode zajedno sa efektom jonizujućeg zračenja; model 2 je efekat jonizujućeg zračenja; model 3 je efekat šuplje katode; p je verovatnoća da GFSA reaguje na prenaponski talas; 1-p je verovatnoća da GFSA ne reaguje na prenaponski talas.

model 3	29	71

IV. ZAKLJUČAK

U radu je pokazano da zaštita elektronskih komponenti primenom GFSA nije efikasna u blizini elektronskog generatora fuzionog reaktora. To je posledica jer takav generator daje impulse brzine porasta čela i začelja reda veličine 1 ns. Kada se tako brzopromenljivo polje indukuje u anteni (ili bilo kojoj žičanoj strukturi) stvara se prenaponski talas brzine u subnanosekundnoj oblasti (pošto je prenaponski talas ustvari induktivni pik koji se matematičkim putem predstavlja diferenciranjem indukovane struje). U tako kratkim vremenskim intervalima nije moguće pokrenuti mikroskopske procese električnog pražnjenja (koji mogu biti mikrosekundnog trajanja). Što se tiče primene hibridne odvodne šeme sa gasnim odvodnikom, odvodnom diodom (vrlo sličnoj Zener diodi) i varistorom ne može se nadati velikoj pouzdanosti. Razlog za to je što preuzimanje punog prenapona od odvodne diode dovodi do njenog fizičkog uništenja. Rezultat, prikazan u ovom radu, nesumnjivo, pokazuje veću efikasnost odvodnika prenapona sa radioaktivnim izvorom. Ipak to rešenje treba izbegavati jer se na taj način u prirodu ubacuje nekontrolisana primena alfa radioaktivnosti koja je izuzetno opasna ako uđe u lanac ishrane. Iz tog razloga svu elektroniku koja upravlja fuzionim generatorom treba zaštiti olovnim štitovima (šildovima). Ta mera bi obezbedila pouzdan rad fuzionih reaktora ali ne bi sprečila da njegova okolina bude kontaminirana brzim nejonizujućim zračenjem što bi rezultiralo nemogućnošću primene savremenih elektronskih naprava u njoj. Međutim, to ne znači da fuzioni reaktori neće, u budućnosti, oko sebe stvarati visoku elektromagnetnu kontaminaciju životne sredine, naročito u domenu tehnosfere.

Sektorski pristup u analizi bezbednosnih rizika upravljanja nuklearnim otpadom

Slavko Dimović, Milica Ćurčić, Nikola Zdolšek

***Apstrakt*—U ovom radu izvršen je uporedni prikaz političkih, ekonomskih, društvenih i ekoloških aspekata u analizi bezbednosnih rizika koji potiču od različitih oblika ugrožavanja poput terorizma, krađa, pronevera, sabotaža i prevara u upravljanju nuklearnim otpadom. Na taj način, primenom sektorskog pristupa bezbednosti, formulisanog u okviru Kopenhaške škole studija bezbednosti, na celovit i sveobuhvatan način pristupa se predmetu ovog istraživanja primenom u teoriji proverenog analitičkog okvira. Nuklearni otpad je nusproizvod aktivnosti nuklearnih reaktora, postrojenja za preradu goriva, bolnica i istraživačkih objekata, a stvara se i prilikom zatvaranja i dekomisije nuklearnih postrojenja. U međunarodnoj politici upravljanje nuklearnim otpadom je kompleksno i osetljivo pitanje koje uključuje veliki broj državnih i komercijalnih aktera i posebno je regulisano kao deo nuklearne industrije, a usaglašeno sa uslovima tretiranja opasnog otpada.**

U odnosu na druge vrste otpada, prilikom upravljanja nuklernim otpadom izraženije su društveni aspekti bezbednosti, pre svega kompleksni bezbednosni rizici ali i briga, neizvesnost i perspektive za buduće generacije. Takođe, sa političkog i ekološkog aspekta, upravljanje i odlaganje nuklearnog otpada predstavlja najveći razlog mimoilaženja između nuklearnih pristalica i protivnika. Troškovi upravljanja i odlaganja otpada iz nuklearnih elektrana obično čini oko 5% ukupnih troškova generisane električne energije, a najveći udeo čine troškovi njegovog privremenog i trajnog odlaganja. Nuklearni otpad bi trebalo skladištiti u dubokim geološkim formacijama, jer rizici protokom vremena postaju niži od rizika skladištenja na površini.

Upravljanje nuklearnim otpadom karakteriše visok nivo složenosti i interkompatibilnosti značajnih faktora: pitanja transporta, finansiranja prerade otpada i raspolaganja, kao i vođenja administrativnih evidencija. Određene tendencije u regulisanje industrije, za koje se tvrdi da su opravdane na bezbednosnim osnovama, smanjuju transparentnost i istinitost izveštavanja i tako otvaraju mogućnost za korupciju i druge oblike tzv. „kriminaliteta belog okovratnika“. Stvaranjem kulture nekažnjivosti ovih, uslovno rečeno blažih kriminalnih akata, ostvaraju se preduslovi za nastanak i ispoljavanje ozbiljnijih krivičnih dela, uključujući terorizam.

***Ključne reči*—upravljanje nuklearnim otpadom, bezbednost, bezbednosni rizici, sektorki pristup, Kopenhaška škola studija bezbednosti**

I. Uvod

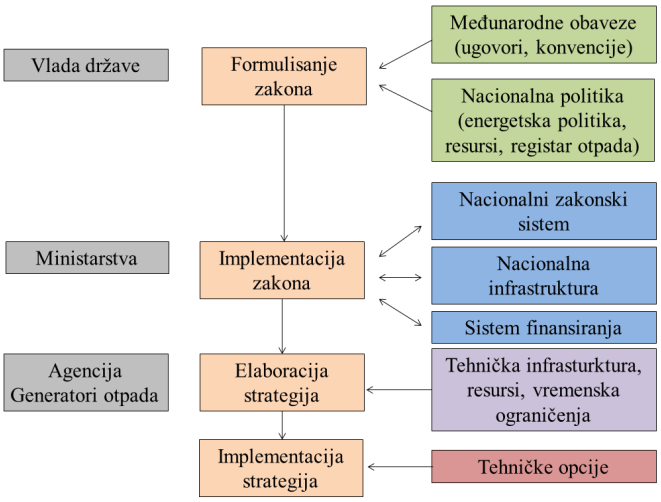
U okviru diskursa aktuelizacije neobnovljivih izvora energije, nuklearna energija je dugo bila kritikovana tema i kontroverzan izvor energije. Kao metod proizvodnje električne energije sa niskim emisijama ugljen-dioksida predstavlja jedan od sigurnih izvora energije u budućnosti, pa je njene pristalice razmatraju kao prelazno ili trajno rešenje za dekarbonizaciju, ali i kao hitan odgovor na klimatske promene. S druge strane, protivnici nuklearne energije smatraju je reč o veoma složenoj tehnologiji koju prate bezbednosni, ekološki i zdravstveni rizici. Neizostavni deo diskusije o nuklearnoj energiji jeste nuklearni otpad kao nusproizvod aktivnosti nuklearnih reaktora, postrojenja za preradu goriva, bolnica i istraživačkih centara. On se takođe generiše prilikom zatvaranja i dekomisije nuklearnih reaktora i drugih nuklearnih postrojenja. Nuklearni otpad čine jalovina nastala pri eksploaticiji rude urana, transuranski (TRU) otpad, nisko, srednje i visoko radioaktivni otpad, kao i istrošeno nuklearno gorivo [1].

Upravljanje nuklearnim otpadom predstavlja jednu od najkompleksnijih postupaka u odnosu na sve druge vrste otpada obzirom da uključuje brojne državne i ne-državne aktere i praćeno je složenijim bezbednosnim rizicima sa potencijalno većim posledicama, ali manjom verovatnoćom ispoljavanja štetnog događaja. Predmet ovog istraživanja jeste multidimenziona analiza upravljanja nuklearnim otpadom primenom sektorske analize formulisane u okviru Kopenhaške škole studija bezbednosti [2]. Sektorski pristup bezbednosti prepoznaje pet sektora - vojni, politički, ekonomski, društveni i ekološki sektor i predstavlja relevantan analitički okvir za objašnjavanje prelivanja bezbednosnih rizika iz jednog sektora u drugi. U konkretnoj studiji slučaja – upravljanju nuklearnim otpadom, analizirano je četiri sektora, a obzirom da je istraživanje koncipirano u redovnom, mirnodopskom stanju iz analize je izostavljen vojni sektor. S druge strane, u ovom radu razmatrana je ideja o proširenom sektorskom pristupu obzirom da je posebna pažnja posvećena tehničkim aspektima bezbednosti. U analizi upravljanja nuklearnim otpadom posebna pažnja posvećena je procesu zatvaranja nuklearnih elektrana nakon završetka njihovog radnog veka, problemi skladištenja, reciklaže i odlaganja visokog, srednjeg i niskog nivoa otpada, kao i bezbedonosni rizici nuklearnog gorivnog ciklusa.

Kada je reč o oblicima ugrožavanja procesa upravljanja nuklearnim otpadom, kao najsloženiji oblik izdvaja se terorizam. Transformacija terorizma, koja uključuje saradnju i

 ISBN 978-86-7466-930-3

koordinaciju aktivnosti većeg broja međunarodnih nedržavnih aktera, imala je reprekusije na objektivnost, pouzdanost i validnost nalaza stručnjaka i regulatora u postupku procene rizika. Preispitivanje ove pretpostavke može da se izvrši na različite načine, a za ovu analizu je najpogodniji prstup koji uključuje osvrt na objektine i subjektivne aspekte. Kada je reč o subjektivnim aspektima, obzirom da javnost uobičajeno nije stručna, svoju zabrinutost po pitanju štetnosti nuklearnog otpada iskazuje na način koji nije uvek potpuno podesan za prikupljanje i procenu dokaza od strane regulatora i stručnjaka. Dizanjem panike i vršenjem pritiska na donosioce odluka ne pruža se adekvatan materijal koji bi regulatori mogli kasnije da koriste u poboljšavanju legislative i radnih procesa u ovoj oblasti, a značajno se otežava njihov rad. S druge strane, usled objektivnih aspekata može doći do enormono povećanih rashoda usled prevelike pesimisticke procene, odnosno najgore moguće procene koja iziskuje najviše finansijskih ulaganja [3]. Zabrinutost javnosti zbog nuklearnog otpada u Evropi uglavnom je usmerena prema pitanju skladištenja nuklearnog otpada i potencijalnih negativnih efekata uskladištenog otpada po životnu sredinu i zdravlje ljudi [4]. Evropska komisija navodi da je stav o opasnostima koje proističu iz ovog procesa postalo najzastupljenije mišljenje među građanima, bez obzira na njegovu neutemeljenost. Pogubnost ove retorike kreirane od različitih anti-nuklearnih pokreta iskazuje se kroz činjenicu da je bez oslonca u nauci oblikovano mišljenje budućih generacija evropskog javnog mnjenja o dugoročnim opasnostima po životnu sredinu i zdravlje ljudi. U ovom radu poseban akcenat stavljen je na analizu bezbednosti transporta nuklearnog otpada kao odličnoj studiji koja se oslanja na prošireni sektorski pristup za sveobuhvatno sagledavanje i upravljanje bezbednosnim rizicima [5].



II. POLITIČKI SEKTOR BEZBEDNOSTI

Politički aspekat bezbednosti u sferi upravljanja nuklearnim otpadom istražuje se kroz tri nivoa bezbednosti: nacionalnog nivoa kao osnovnog nivoa bezbednosti iz koje se deriviraju regionalna i međunarodna. S tim u vezi, politike bezbednosti država u ovoj oblasti složene su i sačinjene od čitavog niza politika kojima se doprinosi dostizanju i očuvanju sekuritizovanih vrednosti države, društva i pojedinaca, prevashodno kroz analizu međunarodne, politike EU kao regionalne politike i nacionalne politike.

A. Nacionalna politika

Iako svaka država određuje svoje modele upravljanja nuklearnim otpadom, moguće je identifikovati određene zajedničke karakteristike. Pre svega, zakonodavni organ, najčešće skupština ili parlament, zaduženi su za usvajanje zakona koji se odnose na upravljanjem ovog tipa otpada. Ovaj zakon zatim treba da predvidi uspostavljanje regulatornog tela i, u brojnim slučajevima, zasebno telo za upravljanje istrošenim gorivom i radioaktivnim otpadom, kao i bitne elemente nacionalne politike u vezi upravljanja ovim otpadom. Moguće je da se nacionalna politika u ovoj oblasti uredi posebnim vladinim dekretom ili ministarskim direktivama. Nacionalna politika treba da odredi: odgovornosti unutar zemlje za upravljanje istrošenim gorivom i radioaktivnim otpadom; aranžmane za finansiranje upravljanja otpadom (uključujući odlaganje i dekomisiju); poželjne opcije upravljanja istrošenim gorivom, politike za odlaganje otpada, uvoz i izvoz istrošenog otpada; dekomisija nuklearnih postrojenja; informisanje i učešće javnosti u donošenju odluka.

Za sprovođenje nacionalne politike upravljanja ovim vrstama otpada potrebno je razviti jednu ili više strategija, što je odgovornost nosioca prakse upravljanja otpadom. Na Slici 1 prikazan je primer koji je dala Međunarodna atomska agencije (IAEA) kako se mogu razviti politika i strategija [6].

Slika 1.

Teorijski i praktično posmatrano, uočljiva je korist od koncentrisanja veoma skupih, potencijalno opasnih i tehnički zahtevnih aspekata nuklearnih elektrana uključujući i otpad, u samo nekoliko zemalja [7]. S druge strane, u promenljivim geopolitičkim okolnostima, mnoge države imaju stah od nuklearne energetske zavisnosti, obzirom da bi prijateljska država u jednom momentu mogla da postane ambivalentna, nekooperativna ili neprijateljski raspoložena i uskrati dalje snabdevanje ovom vrstom energije.

B. Regionalna i politika Evropske komisije

Kada je reč o regionalnom pristupu, odnosno opštoj strategiji upravljanja otpadom evropske zajednice, proklamovan je cilj koji podrazumeva pomirenje dva globalna procesa: nastavka ekonomskog rasta i prosperiteta uz istovremeno smanjivanje uticaja otpada svih vrsta na okolinu. U ovoj viziji, sa povećanjem ekonomskog rasta, korišćenje resursa bilo bi efikasnije što bi uticalo na njegovu manju i racionalniju potrošnju i opadanje negativnog uticaja na životnu sredinu. Težnja za politikom objektivnosti i transparetnosti ogleda se kroz intenciju da najveće troškove snose generatori najveće količine nuklearnog otpada.

Direktiva EU o radioaktivnom otpadu i istrošenom nuklearnom gorivu zahteva da:

- Zemlje EU imaju nacionalnu politiku za upravljanje istrošenim gorivom i radioaktivnim otpadom;
- Zemlje EU sprovode nacionalne programe za

 ISBN 978-86-7466-930-3

upravljanje, uključujući odlaganje, svog istrošenog nuklearnog goriva i radioaktivnog otpada generisanog na njihovoj teritoriji;
- Zemlje EU treba da imaju sveobuhvatan i snažan okvir, kompetentno i nezavisno regulatorno telo, kao i mehanizme finansiranja kako bi se obezbedila adekvatna sredstva;
- Dostupne su javne informacije o radioaktivnom otpadu i istrošenom gorivu i daje se mogućnost za učešće javnosti;
- Zemlje EU podnose Komisiji na svake tri godine (počev od avgusta 2015. godine) nacionalne izveštaje o primeni direktive, na osnovu kojih će Komisija izraditi izveštaj o ukupnoj primeni direktive i inventaru radioaktivnog otpada i istrošenog goriva prisutnog na teritoriji Zajednice i budućim perspektivama;
- Zemlje EU sprovode samoprocene i omogućuju međunarodni uvid svog nacionalnog okvira, nadležnih organa i/ili nacionalnog programa najmanje svakih deset godina;
- Izvoz radioaktivnog otpada za odlaganje u zemljama van EU dozvoljen je samo pod strogim uslovima [8].

C. Međunarodna politika i odgovornost

Na međunarodnom nivou zastupljen je jasan i nedvosmislen stav da je svaka zemlja etički i pravno odgovorna za sopstveni nuklearni otpad. Najveća količina nuklearnog otpada stvara se u nuklearnim reaktorima koji proizvode električnu energiju u 31 državi. Pored toga, ne postoji ni pravna ni moralna obaveza snabdevača uranijuma u pogledu otpada, osim onog koji je uključen u mere zaštite.

S druge strane, Međunarodna atomska agencije (IAEA) istakla je težnju ka multinacionalnom pristupu upravljanju i odlaganju istrošenog nuklearnog istrošenog goriva i radioaktivnog otpada. Svako međunarodno skladište otpada ima implikacije u skladu sa Sporazumom o nešireniu nuklearnog oružja (NPT), a pouzdanost i položaj zemlje domaćina od fundamentalnog su značaja za prihvatljivost projekta prema državama potpisnicama NPT- a [6].

IAEA je 2004. godine iznela tri razvojna principa za multinacionalna skladišta nuklearnog otpada:
- postepeno priključenje velikim nacionalnim programima;
- formiranje nadnacionalnih objekata sa međunarodnim mendžmentom i kontrolom i
- zajedničko partnerstvo između država vlasnica skladišta nuklearnog otpada.

Međunarodni ugovori obuhvataju upravljanje nuklearnim otpadom posredstvom dva pristupa. Prvi pristup se odnosi na sav opasnan otpad, kroz Bazelsku Konvenciju [9], uključujući ne samo radioaktivne materijale već i komprimovane gasove, zapaljive čvrste, korozivne materijale i eksplozive. Drugi pristup odnosi se na nuklearnu energiju, gorivni ciklus i pitanja otpada, posredstvom Sporazuma o Nešireniu nuklearnog naoružanja i drugih relevantnih međunarodnih sporazuma, kao i sporazuma unutar EU kao sto su Sporazum o Euroatomu, Sporazuma Evropske komisije, u zavisnosti od posmatranog problema [10]. U odnosu na upravljanje opasnim otpadom uopšte, u Bazelsknoj konvenciji navedeno je da do nelegalnog transporta opasnog otpada dolazi ako se prekogranično kretanje opasnog otpada odvija pod sledećim uslovima: bez obaveštenja u skladu sa odredbama Konvencije svih zainteresovanih država, bez saglasnosti zainteresovanih država, kroz saglasnost dobijenu falsifikovanjem, lažnim predstavljanjem ili prevarom, kada transport materijalno nije usaglašen sa dokumentima, ili prilikom transporta koji rezultira namernim odlaganjem opasnog otpada u suprotnosti Konvencije i opštih principa međunarodnog prava. Uobičajene metode nelegalnog transporta uključuje izradu lažnih izjava ili izveštaja, prikrivanje, skrivanje u pošiljci ispod materijala koji može regularno da se transportuje i pogrešnom označavanju pojedinačnih kontejnera. S obzirom da opasni otpad predstavlja veliku potencijalnu pretnju po ljudsko zdravlje i životnu sredinu, jedan od vodećih principa Bazelske konvencije jeste da opasni otpad treba da se tretira što je više moguće bliže lokaciji gde se generiše.

III. EKONOMSKI SEKTOR BEZBEDNOSTI

Razvoj nuklearne energije ponekad se posmatra kao jedno od glavnih rešenja za energetskom potrebom uz alternativne izvore energije poput hidroenergije i snage vetra. Strukturu troškova nuklearne energije čine:

• Kapitalni troškovi koji uključuju troškove pripreme, izgradnje, proizvodnje, narudžbine i finansiranja nuklearne elektrane.

• Operativni troškovi koji uključuju troškove nuklearnog goriva, rada i održavanja nuklearne elektrane, troškova dekomisije elektrana, tretiranje i odlaganje isluženog goriva i radioaktivnog otpada.

• Eksterni troškovi za koje se obično pretpostavlja da su nula, ali bi potencijano mogli da uključuju troškove sanacije akcidenata koje ne pokriva polisa osiguranja i u praksi je potrebno da ih podmiri Vlada.

• Drugi troškovi kao što porezi specifični za nuklearnu energiju.

U zemljama u kojima se koristi nuklearna energija pokazalo se da postoje četiri glavna krajnja nosioca troškova: buduće generacije, poreski obaveznici koji preuzimaju deo računa, potrošači električne energije (domaćinstva i/ili industrija) i u nekim zemljama oni koji direktno proizvode ili koriste električnu energiju [11].

Prilikom proizvodnje električne energije nastaju najveće količine nuklearnog otpada, ali nemerljivo manje u poređenju kada se koriste fosilna goriva. Iako nuklearni otpad nema veliku zapreminu, svi aspekti njegovog tretiranja iziskuju značajna finansijska ulaganja. Nuklearna energija je jedina složena tehnologija za proizvodnju električne struje koja preuzima punu odgovornost za sav generisan otpad i u potpunosti ga zaračunava u cenu. Troškovi upravljanja i odlaganja otpada nuklearne elektrane obično čini oko 5% ukupnih troškova generisane električne energije. U okviru ovih troškova, najveći udeo čine troškovi njegovog

 ISBN 978-86-7466-930-3

privremenog i trajnog odlaganja, zatim slede ulaganja u prevenciju i kontrolu izluživanja nuklearnog otpada u životnu sredinu. Dodatni otpad se generiše kad nuklearna postrojenja dođu do kraja svog ekonomskog/sigurnog života i moraju da budu ugašena. Tada cela postrojenja nakon procesa dekomisije postaju radioaktivni otpad.

Angažovanje podizvođača u ograničenom sektoru nuklearne industrije značajno podiže ulazne troskove [12]. S druge strane, istrošeno nuklearno gorivo se može skladištiti u blizini reaktora ili se nakon određenog perioda hlađenja delimično prerađuje stvarajući novi radioaktivni otpad. Proces prerade nuklearnog goriva je veoma skup i delimično efikasan, ali donosi veliki profit ograničenom broju kompanija čija je to delatnost. Pored toga, s obzirom da ima relativno mali broj centara za preradu u svetu, slanje otpada iz zemlje porekla dovodi do pozitivne reakcije domaćeg javnog mnjenja. Nasuprot tome, velike količine nuklearnog otpada zauvek ostaju u zemljama koje ga prerađuju, kao sto su Francuska, Velika Britanija i Rusija. Bez obzira na lokaciju nuklearnih postrojenja i mesta za preradu i odlaganje otpada, finansijski troškovi su značajni.

Upravljanje nuklearnim otpadom karakteriše visok nivo složenosti i interkompatibilnosti značajnih faktora: pitanja transporta, finansiranja prerade otpada i raspolaganje, kao i vođenje administrativnih evidencija [13].

A. Transport i bezbednost nuklearnog otpada

Oko 20 miliona transporta radioaktivnog materijala odvija se širom sveta svake godine javnim putevima, železnicama i brodovima, ali on čini veoma mali udeo u ukupnom transportu svih opasnih materijala. Obzirom na njegovu široku primenu, radioaktivni materijal ne nastaje samo tokom ciklusa nuklearnog goriva, te značajna većina transporta (95%) nije povezana sa nuklearnom energijom. Transport je, međutim, sastavni deo ciklusa nuklearnog goriva, jer većina zemalja koje eksploatiše rudu urana ne proizvodi nuklearnu energiju [14].

Nuklearni otpad se retko skladišti ili prerađuje na lokaciji gde je proizveden. Ovo nameće posebne bezbednosne rizike vezane za transport takvih materijala. Veća je verovatnoća dešavanja terorističkog napada (za stvaranje lokalne kontaminacije) ili kriminalne pronevere (u svrhu prodaje na nedozvoljenom tržištu ili kao kao predmet ucene) u transportu u poređenju sa statičnim lokacijama u kojima je jednostavnije implementirati sigurnosne i bezbednosne procedure. U svrhu uvećanja bezbednosti transporta i smanjenja verovatnoće ispoljavanja rizika potrebno je primeniti različite mere prevencije poput fizičke bezbednosti prevoznih sredstava, procene bezbednosti rute, bezbednosne procene svih učesnika u transportu i sl. U ovom procesu ključnu ulogu imaju obaveštajne službe država i njihova koordinacija sa inostranim službama radi sprovođenja nadzora, infiltracije i drugih specijalnih mera u borbi protiv terorističkih ili radikalnih antinuklearnih organizacija koje bi, potencijalno, mogle da izazivanjem akcidenta poput iskakanja vagona koji prevozi nuklearni otpad, stvore političku nestabilnost s ciljem izazivanja političkih promena. Nasuprot tome, skladištenje otpada na statičnim lokacijma i kontrola pristupa je relativno rutinski postupak zahvaljujući postojanju i poštovanju procedura. Ipak, zajedničko iskustvo sugeriše da, čak i u takvim okolnostima, selektivna pažnja i nemarnost može povećati bezbednosni rizik. Ovo rezultira da se bezbednost u fazi transporta nuklearnim otpadom može održati na visokom nivou, dok se bezbednost u statičnoj lokaciji može smanjiti do te mere da se mogu pojaviti samo krađe.

S druge strane, većina proizvedenog nuklearnog otpada nalazi se u čvrstom i stabilnom keramičkom ili vitrifikovanom (staklenom) obliku, te disperzija radionuklida izazvana terorističkim aktom i opasnost od tzv. prljave bombe nije velika. Istrošeno nuklearno gorivo pruža atraktivnu metu za nuklearne teroriste. Testiranjem probalističkih scenarija razornih eksplozivnih sredstava na kontejnere sa isluženim gorivom koji se transportuju u urbanoj oblasti ustanovljeno je da broj žrtava nije veliki, ali da postoji rizik od intezivne kontaminacije [15]. Nasuprot tome, Međunarodna atomska agencija (IAEA) identifikovala je medicinske i industrijske radioaktivne izvore kao izvor potencijalnih terorističkih pretnji zbog njihove upotrebe u prljavim bombama [14].

Impelementacija kompleksnih sigurnosnih i bezbednosnih aktivnosti tokom transporta zahtevaju velika finansijska ulaganja. Ograničeno tržište proizvodnje uranijuma, restrukturiranje nuklearne industriji širom sveta i smanjenje ekonomske marže posle deregulacije i liberalizacije tržišta električne energije izvršile su dodatni snažan pritisak na industriju nuklearnog transporta [16].

B. Vođenje evidencije

Jedna od najznačajnijih mera zaštite od zračenja jeste vođenje evidencije radioaktivnih materijala, koje prate monitoring, nadzor i inspekcija. U nekim zemljama vođenje evidencija može biti komplikovano usled težnje da se ne evidentira neki visoko radioaktivni otpad kako ne bi postao meta eventualnog terorističkog akta. Do praznina i nedoslednosti u nacionalnom planiranju skladištenja i odlaganja otpada može dovesti nepostojanje evidencije o materijalima kao što su plutonijum, osiromašeni uranijum i istrošeno gorivo za koje ne postoje definitivni planovi za preradu [17].

IV. DRUŠTVENI SEKTOR BEZBEDNOSTI

Društveni aspekti poput prihvatanja ili otpora društva prema korišćenju nuklearne energije, permanentno obrazovanje građanja i ulaganje u nauku u ovoj oblasti, tačno medijsko izveštavanje i percepcija rizika građana su posebno važni u procesu odlaganja nuklearnog otpada [18], te je neophodno obezbediti dostupnost informacija od javnog značaja. Edukacija stanovništva i promocija znanja iz nuklearne energije trebalo bi da ukaže na značaj upotrebe ovog vida energije u smanjenju emisije gasova staklene bašte, ali i emisiju drugih zagađivača kao što su sumpor dioksid, azot oksid, male čestice i isparljiva organska jedinjenja. Takođe, na taj način bi se doprinelo ograničenju zavisnosti od fosilnih goriva što bi dalje uticalo na smanjenje zabrinutosti u

 ISBN 978-86-7466-930-3

vezi sigurnosti snabdevanja energentima i pružilo bi zaštitu od eskalacije cena fosilnih goriva. Postoje najmanje dva univerzalna očekivanja od nuklearnih reaktora najnovije generacije. Prvi zahtev je garancija da neće biti značajnog oslobađanja radioaktivnosti u životnu sredinu pod bilo kojim uslovima. Drugo očekivanje se odnosi na količinu radioaktivnog otpada kroz težnju da se generiše što manje ovog otpada je moguće.

Prema Turkenburgu upravljanje i odlaganje nuklearnog otpada predstavlja najveću tačku sporenja između nuklearnih pristalica i protivnika. Pored radiotoksičnosti, izražava se i otpor usled gubitka vrednosti nekretnina u blizini odlagališta. Debate o prednostima i manama korišćenja nuklearne energije pokazuju da je otpor javnosti povezan sa sledećim problemima: javno prihvatanje ciklusa nuklearnog goriva; bezbednosni rizici nuklearnih elektrana i drugih komponenti ciklusa nuklearnog goriva; životni vek i upravljanje nuklearnim otpadom, naročito visoko aktivnog otpada; širenje fisionih materijala i nuklearnog naoružanja; akumulacija radionuklida u biosferi do neprihvatljivo visokog nivoa; nedostatak nuklearnih resursa; troškovi nuklearne energije; razvoj nuklearne industrije; uticaj na razvoj nenuklearne opcije [19].

Kao i u svim osetljivim sferama bezbednosti, i u upravljanju otpadom javlja se suprostavljena potreba da javnost bude uključena u sve aktivnosti, kao i da informacije ostanu poverlljive. S jedne strane, javnost, posebno stručna, ima kritičnu ulogu u obezbeđivanju nadzora nad nuklearnim elektranama. Nasuprot tome, ograničavaju se informacije o bezbednosti u nuklearnih elektrana iz straha od identifikovanja velikih slabosti, koje bi mogle da pomognu teroristima i drugim zlonamernim akterima. Takva tajnovitost stvara kulturu nekažnjivosti koja može da obezbedi sivu zonu u kojoj menadžerske greške i tehnički propusti mogu da se prikriju, kao i da dođe do povećanja broja drugih zlonamernih aktivnosti zaposlenih. Svaka procena rizika u ovoj sferi je kompleksna, delimično zbog preplitanja političkih, ekonomskih, društvenih, ekoloških i tehnoloških aspekata, a delom i zbog definisanja male verovatnoće zlonamernih i drugih nepovoljnih događaja.

V. EKOLOŠKI SEKTOR BEZBEDNOSTI

U kontekstu uticaja nuklearnog otpada na životnu sredinu, razlikuje se indirektan i direktan uticaj. Indirektan uticaj odnosi se na benefite smanjenja upotrebe drugih vidova energenata u proizvodnji energije, a koji imaju negativan uticaj na životnu sredinu. Direktan uticaj podrazumeva analizu pitanja skladištenja, reciklaže i odlaganje nuklearnog otpada, kao i procene uticaja akcidenata u vezi sa nuklearnim otpadom po životnu sredinu.

Preporuka je da bi nuklearni otpad trebalo skladištiti u dubokim geološkim formacijama, na osnovu toga da bi rizici tokom vremena postali niži od rizika skladištenja na površini [20]. Velika poteškoća se javlja u pogledu predviđanja mogućeg izluživanja ili ventilacije i njihove implikacije u periodu od više hiljada godina. Rešavanje problema nuklearnog otpada skladištenjem pod zemljom može uticati na psihološku relaksiranost kod ljudi, jer skladištenje na površini iako lakše za upravljanje, omogućava potencionalno zlonamerno ekološko ili drugo delovanje. Površinsko skladištenje kondicioniranog, upakovananog otpada u savremenim objektima na period od nekoliko decenija je izvodljivo i bezbedno. Izvan ovog vremenskog perioda biće neophodno da se skladište opsežno renovira ili zameni, dok se otpad morati prepakovati. S druge strane, površinsko skladištenje u dužim periodima od navedenog, zahteva dodatne ljudske angažmane i infrastrukturalna ulaganja. U tako dugom vremenskom periodu može doći do hazarda nevezanih za ovaj tip otpada ili čak klimatskih promena (naročito podizanja nivoa mora), što bi zahtevalo da se otpad premesti u novo skladište na drugoj lokaciji, podrazumevajući nove rizike po zaposlene. Pored toga, tokom dugih vremenskih perioda temelji i ojačanje u skladištima mogli bi da oslabe, čineći ih podložnim posledicama zemljotresa.

U zemljama članicama EU varira aktuelna praksa upravljanja isluženim nuklearnim gorivom. Najjednostavnija opcija, koja takođe minimizira zapreminu takvog otpada, jeste da država ovaj otpad zadrži na mestu nastanka, u bazenima ili u velikim kontejnerima, umesto da ga prerađuje. Posle produženog vremena hlađenja od najmanje 20 godina isluženo gorivo je spremno da se direktno odlaže u konačno odlagalište u dubokim geološkim formacijama, ako je u tom trenutku na raspolaganju takav objekat. U poređenju sa prerađivanjem nuklearnog goriva, neophodni tehnički koraci su manje složeni, dovode do manjih zapremina otpada i mnogo manjeg broja različitih oblika otpada koje treba uskladištiti i konačno odložiti.

Praksa prerađivanja nuklearnog goriva takođe varira među evropskim zemljama. Glavne karakteristike inovativnog gorivnog ciklusa su dodatne tehnologije upravljanja otpadom, kao što su segregacija i transformacija. One imaju za cilj smanjenje mase i radioaktivnosti otpada koji ide na konačno odlagalište. Glavni zadatak je da se zatvori ciklus goriva ne samo za plutonijum već i za manje značajne aktinide. U poređenju sa rezultatima konvencionalnog ciklusa goriva, inovativni ciklusi goriva imaju mnogo više prednosti u smislu upotrebe prirodnog uranijuma i smanjenja količine isluženog goriva. Nažalost, procesi reciklaže nuklearnog goriva, dizajnirani da smanje dugoročnu radioaktivnost otpada i/ili potencijalnu dostupnost materijala za proliferaciju, mogu i sami imati nepovoljne ekološke efekte, kao što je emisija radionuklida u biosferu [12].

VI. ZAKLJUČAK

Upravljanje nuklearnim otpadom kopleksno je pitanje čijoj analizi je neophodno pristupiti sa različitih aspekta, pa je sektorski pristup u istraživanju bezbednosti ove pojave jedan od najadekvatnijih. Sektorski pristup omogućava razumevanje i analizu faktora preplitanja političkog, ekonomskog, društvenog, ekološkog i tehnološkog aspekta, obzirom da dolazi do fenomena prelivanja karakteristika ove pojave iz jednog sektora u drugi. Pitanje upravljanja nuklearnim

 ISBN 978-86-7466-930-3

otpadom jedno je od najznačajnijih pitanja politike jedne države, a regulisano je kao deo nuklearnog industrije i kao deo regulative vezane za opasan otpad. Upravljanje otpadom uključuje prikupljanje, separaciju, skladištenje, transport, obradu, reciklažu i trajno odlaganje nuklearnog otpada.

Trenutna svetska politička situacija po pitanju energenata aktuelizovala je pitanje nuklearnih elektrana, obzirom da države pretenduju da smanje zavisnost od energenata koji potiču sa neuralgičnih područja. Pritom, pored benefita koji se javljaju po životnu sredinu, troškovi upravljanja i odlaganja otpada nuklearne elektrane obično čini oko 5% ukupnih troškova generisane električne energije, a najveći udeo čine troškovi njegovog privremenog i trajnog odlaganja. Upravljanje nuklearnim otpadom karakteriše zavisnost od pitanja transporta, finansiranja prerade otpada, kao i vođenja administrativnih evidencija. Veća je verovatnoća potencijanog terorističkog napada i drugih kriminalnih dela u transportu u poređenju sa statičnim lokacijama u kojima je jednostavnije implementirati sigurnosne i bezbednosne procedure. S druge strane, potencijalno najrazorniji radiološki napad, ali sa najmanjom verovatnoćom realizacije, bilo bi sabotiranje nuklearne elektrane ili bazena sa istrošenim gorivom S tim u vezi, regulator smatra neverovatnim scenarije terorističkih napada i sabotaže na bazene isluzenog nuklearnog goriva Može se tvrditi, s obzirom na potencijalnu ozbiljnost i posledice ovog štetnog dođašaja, kao i mogućnost multipliciranja rizika, da je samo nulta verovatnoća prihvatljiva.

Činjenica da pitanje upravljanja i odlaganja nuklearnog otpada prožima različite sektore utiče da ovo pitanje predstavlja najveći razlog mimoilaženja između nuklearnih pristalica i protivnika. Ovu sferu prati ozbiljna i kontinuirana javna i naučna debatu, permanentno preispitivanje postojanja podrške donosioca odluka, industrijsko lobiranje kao i provera, analiza i nalaženje novih tehničkih i organizacionih rešenja za smanjenje mogućih bezbednosnih rizika. U istom periodu, klimatske promene su postale važno kako političko, tako i naučno pitanje. Globalni rizik od klimatskih promena je, na zaprepašćenje anti-nuklearnih kampanja i oduševljenje nuklearne industrije, delovao afirmativno na pitanje upotrebe nuklearne energije, pa je realno da u budućnosti još veća pažnja bude posvećena pitanjima upravljanja nuklearnim otpadom. S tim u vezi, u budućnosti će zasigurno biti posvećena veća pažnja analizi potencijala skladištenja nuklearnog otpada u dubokim geološkim formacijama, ka modelu koji doprinosi umanjenju bezbednosnih rizika.

S obzirom da određeni produkti nuklearnog gorivnog ciklusa mogu biti iskorišćeni kao naoružanje, pokreću se politička pitanja o proliferaciji od strane međunarodne zajednice. Takođe, posebnu pažnju potrebno je posvetiti organizacionim merama unutar procesa upravljanja nuklearnim otpadom, kako bi se sprečila kultura nekažnjavanja uslovno rečeno blažih kriminalnih dela koja bi mogla da stvore klimu za izvršenje težih i društveno opasnijih dela. Iz tog razloga, ali i radi disperzije stručnih znanja, javnost treba da bude adekvatno informisana o čitavom procesu upravljanja nuklearnim otpadom, bez narušavanja radnih procesa i ugrožavanja bezbednosnih procedura.

ZAHVALNICA

Autori se zahvaljuju Ministarstvu prosvete, nauke i tehnološkog razvoja Republike Srbije (broj ugovora 451-03-68/2022-14/200017).

***Sažetak*—U radu se ispituje efekat neutronskog i gama zračenja na komercijalne gasne odvodnike prenapona. Rad je eksperimentalno-teoretske prirode. Eksperimentalni deo rada je vršen pod dobro kontrolisanim laboratorijskim uslovima. Kombinovana merna nesigurnost je bila oko 5 %. Eksperimentalni sistem je specijalno koncipiran za posmatranu problematiku i ima određena originalna rešenja. Postupak ispitivanja je bio potpuno automatizovan i imao je softversku podršku u upravljanju eksperimentom kao i za prikupljanje i statističku obradu podataka. Dobijeni rezultati pokazuju da neutronsko i gama zračenje popravlja funkcionalne karakteristike gasnih odvodnika prenapona uz memorijski efekat. Dobijeni rezultati su objašnjeni u skladu sa teorijom interakcije neutronskog i gama polja sa materijalom kao i sa teorijom električnog pražnjenja u gasovima. Rezultati prikazani u radu su od važnosti za projektovanje zaštite od prenapona u sistemima koji se mogu naći u polju neutronskog i gama zračenja jer mogu da postignu pozitivan sinergetski efekat zaštite u hibridnim šemama sa drugim komponentama za zaštitu od prenapona čije karakteristike ovo zračenje kvari.**

***Ključne reči*—gasni odvodnici prenapona, neutronsko i gama zračenje, memorijski efekat**

I. UVOD

Minijaturizacija elektronskih komponenti u velikoj meri smanjuje njihovu otpornost na prenaponske pojave. Prenaponske pojave nastaju direktno kao posledica komutacionih procesa unutar mreže na kojoj su uređaji, ili indirektno kao posledica interakcije žičane strukture uređaja sa elektromagnetnim impulsima. Mogući izvori tranzijentnih elektromagnetnih pojava su impulsi prenapona na vodovima, atmosfersko pražnjenje, radarski impulsi i nuklearna eksplozija. U slučaju da prenaponska zaštita uređaja nije dovoljno efikasna prenaponske pojave mogu izazvati oštećenje elektronskih elemenata, sklopova i čitavog uređaja dovodeći do njegovog delimičnog ili potpunog uništenja. Tranzijentni prenaponi, takođe mogu prouzrokovati i prolazne poremećaje u funkcionisanju uređaja [1]–[3].

Alija Jusić, JP Elektroprivreda BiH d.d.-Sarajevo, Bosna i Hercegovina
Ivan Lazović, Institut za nuklearne nauke "Vinča", Univerzitet u Beogradu, Republika Srbija, (e-mail: ivan.lazovic@vin.bg.ac.rs)(https://orcid.org/0000-0002-3877-5157)
Nikola Mirkov, Institut za nuklearne nauke "Vinča", Univerzitet u Beogradu, Republika Srbija, (nmirkov@vin.bg.ac.rs)(https://orcid.org/0000-0002-3057-9784)

Efekti uništenja uglavnom su vezani za poluprovodničke komponente, premda oštećenja izolacije mogu biti izazvana i na drugim komponentama. Poluprovodničke komponente velike snage vezane na linije napajanja, odnosno energetske vodove, mogu biti izložene delovanju visokih vrednosti tranzijentnih prenapona i stoga vrlo ugrožene. Poluprovodničke komponente u niskonaponskim signalima i kontrolnim kolima indirektno su spregnute sa linijom napajanja, ali mogu biti podložne uništenju zbog relativno malog dozvoljenog strujnog i naponskog opsega. Usled visokofrekventnih komponenti tranzijentnog prenapona može takođe da dođe do uništenja poluprovodničkih komponenti u visokonaponskoj oblasti [4]–[6]. Uništenje poluprovodničkih komponenata usled uticaja visokofrekventnih elektromagnetnih polja je dobila na aktuelnosti usled povećane elektromagnetne kontaminiranosti urbanih sredina [7], [8].

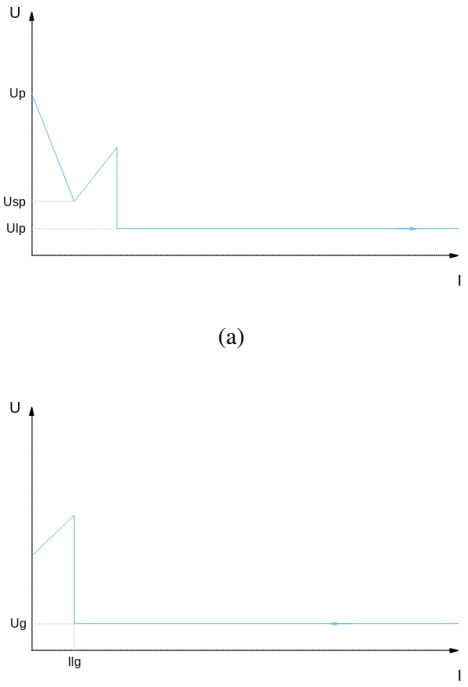
Najrazličitiji poremećaji rada elektronskih uređaja mogu biti izazvani generisanjem tranzijenata u niskonaponskim vodovima. Poremećaji funkcionisanja, u slučaju uređaja za automatsku kontrolu i regulaciju mogu prouzrokovati katastrofalne posledice po kontrolisani objekat. Ipak, većina prolaznih poremećaja funkcionisanja uređaja ne moraju bitno ugroziti njegovo funkcionisanje [9], [10].

Sa aspekta posledica uništenje elektronskih komponenti ili prolazni poremećaji rada su najkritičniji u slučaju da ta elektronska komponenta funkcioniše u okruženju bogatom poljima jonizujućim zračenjem. To je jasno pošto opasnost od jonizujućeg zračenja postoji u nuklearnim energetskim postrojenjima, instrumentima nuklearne medicine, visoko letećim avionima i kosmičkim sistemima. Iz tog razloga je cilj ovog rada da se ispita uticaj neutronskog i gama zračenja na pouzdanost gasnog odvodnika prenapona, komponente koja je nezamenjiva u zaštiti od prenapona na niskonaponskom nivou [11], [12].

A. PRENAPONSKA ZAŠTITA

Elementi prenaponske zaštite mogu se podeliti na nelinearne i linearne. U nelinearne elemente prenaponske zaštite spadaju različite vrste zaštitnih odvodnika prenapona (gasni odvodnici prenapona, varistori i prenaponske diode). U linearne elemente prenaponske zaštite spadaju različite vrste električnih filtera [13]–[15]. U praksi se često koristi

 ISBN 978-86-7466-930-3



kombinacija ovih elemenata, zbog činjenice da većina komercijalnih filtera nije predviđena za korišćenje protiv smetnji koje dostižu nekoliko hiljada volti. Osim toga vrlo je teško obezbediti potreban nivo zaštite uz upotrebu samog filtera [16]. Zaštitni odvodnici sami za sebe imaju nekih nedostataka u slučaju kada je potrebno garantovati zaštitu posebno osetljivih poluprovodničkih elektronskih komponenti.

Kao što je rečeno cilj ovog rada je da se ispita uticaj neutronskog i gama zračenja na gasne odvodnike prenapona.

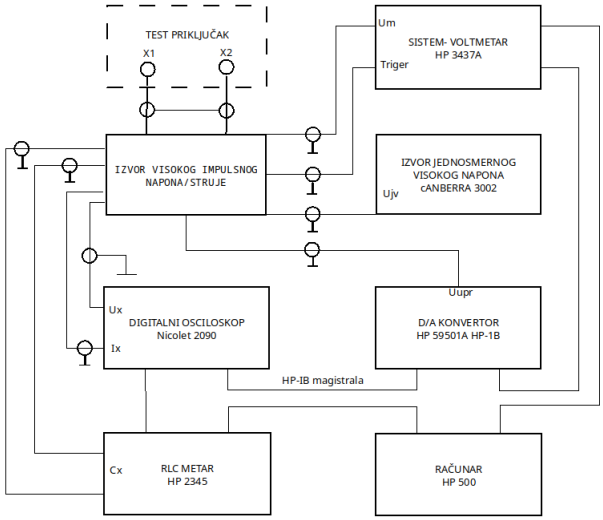
B. GASNI ODVODNICI PRENAPONA

Gasni odvodnici prenapona odlikuju se visokom pouzdanošću i efikasnošću, a koriste se isključivo za prenaponsku zaštitu. Rade na principu električnog proboja gasova i mogu se koristiti za zaštitu od prenapona amplitude od nekoliko desetina do nekoliko hiljada volti [17].

U pogledu energetske izdržljivosti gasni odvodnici prenapona su najizdržljiviji, a u pogledu cene najeftiniji elementi za zaštitu od prenapona. Prednosti gasnih odvodnika prenapona nad ostalim elementima za zaštitu od prenapona su mogućnost provođenja velikih struja (do 60 kA) i niska sopstvena kapacitivnosti (reda veličine 1 pF, što ih čini podesnim za primenu u oblasti visokih frekvencija) [17], [18]. Gasni odvodnik prenapona se sastoji od dve identične elektrode zatupljene u keramičko (ili stakleno) kućište. Međuelektrodno rastojanje je reda veličine 1 mm. Na unutrašnji zid kućišta se, u nekim slučajevima, nanosi radioaktivni izvor da bi se povećala brzina odziva [18]–[20]. Izolacioni gas je neki od plemenitih gasova (u literaturi se za gasni odvodnik prenapona sreće i naziv „osigurač sa plemenitim gasom“) ili smeša plemenitih gasova na pritisku od 1 kPa do 100 kPa. Na slici 1 data je tipična strujno-naponska karakteristika gasnog odvodnika prenapona. Funkcionisanje gasnog odvodnika prenapona zasniva se na Tauzendovom mehanizmu proboja gasa [21]–[23]. Važna karakteristika gasnog odvodnika prenapona je takozvana Pašenova kriva, tj. zavisnost probojnog napona od proizvoda pritiska i međuelektrodnog rastojanja. Pašenova kriva ima oblik asimetrične U-krive. Vršena su istraživanja da se promenom parametara izolacije (materijala elektroda, oblika elektroda, obradom elektrodne površine, ...) Pašenova kriva prilagodi potrebama. Takođe su vršena ispitivanja da se varijacijom parametara izolacije povećava brzina odziva gasnog odvodnika u cilju izbegavanja primene radioaktivnog izvora pri izradi odvodnika [24], [25]. Sama brzina odziva se karakteriše impulsnom karakteristikom, tj. naponsko-vremenskom karakteristikom. Pokazuje se da naponsko-vremenska kriva naglo raste pri brzim impulsnim naponima i to je osnovni nedostatak gasnog odvodnika, tj. gasni odvodnik sporo reaguje.

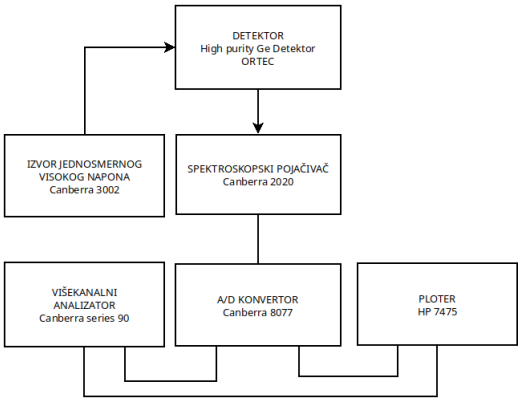
Slika 1: Tipične strujno-naponske karakteristike gasnog odvodnika prenapona

II. EKSPERIMENT



Ispitivanje uticaja jonizujućeg zračenja na karakteristike gasnih odvodnika prenapona vršeno je na komercijalnim. Ispitivan je komercijalni gasni odvodnik nominalnog napona 470 V punjen gasom He [26], [27]. Impulsne karakteristike su računate na osnovu zakona o konstantnosti površine u volt sekundnoj ravni ispod impulsnog napona i konstantnog nominalnog napona. Za potrebu proračuna impulsnih karakteristika razvijen je namenski softver [28], [29].

Za eksperiment je korišćena visokokvalitetna oprema. Radi eliminacije uticaja elektromagnetnih smetnji na elektronskim aparatima ispitni i merni deo opreme su bili odvojeni profesionalnom mernom kabinom zaštite od električnog polja većom od 100 dB i zaštitom od magnetnog polja većom od 40 dB. Veze između ispitnog i mernog dela je bila negalvanska [30], [31]. Merni sistem je bio u potpunosti automatizovan. Na slici 2 prikazana je blok šema mernog kruga. Kao impulsni napon korišćen je duploeksponencijalni napon oblika 8/20 ms.



Za ispitivanje efekta neutronskog i gama zračenja na gasni krug korišćen je izotop kalifornijuma ^{252}Cf. Neutronski spektar kalifornijuma ima maksimum pri energijama od oko 0.8 MeV, a maksimalna energija neutrona je 20 MeV. Analiza spektra izvora vršena je aparaturom čija je blok šema data na slici 3. ORTEC germanijumski detektor bio je hlađen tečnim azotom.

Merenje uticaja neutronskog i gama zračenja vršeno je tako što su određivane impulsne karakteristike i histogrami slučajnih promenljivih jednosmerni probojni napon i impulsni probojni napon pre ozračenja, tokom zračenja i

 ISBN 978-86-7466-930-3

Slika 2: Blok šema mernog sistema

Slika 3: Blok šema aparature za analizu spektra zračenja

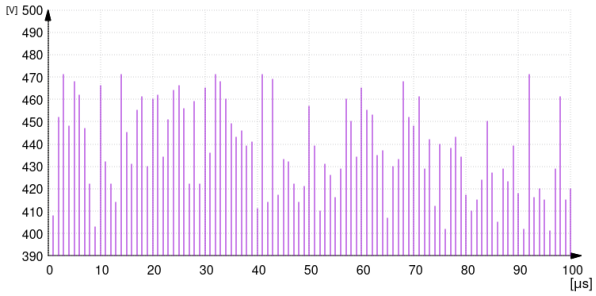
nakon ozračenja. Merenja nakon ozračenja su vršena sa vremenskim pauzama da se utvrdi da li postoji indukovani efekat neutronskog zračenja. Za određivanje jedne vrednosti jednosmernog probojnog napona vršeno je merenje 100 uzastopnih vrednosti jednosmernog probojnog napona (primenom jednosmernog izvora napona brzine porasta 8 V/s). Za određivanje jedne vrednosti impulsnog probojnog napona vršeno je merenje 100 uzastopnih vrednosti impulsnog probojnog napona (primenom impulsnog napona brzine porasta 8/20 ms). Pauza između dva uzastopna proboja bila je jedan minut.

Kombinovana merna nesigurnost eksperimentalnog postupka je bila oko 5 % [30], [31].

III. REZULTATI I DISKUSIJA

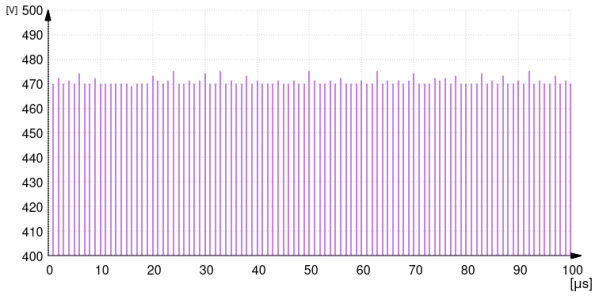
Na slici 4 prikazane su hronološke vrednosti slučajne promenljive jednosmerni probojni napon gasnog odvodnika: a) pre stavljanja u polje neutronskog i gama zračenja; b) za vreme boravka u polju neutronskog i gama zračenja (fluksa neutronske komponente 16.244 • 10^{11} n/cm^2); c) hiljadu sekundi nakon prestanka dejstva polja zračenja; d) 100 000 s nakon prestanka dejstva polja zračenja.

Na slici 5 prikazane su hronološke vrednosti slučajne promenljive impulsni probojni napon gasnog odvodnika: a) pre stavljanja u polje neutronskog i gama zračenja; b) za vreme boravka u polju neutronskog i gama zračenja (fluksa neutronske komponente 16.244 • 10^{11} n/cm^2); c) hiljadu sekundi nakon prestanka dejstva polja zračenja; d) 100 000 s nakon prestanka dejstva polja zračenja.



Na osnovu slika 4 i 5 se vidi da neutronsko i gama zračenje smanjuje rasipanje slučajnih promenljivih jednosmerni probojni napon i naizmenični probojni napon. Interesantno da se ova pojava održava i nakon dejstva polja zračenja ali ograničeno vreme. Naime, nakon 100 000 s od dejstva polja zračenja hronološki niz vrednosti slučajnih promenljivih statički probojni napon i impulsni probojni napon imaju sličan izgled kao u slučaju neozračenog gasnog odvodnika.

Na slici 6 prikazane su impulsne karakteristike gasnog odvodnika: a) pre stavljanja u polje neutronskog i gama zračenja; b) za vreme boravka u polju neutronskog i gama zračenja (fluksa neutronske komponente 16.244 • 10^{11} n/cm^2); c) hiljadu sekundi nakon prestanka dejstva polja zračenja; d) 100 000 s nakon prestanka dejstva polja zračenja.



Sa slike 6 je jasno da dejstvo neutronskog i gama zračenja spušta i sužava impulsnu karakteristiku. Taj efekat je prisutan kada se gasni odvodnik nalazi u polju zračenja i određeno vreme (par sati) nakon što prestane dejstvo zračenja. Nakon više vremena, uočeni, memorijski efekat se gubi. Ovde je posebno važno uočiti da je na slikama 6b i 6c usporavanje porasta impulsne karakteristike u oblastima većih brzina impulsnog napona (to su u praksi kritične oblasti brzih indukovanih prenapona).

Efekti uočeni na slikama 4 - 6 se mogu objasniti efektima jonizacije radnog gasa u neutronskom i gama polju. Pošto je odvodnik izolovan He gasom neutronska komponenta primenjenog polja je sudarnim procesom pomerala jezgro He (α-česticu) koja je vršila jonizaciju He gasa i stvarala jonsko-elektronske parove. Isti efekat je izazvalo i gama zračenje foto-elektronskim efektom i Komptonovim rasejanjem. Na taj način dolazi do povećanja broja elektrona u međuelektrodnom prostoru, a svaki elektron koji se nađe u homogenom polju može da postane inicijalni tj. da pokrene lavinski proces Tauzendovog proboja. To je posledica što je polje u međuelektrodnom prostoru (tj. na svakoj srednjoj dužini puta elektrona on stekne dovoljno energije da izvrši jonizaciju) [34], [35]. Što se tiče memorijskog efekta (ustanovljenog efekta dejstva neutronskog i gama zračenja i nakon uklanjanja polja zračenja) posledica je aktiviranja materijala odvodnika neutronima. To aktiviranje ima relativno kratko poluvreme raspada. Potvrda ovog tumačenja jesu spektrometri (aktivacione analize) gasnog odvodnika 1000 s i 100 000 s nakon dejstva zračenja, slike 7a i 7b.

IV. ZAKLJUČAK

Cilj ovog rada je bilo ispitivanje neutronskog i gama zračenja na stabilnost karakteristika gasnih odvodnika prenapona. Izabrano je neutronsko i gama zračenje (iako neutronsko zračenje ne spada u direktno jonizujuće zračenje, ono je indirektno jonizujuće) pošto ta dva tipa zračenja najlakše prodiru kroz telo gasnog odvodnika i deluju u međuelektrodnom prostoru. Dejstvo neutronskog i gama zračenja je interesantno i radi primene gasnih odvodnika prenapona u upravljačkim sistemima nuklearnih energetskih postrojenja pošto u njima postoji verovatnoća pojave ovog polja zračenja. Dobijeni rezuktati su interesantni pošto pokazuju da dejstvo neutronskog i gama zračenja popravlja funkcionalne karakteristike gasnog odvodnika prenapona. To poboljšanje karakteristika ima i memorijski efekat, tj. zadržava se i nekoliko sati nakon prestanka dejstva polja zračenja. Ovaj rezultat je od važnosti za praktične primene prenaponskih zaštitnih komponenti u hibridnim šemama pošto neutronsko i gama zračenje utiče na smanjenje zaštitnih osobina odvodnih dioda i varistora što se može kompenzovati poboljšanjem zaštitnih osobina gasnog odvodnika prenapona.

One Solution For Multimedia Subscription Using Blockchain

Igor Srdić, Đorđe Glišić, Marija Jovanović

***Abstract*—With the expansion of blockchain technologies in different areas from health care to voting systems and emerging demand on video content delivery platforms, it is interesting to investigate possibilities to combine those two into a new system that will help digital content availability. We present and discuss relevant work in the industry. Paper proposes one solution for subscription rights management using blockchain technologies. Proof of concept is done using the Ethereum blockchain ecosystem for a video-on-demand service. A similar approach could be used in other fields of DTV services, like cable TV subscription services.**

***Index Terms*—subscription management, blockchain, smart contracts, Ethereum, DTV content subscription, Android TV, solidity, web3j.**

I. Introduction

Blockchain is a growing list of records linked to the use of the cryptocurrency method. After the sudden expansion of Bitcoin [1], it became clear that the potential of blockchain is a lot greater than its use for money. This technology's decentralized system is fertile ground for many ideas and provides a new approach and opportunities [2]. There are ideas like a voting system for elections, where vote theft and rigging of results could not occur, and many other ideas, each of which aims to improve the current system, which has its virtues and many flaws. The system's main problem with the central authority, with a central database, is that such systems have one critical point - the system's bottleneck, which, if endangered, puts the whole system in danger.

Ethereum is a platform that works on top of blockchain technology which has revolutionized this field. It is a platform that allows its users to develop their decentralized applications [3]. It also resolves one additional issue in such networks: they cannot function without many users - nodes - who work on them.

Buying and renting multimedia content is the default functionality on all TVs, most often as Video On Demand (VOD), where users temporarily purchase rights to view a movie or series. With increased online shopping abilities, new options come to mind. What if a user can sell its rights to another user? Does it always have to be between the content provider and the end-user? In the real world, there are second-hand shops for used goods. Why don't such digital shops exist in the entertainment industry? Blockchain technology may be the right step towards that. It is reasonable to think that users would rather sell digital valuables than offer them free to the public. Some movements are done in that direction with the appearance of NFT (non-fungible token).

Some work has been done toward decentralized video streaming platforms using blockchain technologies in work by Tan et al. [4]. Focus that work was around content creators, advertisers, and consumers and the availability of the content in networks based on blockchain. More discussion on the usability of blockchain smart contracts in the entertainment industry could be found in the work of Pons [5].

Working consortium grouped around Sony, Samsung, and Google work on creating a next-generation video entertainment blockchain. A published white paper [6] presents the new architecture of the distributed content delivery network called Theta Mainnet 4.0. They have anticipated Theta Metachain and Theta Edge Network, as illustrated in Fig. 1. The first network is distributed blockchain of blockchains, where the "metachain" name comes from, resulting in support for an unlimited number of blockchains. The second network is responsible for interaction with users. Using publicly available Theta Video API, users can upload content and request access to content. The network has endpoints for protected content storage, encoding new content uploaded, and delivery to the user with an appropriate NFT-based digital rights management (DRM) system. It is expected to be available by the end of 2022.

 ISBN 978-86-7466-930-3

In this paper, we are investigating the possibilities of using blockchain technology in the world of digital television. In particular, we tried to use the smart contracts concept from the Ethereum ecosystem to allow users to buy video content from their homes [7]. Once a transaction is initiated, it takes more than 10 seconds for the change to be permanently stored in the blockchain, which is the waiting time for the return values of these functions. Detailed workflow can be seen in Fig. 2. This implies that Ethereum applications are not suitable for all systems that need faster data exchange and cannot correctly use current blockchain technology.

A smart contract as a programming code cannot be changed once it enters the blockchain. The mistakes and oversights are only solvable by creating new smart contracts and redirecting the applications to new contracts. The main problem is that errors are discovered only when they happen, and in such a system, the results of errors are harmful to the user.

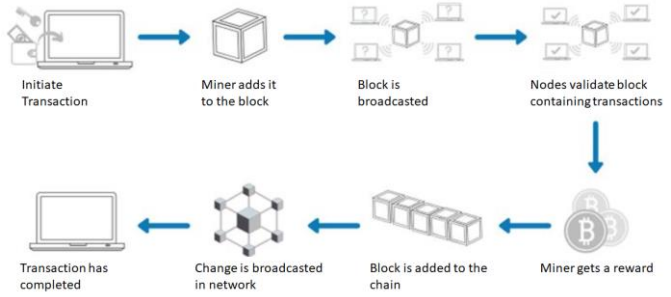

Fig. 2. Workflow for a transaction in the Ethereum network

In this work, smart contracts will be used for exchanging digital currencies for video-on-demand (VOD) services. We will introduce a digital wallet, an application used for storing digital funds (for example, cryptocurrency). On the side of the DTV device, a DTV application will be altered to support additional payment methods for its video-on-demand service. Those are the building blocks necessary to complete the task of creating a subscription management system with blockchain technology.

The paper consists of three parts. The second section will present functional requirements. The third section will explain all technologies and implementation of the system and the TV application adopted to be the client for the blockchain payment method. The fourth and last part contains an overview of the solution itself, shortcomings, and problems that have arisen during implementation and testing, and finally, we will discuss possible improvements.

II. Requirements

Purchase of content should be made on the chain itself. It should be implemented as an Ethereum smart contract that will provide functionalities such as purchase and storage purchase history. Purchased history has two parts, valid and expired. A valid subscription is the one that is still active and allows the owner to consume it (Fig. 3), in our case, to watch a movie or TV show. An expired subscription is essential for validating existing payments and resolving any problems. Additional requirements involve checking content access rights for specific users, content validation by the provider, etc. There is a set of functions related to administration, which can be performed exclusively by the provider. It must be ensured that the user cannot call them.

Fig. 3. The user interface for the Video on Demand service

In addition to the account user created in the TV application, the user also received his Ethereum account and can deposit money at physical ATMs or online. That order is permanently linked to a TV application account, and every content purchase is made through that account.

In this research, we did not want to use any currency assets. Instead, we selected the Ethereum test network Rinkeby. In this network, the currency has no real value, so we could deposit any amount of money into the account for testing purposes. For that reason, work does not cover depositing currencies. That does not reduce the applicability of the proposed solution, as only the target network has to be changed to make it usable in the real world.

Executing the method from smart contracts may take some time, but it is necessary to ensure that the application runs smoothly while waiting for the answers to those calls. An example screen for purchasing content is shown in Fig. 4. In particular, Android has a built-in capability to interrupt application execution that does not work for a while by sending ANR - Application Not Responding error.

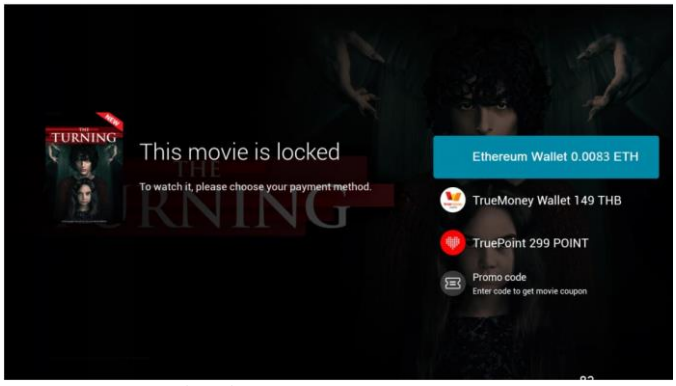

Fig. 4. The user interface for Video on Demand service when content is locked (needs payment)

After the purchase, the user should be able to view the content for 30 days before the first review or two days from

 ISBN 978-86-7466-930-3

when the content was first viewed. After the period expires, the content should be locked again until the next purchase. Given that money can be sent by calling smart contract functions, it is necessary to ensure that, in case of any error when calling these functions, the payments are aborted, and user funds remain untouched in the account.

III. IMPLEMENTATION

To implement our system, we had to implement two main components. The first one is smart to contact that will be positioned in the Ethereum test network. We used Solidity high-level object-oriented programming language especially designed for Ethereum networks. We selected Remix development environment (IDE), written in JavaScript and running under any web browser as a development environment.

On the client-side, we had an Android TV application [7] running on a set-top box (STB) device [8][9]. The application was written in Java. We have selected the web3j library for integration into the existing application to establish a connection with Ethereum smart contract API [10].

For storing the user's digital currency, we selected a digital wallet Metamask, which was used to create the Ethereum account. Its purpose is to save access to the digital currency details in the Ethereum network.

To simulate the Ethereum network, we created a network of miners. For that purpose, we used an Infura cluster made of full nodes. The cluster can execute contracts and alter the chain.

Part of the smart contract is present in Fig. 5. There are three fields of integer type. The *myEtherValue* field is an auxiliary used to convert some numerical data into currency Ether. At the same time, *shortDuration* and *longDuration* represent the lengths of the period in which the buyer is allowed to watch content. The *ctAddress* field is of the address type, the type of data it represents in Solidity public addresses of users in the Ethereum network. This is the address of the crypto-telecom (provider) which will have administrator privileges in the system.

In addition, there are two structures, *Content* and *Deal*. Structure *Content* represents the content and contains fields for name, price, and one auxiliary field. Structure *Deal* is proof of purchase, the contract concluded between provider and customer. It has the identifier of purchased content, the time of the purchase, the time when the user first looked at the content, and the field that indicates whether the content is still viewed. The content folder, which maps the content identifiers to data of the *Content* type, contains all available content of the provider. Maps *validDeals* and *archivedDeals* map users (addresses) into concluded contracts and are in the valid and expired contracts, respectively.

The Web3j library receives the output of the Solidity compiler [11][12] consisting of binary and ABI file and generates a Java surrounding class smart contract, in this case, class *CryptoTelecom*. Some of the methods of this class:

- *load* - loading the contract instance with the given address, web3j object, user credentials, and gas variables.

- *order* – Wrapper method of the smart contract order function. The return value is *RemoteFunctionCall <TransactionReceipt>*, which represents identification of transaction. Once the function is called, it will return its value after the function is executed, the state of the contract is changed, and that state is saved in the new transaction as part of a new block in the blockchain.

```
contract CryptoTelekom {

    uint256 private myEtherValue;
    uint256 private shortDuration;
    uint256 private longDuration;

    address payable private ctAddress;

    struct Content {
        string name;
        uint256 price;
        bool isValid;
    }

    mapping(string => Content) content;

    struct Deal {
        string contentId;
        uint256 startedTime;
        uint256 startedWatchingTime;
        bool startedWatching;
    }

    mapping(address => Deal[]) validDeals;
    mapping(address => Deal[]) archivedDeals;

    modifier onlyCT() {
        assert(msg.sender == ctAddress);
        _;
    }

    event Order(uint256 ret);
    event CheckDeal(bool ret);
    event ValidDeal(string contentId,
                    uint256 startedTime,
                    uint256 startedWatchingTime,
                    bool startedWatching,
                    bool isRetValid);
```

Fig. 5. The interface of the contract class in Solidity.

- *getOrderEvents* - Read events from the order method in a given transaction.

- *getNumValidDeals* - Wrapper method for function *getNumValidDeals()* from smart contract. Example of a return method that does not change the state of the contract. The return value is immediately available because only data is read.

Details about how we used Metamask, Rinkeby network, and Infura cluster can be found in [13]. Also, the authors omitted implementation details about the Android Java application as reference code can be found in [9]. Work does not lose clarity or applicability without those details, as that information can be found both in given references and online resources.

 ISBN 978-86-7466-930-3

IV. Conclusion

The novelty that this approach brings, and at the same time one of its advantages, is that proof of the contract is no longer stored in the provider's database - all are stored on the Ethereum chain. This is interesting for the provider for two reasons. The first is that maintenance of the database by the provider is completely avoided, and the second is that no one can write data to a chain without the consensus of the entire network. Therefore, no one can falsely present themselves as having the right to specific content. Furthermore, users who purchase content are confident that their content rights will remain untouched because data ends on a chain that cannot be changed.

The virtues of this approach are numerous. However, there are also drawbacks. Developers must pay close attention when developing smart contracts because consequences in a system that operates with money can be substantial [14]. Also, it is important to optimize the program code as much as possible. The gas is charged to the initiator of the transaction. Calls to the smart contract function are calculated for every assembler instruction executed. Therefore, additional effort should be made to make the code as optimal as possible to lower gas prices. Also, as transaction initiators are charged for gas, and transactions are initiated by the users who buy the content, the provider has no operating cost for the network. Another approach is to subtract the price gas from the total price of the content that the user buys, which would result in the situation where the provider pays for network service and the user for the content.

Model-Driven Approach to Blockchain-Enabled MLOps

Nenad Petrović

***Abstract*—In recent years, machine learning has reached quite sophisticated level of usability within applications across various domains – ranging from boo ing reservations and media content delivery to business and healthcare. owever, the deployment of machine learning models, together with parameter tuning and periodic training, which are necessary to maintain satisfiable performance, represent time consuming processes, requiring various types of s ills - both Dev ps and data analysis-related. In this paper, we leverage model-driven approach in synergy with code generation with aim to automatize the so-called ps activities, relying on en framewor for pipeline automation and ubernetes for containerized tas orchestration. n top of that, we leverage loc chain for infrastructure provisioning. ur goal is to reduce the cognitive load of infrastructure and services management within systems relying on machine learning. The framewor is evaluated in scenarios using PyTorch-based deep learning predictive models. According to the results, the proposed approach reduces both the time and s ill required for successful ps activities.**

***Index Terms*—Dev ps; ubernetes; ps; PyTorch; loc chain.**

I. Introduction

Continuous integration and delivery have become standard in software engineering workflow within the last decade. The goal of so-called DevOps practice is to align the deployment of software artifacts with business goals which are enabled by them, so the customer's organization can benefit from them as quickly as possible. However, operations related to underlying infrastructure management are becoming more and more complex, due to heterogeneity of services, devices and increasing performance demands. Therefore, due to fact that machine learning (ML) services are recognized as crucial enablers of novel usage scenarios across various domains, a distinct subfield with focus on them has emerged, known as MLOps [1-4]. It is an extension of now well-established DevOps paradigm with aspects specific to service delivery in machine learning, such as continuous model training for prediction performance improvement, rapid deployment and parameter tunning towards automated generation of complex ML task pipelines [1-4].

In this paper, the focus is on reducing the complexity of MLOps-related activities and service delivery relying on model-driven approach [5]. Moreover, the business-related aspects of infrastructure resource provisioning and usage charging using blockchain by the provider are also considered. The main contributions of this paper are the following: 1) MLOps metamodel – defining the structure of user-created model instances representing machine learning pipelines with several distinct steps together with aspects related to its deployment 2) code generator – leverages the model for automated code generator covering several aspects: pipeline script, predictive model, infrastructure management 3) blockchain-based transaction model making use of smart contracts for renting high-performance computing resources aiming accelerated machine learning.

In our previous works, metamodel-based approach in synergy with ontologies was leveraged for automated container-based service deployment in Fog Computing [6]. On the other side, a similar method was adopted in [7] for generation of predictive models starting from high-level predictive problem descriptions aiming state-of-art mobile network infrastructure planning and management.

II. Background

A. ZenML

ZenML [8] is open-source, high-level Python framework for machine learning pipeline automation. It is available as Python library in form of function decorators and specific classes inside scripts, while it imposes pre-defined code structure. The overview of main ZenML-related concepts and terminology is given in Table I.

TABLE I
ZenML Concepts Overview

Concept	Description
Repository	A special type of directory, declared used `zenml init` command. Each ZenML action must take place within a repository, which is created
Step	Single stage within ML flow, representing a node of in ML flow computation graph. Implementation-wise, they represent Python functions with typed parameters in signature for both arguments and return value. Decorator used is `@step`, while step result caching can be enabled using `enable_cache=True` parameter
Pipeline	A sequence of steps. It connects all the steps, their inputs and outputs. Decorator used is `@pipeline`. Moreover, it is possible to set the list of external libs/dependencies from .txt file can be done using `requirements_file` attribute of the decorator. It is run by invoking `pipeline.run()` method inside Python script. Optionally, a scheduler object can be assigned for periodic execution of certain steps enabling scenarios such as continuous model training.

 ISBN 978-86-7466-930-3

Stack	Represents environment and configuration of MLOps platform infrastructure. It consists of: artifact store, metadata store, container registry, orchestrator and custom step operators. Creating a new stack with desired parameters is done using `stack register`, while it is run using `stack up` command., which has to be done before running any pipeline.
Artifact store	Persistent storage of step results.
Materializer	Defines how data is passed between steps. Serialization and deserialization are used while storing/retrieving results.
Metadata store	Keeps the data related to pipeline, step and experiment configuration and references for tracking of inputs/outputs within artifact store created within ML pipeline.
Orchestrator	Component for scheduling and running pipeline steps
Container registry	Stores Docker images required for running the steps
Custom step operator	User-defined environments for running ML flow tasks within Docker containers
Integration	Enable usage of various third-party tools enriching ML development like pytorch, tensorflow and sklearn. Apart from that, it also includes orchestrator-enabled stacks, such as local-kubeflow (Kubernetes-based) and airflow.

Depiction of ZenML architecture showing how the previously mentioned concepts are related is given in Fig. 1.

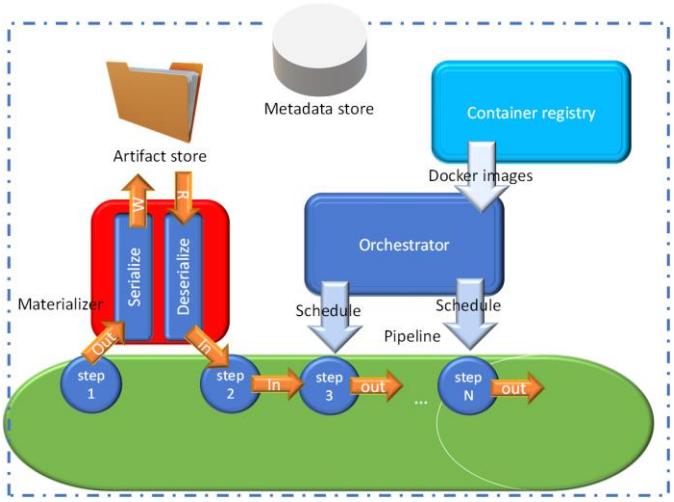

Fig. 1. ZenML concepts and their relations.

Additionally, Fig. 2 shows the programming workflow using ZenML. First, we initialize a repository inside the desired directory where we place our Python script. After that, in Python code we define the typical steps of ML flow: 1) importer – downloading and loading dataset 2) trainer – passing through dataset and updating model weights for new predictions 3) evaluator – estimates how good the prediction performance is, according to the given metric (accuracy for classification; mean relative error - MRE for regression). Moreover, we connect the steps in a sequence as shown within the pipeline object and finally run the pipeline object instance.

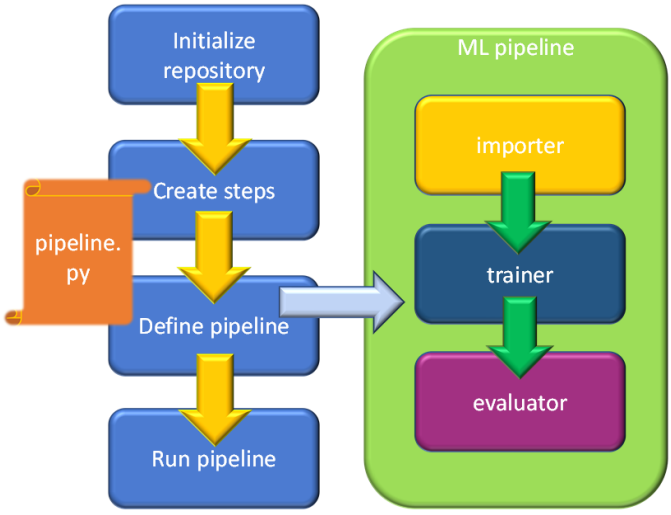

Fig. 2. ML pipeline creation using ZenML in Python.

B. *ubernetes*

Kubernetes [9] represents an open-source platform whose goal is to enable deployment and management of containerized services run on multi-server clusters. Furthermore, it provides convenient access to useful features, such as scalability, fault-tolerance and declarative configuration. Table III gives an overview of key concepts within Kubernetes-based architectures.

TABLE III
KUBERNETES CONCEPTS OVERVIEW

Concept	Description
Control plane	Cluster management component, responsible for global decisions, and scheduling
Node	Worker machines within the cluster running containerized apps
Pod	Smallest deployable unit, which consists of one or more app containers. These containers share storage, network specification and config. Optionally, might include data volumes for persistent storage
Service	A logical set of pods
Kubectl	Comamnd-Line Interface (CLI) tool for running commands against Kubernetes cluster, such as: -Deployment (`kubectl apply deployment.json` and `kubectl create deployment dep_name --image=docker_image` -Scaling up/down (`kubectl scale --replicas=num resource_name`) -Retrieval of node, pod and service info (`kubectl get pods, nodes, services`)

Despite the fact that Kubernetes provides automatic scheduling capabilities, there might be situations where deployment of pod has to be done on a specific node. In that case, we leverage node labels. The corresponding command for labelling a node has the following form: `kubectl label nodes <node_name> label_name=label_value`. After that, when we want to create a pod using YAML configuration file, it would be necessary to make use of `nodeSelector` property and set it as `label_name:label_value`.

 ISBN 978-86-7466-930-3

Kubernetes-based architecture is depicted in Fig. 3. In this paper, we make use of containerized custom step operators in ZenML run as Kubernetes pods, which are actually containers running PyTorch code. Moreover, node labels are leveraged in order to have low-level scheduling control and determine where each of these steps will be executed, enabling additional flexibility.

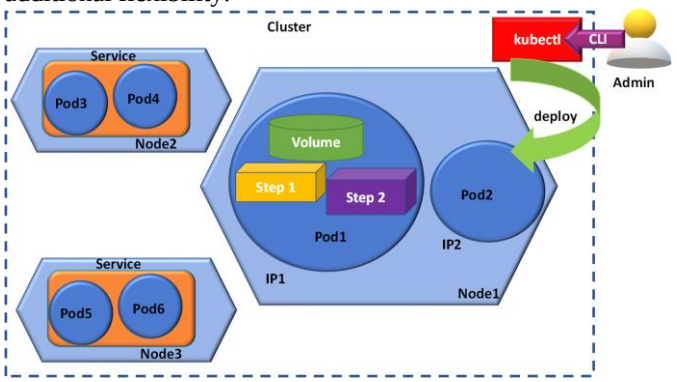

Fig. 3. Kubernetes-based containerized app architecture.

III. IMPLEMENTATION

A. Workflow overview

Model-driven workflow of the proposed framework for automated ML-related task deployment is illustrated in Fig. 4. In the first step, user creates a deployment diagram model instance which describes the ML pipeline and underlying execution infrastructure details. After that, the model is parsed, so code generator constructs Python script containing the ML pipeline code relying on ZenML and PyTorch in synergy with numpy. Moreover, corresponding Kubernetes orchestrator commands are generated in order to ensure that distinct pipeline steps are executed on the desired cluster nodes. Additionally, the allocated resources are charged to the customer by parametrizing smart contracts for blockchain-based transactions, while the price might vary due to presence of deep learning accelerator cards on some of the nodes. Finally, the generated machine learning Python script is executed on the allocated computing nodes.

Fig. 4. Blockchain-enabled model-driven MLOps workflow.

B. MLOps Metamodel

When it comes to adoption of model-driven engineering, we make use of metamodel which defines the structure of user-created deployment diagram (shown in Fig. 5). For implementation, Ecore [10] within Eclipse Modelling Framework (EMF) [11] in Java is used, which automatically generates all the auxiliary classes for model manipulation, together with convenient GUI-enabled editor.

The highest-level concept is *Pipeline*, which consists of one or more machine learning tasks, referred to as *Step*. A Pipeline can be executed periodically for purpose of continuous training, which is defined by *repeatTime* property. Moreover, each of the Steps can be one of the following type with specific, distinct properties: *Importer*, *Trainer* or *Evaluator*. Importer represents ML task which downloads the corresponding dataset and opens the downloaded file. In this context, it is necessary to set URL corresponding to the location where dataset is stored online, denoted as *onlineData*. Otherwise, if dataset is local and already present on disk, another parameter is used – *localData*. When it comes to trainer step, it is possible to set its learning rate, number of batches, select the target implementation technology, but we make use of PyTorch in this paper. Each trainer can use pre-created model, given by *modelPath* or it is necessary to define a custom neural network. For custom neural network, its architecture is described using *layer* element, while each of them has type (such as Convolutional – in image classification or standard Fully Connected in Multi-Layer Perceptron), number of processing units (neurons) and activation function (such as ReLU, softmax, sigmoid). Finally, the performance metric used within Evaluator step depends on the type of machine learning task, and we cover two possibilities relevant to supervised learning as *predictionType* property of *Pipeline* – classification (*Accuracy*) and regression (*MeanRelativeError*).

On the other side, the aspects of distinct Step deployment are covered by the metamodel as well. For each pipeline part, there is an attribute *targetLabel*, describing which worker node within Kubernetes cluster would be preferred for execution of pod created within custom step operator. Additionally, infrastructure executing the pipeline is represented as *Cluster* that consists of *Nodes*. For each *Node*, the following properties are customizable, such as label, location, IP address, accelerator (whether it has dedicated hardware for deep learning attached) and unit price (depending on the node performance).

 ISBN 978-86-7466-930-3

C. Code Generation

The user-drawn deployment model is first parsed and then traversed relying on Ecore-generated classes. Pipeline element and iterated for each of the contained steps. When it comes to each step, it is necessary to get the target label and insert it into nodeSelector section within Kubernetes deployment YAML file. After that, depending on the step type, corresponding template is used. For importer steps, it is only necessary to change the path where pre-created model is located. When it comes to trainer, it contains model training loop iterating for given number of epochs through batch number of dataset samples and desired learning rate (α) value. For evaluator step, the corresponding method is chosen according to the type of prediction problem. Additionally, the leasing of resources is charged to the customer by valorizing blockchain smart contract with unit price of the selected node. Finally, the previously created Kubernetes YAML describing step deployment is applied, so the pod with Docker container running ML task inside is spawned on the selected node. Pseudocode of the code generation procedure is given in Table IV.

TABLE IV
CODE GENERATION PSEUDOCODE

Input: MLOps deployment model
utput: Python script, Kubernetes commands, Smart contract
Steps
1. deployment.elements:=parse(model);
2. Retrieve pipeline from deployment.elements;
3. For each step in pipeline
4. Create nodeSelector for step.targetLabel;
5. If(step is Importer)
6. Generate importer loading dataset from step.localData or onlineData;
7. If(step is Trainer)
8. Load model from step.modelPath;
9. Generate TrainerCode(step.epochs, step.batch, step.alpha);
10. If(step is Evaluator)
11. If pipeline.predictionType is regression
12. Use Mean Relative Error;
13. Else
14. Use Accuracy;
15. Get node.unitPrice;
16. Calculate total leasing price as step.estimatedTime*step.node.unitPrice
17. Genrate smart contract between pipeline.customerId and step.node.providerId for total price;
18. Apply Kubernetes deployment for pod with step.id;
19. End for each
20. End

. ZenM pipeline elying on PyTorch eep earning Models

Deep learning refers to approach in artificial intelligence making use of neural networks with one or many hidden layers between the inputs and outputs. PyTorch [12] is library for Python which covers the required set of capabilities for deep learning: tensor manipulation and high-level object-oriented representation of both models and datasets. In Fig. 6, an excerpt of typical ZenML pipeline relying on PyTorch models is given. This kind of Python script actually represents one of the outputs of code generator. When it comes to neural network models in PyTorch, their capabilities are encapsulated within *Module* class which has to be inherited by any custom model. In this class, within the constructor we define neural network architecture (layers, nodes and activation functions), while *forward* connects the layers defining how data passes through neural network. In given example, we use MNIST dataset [13] of handwritten digits for purpose of classification.

```
class Net(nn.Module):

    def __init__(self):
        super(Net, self).__init__()
        self.flat_network = nn.Sequential(
            nn.Flatten(),
            nn.Linear(784, 311),
            nn.ReLU(),
            nn.Linear(311,10)
        )
        # fully connected layer, output 10 classes
        self.out = nn.Linear(10, 10)

    def forward(self, x):
        x = torch.unsqueeze(x, dim=0)
        x = self.flat_network(x)
        x = self.out(x)
        output = self.out(x)
        return output

def get_data_loader_from_np(X: np.ndarray, y: np.ndarray) -> DataLoader:
    tensor_x = torch.Tensor(X)  # transform to torch tensor
    tensor_y = torch.Tensor(y).type(torch.LongTensor)

E. esource easing elying on Solidity Smart Contract

Blockchain enables decentralized approach to immutable and irreversible transactions relying on approval by huge network of computer nodes, making it secure and reliable. On the other side, smart contracts define actions executed within protocol for realization of blockchain-based transaction. In this paper, we make se of Ethereum blockchain in synergy with Solidity smart contracts [14]. Solidity code of the underlying transaction mechanism for resource leasing in context of ML task execution is given in Fig. 7. As it can be seen, the information stored as part of transaction consists of *customerId*, *pro iderId* and identifier of node which will execute some ML task which represents a step within pipeline. First, the total price is calculated by multiplying *unitPrice* and *estimatedTime* required for step execution. After that, the transaction itself is performed by transferring the previously calculated total amount of tmokens from customer's to provider's account.

```
contract LeasingInfrastructure {
   address public providerId;
   uint32 public nodeId;
   uint32 public stepId;
   mapping (address => uint) public balances;

   event Sent(address customerId, address providerId, uint total);

   function leaseNode(address received, uint unitPrice, uint estimateTime) public {
      total = uintPrice*estimatedTime;
       require(total <= balances[msg.sender], "Not enough tokens");
      balances[msg.customerId] -= total;
      balances[providerId] += total;
      emit Sent(msg.customerId, providerId, total);
   }
}
```

Fig. 7. Solidity smart contract for ML task resource leasing.

IV. Experiments and Evaluation

For evaluation of the proposed framework, three publicly available image classification datasets were used. The first two tackle image classification problem: 1) yoga pose determination (our previous work presented in [15]) - 5 poses in dataset of 1551 images 2) MNIST [13] – 70 000 images of handwritten digits 0-9. On the other side, a regression problem of service demand prediction in telco networks from [7] was considered as the third case. In all of the experiments, test was 20% of the overall dataset with no overlapping samples from training set. The presented experiments were run on MacBook Pro (16-inch, 2019) laptop, equipped with 2.3GHz 8-core Intel Core i9 CPU, 16GB of DDR4 memory, 1TB SSD and Intel UHD Graphics 630 with 1.5GB VRAM. On the other side, Kubernetes cluster consisted of two more Ubuntu machines equipped with Intel i5 CPU, 8GB DDR4 RAM and 4GB GPU.

The results of the experiments are given in Table IV. Several aspects were considered: code generation time, model training time, speed-up compared to manual pipeline creation including model creation (moderately experienced machine learning engineer) and achieved prediction performance (MRE for regression, accuracy for classification).

TABLE IV
Experiment results

Case	Code generation [s]	Model training [s]	Speed-up [times]	Performance [%]	Manual pipe [s]
Yoga pose [15]	0.911	317	45	Accuracy 73%	104
MNIST [13]	0.87	124	36	Accuracy 96%	91
Telco [7]	0.93	27	21	MRE 9%	88

As it can be seen, in all the cases, the achieved speed-up was more than 20 times compared to traditional approach involving manual Python code writing from scratch. However, the speed-up is more significant is case of more complex models based on convolutional neural networks with huge number of layers – it was yoga pose determination. In our case, the only manual operation is pipeline deployment model creation using GUI tool, which took about 1.5 minutes in our experiments. All the models show almost identical performance to traditional counterparts, as expected. When it comes to code generation, execution time does not exceed 1 second in the presented case studies. Finally, the overhead of model training compared to execution without MLOps framework is around 15% when run on single machine and k3d [16] local Kubernetes cluster, but can be compensated by smart scheduling techniques, especially for larger datasets.

V. Conclusion and Future Work

According to the achieved experimental results, the proposed model-driven approach to MLOps leveraging automated code generation further speeds up the development of machine learning services, required administration operations and their delivery to the customers. Moreover, it also accelerates resource leasing protocols adopting blockchain-based smart contracts for transactions and their automated generation. Finally, the adoption of intuitive model-driven tools opens new horizons of machine learning service adoption and management even by persons without expertise in this area.

However, there are several possible research directions in future. First, we would work on integration of model-driven resource allocation mechanisms relying on multi-objective optimization approach [17] for energy and cost-efficient ML pipeline task scheduling. Moreover, the incorporation more sophisticated federated learning mechanisms and neural network layer splitting strategies across multiple cluster nodes aiming time-critical scenarios would be considered as well.

***Abstract*—We consider the controllability of multi-agent dynamical systems modeled by a special class of bipartite graphs, called chain graphs. Our particular attention is focused on chain graphs that have one repeated degree. We derive properties of eigenvectors of graphs under consideration as well as some of their Laplacian spectra. On the basis of the obtained theoretical results, we determine the minimum number of leading agents that make the system in question controllable and locate them in the corresponding graph.**

***Index Terms*—Chain graph, Laplacian spectrum, Eigenvectors, Controllable dynamical system**

I. Introduction

Let $G = (V(G), E(G))$ be a simple graph (without loops or multiple edges) of *order* $n = |V(G)|$. By $A(G)$ we denote its $(0,1)$-*adjacency matrix*. If $D(G)$ is the diagonal matrix of vertex degrees, then $L(G) = D(G) - A(G)$ stands for the *Laplacian matrix* of G. The *Laplacian eigenvalues* of G are the eigenvalues of $L(G)$ and they form $\sigma(G)$, the *Laplacian spectrum* of G.

We consider a multi-agent system with n linear agents $\{1, 2, \ldots, n\}$ modeled by a graph G. If x_i denotes the state of the agent i, its dynamics is described by the single integrator

$$\dot{\mathbf{x}}(t) = -\sum_{j \in N(i)} (x_i(t) - x_j(t)),$$

where $N(i)$ denotes the set of neighbours of i. The compact dynamics can be written as $\dot{\mathbf{x}}(t) = -L(G)\mathbf{x}(t)$, where $\mathbf{x}$ is the vector of the agents' states and $L(G)$ is the graph Laplacian.

Following [6] by ℓ and f we denote affiliations with leaders and followers. A *follower graph* G_f of G is the subgraph induced by the set of followers. Consequently, the graph Laplacian $L(G)$ of G may be written as

$$L(G) = \begin{pmatrix} \mathcal{L}_f(G) & l_{f\ell}(G) \\ l_{f\ell}^{\mathsf{T}}(G) & \mathcal{L}_\ell(G) \end{pmatrix}. \tag{I.1}$$

The control system we consider is the leader-follower system

$$\begin{pmatrix} \dot{\mathbf{x}}_f(t) \\ \dot{\mathbf{u}}(t) \end{pmatrix} = -\begin{pmatrix} \mathcal{L}_f(G) & l_{f\ell}(G) \\ l_{f\ell}^{\mathsf{T}}(G) & \mathcal{L}_\ell(G) \end{pmatrix} \begin{pmatrix} \mathbf{x}_f(t) \\ \mathbf{u}(t) \end{pmatrix},$$

where followers evolve through the Laplacian-based dynamics

$$\dot{\mathbf{x}}_f(t) = -\mathcal{L}_f(G)\mathbf{x}_f(t) - l_{f\ell}(G)\mathbf{u}(t), \tag{I.2}$$

and $\mathbf{u}$ denotes the external control signal ran by the leaders' states.

The system modeled by (I.2) is said to be *controllable* if it can be driven from any initial state to any desired final state in a finite time. In the study of the controllability of multi-agent systems, the main problem is to determine the locations of leaders under which the controllability can be realized. The multi-agent system (I.2) is said to be k-*leaders controllable* if there exist minimum number of k leaders to make (I.2) controllable. In particular, if $k = 1$, the system (I.2) is called *single leader controllable*.

We recall a useful argument for further analysis of controllability of multi-agent systems.

Lemma I.1. ([5]) *The system* (I.2) *is controllable if and only if there is no eigenvector for $L(G)$ taking 0 on all entries corresponding to leaders, i.e. if and only if $L(G)$ and $\mathcal{L}_f(G)$ do not share any common eigenvalues.*

Multi-agent systems arise in many areas of science and engineering (see for example [1], [5], [7], [8], [10], [12]). In this paper we focus on controllability of chain graphs, in particular to chain graphs with one repeated degree. Chain graphs are $2K_2, C_3, C_5$ graphs, which implies that they are also bipartite graphs. We determine the minimum number of leaders needed to make the corresponding system (I.2) modeled by such a graph controllable and provide the locations of leaders in the graph.

The paper is organized as follows. In Section II we give some preliminary results on the structure of chain graphs and on their spectrum. In Section III we present several results concerning Laplacian spectrum and eigenvectors of chain graphs with one repeated degree. In Section IV we consider the controllability of systems (I.2) modeled by a corresponding chain graph. In Section V we present several concluding remarks.

 ISBN 978-86-7466-930-3

II. Preliminaries

The Laplacian matrix $L(G)$ of any graph G is symmetric and positive semidefinite. Moreover, 0 is an eigenvalue of G afforded by the all-1 vector $\mathbf{j}$. Therefore, we may assume that the eigenvalues of G (in fact, the roots of the characteristic polynomial $\phi(L(G),x) = \det(xI - L(G))$) are indexed in non-increasing order and given as follows:

$$\mu_1(G) \geq \mu_2(G) \geq \cdots \geq \mu_n(G) = 0\,.$$

We denote by $\sigma(G)$ the spectrum of G, i.e. the multiset of its eigenvalues.

The vertex set of a chain graph G consists of two colour classes that are partitioned into h non-empty cells $\bigcup_{i=1}^{h} U_i$ and $\bigcup_{i=1}^{h} V_i$, respectively. All vertices in U_s are joined to all vertices in $\bigcup_{k=1}^{h+1-s} V_k$, for $1 \leq s \leq h$. Therefore, all vertices in U_i (resp. V_j) are *co-neighbours*, i.e. they share the same set of neighbours. If $m_s = |U_s|$ and $n_s = |V_s|$, for $1 \leq s \leq h$, then G is denoted by

$$\mathrm{DNG}(m_1, m_2, \ldots, m_h; n_1, n_2, \ldots, n_h)\,.$$

A chain graph is sketched in Figure II.1.

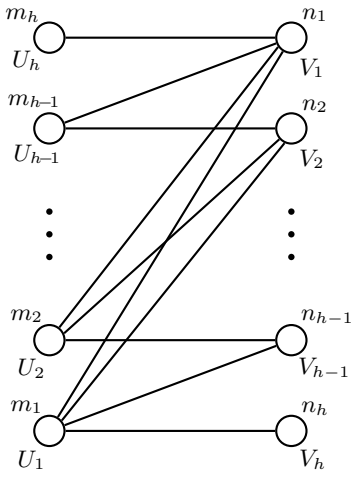

Fig. II.1. The chain graph $G = \mathrm{DNG}(m_1, m_2, \ldots, m_h; n_1, n_2, \ldots, n_h)$.

If we follow the vertex ordering from the partition $\left(\bigcup_{i=1}^{h} U_i\right) \cup \left(\bigcup_{i=1}^{h} V_i\right)$, then the *quotient matrix* $Q(G)$ of a chain graph G has the form

$$\left(\begin{array}{cccc|cccc} d_1 & & & & -n_1 & \cdots & -n_{h-1} & -n_h \\ & d_2 & & & -n_1 & \cdots & -n_{h-1} & \\ & & \ddots & & \vdots & \iddots & & \\ & & & d_h & -n_1 & & & \\ \hline -m_1 & \cdots & -m_{h-1} & -m_h & d_1^* & & & \\ -m_1 & \cdots & -m_{h-1} & & & d_2^* & & \\ \vdots & \iddots & & & & & \ddots & \\ -m_1 & & & & & & & d_h^* \end{array}\right). \tag{II.1}$$

The corresponding diagonal blocks we shortly denote by D_1, D_2, while off-diagonal ones we denote by B_1, B_2.

It is well-known that every eigenvalue of $Q(G)$ is an eigenvalue of G. For more results on spectral properties of chain graphs the reader is referred to [4], [9], [11].

III. Laplacian Spectrum of $\mathrm{DNG}(k, 1, \ldots, 1; 1, \ldots, 1)$

In this section we investigate spectral properties of chain graphs with one repeated degree. These graphs are of the form $\mathrm{DNG}(\underbrace{k, 1, \ldots, 1}_{h}; \underbrace{1, \ldots, 1}_{h})$. Since G has only one repeated degree, then $k > h$.

Theorem III.1. *Let* $\mathrm{DNG}(\underbrace{k, 1, \ldots, 1}_{h}; \underbrace{1, \ldots, 1}_{h})$, $k > h$. *Then*

$$\sigma(G) = \{0, h^{k-1}, \kappa_1, \kappa_2, \ldots, \kappa_{2h-1}\},$$

where

$$\begin{cases} \kappa_i \in (i-1, i), & i \in \{1, \ldots, h-1\} \\ \kappa_{h+i} \in (k+i-1, k+i), & i \in \{1, \ldots, h-1\} \\ \kappa_{2h} \geq k+h, \end{cases}$$

Proof. Taking into account that $d_i = h+1-i$, $1 \leq i \leq h$ and $d_j^* = k+h-j$, $1 \leq j \leq h$ and employing [13, Theorem 3.5], we get that the characteristic polynomial $\phi(L(G),x)$ of $L(G)$ is given by

$$x(x-h)^{k-1} \prod_{i=1}^{k+h-1} (x-i) \left(\frac{1}{p_1} + x \sum_{j=2}^{h} \frac{1}{(x - d_{h+2-j})p_j} + \frac{1}{x - d_1} \right).$$

Since $x(x-h)^{k-1}$ is a factor of $\phi(L(G),x)$, the remaining eigenvalues are the roots of the polynomial

$$p(x) = \prod_{i=1}^{k+h-1} (x-i) \left(\frac{1}{p_1} + x \sum_{j=2}^{h} \frac{1}{(x - d_{h+2-j})p_j} + \frac{1}{x - d_1} \right).$$

Then we have:

- $p(0) = (-1)^{k+h}(2h+k-1)\frac{(k+h-2)!}{h}$;
- $p(1) = (-1)^{k+h+1}(k+h-3)(k+h-3)!$;
- $p(\ell) = (-1)^{k+h+\ell} 2\ell(h+1)(\ell-1)!(k+h-2\ell-2)!\frac{(k+h-\ell-1)!}{(k+h-2\ell)!}$, for $2 \leq \ell \leq h-1$;
- $p(k) = (-1)^{h+1}\frac{k!}{(k-h+1)(k-h)}(h-1)!$
- $p(k+\ell) = (-1)^{h-\ell+1} 2(\ell+1)\frac{(k+\ell)!}{(k+2\ell-h+1)(k+2\ell-h)}(h-\ell-1)!$, for $1 \leq \ell \leq h-1$;
- $p(k+h) = -(k+h-2)\cdot(h-1)! < 0$.

From the obtained values, we conclude that $p(0), p(1), \ldots, p(h-1)$ alternate in sign. Therefore, for any $i \in \{1, 2, \ldots, h-1\}$, we have $p(t) = 0$, for some $t \in (i-1, i)$. Similar argument holds for $p(k), p(k+1), \ldots, p(k+h-1)$, and consequently, for every $i \in \{k+1, \ldots, k+h-1\}$ we have $p(t) = 0$ for some $t \in (i-1, i)$. Also, since p is a monic polynomial and $p(k+h) < 0$, it follows that $p(t) = 0$ holds for some $t > k+h$. □

 ISBN 978-86-7466-930-3

We illustrate the results of Theorem III.1 on the following example.

Example III.2. Let $G = \mathrm{DNG}(6,1,1,1,1;1,1,1,1,1)$. Then

$$\sigma(G) = \{13.03, 9.64, , 08.6, 7.58, 6.58, 3.82, 2.86, 1.92, 0.96\} \cup \{5^5, 0\}.$$

Next we observe the structure of eigenvectors of $L(G)$ corresponding to non-integer eigenvalues.

Theorem III.3. *Let $G = \mathrm{DNG}(k,1,\ldots,1;1,1,\ldots,1)$ with $k > h$, μ a non-integer eigenvalue of G and $\mathbf{x} = (x_1, x_2, \ldots, x_n)^\intercal$ an associated eigenvector. Then $x_i \neq 0$ for any $1 \leq i \leq k$.*

Proof. We recall first, (see, for example, [13]) a relation between the eigenvectors of $Q(G)$ and those of G for the same eigenvalue. A vector $\mathbf{v} = (y_1, y_2, \ldots, y_h, z_1, z_2, \ldots, z_h)^\intercal$ is an eigenvector of $Q(G)$ for μ, if and only if the corresponding eigenvector of G for the same eigenvalue has the form

$$\mathbf{x} = (\underbrace{y_1, y_1, \ldots, y_1}_{k}, y_2, \ldots, y_h, z_1, \ldots, z_h)^\intercal.$$

Assume on the contrary that $\mathbf{x}$ is an eigenvector for the non-integer eigenvalue μ of $L(G)$ such that $x_i = 0, 1 \leq i \leq k$. By [13, Lemma 3.4], μ is also an eigenvalue of $Q(G)$. So there exists a non-zero vector $(\mathbf{y} \quad \mathbf{z})^\intercal \in \mathbb{R}^{2h}$ such that $Q(G)(\mathbf{y} \quad \mathbf{z})^\intercal = \mu(\mathbf{y} \quad \mathbf{z})^\intercal$ with $y_1 = 0$. Then the eigenvalue equation

$$\begin{pmatrix} D_1 & -B_1 \\ -B_2 & D_2 \end{pmatrix} \begin{pmatrix} \mathbf{y} \\ \mathbf{z} \end{pmatrix} = \mu \begin{pmatrix} \mathbf{y} \\ \mathbf{z} \end{pmatrix}$$

can be rewritten as

$$D_1\mathbf{y} - B_1\mathbf{z} = \mu\mathbf{y}$$
$$-B_2\mathbf{y} + D_2\mathbf{z} = \mu\mathbf{z}.$$

The matrices B_1, B_2 have full rank, and therefore are invertible. Next, from

$$\mathbf{z} = B_1^{-1}(D_1 - \mu I_h)\mathbf{y}$$
$$\mathbf{y} = B_2^{-1}(D_2 - \mu I_h)\mathbf{z},$$

we conclude that

$$\mathbf{y} = B_2^{-1}(D_2 - \mu I_h)B_1^{-1}(D_1 - \mu I_h)\mathbf{y},$$

i.e. $\mathbf{y}$ is an eigenvector of

$$P = B_2^{-1}(D_2 - \mu I_h)B_1^{-1}(D_1 - \mu I_h)$$

for the eigenvalue 1. The latter product is the product of two anti-bidiagonal matrices $B_2^{-1}(D_2 - \mu I_h)$ that is

$$\begin{pmatrix} & & & (k-\mu)/k \\ & & & -(k-\mu) \\ & & \iddots & \iddots & \\ & & & & \\ & & (k+h-2-\mu) & & \\ (k+h-1-\mu) & & -(k+h-2-\mu) & & \end{pmatrix}$$

and $B_1^{-1}(D_1 - \mu I_h)$

$$\begin{pmatrix} & & & (1-\mu) \\ & & (2-\mu) & -(1-\mu) \\ & & \iddots & \iddots & \\ & & & & \\ & (h-1-\mu) & & \\ (h-\mu) & -(h-1-\mu) & & & \end{pmatrix},$$

and hence it is a tridiagonal matrix with

$$p_{1,1} = \frac{(h-\mu)(k-\mu)}{k}$$
$$p_{\ell,\ell} = (h+1-\ell-\mu)\Big(\frac{k+\ell-1-\mu}{m_{h+1-\ell}} + (k+\ell-2-\mu)\Big),$$

$2 \leq \ell \leq h$,

$$p_{\ell,\ell-1} = -(h-\ell+2-\mu)(k+\ell-2-\mu), \quad 2 \leq \ell \leq h,$$
$$p_{\ell,\ell+1} = -\frac{(h-\ell-\mu)(k+\ell-1-\mu)}{m_\ell}, \quad 1 \leq \ell \leq h-1,$$

taking into account that $m_1 = k$ and $m_i = 1$, $i \geq 2$. From $\mu \notin \mathbb{Z}$, we have $p_{\ell,\ell-1}, p_{\ell,\ell+1} \neq 0$.

If $y_1 = 0$, then from the first equation in $P\mathbf{y} = \mathbf{y}$ we obtain $y_2 = 0$ ($p_{1,2} \neq 0$). Next, in the similar way, the second equation gives $y_3 = 0$, and so on, until we obtain $y_h = 0$, i.e. $\mathbf{y} = \mathbf{z} = \mathbf{0}$.

Therefore, we obtain that $\mathbf{x} = \mathbf{0}$, which is a contradiction. This completes the proof. □

IV. Controllability of systems modeled by $\mathrm{DNG}(k,1,\ldots,1;1,\ldots,1)$

Previously obtained results, in this section will be employed to determine the number of leading agents in (I.2), where the system is modeled by a chain graph $\mathrm{DNG}(k,1,\ldots,1;1,\ldots,1)$ for $k > h$.

Theorem IV.1. *Let G be a chain graph $\mathrm{DNG}(k,1,\ldots,1;1,\ldots,1)$ with $k > h$. Then the system (I.2) modeled by G is controllable with $k-1$ co-neighbour vertices in the role of leaders.*

 ISBN 978-86-7466-930-3

Proof. The eigenvectors corresponding to the eigenvalue h of the multiplicity $k-1$ are of the form

$$\begin{aligned}
\mathbf{v}_1 &= (\underbrace{1,-1,0,0,\ldots,0}_{k},0,\ldots,0)\\
\mathbf{v}_2 &= (\underbrace{1,0,-1,0,\ldots,0}_{k},0,\ldots,0)\\
&\vdots\\
\mathbf{v}_{k-1} &= (\underbrace{1,0,\ldots,0,0,-1}_{k},0,\ldots,0).
\end{aligned}$$

We first conclude that vertices $\{2,\ldots,k\}$ should be selected as leaders. Moreover, any vector corresponding to $\mu = h$ is of the form $(t_1,\ldots,t_k,0,\ldots,0)^{\intercal}$. Any $k-1$ of these t_i's cannot be zeros simultaneously. For any $\mathbf{x}_1,\ldots,\mathbf{x}_l$, $l < k-1$ there exists $\mathbf{x}_s$, such that $\mathbf{x}_s\mathbf{x}_i = 0$ for each $i, 1 \leq i \leq l$.

The remaining eigenvalues by Theorem III.1 are non-integer and therefore their eigenvectors, by Theorem III.3 satisfy $x_i \neq 0, 1 \leq i \leq k$. Now the statement follows by Lemma I.1. □

Example IV.2. For $G = \mathrm{DNG}(6,1,1,1,1;1,1,1,1,1)$ the system (I.2) is 5 leader controllable. The leaders $\ell_1,\ldots,\ell_5 \in U_1$ are 5 of 6 vertices with repeated degrees, that are joined to the followers $v_1,\cdots,v_5$ as illustrated in Figure IV.1.

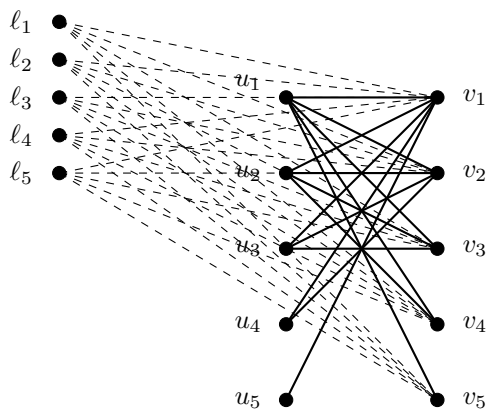

Fig. IV.1. A 5-leader controllable system modelled by $\mathrm{DNG}(6,1,1,1,1;1,1,1,1,1)$.

V. Conclusion

In this paper we have covered the controllability of multi-agent systems that are modelled by special class of bipartite graphs: chain graphs. We have proved that if a chain graph has only one repeated degree with multiplicity k, then the system requires at least $k-1$ controllers in order to be controllable. In this way we positively addressed the questions raised in [7], where the authors asked if there is a family of graphs other than threshold graphs with one multiple degree of multiplicity m for whose controllability at least $m-1$ controllers are needed. Consequently, we expanded the known classes of the controllable multi-agent systems. Taking into account that many engineering systems are modelled by graphs, the obtained results are of particular importance in creating new controllable systems, since the known structures are limited (they mainly include paths, grids, cycles and circulant networks). Another advantageous aspect is a possibility to generate graphs with some desirable properties. One of them is algebraic connectivity, i.e. the second smallest Laplacian eigenvalue. It is a useful tool to measure the robustness and synchronizations of the graphs. For the chain graphs that we considered the algebraic connectivity is always in $(0,1)$ and it approaching to 1 as the size of the graph increases. This brings another benefit, since in general graphs the algebraic connectivity usually decreases if the order of a graph is increased.

Secret Keys Distillation using Speech Signals and Discussion over Public Authenticated Channel

Jelica Radomirović, Milan Milosavljević, and Aleksandra Krstić

***Abstract*— This paper discusses a system for generating and distributing secret cryptographic eys based on the principle of common randomness and discussion over an authenticated public channel. The use of speech as a source of common randomness is one possibility and to our nowledge the first for this type of system. We consider different reconciliation algorithms and compare them with e periments. perimental results show that it is possible to generate information-theoretical secret eys with rates between and 5 . This result proves the practical feasibility of absolutely secret autonomous cipher systems with speech control.**

***Index Terms*—secret ey; distillation; symmetric cryptography; speech signal; reconciliation; privacy amplification; secret ey rate;**

I. Introduction

The information-theoretical approach to the analysis and synthesis of cipher systems came into focus with the availability of quantum computers in the near future. The classical result of this approach states that the entropy of secret keys in a cryptographic system must be no less than the entropy of plaintext [1]. As is well known, systems designed in this way are resistant to the unlimited computing resources of the adversary, and thus to cryptanalysis based on quantum computers [2].

From the point of view of generating and distributing high-quality secret keys, special attention is drawn to the fundamental results of Alswede and Csiszar [3], Maurer [4], and Csiszar and Narayan [5]. The basic idea of information-theoretical approach in these results is to identify and use mutually correlated signals available to legitimate parties.

Depending on the location of the source of common randomness, there are two approaches, [3]:

(i) Secret key extraction from sources independent of communication channels (source model),

(ii) Secret key extraction from existing communication channels (channel model).

The difference between these two models is how the parties observe the initial sequence. While in the source model, random source is controlled by nature, in the channel model, one of the parties governs the input of a noisy channel (independent of the main channel) while others observe the output.

In this paper, we will analyze the possibility of extracting cryptographic keys from a speech signal, applying an approach based on the source model.

In Section 2, the basic blocks of the proposed secret key generation system will be presented, in two variants: (i) when the input is a speech signal and (ii) when the input is a residual speech signal, filtered by an adaptive linear predictive model [6].

In Section 3, the information and statistical characteristics of this source will be analyzed and the key parameters of the sequential procedure for extracting secret keys will be identified, separately for each of the phases: Advantage Distillation (AD), Information Reconciliation (IR) and Privacy Amplification. -PA).

In Section 4 we present the results of the experiment of obtaining secret keys for all pairs (Alice, Bob) of legitimate participants for 5 speakers, one of which was chosen as an eavesdropper (Eve).

The Conclusion discusses the upper limits of the rate of generating secret keys and the possibility of further improving the performance of the proposed system.

II. Discrete Memoryless Source

As illustrated in Figure 1, a source model for secret-key agreement represents a situation in which three parties, Alice, Bob, and Eve, observe the realizations of a DMS - Discrete Memoryless Source (XYZ, P_{XYZ}) with three components.

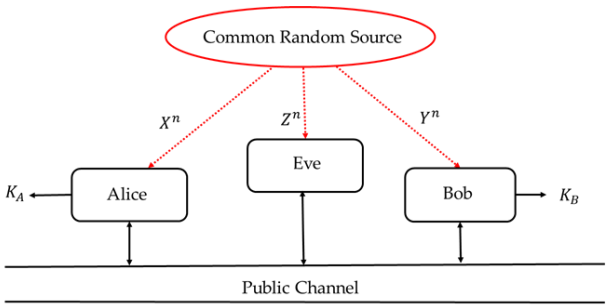

Fig. 1. Secret-key Agreement by Public Discussion from Common Randomness [4].

 ISBN 978-86-7466-930-3

The DMS is assumed to be outside the control of all parties, but its statistics are known. By convention, component X is observed by Alice, component Y by Bob, and component Z by Eve. Alice and Bob's objective is to process their observations and agree on a key K about which Eve should have no information.

Alice and Bob can exchange messages over a noiseless, two-way, public and authenticated channel. That is, all messages are overheard by Eve and the existence of the public channel does not provide Alice and Bob with an explicit advantage over Eve. The rules by which Alice and Bob compute the messages they exchange over the public channel and agree on a key define a four-stage key distillation strategy, [4]:

1. Randomness sharing. Alice, Bob, and Eve observe *n* realizations of a DMS (XYZ, P_{XYZ}).
2. Advantage distillation. If needed, Alice and Bob exchange messages over the public channel to process their observations and to "distill" observations for which they have an advantage over Eve.
3. Information reconciliation. Alice and Bob exchange messages over the public channel to process their observations and agree on a common bit sequence.
4. Privacy amplification. Alice and Bob publicly agree on a deterministic function they apply to their common sequence to generate a secret key.

The largest achievable key rate is defined as the key capacity and is given by

$$C_K = max\{I(X;Y), I(X:Y|Z)\}, \quad (1)$$

where I(X;Y) denotes mutual information between X and Y, while I(X:Y|Z) denotes the same quantity conditioned by Z. In the special case, when Eva is totally independent of Alice and Bob, or equivalently, when Z is independent of X and Y, maximal key capacity is equal to

$$C_{K\,max} = I(X;Y). \quad (2)$$

In this work, we use speech the signals of participants as DMS of the proposed system, see Fig.2.

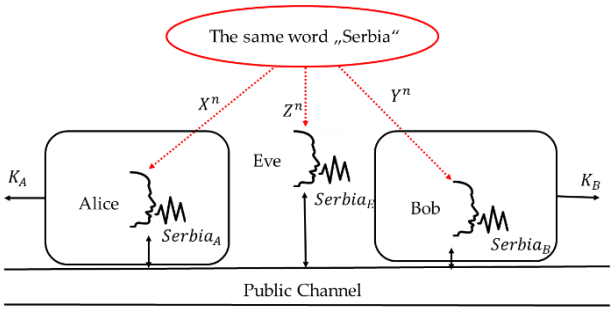

Fig. 2. Secret-key Agreement by Public Discussion based on the speech signals obtained by pronouncing the word "Serbia".

III. System Architecture

As already mentioned, we will analyze two DMS, the first one corresponding to the original speech signal, and the second one corresponding to the residual signal. Residual DMS is obtained after inverse filtering by an adaptive linear autoregressive model, estimated every 10 ms of input speech, see Fig.3.

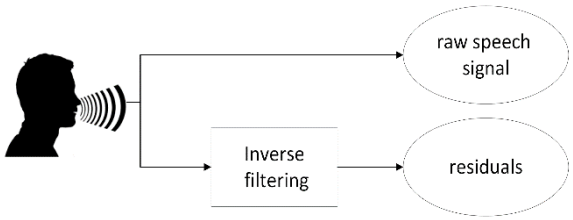

Fig. 3. Two different DMS based on the same input speech signal

The general architecture of the system is given in Fig.4. Speech input (or residual) is transformed into binary DMS by a non-uniform quantization, based on estimating the probability density function of input samples.

Advantage Distillation (AD) blocks are used to eliminate the advantage that the eavesdropper may have over legitimate parties. In that case, Eve knows more information about Alice's initial bit string, than Bob does. We will use the bit pair advantage distillation/degeneration protocol [7]. Algorithms are based on the exchange of parity information of 2-bit blocks and the elimination of one bit of each block to ensure security. After this step, the number of different bits of the sequence is reduced. The number of non-matching bits of the eavesdropper sequence decreases but much slower than for the legitimate parties. The protocol runs for several rounds until the sequences differ only in a few bits.

The Information Reconciliation (IR) is intended to correct the remaining erroneous bits in the Alice and Bob sequences. The most popular IR protocols are Winnow [7] and Cascade [8] protocols. They are based on the exchange of block parity information until the error of a certain block is detected. For each block parity query, some bits are deleted to ensure security. In the end, we get the same sequence on legitimate sides that represents the secret key. Even though we tried to ensure privacy by deleting potentially compromised bits, the eavesdropper has still gained some information about the secret key. To make the secret key absolutely secure, we proceed to the next step of our system, privacy amplification (PA).

In Privacy Amplification (PA) block sequences are transformed such that m bits are discarded due to the eavesdropper's knowledge. One of the possible transformations is a hash function $g: \{0,1\}^n \rightarrow \{0,1\}^r$ where n is the length of a sequence before PA and r is the length after PA, i.e., the length of the final secret key. It is common to use so-called universal hash functions, such as random $r \quad n$ matrices, over GF(2), [9].

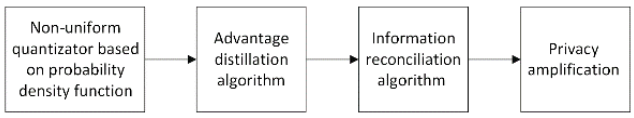

Fig. 4. Secret key agreement algorithm [3]

 ISBN 978-86-7466-930-3

IV. Results

Raw speech signal and its residuals, obtained from inverse filtration of AR model of 10th order, were used for experimental proof of the proposed system, Fig 5. Four participants recorded the word 'Srbija' for two seconds. Beginning. as well as the end of the word, were determined so the initial signal is reduced to 0.6 second length. The recordings were sampled at 44.1 kHz.

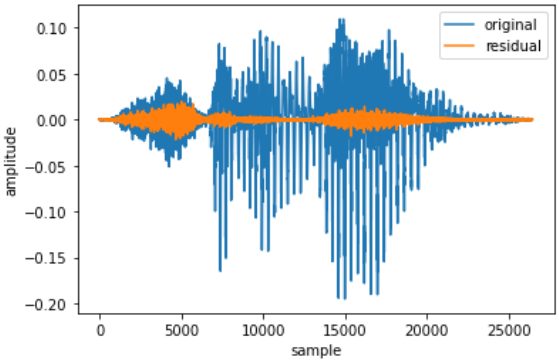

Fig. 5. Comparison of source signals

Normalized Hamming distance is an appropriate metric for measuring the difference between two binary sequences. Depending on the number of bits we use to quantize continuous signal we get more or less similar sequences. That directly affects how much information circulates over a public channel and how long is the final secret key length. The key rate is an indicator of how much of the sequence at the beginning is useful

$$\text{key rate} = \frac{\text{final length of secret key}}{\text{length of input sequence}} * 100\ [\%].$$

In Fig 6. the key rate in function of normalized Hamming distance is presented. In order to determine the optimal value for the number of quantization bits, we try five different values 6,8,10,12, and 14.

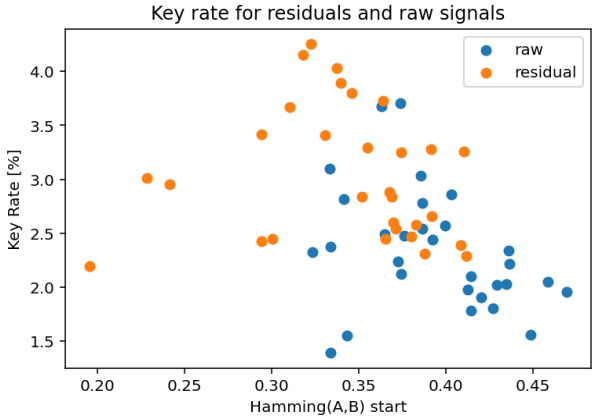

Fig. 6. Comparison of key rate for source signals. A and B denote legitimate parties

From Fig.6 can be seen that residuals are closer to each other than raw signals because of the corresponding higher key rate.

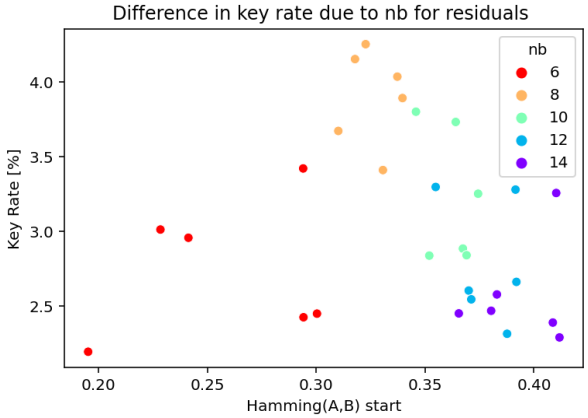

Fig. 7. How the number of quantization bits affects distance at the beginning

As shown in Fig 7., the highest rate is achieved for normalized Hamming distance between 0.3 and 0.35, which corresponds to 8 quantization bits.

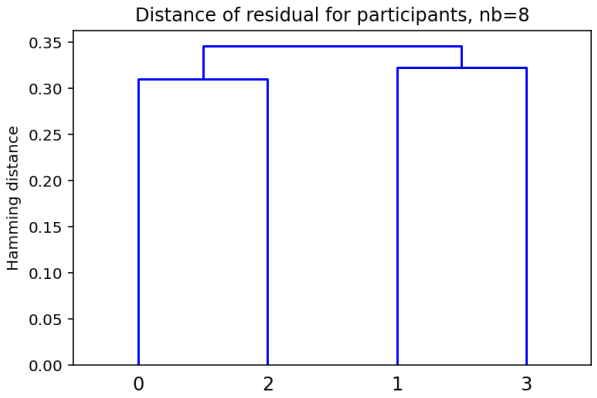

Fig. 8. Dendrogram represented distance of all sequences

In Fig 8. we use a dendrogram to show how close to each other are the participant sequences. The dendrogram was obtained as a result of hierarchical cluster analysis by the Ward method [10]. To compare Cascade and Winnow algorithms we conduct 4 experiments, 2 for each, that is one for residual signals and one for speech signals. Results are represented in table 1.

TABLE I
Experimental results

		Final key size	Key rate [%]
Winnow	Residual	10116.83 ± 788.93	4.78 ± 0.37
	Raw	8670.30 ± 1033.87	4.10 ± 0.49
Cascade	Residual	8432.24 ± 624.18	3.98 ± 0.29
	Raw	6833.72 ± 1433.26	3.22 ± 0.68

 ISBN 978-86-7466-930-3

Based on the results we conclude that the Winnow algorithm is a better choice for reconciliation because it gives an almost 1% higher key rate. If we compare two DMS, the one corresponding to the residual signal gives longer secret keys due to a smaller normalized Hamming distance at the beginning, for the same pair of sequences. Final hamming for all sequences and all experiments toward the eavesdropper after PA is ~0.5. In other words, all the information that leaked through the public channel will not reveal anything to the eavesdropper about the distilled secret key.

V. Conclusion

In this work we proposed a speech based secret key agreement system with message transmission over a public channel. The proposed system can distill secret keys from speech signals, with the key rate of up to 5%, and with negligible information leakage to an eavesdropper. This opens up the possibility of practical realization of absolutely secret cipher systems controlled by voice. Such systems can be used both in the security services for critical information and communication infrastructure of the government, as well as in commercial applications.

Future work will include generalization in terms of the largest achievable key rate and a testing of the proposed system on more participants as well as more different spoken words.

One solution for voice commands on Android based STB

Jovana Simić, Đorđe Glišić, Nikola Vranić, Marija Jovanović

***Abstract*—With the introduction of voice recognition and its support by various research groups, it became possible to add voice commands to different devices in use. We are seeing them on PCs, phones, and tablets. This paper presents a solution to order and control set-top box devices and TVs based on Android OS. It is a cloud-based solution supported by Google API for voice recognition.**

***Index Terms*—set-top box, android, voice commands, voice recognition, TV voice commands, Actions on Google, Android, Google Assistant, Dialogflow, Firebase.**

I. Introduction

Virtual assistance is becoming more popular with artificial intelligence and machine learning advances. Particularly with voice recognition available on PC and even mobile devices, with capabilities to support more languages, not just English. Popular operating systems come with support for virtual assistance and voice recognition as one service. There is Cortana on Windows operating system. In iOS, there is Siri. For Android devices and Google products, there is Google Assistant. Additionally, Samsung has Bixby, and Amazon has Alexa.

All mentioned virtual assistance is based on cloud architecture that employs the internet. Some solutions are standalone and work reasonably well in a narrow field, but cloud-based solutions give better results for general-purpose tasks.

This paper will investigate the possibilities of adding virtual assistance to set-top box devices to speed operations with DTV sets and improve user experience. We have selected an Android-based device with a remote controller that supports voice recording [1]. Early work on the subject was done with [1] and [2]. More similar work was done on narrow areas for content playback on set-top box devices by Petrovic et al. [3] and Visekruna et al. [4], and Lazic et al. [5].

II. Section Title (e.g., The Method)

Google Assistant is Google's virtual assistant available on mobile phones, smart home devices, TVs, cars, etc. It has artificial intelligence and enables two-way communication in voice communication and text messages with the user. It can browse the Internet, set alarms and events, access device settings, display user account information, etc. It also supports a lot of functionality for smart homes. For example, the user can control lighting, temperature, TV, and other items in the house. To prevent the service from being constantly active, the recognition of the keywords "OK, Google" and "Hey, Google" was introduced, after which the service became active. After activating Google Assistant, the voice command recording begins, and it collects an audio message which is further processed. The resulting response is reproduced depending on the device on which Google Assistant is used, e.g., in the case of Google Home devices, the answer is in the form of audio sound, while when using a smartphone or TV, a text record is also obtained [6]. If you want to run Google Assistant on an Android TV, you need a microphone to record your voice, integrated into the remote control [6].

Actions on Google (AoG) is a platform that allows you to expand your personal Google Assistant by adding your services called Actions. To enable device management, Action has been implemented. Suppose you want to access the Action described in this paper. In that case, you need to tell Google Assistant: "Talk to True TV" or "Ask True TV", after which he asks the AoG platform to run the application, AoG sends a request to the web service and receives a response forwards to Google Assistant, which displays the answer to the user. Furthermore, Google Assistant forwards the user input directly to the Action, and the Action responds directly to the Assistant.

When creating an Action, it is also possible to use the Dialogflow platform to simplify the understanding of user input. The Dialogflow agent translates user input during a conversation into structured data that applications and services can understand. As the call center, they are trained to handle expected conversation scenarios. The platform itself provides the ability to reply with static responses. If you want to respond with dynamic answers and additional logic, it is possible to implement a web service. In this case, Dialogflow is a proxy between Actions on Google and the web service, as shown in the figure. Instead of sending the request directly to the web service, AoG sends it to Dialogflow. Also, the web service sends a response to Dialogflow, which forwards it to AoG.

The answer must be returned to the user within 10 seconds. Otherwise, the request will expire. Also, the response must be less than or equal to 64 kilobytes. Dialogflow processes the user's input, and it sends an HTTP POST request to the web

service, which is set as a function on the Firebase platform. The Cloud Functions for Firebase service automatically starts the function when an HTTP request arrives.

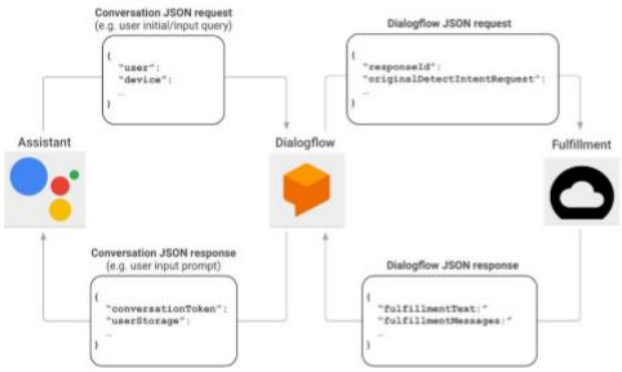

Fig. 1. The diagram shows the path that requests go from Assistant through the Dialogflow till the Fulfillment and response traveling back to the Assistant.

The Actions on Google, Dialogflow, and Firebase platforms are well integrated, as seen in Fig. 2. The figure shows a simple interaction between the end-user, the assistant, Dialogflow, and the web service built in the cloud, like Functions for Firebase and the Firebase Real-time Database.

The user enters his request as a voice command and starts the assistant himself. The assistant converts the voice command into text and starts the Dialogflow searching for the initial action (Welcome intent). Dialogflow uses machine learning to map text to intent and to isolate recognized entities (such as TV channel, TV channel number, time, etc.). Dialogflow triggers a web service, implemented as Cloud Functions for Firebase, sending it a JSON request that contains all the necessary information from the text. The web service processes the JSON request and implements logic (checks the Firebase Real-time Database) to respond to the assistant (or Dialogflow). Device Assistant converts the answer to speech and display (for devices that do not have a screen).

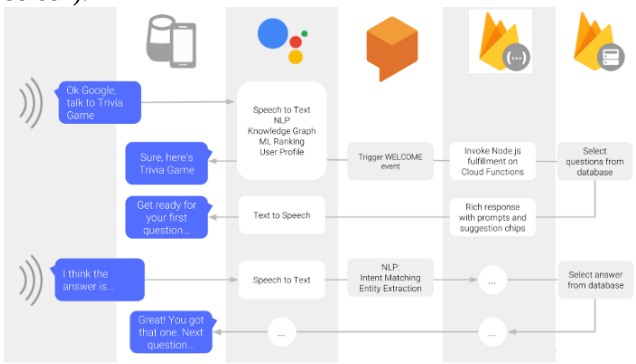

Fig. 2. Voice command workflow from Actions on Google, Dialogflow to Firebase fulfillment web service and back.

III. Implementation

This section describes one way to train and integrate Google Assistant. The Dialogflow agent needs to be trained first. The intent has been created for each supported command, in which it is necessary to enter a large number of phrases that the agent will understand, as shown in Fig. 3.

The pairing of the Action user and the STB device user was solved using a Google account, precisely his email address. To be able to manage the STB during the first launch of the Action, it is first necessary to link the account with the Action. The AoG platform provides the Google Sign-In option, the easiest way to connect and create accounts with the Action. The Action may request access to the user's Google profile, including the user's name, email address, and profile picture. Of course, you need to ask the user if he agrees to access his Google profile.

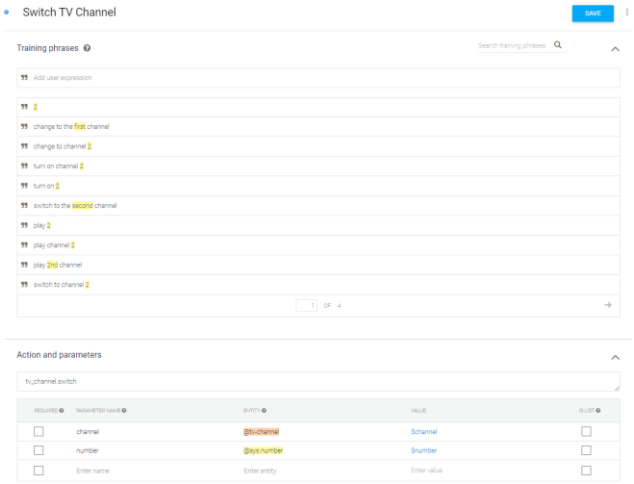

Fig. 3. Training phrases for specific action in Dialog flow and the required parameters defined.

After recognizing the command by the Dialogflow platform, it is necessary to send a signal to the TV application, which should execute the given command. Therefore, for each intent in the agent, an intent handler has been created in the web service. The operator first checks whether the user has linked his account with the Action. If this is not done, the user is first asked to link his account, and the user receives a list of suggested cards with commands for linking the account. Otherwise, the triggered command is entered in the Firebase Realtime Database database in a node whose email field value equals the user's email address accessing the Action. If such a node does not exist, the user with that email address is not logged in to any TV application. If there is, wait a while for the TV application to process the command and return the answer to be displayed to the user.

As already mentioned, the pairing of users of the Action and users of STB devices was done through a Google account. Therefore, the *AccountHandler* class is implemented in the TV application, which detects adding and removing accounts from the application. The class diagram of the *AccountHandler* class is shown in Fig. 4. Each account should have its node in the Firebase Realtime Database. Each account is associated with an object of the type *VoiceHandler* given in Fig. 5, which is used to detect database changes and execute commands.

 ISBN 978-86-7466-930-3

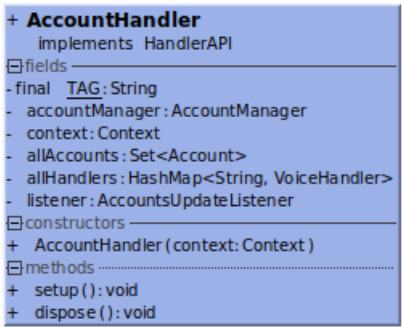

Fig. 4. Account handle class diagram.

When a new account is added to the TV application, it is necessary to add a new node to the database for that account and set the application to listen for changes on that node, for which the *VoiceCommand* class is used. In the class constructor, a reference to the root node of the database is retrieved, and in the *subscribe()* method, a listener is registered to the node in the database for which changes need to be detected.

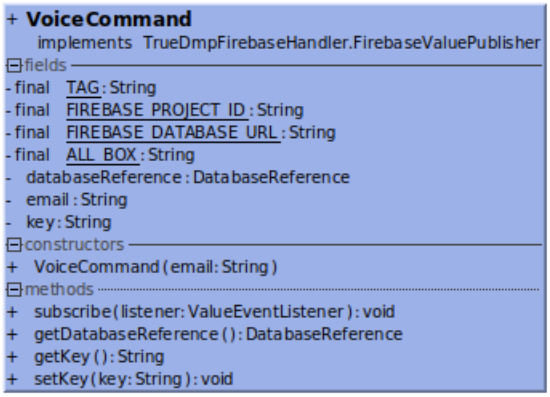

Fig. 5. Voice command class diagram.

IV. Results

A vital result of the presented work is that the voice commands apply to set-top-box devices with acceptable latency. Additionally, the phrase database could be upgraded without changing the actual code on any STB device.

Testing was performed via the Google Assistant application on a mobile device. The response time of the Action from the user's input to the return of the response to the user was tested. The tests were performed under normal conditions, under certain noises, using commands in English.

The table gives a comparative overview of the response time for commands implemented in this system. Response time averages 1 to 2 seconds, depending on the command. As shown in Table 1, the most time-consuming commands are for displaying information about events. These timings are comparable with the times it takes for users to do those actions using RCU. Key benefits could be seen in more complex scenarios, like adding services to favorite lists or scheduling PVR recordings based on the TV show's name for a specific period. Those cloud-based services will outperform manual user interaction with the graphical user interface.

TABLE I
VOICE COMMANDS AND RESPONSE TIME

Command for set-top box	Response Time[s]
Change to the next channel	~1,174
Change to the previous channel	~1,172
Change to a channel with a specific name	~1,195
Change to a channel with a specific number	~1,222
Complete tone reduction	~1,156
Restore volume before complete mute	~1,190
Tone amplification	~1.075
Mute the tone	~1,199
Increase the tone to maximum	~1,036
Check if the STB is in sleep mode	~1,353
View information about the current event on the current channel	~1,535
View information about the current event on a specific channel	~1,599
View information about the next event on the current channel	~1,469
View information about the next event on a specific channel	~1,445
Setting reminders	~1,169

V. Conclusion

In this paper, we have implemented a proof of concept for the voice commands on STB. For more implementation details refer to works [5], [6], and [7]. As with any cloud-based service, it relies on the internet and its stability. Further work shall be done to benchmark latency depending on the internet connection speed, location, and type of connection (WiFi, cable, mobile). It makes that operators supporting this feature offer stable enough internet.

If a set of basic commands is appropriately selected to cover all actions that the user can execute, then a cloud solution can make a chain of commands based on the user's voice request. Dialog flow cloud platform could process arbitrary complex requests that could be transformed and fulfilled as a series of actions. This hides a real benefit, as requests like "make a list of my top five sports channels and record NBA finals on internal disk" could be executed.

Additionally, requests like "Find me a movie with Tom Hanks for Saturday evening" contains more than just a request for STB. They hold user preferences so that operators can train recommendation systems. It opens up a vast field of opportunities as well as privacy concerns.

It does not end with voice commands for STB. It can be a command supported by a third-party application for food delivery or a calendar application.

One solution for simulating conditional access in DTV Software on PC platform

Milan Petrović, Đorđe Glišić, Uroš Jokić and Marija Jovanović

***Abstract*— Digital television (DTV) software runs on various hardware platforms, from low-cost low-performance devices to high-end devices that could compare with modern smartphones and PC configurations. The development quality depends on the tools available for the target platform. A new approach was taken to improve development by moving to the PC platform to avoid this dependency. The benefits are apparent, but it comes with some constraints. Typical examples are components available for target platforms but not PC platforms for security and legal reasons. One such component is the conditional access system (CAS) and digital rights management (DRM) components. This paper will present one solution to simulate conditional access (CA) in software without vendor CA libraries and support in hardware. The aim is to get the ability to test and verify various parts of DTV software that depend on CA functionalities.**

***Index Terms*— digital television, simulation, conditional access, DTV stack test environment.**

I. Introduction

A device that can reproduce digital television needs to comply with some DTV standards (DVB, ATSC, ISDB, etc.). Often it needs to support some content protection mechanism (encryption, signing, etc.). Additionally, the device needs to have a certain number of standard features and a few unique features dictated by the operator that will be available to the user.

In developing DTV software, specific components are delivered from third parties, like a software development kit (SDK) for the target platform or CA libraries for content protection. Content protection certification is an essential step in the development life-cycle, and DTV software is adopted according to the specification documents and APIs delivered. Upon development completion, the application is verified using several test suites that prove it behaves in the required way. This process repeats for every new target platform.

The DTV software development is tightly coupled with the target platform. Depending on the platform and its supporting packages, it may be impractical to develop a more complex project using them as a development platform. Instead, one way to overcome those difficulties is to develop on more suitable platforms. That platform should support at least logging mechanisms, the ability to re-write persistent memory, access to hardware debuggers, and good enough software packages to use those features. In practice, this is not the case, and almost always, given components are missing, and software packages are always behind the state-of-the-art counterpart packages available for PC. Selecting a more applicable platform instead of the target one for development is not applicable if the target CA library has different requirements (hardware or software) compared to its counterpart on a development platform.

For DTV software to be as robust as possible, there was a need to implement support for different CAS vendors. They shared core concepts for content access rights, content protection, operator box management, operator messaging to users, and other customized product and feature protections.

The CAS vendors' APIs significantly differ, although concepts are very similar. The differences between versions from the same vendor may not be compatible. Older libraries tend to have fewer restrictions, while newer versions have more demands and APIs to support, as new scrambling algorithms are added, and more security protocols are employed. It is necessary to have a level of abstraction in DTV middleware to adopt those changes and differences.

As a result, the first DTV simulator was developed on a PC platform [1]. It aimed to support the development of a graphical user interface. It became clear it could be used for implementing DTV middleware features as well. Those features were related to the DTV standard. To support it, the middleware test environment (MTE) [2] was created to test and verify different parts of the software on a PC platform using white box testing [3] [4]. This approach could not cover the code developed for a CA subsystem and the application code that was connected and dependent on that CA subsystem.

This paper aims to discuss paths that could be taken to overcome those obstacles. It gives one solution that is implemented and tested to prove the concepts. We could not find any relevant work on this topic. Closes to the work are discussions on testing approaches made in [5], [6], and [7].

Section two details the challenge and introduces the DTV system's architecture. Section three provides more information on the implementation and final solution. Section four explains verification and test results. Section five concludes the work.

II. PROBLEM STATEMENT

The CA vendor dictates two primary CA integration approaches depending on the target platform and selected operating system. If the target platform runs an operating system (OS) that does not support processes, only threads (tasks), the architecture looks as in Fig. 1. Here DTV software consists of OS, software development kit (SDK, drivers), hardware abstraction layer (HAL), middleware, and application layer. The application depends on middleware, and middleware depends on the abstraction layer (HAL) API that abstracts OS and SDK APIs [8].

The middleware and application layers contain all the business logic, whereas the remaining layers, like HAL, are porting layers designed to be very thin. Application is oriented toward user interface and feature logic, whereas middleware is oriented toward controlling hardware, supporting DTV standards, and interacting with CA subsystems.

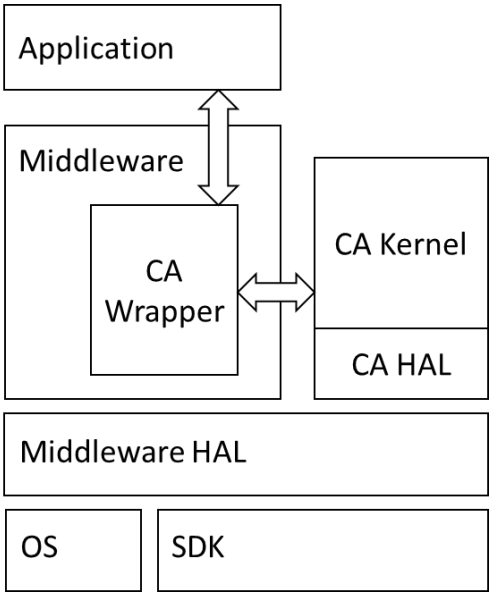

Fig. 1. Typical architecture of DTV software in case of OS where processes are not supported.

The module depicted as CA Wrapper is the actual module seen by the DTV middleware. It interacts with the middleware and application-level modules. It behaves like a proxy between the DTV stack and the existing vendor-specific CA subsystem. The conditional access subsystem consists of the kernel part where the logic is implemented and the hardware abstraction part (CA HAL) used as a glue layer between the CA kernel and underlying OS and SDK APIs. In this architecture, middleware HAL acts like a resource manager and has the information about allocated resources and tasks running in the system. This allows better resource management compared to the second approach.

The second approach is required with the OS supporting processes, like Linux and Android. As depicted in Fig. 2, the CA kernel and CA HAL depend directly on the underlying OS and SDK. They are running in a separate process. If the DTV stack is unstable or crashes, it does not affect the CA kernel. This approach ensures that the rest of the system never compromises CA. Still, the CA wrapper serves as a proxy between the CA kernel and DTV stack. It is up to the SDK vendor to ensure that multiple clients can access the same hardware peripherals. If not provided, some features like PVR may need to be carefully designed to ensure that components do not overlap in responsibilities.

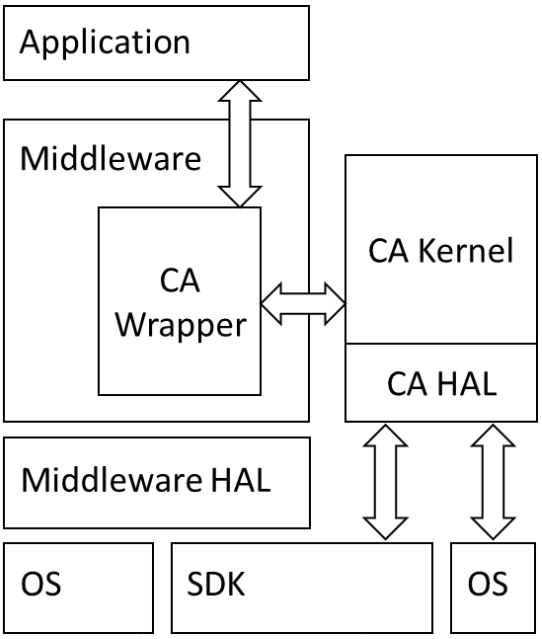

Fig. 2. Typical DTV software architecture in platforms with OS supporting processes.

We need to add CA subsystem support on a PC platform to test CA-related features. There are two possible paths:

1. Implement CA wrapper replacement module
2. Implement CA kernel replacement module (supporting CAS API)

The first solution gives us the ability to have a general CAS subsystem, irrespective of the actual CAS vendor. However, it puts aside CA wrapper code that interacts with the existing CA subsystem. Changes in the requirements of the CAS do not directly affect this solution.

The second approach is to develop the CA kernel module and the CA HAL module. It will preserve the CA wrapper module and allow it to be appropriately tested. However, this approach is considerably more time-consuming and has open questions related to all behaviors implemented in CA kernel API.

Our aim is not to implement content protection as software or hardware encryption. That is transparent to the middleware. Middleware only knows that content is protected and that the CA subsystem must start. CA subsystem is entirely responsible for the content decryption.

Encrypted content is never used in testing on PC because it has a complicated decryption procedure requiring specialized hardware protected by patents and legal documents. Only unencrypted content is used. This type of content can be generated using open-source tools like TS-duck [11] and video content available.

 ISBN 978-86-7466-930-3

III. IMPLEMENTATION

We have decided to take a hybrid approach given the above pros and cons. We implemented CA wrapper API on the DTV stack side as it already exists, allowing the remaining parts of the system to be unaware of the difference. CA kernel is partially shifted to the Middleware Test Environment (MTE). It is a framework for testing the DTV stack on PC.

The DTV software is running as a standalone executable. It has a middleware hardware abstraction layer (HAL) adjusted for the PC platform. Hardware devices are simulated in HAL using SDL [9] and FFmpeg [10] open-source libraries. The test environment is written in Python and communicates with the PC simulator using interprocess communication, particularly sockets. The test environment supported remote control, logging, and execution of automated tests. It can fully control the PC simulator, user input, and DTV stream input. Automated tests are supported by different APIs that are implemented in MTE. More about it can be found in [1] and [2] papers.

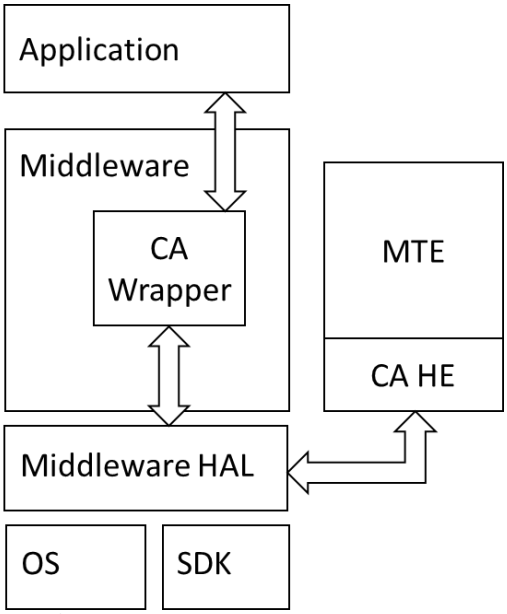

Fig. 3. DTV software architecture with middleware test environment (MTE) supporting conditional access head-end (CA HE)

As given in Fig. 3. the middleware test environment communicates with the PC simulator through the HAL layer that implements interprocess communication. A module CA wrapper uses send/receive routines from HAL. This is to mimic actual data flow, where CA information comes from a demultiplexer connected to the data stream. It will parse received commands and act accordingly. One typical example is the zapping procedure, where service is changed from one to another. In that case, middleware notifies the CA wrapper who needs to check access rights for that service in the database, sharing the data about the service being connected to and additional information about tracks to be descrambled. The module checks access rights in the database and responds to middleware. In our work, descrambling is not implemented, as it does not add any test value since all the descrambling is done in hardware, and none of that logic is done in the DTV stack.

Module CA wrapper is responsible for maintaining the CA kernel database. It exchanges data with the remaining parts of the DTV system. The middleware test environment can get the CA kernel database and modify it by sending appropriate commands. It communicates with a PC simulator using conditional access head-end (CA HE).

Following features (commands) we implemented in the CA HE subsystem and CA wrapper:

1. Device activation in a network
    a. Smart card
    b. Virtual smart card
2. Product access rights
    a. Checking rights
    b. Adding rights
    c. Removing rights
3. Service access rights
    a. Checking rights
    b. Adding rights
    c. Removing rights
4. Content protection
    a. Covered fingerprint
    b. Periodic fingerprint
    c. Permanent fingerprint
5. Mails
6. Changing service bouquet
7. Forced software update
8. CA notification messages
    a. Periodic messages
    b. Permanent messages
    c. User acknowledges messages

In Fig. 4, a window containing the setup for generating CA messages is presented. This CA HE submodule of MTE supports creating test cases. The test case is a message with all the parameters for that particular command. This way, the QA tester or developer does not have to enter test commands each time manually. Instead, he can select test cases saved as an XML file.

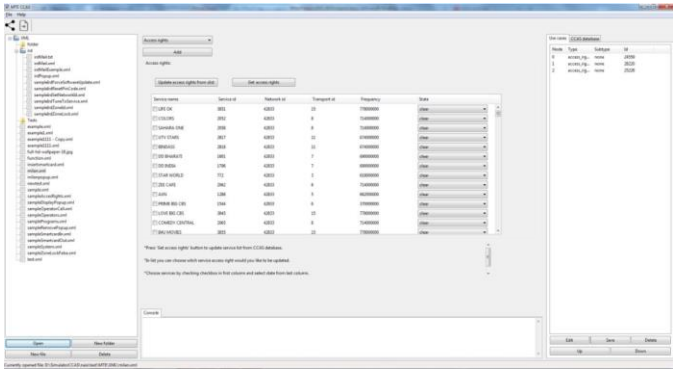

Fig. 4. CA HE main window consists of three parts, the user can re-use existing test cases or make new CA commands and send them in bulk.

CA HE main window consists of three parts, the left part reserved for displaying a tree of saved test cases, the middle

 ISBN 978-86-7466-930-3

part consists of a panel for generating CA commands, and the right part for listing generated commands ready for sending.

The middle panel for adjusting access rights for particular services is depicted in Fig. 5. There can be a list of services available on the box and the access right for that service.

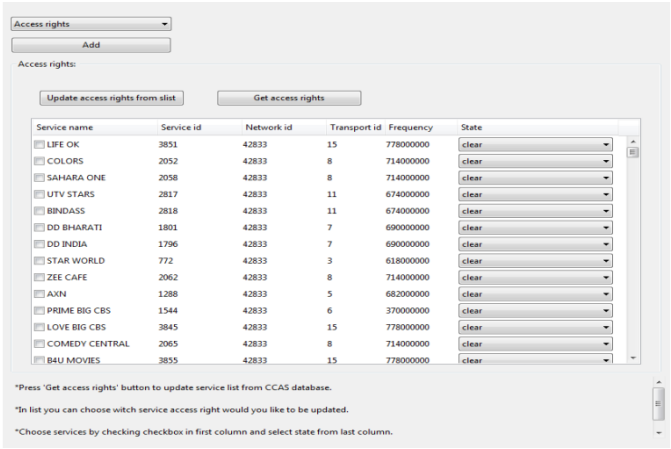

Fig. 5. The middle panel of the CA HE main window, where users select options to modify the service database's access rights.

The service access rights database is saved on the simulator side at runtime. The database can be exchanged between the simulator and MTE upon request sent from MTE. Once they are synced, MTE can send commands related to services access rights to the simulator. When the CA wrapper module receives a command, it processes the message, updates the database and saves it in an XML document. The CA state simulated in the CA wrapper can be restored from the XML file upon simulator restart. With this approach, the simulator is a standalone application, and MTE can communicate with it, but there is no dependency on MTE.

IV. Verification and Results

To test prepared CA subsystems, we have created a set suite that covers all supported types of messages that could be sent to the CA or received from the CA module by the DTV middleware [4]. We have observed that the code is executing correctly and that middleware behaves in the same manner as it is expected in the production environment.

In the case of sending chains of commands, we have observed new failure cases that were not covered by the DTV middleware and application. Those cases involve low probability cases like at the same time receiving a fingerprint message and a CA message. Those cases uncovered several combinations that could not be adequately tested on the development side, the operator's production live network or the lab network. They are not simple to prepare as a test case in those environments.

Scenarios that combine user interaction, CA signaling, and DTV signaling can reveal hidden bugs. Those bugs could be reported as software malfunction in a production. Yet those issues are impossible to reproduce manually unless the exact preconditions are known, which is rarely the case. Troubled combinations may be of low probability, but in networks with many end users, the chances that the failure will be seen and reported are very high. Still, the ability to troubleshoot it efficiently is very poor.

V. Conclusion

This paper focused on expanding capabilities for testing DTV software on a PC platform. It allowed more complex test cases to be executed that would be very hard or impossible to replicate in a network with real hardware. A further way of improving the solution is making a CA API on the MTE side. That could allow the creation of automated tests for testing application behavior as a response to CA events and user interaction.

Work could be extended toward implementing specific CA vendors' API allowing the whole DTV stack to be tested for required functionalities. It will increase the coverage of testable code to almost 100%. But gains versus cost ratio for doing this may not prove as an appropriate step. Another improvement can be made towards implementing some descrambling capabilities.

One solution for testing embedded DTV software on the PC platform

Branka Ševa, Đorđe Glišić, Uroš Jokić and Marija Jovanović

***Abstract*—In an embedded device industry, applicable software is developed for a particular platform and device. Reusability, functional correctness, and quality control of the software are of great importance. The digital television industry is no different. Moreover, it requires compliance with device safety, security, and functionality standards. Compliance testing is often done with near-end products, as most functionalities require that all components be put together. Secondly, most development is done using target platforms that often lack tools and add significant delays in development. This paper gives one solution for testing the embedded DTV software on PC. The authors give a road map for developing testing environment to safeguard the product's quality. It allows early-stage testing by the development team and helping the QA team test the end product.**

***Index Terms*— automated testing, DTV, middleware test environment, python, OpenCV, tesseract.**

I. Introduction

In embedded devices, hardware capabilities vary in many areas. Available RAM, platform instruction set, supported peripherals, hardware accelerators, and dedicated specialized hardware blocks. On the other side, depending on the product or manufacturer, there are support variations, incomplete documentation, and very little support for the supporting development software packages.

On the other side, there is a problem with integrating third-party components. They may or may not come with the test suite or test application. In the case of open-source software, source code is available, but it was written for specific operating systems (OS), sometimes depending on unique OS features.

A common component for all devices is DTV middleware software. It grows with new requirements, new standards, etc. Testing is always pushed to the end product, verified against predefined sets of tests. The reason behind it is that many features depend on all components being put together, and it is tough to test partially completed software [1].

Additionally, suppose such a DTV stack is inherited from another source without a test suite. In that case, it is always commercially unjustifiable to spend engineering time preparing a test suite that will verify the DTV stack. Instead, it is pushed to develop the end product and confirm its functional compliance [2].

Commercially available solutions are focused on testing the end product. Depending on the solution, it may offer hardware compliance testing or functional testing. Some tools like Intent+ [3][4] offer automated and manual testing. Automated testing is accomplished using dedicated test suite applications. Suitest [5] offers visual preparation of tests. Other solutions provide general-purpose languages like Stb-tester [6]. Others provide APIs like black-box-testing (BBT) API from Intent+. They mainly focus on automating the remote controller, capturing the screen, recording audio, and processing it using a test suite.

As a result of described practices, software products' quality may be at a reasonable level, but the quality of the code may be poor. Reuse of already developed code is very inconvenient across projects. Feature development may slow down as maintaining code becomes more and more expensive. Products may suffer from bugs that have low repeatability rates and high severity. In such cases, black-box testing [7] is not suitable. It is necessary to implement white box testing [8] procedures.

Section two details a problem and describes the system's architecture. Section three explains the proposed solution and provides implementation details. Section four discusses the results. In section five, we conclude our work.

II. Problem statement

In the development stage, verifying a new feature is time-consuming. Platforms with limited hardware capabilities offer unique tools to write software to devices. It may need from 30 seconds up to 5 minutes to run the software. Often those platforms do not support hardware debuggers.

A typical application in DTV consists of the following components:

1. Application layer (APP)
2. Middleware layer (MW)
3. Hardware abstraction layer (HAL)
4. Platform-specific SDK (SDK)
5. Operating system (OS)

Platform-specific SDK is a set of libraries and APIs that provide access to platform hardware components and allows control over them. This layer and the OS layer are closed for the development team. Also, those layers are highly platform-specific, so they cannot be ported to other platforms without

Marija Jovanović – RT-RK Institute for Computer Based Systems, Novi Sad, Srbija, (e-mail: Marija Jovanovic@rt-tk.com
Uroš Jokić – RT-RK Institute for Computer Based Systems, Novi Sad, Srbija, (e-mail: Uros.Jokic@rt-tk.com.

 ISBN 978-86-7466-930-3

considerable effort.

The hardware abstraction layer (HAL) provides a defined API [9] that exposes all necessary functions for upper layers (middleware and application) and abstracts platform devices and operating systems. It is implemented again with every new platform. It is common to have abstraction layers for every portable software and a test suite that verifies that the layer is ported correctly.

The middleware layer provides support for the DTV standard and is responsible for all functionalities in the DTV application. It consists of modules controlling hardware service change, acquiring information from DTV signal tables, maintaining program database, service lists, event information database, user interface engine, etc. Those modules are often interdependent. It is not simple to decouple one from the rest of the system and check their correctness using white box testing (e.g., unitary testing).

An essential component of the middleware layer is the conditional access system (CAS) or digital right management (DRM) system. It provides access to protected content. It is also a closed component that comes with the pre-defined test suite.

The application layer covers the graphical user interface and specific logic for the user interface. It is connected to the middleware layer and highly depends on it. Black-box testing mainly verifies this layer.

Architecturally higher-level components depend only on lower layer components. Key components that are developed are the application layer and middleware layer. Hardware abstraction layer API stays the same across different target platforms. We want to create a system that will test those two main components.

The goal is to prepare a software test environment that can support:

1. Functional tests as end-user
2. Scenario tests as end-user and operator
3. Monitoring and testing internal state
4. Code coverage

Functional tests cover black-box testing, where implemented features are verified [1]. Examples are video presence, audio presence, switching service, changing volume, displaying graphics, and event information presented. Besides core DTV tests, additional tests unique to the application have to be supported, like the position of some element on the screen, at the right time, for the correct period, etc.

Scenario tests verify DTV software in more complex cases. Those use-cases involve changing information in DTV tables signaling, new commands from the CAS/DRM system, or new data from other custom protocols that affect the device's state. Tests shell cover application responsiveness to the user interaction and user interface changes based on the system's internal state.

The monitoring system needs to monitor the execution and report critical situations. It should consist of a logging mechanism and software/hardware debuggers to automate the testing of internal states by inspecting calls to specific modules, APIs, and execution paths.

Code coverage gives insight into the test suite coverage of the existing code. If test coverage is low, it may mean that the test suite has to be expanded to cover some exceptional cases or that some source code is unnecessary occupying space (dead code). This work did not cover code coverage testing. Due to the complexity of this feature, implementation details are not covered in this paper.

The test environment defined would be capable of inspecting every module for its dependencies and behavior. Afterward, proper refactoring will allow white box testing (unitary testing, scenario testing).

III. Implementation

We decided to create a test environment to run and test DTV software on a PC. The reason behind it is to use current and future state-of-the-art tools. The first step was to port DTV software to the PC platform. It was done by porting the HAL layer. More details about it can be found in [10]. It supports working with actual transport stream data and makes DTV middleware fully operational. Compared to the commercial product, the only difference is that it does not support targeted CAS, as it is proprietary, and its libraries are only delivered for specific target platforms. Work is done to overcome this, using simulated CAS. Due to the complexity of this feature, implementation details are the subject of another paper and are not given here.

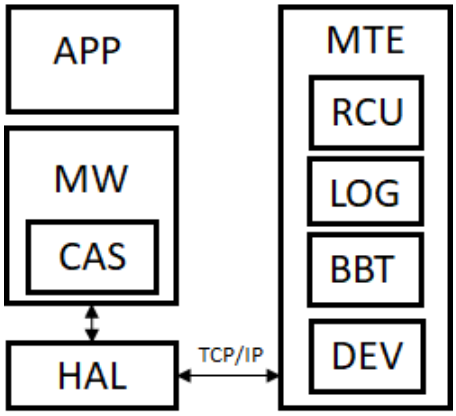

Fig. 1. Key components of DTV software running as part of the PC simulator are on the left side. On the right side are components of the MTE.

We decided to run separate processes for the test environment and DTV simulator. The DTV application runs stand-alone as it would be on the actual device. It allows us to have more options for the middleware test environment (MTE).

Communication with the PC simulator is done using TCP/IP. The communication protocol is designed to be minimalistic. The aim was not to disrupt the dynamics of the DTV middleware execution compared to its expected dynamics on the device. The protocol covers commands from MTE to PC simulator and data from PC simulator to MTE. Commands consisted of remote controller (RCU) events and requests for device state (screen capture, audio status, and

 ISBN 978-86-7466-930-3

similar).

We have decided to implement a test environment in Python language. We saw that this language is widely used in automation testing. Two STB automation test suites [4][5] already support Python scripting. It has extensive library support for user interface, computer vision, text recognition, communication protocols, etc. It is cross-platform, so we could design a tool to run on different platforms. It supports documenting code and a capable development environment (IDE).

We have selected the following frameworks to implement MTE:

1. wxWidgets - UI library (platform-independent, supports all major operating systems)
2. openCV - cross-platform library for computer vision, used for image manipulation and comparison
3. Tesseract - OCR engine for text recognition and extraction

The application was developed to support four different APIs:

1. Remote control API
2. Logger API
3. Black-box testing API
4. Development API

Remote control API covers control over RCU and sends commands to the PC simulator the same way a user would do using a remote control unit (RCU). To send commands, a TCP/IP protocol is used. On the side of the simulator, an existing module for receiving RCU input is adapted to receive TCP/IP commands from MTE.

Logger API is responsible for collecting log information from remote PC simulators using TCP/IP protocol. The existing logging module was improved to send log information over TCP/IP and the serial console on the simulator side. It supports filtering and searching for logging information.

Black-box testing API is a set of predefined APIs implemented on top of RCU API and an additional acquiring protocol for collecting screen output. It is aimed to be used for writing test cases. We selected to support the commercial black-box testing (BBT) API as part of Intent+. It was available to compare with the framework against an existing set of automated tests. Other solutions like Stb-tester API [5] are similar in API and exposed functionality.

Development API is created to support debugger integration in the MTE framework. It is implemented to support GNU GDB compatible debuggers. The framework can run the debugger and start the application or run the debugger and connect to the remote debugger server running the application (Fig. 2). This API makes it possible to start debugging software and send commands like setting breakpoints and watchpoints, printing values, etc. In this scenario, MTE spawns two processes, one for the GDB server that starts the PC Simulator and the second one for GDB used to control the remote PC simulator.

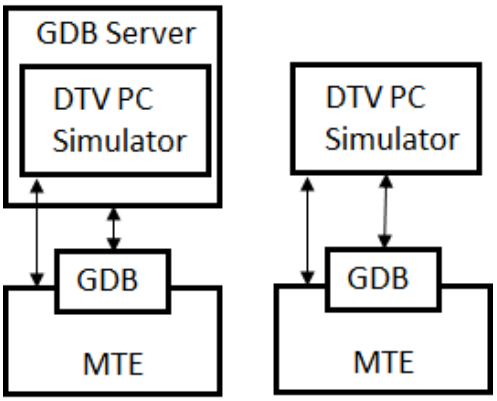

Fig. 2. Possible setups for running PC simulator using GDB debugging software with MTE.

Application consists of four parts similar to the APIs given above:

1. RCU controller
2. Stream controller
3. Logger
4. Test suite controller

Using an RCU controller, the user or developer can control the PC simulator using commands in the window that resemble the real RCU, as shown in Fig. 3.

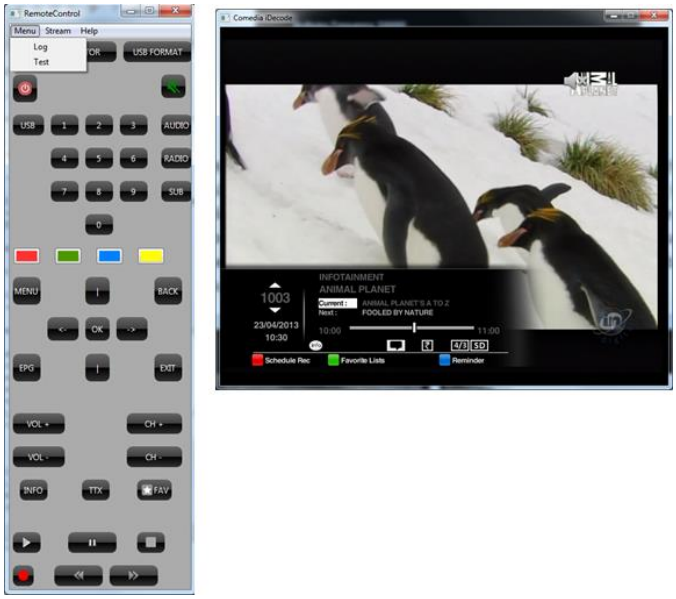

Fig. 3. Key components of DTV software running as part of the PC simulator are on the right side. On the left side are elements of the MTE.

The stream controller window is responsible for adjusting input DTV streams for the PC simulator. It allows setting stream files and broadcasting parameters.

Logger windows give information about logging data and allow users to filter and search for specific data in the log. The search pattern is highlighted in the log. In the filter window, only lines matching patterns are presented (Fig. 4).

 ISBN 978-86-7466-930-3

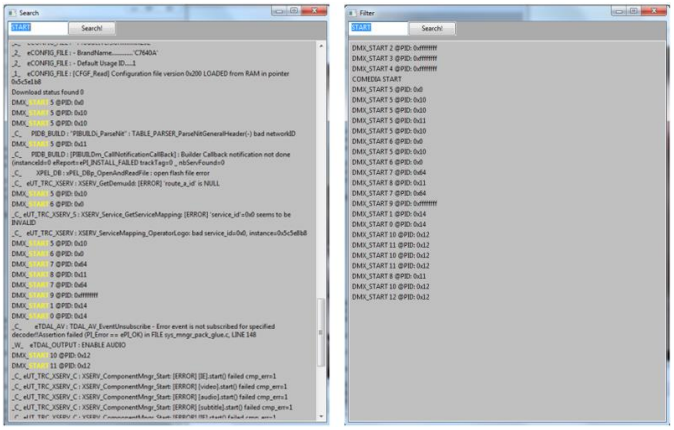

Fig. 4. Search and filter windows for logged information.

IV. Verification and Results

As a result of the following implementation, a test suite was created for commercial products using only BBT API (black-box testing). Test suites are grouped by the features they are testing. A list of all test groups and the number of tests are given in Table 1.

TABLE I
List of test suites prepared and results

Info channel	5 test cases	PASSED
EPG	6 test cases	PASSED
Genres	2 test cases	PASSED
Menus	10 test cases	PASSED
PVR	8 test cases	PASSED
Reminders	3 test cases	PASSED
Favorite lists	6 test cases	PASSED
Service lists	5 test cases	PASSED
Volume	6 test cases	PASSED
Service lists	5 test cases	PASSED
Zapping	5 test cases	PASSED

In the case of automated black-box testing, some graphical test cases may be challenging to create and prove reliable. User interface graphics blended with background video make it more difficult for AI-based engines to recognize certain visual elements' fonts, text, and shapes. Also, the comparison rate with expected images (shapes) may drop due to the background video. Our solution can compare video and graphical layers separately, resulting in higher recognition rates than blended image recognition using tools like OpenCV and tesseract. As a result, our MTE showed fewer errors than hardware running as part of the Intent+ solution.

Verification time was about 15 minutes, compared to manual testing, which will take 1-2h depending on tester skills. This allows developers to save considerable time when developing new features. Compared to automated hardware testing, execution time is around the same. It will enable continuous integration (CI) systems like Jenkins to repeat testing on selected changes.

V. Conclusion

With the proposed solution DTV application could be tested in the development phase by research and development teams or by dedicated QA teams. Automated tests written for MTE are usable for BBT devices in hardware testing, as they are written using the same API.

The essential contribution of this work is automated testing using software debuggers, where developers can inspect certain parts of the system multiple times and summarize information in reports. This type of testing can mimic unitary testing and complex scenario testing having internal systems state exposed for examination and reporting. It allows tightly coupled modules to be slowly refactored and isolated to introduce unitary testing and low-level verification.

Additionally, any other DTV software capable of porting to the PC platform could be tested using this MTE framework. It has to implement necessary features for that middleware and additional requirements to support communication protocol with MTE.

Further work could be done toward implementing support for CAS/DRM simulator or emulation. Also, it would be of great benefit to change DTV signaling from within the MTE application, as now it relies on signaling transported in DTV streams captured from live DTV networks. Another path for improvements is to add systems for code coverage and memory leak checks like Valgrind that could check applications in specific test scenarios as part of the automatic test.

Comparison of type-2 hypervisor performance on the example of VirtualBox, VMware Workstation player and MS Hyper-V

Borislav Đorđević, *Member IEEE*, Iva Jovičić, Nenad Kraljević and Valentina Timčenko, *Member IEEE*

***Abstract* – This paper presents a comparison of the performances of type-2 hypervisors, on the example of desktop virtualization applications, which include VirtualBox, VMware Workstation Player, and MS Hyper-V. The qualities of all three tested hypervisors, from many aspects of performance, were tested through the performance of the files system. Tests were performed under the same conditions and the same testing methods, using the Filebench program. CentOS 7 was used as the guest operating system. The hypervisor's performances were compared taking into consideration the tests performed for the system with one, two, and three virtual machines in operation. Hypotheses about expected behavior were set, and then they were validated through the obtained results using the Filebench program.**

***Index Terms* – VirtualBox; VMware Workstation; MS Hyper-V; CentOS; hypervisor; virtual machines.**

I. Introduction

Virtualization as a concept is increasingly used and conquers new spaces. It has become a part of everyday life for the simple reason that information technology are all around us. As these technologies are increasingly present in modern life and are constantly advancing, virtualization has taken its place in this development. The main advantages obtained by applying virtualization can be seen in the reduction of costs of IT equipment, electricity and storage space for this equipment. The concept itself provides high security and resistance to failures, and makes administration easier. The choice of virtualization methods and techniques depends on the specific situation and the needs of the end user. This is due to the fact that some virtualization techniques achieve greater flexibility in operation, while others achieve better performance or security. The most commonly used virtualization techniques are: virtualization of hardware, software, data, memory, storage space, virtualization of network infrastructure and virtualization of desktop computers. [1]

Virtualization involves the encapsulation and abstraction of computer components, so these components can be used in a way that suits a particular application. Hardware virtualization involves usage of hypervisor, a software layer, which is an intermediary between the hardware and the guest operating system in a virtual machine. This is a simulated environment that could have characteristics equal to the physical environment. The hypervisor can be native, or type-1, which runs directly on the hardware, or hosted, type-2, which runs on the operating system. Examples of this type of hypervisor are VirtualBox 6.1 and VMware Workstation 16 player which have been tested for the purpose of this paper. MS Hyper-V is a bare metal, type-1 hypervisor. However, when activated as a roll, in this case in Windows 10 Pro, it behaves as a type-2 hypervisor. This version of MS Hyper-V was used in the testing process for this paper. [2]

Other than above described classification, hardware virtualization also depends on whether full, partial, or paravirtualization is selected. Full virtualization (Figure 1), topic of this research, represents a simulation of complete hardware, so guest operating systems can be installed and ran without problems. The guest operating system is separated from the physical layer of the host, the hypervisor layer. The advantage of this method of virtualization is increased security and scalability, as well as system flexibility. This solution is the easiest to use, but the performance is slightly lower. [3,4]

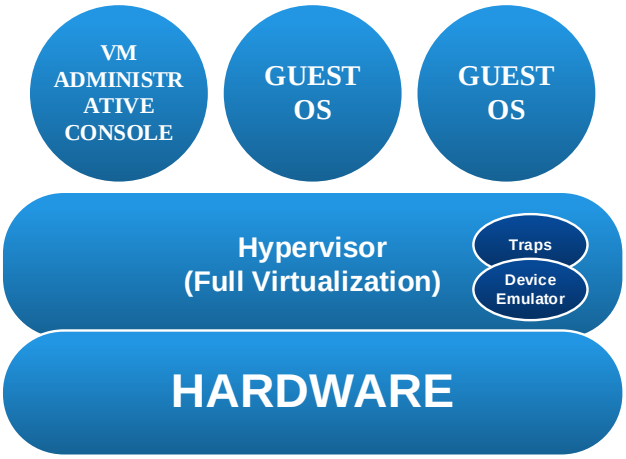

Figure 1. Full virtualization

 ISBN 978-86-7466-930-3

II. Related work, objective and motivation

The focus of this research are the performance characteristics of hypervisors as one of the basic factors in achieving service quality. The problem itself, which can be found in the literature as well as by using these systems in practice, can be viewed from several angles. There are many papers and discussions that use different methodology and approach to evaluating the performance of virtual platforms. The most common is a comparative performance analysis of VMware, Xen, MS Hyper-V and other hypervisors by using various benchmark tools such as HD Tune Pro, ATTO, Filebench, Bonnie ++, etc. Virtualization is a great solution in both desktop and server versions. The needs for virtual platforms for personal use are growing. The main contribution is the mathematical modeling of the file system performance in hypervisor-based virtualization. The modeling of complex virtual environment includes many factors, and modeling expects there is no single winner hypervisor. Similar mathematical model, we used in this paper and most our references [3], [5], [10], [11]. Our model is open for enhancing. We think we are different from related work by our methodology. Its essence is a mathematical model, apply it on a particular case study, and then provide the interpretation of practical results as a validation of model. Using by large number of case studies, we recommend the creation of Knowledge Data Base (KDB) related to the file system performance in virtual environment. Case study in this paper include the performance comparison of three hypervisors in the desktop version, namely VirtualBox, Vmware Workstation player and Hyper-V, in fair-play conditions. This implies identical hardware, the same virtual machines, and an identical version of the guest operating system, which in this case was CentOS 7, an operating system from the Linux distribution family. As VirtualBox and Vmware Workstation player use full virtualization, and MS Hyper-V and paravirtualization as well, the effects of full virtualization for three different hypervisors were examined, using the Filebench benchmark program with four different workloads. Hypotheses about expected behavior are set, followed by a mathematical model for workloads and a hypervisor environment. Performance was measured and the obtained results were interpreted on the basis of models and hypotheses. This paper has some similarities with reference at the serial number five in our literature. The results have the similarities and differences, because the hardware and many other factors are quite different, but we think that both papers are interesting and useful cases of study.

III. VirtualBox, VMware Workstation player and MS Hyper-V

Oracle's VirtualBox is a very powerful program for virtualizing 32-bit and 64-bit operating systems, on computers with Intel or AMD processors. VirtualBox is the only professional solution that is available for free as open source software under the terms of *"GNU"* version 2. This software runs on Windows, Linux, Mac and Solaris operating systems. The technical requirements for running this software are:

- 32-bit or 64-bit operating system with AMD or Intel processor,
- 512MB or more RAM (depending on the number and type of operating systems being virtualized. The RAM memory space allocated to the virtual machine environment can go up to half capacity, as the software itself will not allow more than half of the base system's RAM.
- available hard disk space for the virtual machine environment (recommended size is a minimum of 8GB).

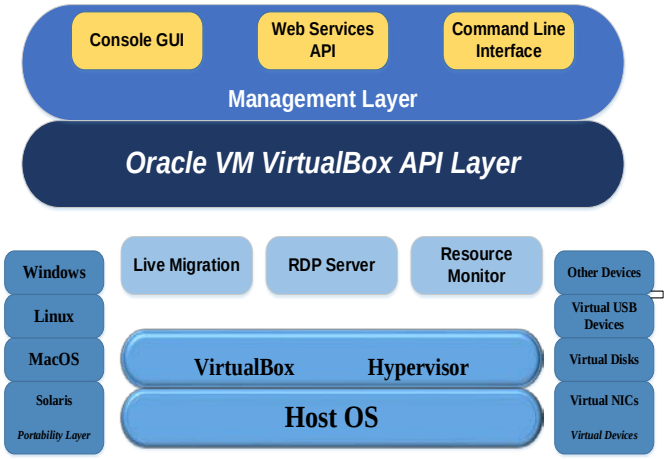

Figure 2. VirtualBox architecture

VirtualBox allows quick and easy data sharing between virtual machines (Figure 2). As VirtualBox is open source, or rather it's software, it tends to solve problems quickly and can be upgraded with new features. Since version 6.1, which is used in this paper, the ability to export and import virtual machines to Oracle Cloud has been added. Software virtualization has been deprecated since this version, and VirtualBox 6.1 uses only hardware-assisted virtualization. [5,6]

VMware® is considered one of the largest manufacturers of software virtualization. The solutions of this company occupy over 70% of the market share in this area, primarily due to the quality of products and the availability of technical support. VMware® has been acquired since 2004 and became part of the EMC Corporation. VMware Workstation 16 player is a software package that runs on standard x86-based hardware with 64-bit Intel and AMD processors and on 64-bit Linux and Windows operating systems. [7,8]

VMware Workstation 16 player (Figure 3) can run existing virtual machines and create their own virtual machines. It uses the same virtualization core as VMware Workstation Pro, a similar multi-featured, non-free program.

 ISBN 978-86-7466-930-3

VMware Workstation 16 player is available for personal non-commercial use (free), for distribution or other use by written agreement. The technical requirements for running this software are:

- 64-bit operating system from the Windows or Linux family with AMD or Intel processor,
- 2GB or more RAM (recommended 4GB or more),
- 1.3GHz or higher core speed,
- available hard disk space.

Figure 3. VMware Workstation player architecture

Microsoft is one of the leading companies in information technology. At the server level, virtualization has become the standard, but interest in virtualization has also emerged among users for personal use. Microsoft occupies about 15% of the market with MS Hyper-V virtual platform. With the release of Windows 8 in 2012, MS Hyper-V became an integral part of its Enterprise, Education and Pro editions. MS Hyper-V is a type-1 hypervisor-based system for x86-64 operating system architectures. It is activated in the Windows operating system as a roll, just like any other service in the Microsoft family. There are some MS Hyper-V features that work differently in Windows OS and Windows server. The memory management model is different for MS Hyper-V, where MS Hyper-V manages memory on the server assuming only virtual machines run on the server, and in the Windows operating system, it is managed with the expectation that most client machines run software on the host in addition to virtual machines. [9-11]

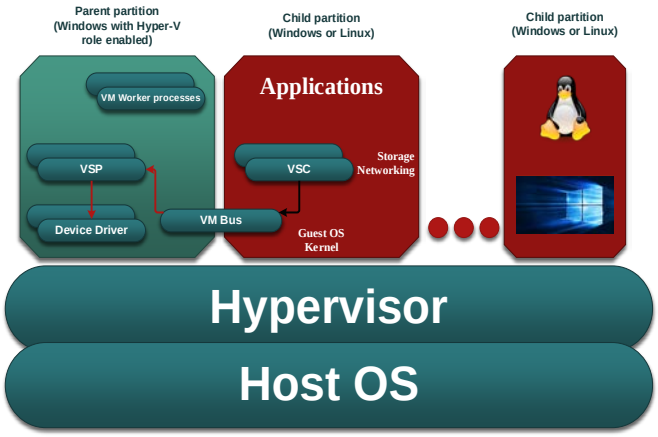

Figure 4. MS Hyper-V architecture

MS Hyper-V (Figure 4) supports virtual machine isolation and uses partitions in which guest operating systems will run.

IV. Hypotheses about expected behavior

As the Type-2 hypervisor running under the guest operating system was used, we can point out that each workload generates typical random and sequential data read times, as well as random and sequential data write times. Each workload is defined by the access time for file systems. Workload represents the total time to complete all operations, the time required to complete all operations related to directories, metadata, file blocks, free lists, house-keeping and journaling operations in the file system. There are five components in a virtual environment that have an impact on workload time (Tw – Time Workload):

$$Tw = f\,(Bn, gFS, VHw\text{-}pr, Hp\text{-}pr, hFS) \qquad (1)$$

The first and second components, Bn (Benchmark) and gFS (guest OS file system) are exactly the same for VMware Workstation player, Oracle VirtualBox and MS Hyper-V. The analysis focuses on the interaction between the reference values and the guest operating system. Because the test environment relies on the use of an identical benchmark, identical virtual machines, and ext4 as the guest file system, these components are expected to have an identical effect on Tw. Processing time for full hardware virtualization is the third component of VHw-pr (virtual hardware processing). Each hypervisor uses its own solution for full hardware virtualization, so the performance will be different too. The fourth component, Hp-pr (hypervisor processing), represents the time it takes for the hypervisor to receive requests from the virtual hardware and forward them to the host drivers. In particular, guest FS requests (guestOS-FS) are forwarded to host FS (hostOS-FS). All of these hypervisors, VMware Workstation player, Oracle VirtualBox and MS Hyper-V, generate different hypervisor processing times. The fifth component, hFS (host OS file system), represents the

 ISBN 978-86-7466-930-3

processing time of the host OS file system. All hypervisors have MS NTFS as hostOS-FS, so this component is expected to have similar processing times for all hypervisors. The dominant influence of the third and fourth components of formula (1) is expected as the tests are focused on the performance of natively virtualized guests (complete hardware virtualization). [12]

V. Test configuration and benchmark application

The prerequisite for quality and adequate testing is the application of one hardware configuration, the same operating system, then the selection of a quality benchmark program and the same measurement methodology for all testing procedures. Testing was done on a personal computer whose characteristics can be seen in Table I, while the characteristics of the disk are given in Table II. CentOS 7 from the Linux distribution family is installed as a guest operating system.

TABLE I - Test environment/PC

Components	Characteristics
Processor	Intel Core i5-4590S 3GHz
Memory	8GB DDR3
Cache	6MB L3
Hard drive	Seagate Barracuda 7200.12
Operating system	Windows 10 Pro, 64-bitni

VirtualBox 6.1 virtualization platforms, VMware Workstation 16 and MS Hyper-V, a version for Windows 10 Pro, are installed or activated on the hard drive, where the tests were done. The hard drive was also used to install virtual machines.

TABLE II - Test environment/Hard Disk

	Seagate Barracuda 7200.12
Model Number	Seagate ST3500418AS
Capacity	500GB
Interface	Serial-ATA/300
External Transfer Rate	3.0Gb/s
Max Sustained	300MB/s
Cash	16MB
Average Latency	4.17ms
Spindle Speed	7200rpm
Average Seek Time Read	8.5ms
Average Seek Time Write	8.5ms

All tests were performed using the benchmark program Filebench 1.4.9.-1. This program is designed to measure storage space and performance of file system. Filebench is capable of generating several types of workloads, it can simulate environments when using certain services such as mail server, fileserver, web server, etc. [13, 14]

VI. Testing and results

This paper shows a comparison of the performance of virtual platforms for personal use with their capabilities. Disk performance and data flow were measured. To make testing meaningful, all virtual machines are created exactly the same and have the same characteristics (Table III).

TABLE III - Virtual machine parameters

Components	Characteristics
Virtual processor	1
Memory	2GB
Virtual hard drive	60GB
Operating system	CentOS 7

During the testing, modified base code files were used, such as *varmail.f*, *fileserver.f*, *webserver.f* and *randomfileaccess.f*, which test the web, mail and file server. The appearance of the set parameters of the benchmark program can be seen in Table IV. To achieve the most realistic results, each test lasted 120 seconds. Each test was repeated ten times, and the obtained results were expressed as the average value of these tests.

TABLE IV – Base code parameters of **F* file

	Varmail	Web server	File server	Random file access
nthtreads	16	100	50	5
nfiles	1000	1000	10000	10000
meandir widht	1000000	20	20	20
meanfile size	16k	16k	128k	random

Tests were conducted by first installing VirtualBox and then creating a virtual machine in this program. It was tested, and then this procedure was repeated when two and afterwards three virtual machines were created. The testing system was exactly the same when the virtual machines in the VMware Workstation 16 player application were tested. Of course, before testing on this platform, previous virtual machines and VirtualBox applications were uninstalled. At the end of the testing, the MS Hyper-V roll was activated and tests were performed, as in the previous two cases. In that way, fair-play conditions were created for all three virtual platforms. The results of the Fileserver workload test can be seen in Table V and Figure 5.

TABLE V - Fileserver benchmark results

 ISBN 978-86-7466-930-3

Fileserver	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)
VMware	74,58	64,33	56,41
VirtualBox	42,03	35,16	29,76
MS Hyper-V	33,34	28,12	21,53

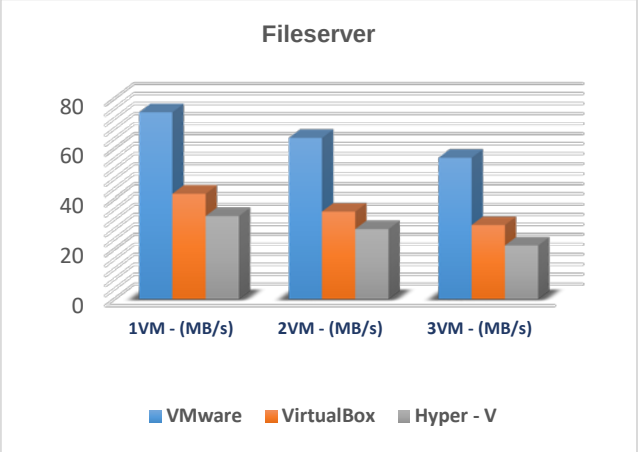

Figure 5. Fileserver test results

The results of testing other workloads are shown in Tables VI, VII and VIII, as well as graphical representations in Figures 6, 7 and 8.

For the *"Fileserver"* workload, we note that VMware is by far the best, while VirtualBox is better than Hyper-V. In a complex workload such as Fileserver with sequential and random write components, the FS cache effect on guest and hostOS is significant, so VMware wins convincingly primarily because of the 3rd component of formula (1) and the best cooperation with FS caching.

TABLE VI - VARMAIL BENCHMARK RESULTS

Varmail	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)
VMware	44,58	42,62	39,87
VirtualBox	18,46	17,83	16,62
MS Hyper-V	14,06	12,77	10,11

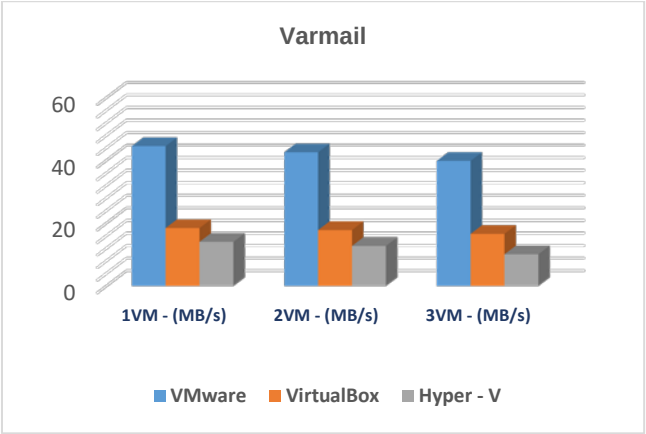

Figure 6. Varmail test results

For the *"Varmail"* workload, we note that VMware is by far the best, while VirtualBox is again slightly better than MS Hyper-V. In the Varmail workload, in addition to random reading, there are also synchronous components of random write, the impact of FS caching is small, so VMware and then VirtualBox obtain wins, primarily because of the 3rd and 4th components of formula (1).

TABLE VII - WEBSERVER BENCHMARK RESULTS

Webserver	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)
VMware	84,68	81,04	77,68
VirtualBox	47,73	42,26	37,86
MS Hyper-V	80,92	76,61	71,92

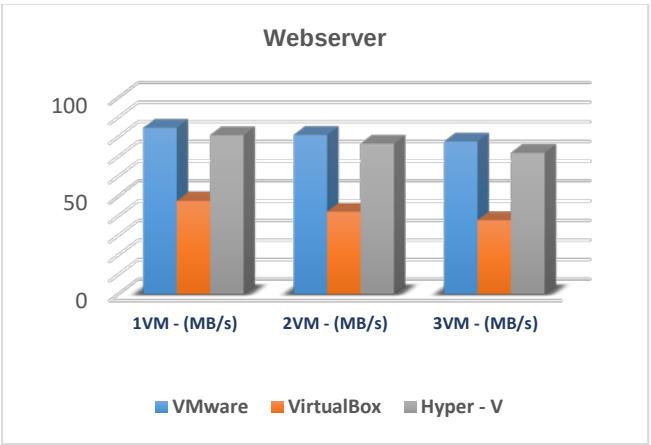

Figure 7. Webserver test results

For the *"Webserver"* workload, we note that VMware is slightly better than MS Hyper-V, and VirtualBox is significantly weaker. In the Webserver workload, which has both random read components and very few random write components, there is less influence of FS caching, so VMware and MS Hyper-V did better than VirtualBox, and win primarily because of the 3rd and 4th and the components of formula (1) and the cache effect in random reading, the dominant workload in Webserver environment.

 ISBN 978-86-7466-930-3

TABLE VIII – RANDOMFILEACCESS BENCHMARK RESULTS

Randomfile access	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)
VMware	5141,56	5034,02	5008,76
VirtualBox	2595,11	2546,56	2517,36
MS Hyper-V	4888,85	4816,64	4790,44

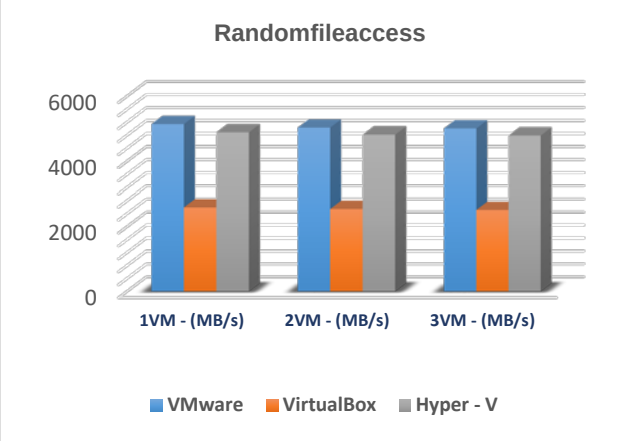

Figure 8. Randomfileaccess test results

For the *"Randomfileaccess"* workload, we can see that Hyper-V is slightly weaker than VMware, and VirtualBox is significantly weaker again. In the Randomfileaccess workload, which has both random read components and a lot of asynchronous random write components, there is a solid impact of FS caching primarily for random writing, so VMware and MS Hyper-V fared better than VirtualBox, primarily because 3rd and 4th components of formula (1) and solid cache effect in random entry.

VII. CONCLUSION

When it comes to virtualization, it should be noted that it brings major changes in the information technology and computer industry, primarily in reducing investment in infrastructure and saving electricity consumption. In area of personal computers, virtualization has made great strides by bringing a large number of software for this purpose. Some of them are also presented in this paper. The advantage of using these applications is the ease of installation and usage, and the fact that the platforms tested in this paper are completely free. For this case study, VMware is the absolute winner in all workloads. We believe that the differences is made by the 3rd and 4th components of formula (1), as well as by the powerful hypervisor usage of the FS cache effect. For workloads with many sequential features and weak cache effect (Fileserver and Mailserver) VirtualBox is better than MS Hyper-V, and for workloads with random dominance and solid cache effect (Webserver and Randomfileaccess) MS Hyper-V is better than VirtualBox. Future work on this topic will focus on testing other virtual platforms in the field of desktop computers, as well as the use and testing of various operating systems that are applied in practice.

Comparison of file system performance in full virtualization with MS Hyper-V and KVM hypervisors

Borislav Đorđević, *Member IEEE,* Miloš Piljić, Nenad Kraljević and Valentina Timčenko, *Member IEEE*

***Abstract* - This paper presents a comparison of the performance of native hypervisors on the example of MS Hyper-V and QEMU/KVM virtual platforms. Their quality was examined through aspects of file system performance. Filebench program was used for testing procedure, which is an application that guarantees equality and independence from the impact of hardware environment. CentOS 7, an operating system from the Linux distribution family, was used as the guest operating system. The tests were performed for one, two and finally three virtual machines that are running simultaneously. The results were further validated based on the defined hypotheses related to the expected behavior of the hypervisors.**

***Index Terms* - MS Hyper-V; QEMU/KVM; CentOS; virtual machines; performance.**

I. Introduction

In the area of information technology, virtualization is a way of creating a virtual version of computer resources. Virtualization is a simulation of the hardware or software that other software, such as various operating system, is running. Virtualization is initially applied by IBM in 1960s as a method for the logical division of mainframe computer system resources between different applications. The need to manage the "one server-one application" model has been eliminated, opening the possibility of running multiple operating systems on the same hardware platform. The advantages and savings that are obtained by using such a system are more than obvious: hardware, CPU, memory resources, administration staff. All this is a plus for virtualization in the reliability segment. The virtualization solutions allow easiness in adding new servers, as well as in data migration from one server to another. This is an additional advantage of this technology in the field of scalability.

Hardware virtualization, which is the topic of this paper, is the most popular and widespread type of virtualization [1]. The software that controls virtualization is called a Virtual Machine Monitor (VMM). According to the most common form of use in a professional IT environment, the process of creating and managing virtual machines is also called server virtualization. There are two categories of hypervisor: type-1 (native) and type-2 (hosted). In this paper, type-1 hypervisors were tested for the case of MS Hyper-V and QEMU/KVM virtual platforms (Figure 1) [2].

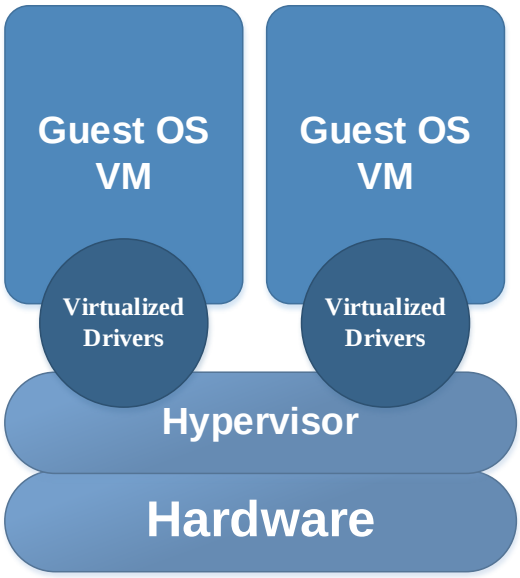

Figure 1. Native hypervisors

II. Research work, goal and motivation

The literature related to this field is mostly focused on comparative analysis of hypervisor performance, using by different test methodology and benchmark tools. For this purpose, some proven benchmark tools are usually used, which is one of the cornerstones for obtaining quality level results. We recommend the Filebench, as open source solution, because it is a versatile, powerful, multithread and it simulates the real application workloads. We recommend the Fio tool, similar benchmark as Filebench, and some synthetic benchmarks such are Bonnie++, Postmark etc. The main contribution of this paper is the mathematical modeling

 ISBN 978-86-7466-930-3

of hypervisor-based virtualization in the context of the file system performance and applying the model on a performance case study for the interpretation of benchmark results. Because the complex virtual environment includes large number of factors, model expects there is no single winner hypervisor and depends on the case study i.e. the workload characteristics. In relation to competition, we are forcing a mathematical model and a number of case studies based on model with practical performance tests. The server variant of the virtualization stands for a great solution, primarily due to the introduction of the infrastructure costs and hardware reduction, followed by the easier administration. Still, there is a lot of room and opened questions for the improvement in this area. This paper contribution is the validation and comparison of two hypervisors, namely MS Hyper-V and QEMU/KVM, for which we have tested the quality and performances in identical conditions. Both hypervisors use full virtualization, while MS Hyper-V is also suitable for the use of the paravirtualization. As the guest operating system we have used CentOS 7, popular distribution from the Linux OS family, while for testing needs we have applied Filebench benchmark program with 4 different workloads. After defining the hypotheses, a mathematical model was set up, and validated by the obtained results [3], [4].

III. MS HYPER-V AND QEMU/KVM

MS Hyper-V is an efficient hypervisor, developed by Microsoft, which enables virtualization of operating systems in a server environment (Figure 2). With the release of Windows Server 2008 R2 version, Microsoft has included a Hyper-V virtualization solution in the operating system itself. MS Hyper-V is a role that allows administrators to create multiple virtual machine, and supports isolation of partitions in which guest operating systems will run [5], [6].

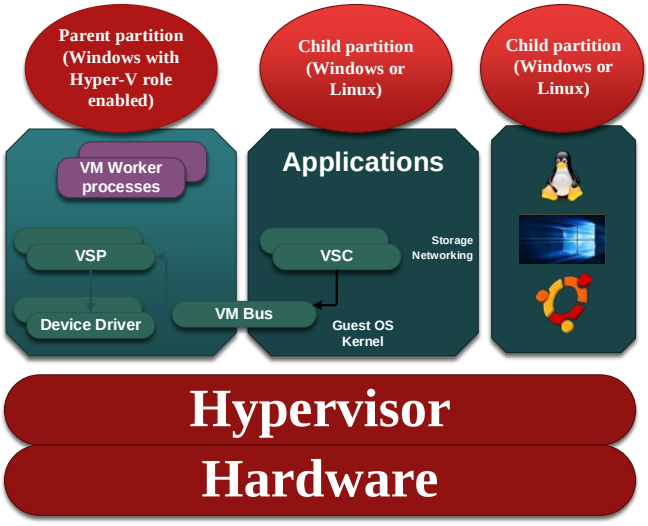

Figure 2. MS Hyper-V architecture

When it comes to virtualization under the Linux operating system, KVM (Kernel-based Virtual Machine) is almost indispensable technology. It is originally created as the Red Hat sponsored project. KVM is implemented in the form of a kernel module and is an integral part of the Linux kernel from version 2.6.20. For the KVM it cannot be said that it is a type-1 or type-2 hypervisor. On the one hand, KVM extends the Linux kernel and adds virtualization capabilities to it, allowing Linux itself to be treated as a native hypervisor (Figure 3). On the other hand, Linux is a standalone OS on which KVM functionality relies orthogonally, so it can be said that KVM runs above the main OS (hosted hypervisor), using already implemented system functions in the absence of its own (QEMU) [7-9].

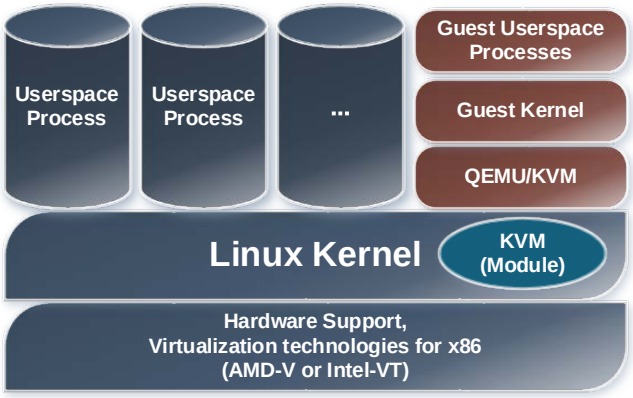

Figure 3. QEMU/KVM architecture

IV. HYPOTHESES ABOUT EXPECTED BEHAVIOR

Both hypervisors are native, they work directly on the hardware and are realized in the microkernel architecture. The total processing time for each load *Tw* (Time workload) can be calculated as follows (eq. 1):

$$T_W = T_{RW} + T_{SW} + T_{RR} + T_{SR} \quad (1)$$

where T_{RW} and T_{SW} represent random and sequential data entry times, while T_{RR} and T_{SR} represent random and sequential read times. For each of these workloads, there is an expected access time for a file system that includes five components (eq. 2):

$$T_{WL} = T_{FB} + T_{FL} + T_J + T_{HK} + T_{DIR} + T_{META} \quad (2)$$

where T_{WL} represents the total time for the implementation of all operations for a defined workload, and the elements from equation (2) represent the time required for the implementation all operations related to file blocks, file lists, journaling, house-keeping, metadata and directory in the file system. There are 5 components that have an impact on the workload time T_W (eq. 3):

$$T_W = f\,(\text{Bn, gOS-FS, Hp-proc, VH-proc, hOS-FS}) \quad (3)$$

 ISBN 978-86-7466-930-3

The first and second components Bn (Benchmark) and gOS- FS (guest file system) are identical for KVM and Hyper-V. Since an identical benchmark and the same virtual machines with their ext4 guest file system are used in testing, we can assume that these components will have the same impact on the third component, Hp-proc (hypervisor processing) which represents a typical delay of hypervisor (KVM-delay, Hyper-V-delay). This represents the time that takes the hypervisor to receive a request from the virtual hardware and forward it to the host drivers. The fourth component, VH-proc (virtual hardware processing) for KVM is QEMU full virtualization, and for Hyper-V MS full virtualization. Although these are full hardware emulations, both hypervisors have their own solutions that will certainly differ in performance. The fifth component is hOS-FS (host file system). KVM uses ext4 and the Hyper-V NTFS file system, and this component is expected to cause different processing time for hypervisors. Since the tests are focused on the performance of native virtualized guests, the dominant influence of the third, fourth and fifth components of formula (3) is expected.

V. Test configuration and benchmark application

In order for testing to be adequate and high quality, it is necessary to use the same hardware configuration, the same guest operating system, choose a quality benchmark test program and the same performance measurement methodology. The tests were performed on an IBM server, whose characteristics can be seen in Table I, and the characteristics of the hard disk on which the tests were performed can be seen in Table II. CentOS 7 was used as a guest OS [10].

TABLE I - Server/Test Environment

	IBM 7945J2G - System x3650 M3
Processor	Intel® Xeon E5620 2.4GHz
Memory	32GB DDR3
Cache	12MB L3
Hard Disk	8 x Kingston 240GB SSD Now V300 SATA 3 2.5 (SV300S37A / 240G)
Network	2 x 1Gb / s

Virtual Platforms MS Hyper-V and QEMU/KVM are installed on hard drives converted into RAID 10, size 960GB (4x240GB SSD), while the other (RAID10/960GB) served as a repository on which virtual machines were created.

TABLE II - Hard Disk/Test Environment

	Kingston 240GB SSD Now V300
Model Number	SV300S37A/240GB
Model Name	SSD Now V300
Capacity	240GB
Interface	SATA 3.0 (6Gb/s)
Connectivity Technology	SATA
Hard Disk Form Factor	2.5 Inches
Read / Write Speed	450MB/s
Cache Size	240GB

All tests were done using Filebench, a benchmark program version 1.4.9.1-3. This program is designed to measure the performance of file systems and storage space and is capable of generating a large number of workloads. In this paper, 4 different workloads are used simulating environments when using services: web, mail and file server [11].

VI. Testing and results

This paper presents a comparison of the performance of virtual platforms for server use. Disk performance and data throughput were tested. In order to make testing meaningful, all virtual machines were created with identical characteristics (Table III).

TABLE III - Virtual Machine Parameters

Components	**Characteristics**
Virtual Processor	1
Memory	8GB
Virtual Hard Disk	200GB

For mail, file and web server test needs, we have modified the base code files for analyzed workloads: *webserver.f, varmail.f, fileserver.f* and *randomfileaccess.f*. First, Hyper-V was tested, which was activated as a role on Windows Server 2016, by creating one virtual machine that was tested. The same procedure is repeated for testing the environment with two and three virtual machines. Each test lasted 120 seconds and was repeated ten times. The final result represents the average value of the obtained test results. Before testing the KVM virtual platform (using CentOS 7 with the KVM option checked), the Windows server with its virtual machines was uninstalled in order to clean the environment. An identical installation and testing procedure were then conducted with the KVM virtual platform. In this way, fair-play conditions were acquired for

 ISBN 978-86-7466-930-3

both virtual platforms. The results of Varmail workload testing can be seen in Table IV and Figure 3.

TABLE IV - VARMAIL BENCHMARK RESULTS

Varmail	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)	Native (MB/s)
MS Hyper- V	25.21	19.82	13.11	
QEMU/KVM	13.04	12.79	12.22	
Native OS				68.77

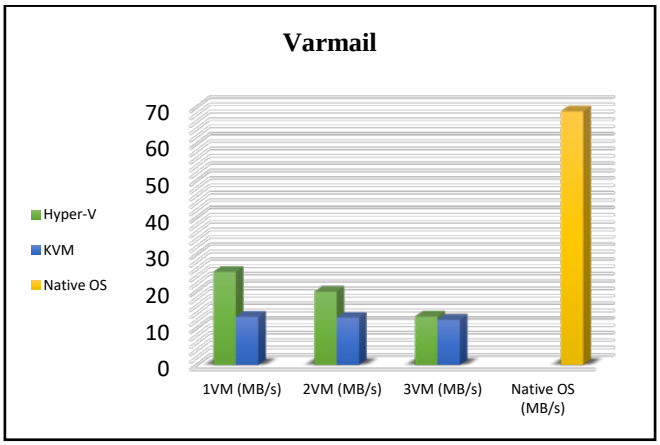

Figure 3. Varmail test results

For the "*Varmail*" workload, we notice that Hyper-V is solidly better than KVM. In this workload, besides the random read components these are synchronous random write components too for which the impact of the FS caching is very small. In this case, Hyper-V is better, primarily due to the fifth component of formula (3), where NTFS for this workload performed better in FS pair (ext4 on NTFS compared to ext4 on ext4).

The results of testing other workloads can be seen in the graphs (Figures 4.5 and 6), as well as in Tables V, VI and VII.

TABLE V - FILESERVER BENCHMARK RESULTS

Fileserver	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)	Native (MB/s)
MS Hyper-V	146.04	83.75	47.43	
QEMU/KVM	155.44	138.84	115.46	
Native OS				555.63

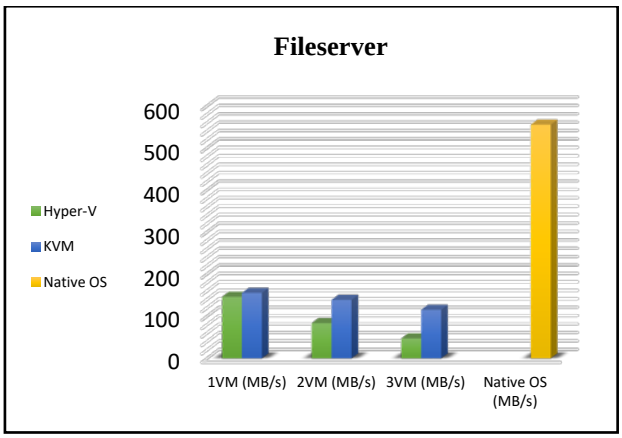

Figure 4. Fileserver test results

For the "*Fileserver*" workload, we notice that KVM is better than Hyper-V. In a complex workload such as Fileserver in which there are random and sequential write components, the FS cache effect on the guest and host OS is significant, so KVM wins primarily because of the third and fourth components of formula (3). We believe that KVM has better virtual hardware processing and less hypervisor latency.

TABLE VI - WEBSERVER BENCHMARK RESULTS

Webserver	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)	Native (MB/s)
MS Hyper-V	53.94	47.73	43.28	
QEMU/KVM	39.62	37.99	36.44	
Native OS				115.26

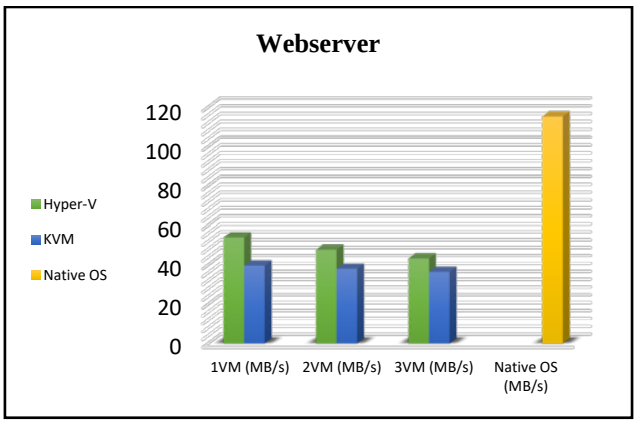

Figure 5. Webserver test results

For the "*Webserver*" workload, we can see that the Hyper-V is again solidly better than the KVM. In the Webserver workload, which has random read components and very few random write components, there is less influence of FS caching, so Hyper-V manages better, primarily due to the fifth component of formula (3), or FS pair (ext4 on NTFS in relative to ext4 to ext4) and the combined effect of FS caching.

 ISBN 978-86-7466-930-3

TABLE VII - RANDOMFILEACCESS BENCHMARK RESULTS

Random fileaccess	1VM (MB/s)	2VM (MB/s)	3VM (MB/s)	Native (MB/s)
MS Hyper-V	3153.46	2588.48	2056.96	
QEMU/ KVM	2121, 15	2007.26	1890.35	
Native OS				13780.52

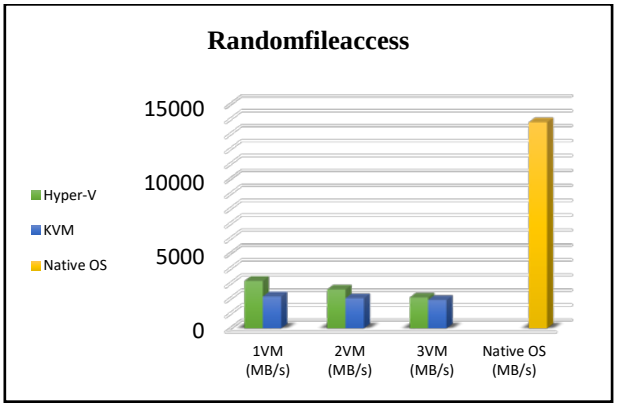

Figure 6. Randomfileaccess test results

For the "*Randomfileaccess*" workload, we again notice that Hyper-V is solidly better than KVM. In this workload, which has a lot of asynchronous random write components as well as random read components, there is a solid impact of FS caching, especially for random write, and for that reason Hyper-V performed better than KVM. This is primarily the effect of the fifth component of formula (3), NTFS, i.e. FS pair (ext4 on NTFS versus ext4 on ext4) and solid cache effect in random write.

VII. CONCLUSION

Virtualization has already proven itself in the field of information technology and has found an adequate place. In addition to all the benefits that this technology brings, it is necessary to emphasize that it's large share in the preservation of the human environment, and we can emphasize that it can be successfully used in the domain of green technologies. For the research presented in this paper, Hyper-V outperformed KVM in 3 out of 4 workloads, while in the most complex workload (*Fileserver*), KVM was dominant. For this kind of hardware and experiment, the crucial role in the differences in performance was brought by the difference in the file system of the host OS, the difference in the FS pair (ext4 on NTFS vs. ext4 on ext4). There are also differences in virtual hardware processing and hypervisor processing, which have proven to be the most complex workload (*Fileserver*). Future work in this area may focus on testing different types of servers, as well as other commonly used virtual platforms.

ACKNOWLEDGMENT

The work presented in this paper has been partially funded by the Ministry of Education, Science and Technological Development of the Republic of Serbia.

A Review of Wazuh Tool Capabilities for Detecting Attacks Based on Log Analysis

Stefan Stanković, Slavko Gajin, and Ranko Petrović, *Member, IEEE*

***Abstract*— During the difficult times of the Covid pandemics and the transfer of wor from the office to the home, security has never been more challenging. ecause the development of information technology is e panding day by day, there is increasing amount of networ traffic. Within that traffic, a potential attac er can often cover up his evil intentions. To detect attac s on host computer and prevent it from further malicious activities, ost Intrusion Detection ystems are often used. ne of these systems is Wazuh and than s to its powerful features it has been adopted by many companies. This paper provides an overview of the possibilities of Wazuh tools with a special emphasis on well- nown attac detection on web servers.**

***Index Terms*—Wazuh, web-server, networ , security, monitoring, attac .**

I. Introduction

The network monitoring system is used in the internal or external network in order to best identify risk components and prevent system crashes. The task of these systems is to find a weak point, submit a report and, if possible, solve the problem. Given the growing challenges in cyber security and the increasing amount of data generated globally, network and security administrators face a growing challenge. Most engineers use the Host Intrusion Detection System to detect and identify attacks and the Intrusion Prevention System to prevent them.

One of the main components of any application and an almost inevitable part of any data center is a web server - a hardware-software component that houses websites that serve end-users. Web servers are mostly exposed to the Internet and thus exposed to a large volume of potential attacks coming either from real attackers or from automated bots. Identifying attacks on web servers is a basic task of any administrator who maintains them because if protection is breached, the application may be inaccessible to a large number of users or permanently destroyed [1]. There are many network security monitoring solutions used worldwide [2]. One of the tools that helps identify and detect attacks on web servers is Wazuh. This paper will present the main features of the Wazuh tool installed in the University of Belgrade Computer Center.

Wazuh is a tool used around the world for various purposes. Paper [3] describes how the Wazuh tool can be used to test solutions that detect attacks within their constructed honeypot. On the other hand, Wazuh can integrate with machine learning as described in [4]. The advantage of this work is that it can serve network and security engineers very well in network and host security monitoring.

This work demonstrates Wazuh tools when collecting data exclusively from web servers. The results obtained through this paper give administrators an insight into what needs to be changed within their configurations in order to bring their servers and the entire infrastructure to the highest security level.

The paper is written in 4 major sections. After the introduction, Section 2 describes the basic functionalities of Wazuh tools and experimental setup, followed by Section 3, where statistic data are shown. Section 4 presents the results related to known attacks such as SSH (Secure Shell) brute force. The last section presents the main conclusions with ideas for future work.

II. Wazuh Overview and Experiment Setup

Wazuh is a free and open-source platform for threat detection and security monitoring according to predefined security rules. It can be used to monitor endpoints such as desktops, laptops, servers, or network devices such as firewalls and routers, and to aggregate and analyze data in real-time. Wazuh provides the following capabilities [5]:

- Security analytics - collection, aggregation, indexing and processing of security data, helping organizations detect intrusions, threats and behavioral anomalies.
- Intrusion Detection - Wazuh agents scan the monitored systems looking for malware, rootkits and suspicious anomalies. They can detect hidden files and processes.
- Log Data Analysis - Wazuh agents read operating system and application logs, and securely forward them to a manager for rule-based analysis.
- File Integrity Monitoring - Wazuh monitors the file system, identifying changes in content, permissions, ownership and attributes of files that need attention.
- Vulnerability Detector - Wazuh agents pull software inventory data and send this information to the server, where it is correlated with periodically updated CVEs (Common

Stefan Stanković is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia and with Vlatacom Institute oh High Technologies, 5 Milutina Milankovica, 11070 Belgrade, Serbia (email: stefan.stankovic@vlatacom.com).

Slavko Gajin is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (email: slavko.gajin@rcub.bg.ac.rs).

Ranko Petrović is with the Vlatacom Institute oh High Technologies, 5 Milutina Milankovica, 11070 Belgrade, Serbia (email: ranko.petrovic@vlatacom.com).

 ISBN 978-86-7466-930-3

Vulnerabilities and Exposures) databases, in order to identify well-known vulnerable software.

- Configuration Assessment - Wazuh monitors system and application configuration settings to ensure they are compliant with security policies and standards. Agents perform periodic scans to detect applications that are known to be vulnerable, unpatched, or insecurely configured.

A. Wa uh components

The Wazuh solution is based on the following 3 components [6]:

- Wazuh agent - Installed on endpoints such as laptops, desktops, servers or virtual machines, it provides prevention, detection and response capabilities. It supports Windows, Linux, MacOS, HP-UX, Solaris and AIX platforms.
- Wazuh server - It analyses data received from the agents, processing it through decoders and rules, and using threat intelligence to look for well-known indicators of compromise.
- Elastic Stack -Elastic Stack is a unified suite of open-source projects for log management, including Elasticsearch, Kibana, Filebeat, and others. The projects that are especially relevant to the Wazuh solution are: Filebeat, Elastic Search, Kibana. Filebeat is A lightweight forwarder used to transfer logs across a network, usually to Elasticsearch. It is used on the Wazuh server to transfer events and alerts to Elasticsearch. Elastic search is A highly scalable, full-text search and analytics engine. A flexible and intuitive web interface for mining, analyzing, and visualizing data. It runs on top of the indexed content in an Elasticsearch cluster. Wazuh web user interface has been fully embedded in Kibana, in the form of a plugin. Wazuh architecture.

B. Wa uh architecture

The Wazuh architecture is based on agents, running on the monitored endpoints, that forward security data to a central manager. Moreover, agentless devices (such as firewalls, switches, routers, access points, etc.) are supported and can actively submit log data via Syslog. The manager decodes and analyzes the incoming information, and passes the results along to an Elasticsearch for indexing and storage.

C. E periment setup

The results described in this paper were collected from several web servers with CentOS operating system version of 7.9, located in the University of Belgrade Computer Centre. Wazuh agents are installed on them to send Wazuh manager data. Wazuh manager has been installed on a virtual machine with Ubuntu operating system. Alternative to the implementation on virtual machine, dockers can be used, according to [7]. Some Wazuh manager functionalities are not included by default, such as Vulnerability Detector.

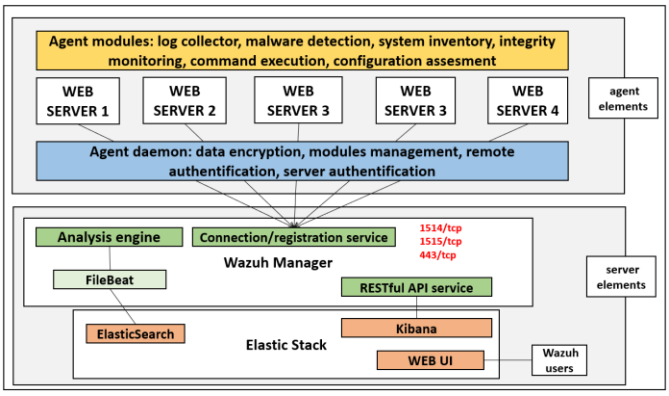

Fig. 1. Wazuh architecture on experiment setup

III. WEB SERVER ATTACK DETECTION OVERVIEW

In this section the results within each element of Wazuh Managers will be presented in brief outlines and special emphasis will be placed on the analysis of well-known attacks. Within the main dashboard, there are 4 basic sections with options in which you can monitor data in real-time.

A. Security Information Management

Within this module there are 2 units in which statistics on security events and integrity monitoring are located.

1 Security e ents

In this section, it is possible to search for all security events recorded within the Wazuh system. The operation of the system is based on agents that send data (logs) to the server where they are processed. There is a whole set of rules defined to identify threats. The results are processed and when a rule is met then it is recorded within the dashboard. By default, the rules are divided into 12 levels based on defined standards. Wazuh provides the option to write custom rules according to user needs. Figure 2 shows the sorted list of security alerts. We see that the 'Web server 400 error code' is the most prevalent error. In each unit within the Wazuh manager, it is possible to display the results in a given time range. Within each section, there is an option to generate reports and for better visibility top 10 alerts from each report will be displayed. Figure 2 presents the top 10 alerts from 31-Mar-2022 to 27-Apr-2022.

Description	Level	Count
Web server 400 error code.	5	603474
Auditd: SELinux permission check	3	473912
sshd: Attempt to login using a non-existent user	5	285016
PAM: User login failed.	5	247417
sshd: authentication failed.	5	215293
unix_chkpwd: Password check failed.	5	117091
syslog: User missed the password more than one time	10	50267
Multiple web server 400 error codes from same source ip.	10	30149
sshd: Reverse lookup error (bad ISP or attack).	5	19515
sshd: insecure connection attempt (scan).	6	15187

Fig. 2. Top 10 security alerts

2 Integrity Monitoring

In this module, it is possible to monitor the statistics of changes over system files on the host with the installed agent. These changes include modifying files, deleting files, and

 ISBN 978-86-7466-930-3

adding new files. Changes are detected based on the change in the checksum of each file.

Within the Events tab, it is possible to follow each change in detail, where you can find out the details of when a file was changed, which user did the action and what are the file permissions. This type of monitoring can be very useful, especially for sensitive systems. The performed actions and the list of files that are most often modified are shown in Figure 3.

Path	Action	Count
/etc/httpd/sites-available/h2020.rcub.bg.ac.rs.conf	modified	28
/etc/httpd/sites-available/lira.f.bg.ac.rs.conf	modified	28
/etc/httpd/conf/httpd.conf	modified	27
/etc/httpd/sites-available/amres.ac.rs.conf	modified	27
/etc/httpd/sites-available/amres.rs.conf	modified	27
/etc/httpd/sites-available/arhiva.fpu.bg.ac.rs.conf	modified	27
/etc/httpd/sites-available/arts.bg.ac.rs.conf	modified	27
/etc/httpd/sites-available/bpd.amres.ac.rs.conf	modified	27
/etc/httpd/sites-available/bsaae.bg.ac.rs.conf	modified	27
/etc/httpd/sites-available/careers.ac.rs.conf	modified	27
/etc/httpd/sites-available/cbp.rcub.bg.ac.rs.conf	modified	27

Fig. 3. The list of top modified files detected by Wazuh

B. *Auditing and Policy Monitoring*

This module offers 3 sections in which statistics and details about the system configuration and how much that configuration deviates from global standards.

1 Policy monitoring

This chapter shows the data obtained from the log analysis of policy monitoring. System configuration verification, such as kernel and security configuration files, is performed based on predefined rules. Wazuh uses 3 components to perform this task: Root check, OpenSCAP (Security Content Automation Protocol) and CIS-CAT. If some process is hidden from the virtual process file system (procfs), that file is marked as an alert.

Rule description	Control	Count
Possible kernel level rootkit	Anomaly detected in file '/etc/letsencrypt/.certbot.lock'.	1
Possible kernel level rootkit	Anomaly detected in file '/tmp/#sql-temptable-68c6-2faed-b5e7.MAD'.	1
Possible kernel level rootkit	Anomaly detected in file '/tmp/#sql-temptable-68c6-2faed-b5e7.MAI'.	1
Possible kernel level rootkit	Anomaly detected in file '/tmp/#sql-temptable-68c6-6e16f-f03c.MAD'.	1
Possible kernel level rootkit	Anomaly detected in file '/tmp/#sql-temptable-68c6-6e16f-f03c.MAI'.	1
Possible kernel level rootkit	Process '4859' hidden from /proc.	1
Possible kernel level rootkit	Process '8798' hidden from /proc.	1

Fig. 4. The list of detected anomalies

2 System auditing

This section presents data based on which user behavior can be monitored, command execution monitored and possibly an alert raised if sensitive files are accessed. User behavior is monitored by a powerful auditing facility called *auditd* which provides a detailed accounting of actions and changes in a system. Thanks to the Wazuh agent who sends *auditd* logs to the manager, administrators can have insight into users' behavior. The statistics from this section are shown in Figure 5.

Event	Command	Count
Auditd: SELinux permission check	/usr/sbin/php	192484
Auditd: SELinux permission check	/usr/sbin/php	119432
Auditd: SELinux permission check	/opt/remi/php74/root/usr/sbin/php	68985
Auditd: SELinux permission check	/usr/sbin/httpd	27612
Auditd: SELinux permission check	/usr/sbin/httpd	24822
Auditd: SELinux permission check	/usr/sbin/php	13641
Auditd: SELinux permission check	/usr/sbin/httpd	10602
Auditd: SELinux permission check	/opt/remi/php80/root/usr/sbin/php	4945

3 Security Configuration Assessment

Within this unit, before displaying the data, it is necessary to select the agent where the configuration check will be performed. When the check is performed, the statistics and scores of that host are displayed. Verification is performed based on CIS (Center for Internet Security) benchmark recommendations for particular operating system distribution. The check consists of executing a set of commands whose result is binary: pass or fail. A detailed report is obtained when exported in CSV format where the columns show, among other things, commands, results, references and recommendations. This statistic gives a very good insight into the system configuration and draws the administrator's attention to important configuration elements.

C. *Threat etection and esponse*

In this unit there are 3 entities in which it is possible to gain insight into data related to threat detection. These entities are vulnerabilities, virus Total and MITRE ATT&CK, a globally accessible database of adversary tactics and techniques based on real-world observations. Evaluation of Wazuh tool with persistence tactic of MITRE ATT&CK is nicely described in [8]. As the targeted system is not related to antivirus software, no data has been collected.

1 ulnerabilities

This module is not included in the main configuration file by default and needs to be enabled. It performs vulnerability searches according to the latest indexes that are updated in real-time with Canonical, RedHat and National Vulnerability databases. The detector on the manager inspects the list of installed applications periodically sent by the agents. Based on this list, search and verification processes are performed within the local database with the latest CVE elements (Common Vulnerabilities and Exposures). Alerts are generated when a CVE affects a package installed on one of the monitored servers. That package is then marked as vulnerable. There are 2 types of scanning: full and partial. A full scan is done the first time the Vulnerability Detector is activated and then each packet is scanned individually. Partial scanning is done when new packages are installed.

Fig. 6. The list of matched CVEs detected by Wazuh

2 MITT E ATT C

This feature allows the user to customize the alert information to include specific information related to MITRE ATT&CK techniques. MITRE ATT&CK matrix stores all possible attacks that can be made and what to do to detect them and mitigate the risk [9]. This can be useful when an attack is detected through an alert and a user wants to know more about it. MITRE ATT&CK assigns each attack technique an ID (identification). These techniques are grouped by tactics (Defense Evasion, Privilege Escalation, etc.) although some of them belong to more than one tactic.

. *egulatory Compliance*

The Wazuh platform is often used to meet the technical aspects of regulatory compliance standards. Wazuh not only provides the necessary security controls such as host intrusion detection, configuration assessment, log analysis, and vulnerability detection, among others, to meet compliance requirements but also uses its SIEM (Security Information and Event Management) capabilities to centralize, analyse and enrich security data. In order to provide regulatory compliance support, the Wazuh rules have been mapped against compliance requirements [10]. This way, when an alert is generated (a rule condition has been matched), it automatically includes compliance information. The following standards are supported: Payment Card Industry Data Security Standard (PCI DSS), General Data Protection Regulation (GDPR), NIST Special Publication 800-53 (NIST 800-53), Good Practice Guide 13 (GPG13), Trust Services Criteria (TSC SOC2), Health Insurance Portability and Accountability Act (HIPAA)

IV. EXPERIMENT, RESULTS AND SYSTEM PERFORMANCE

As already mentioned, one of the attacks analyzed in more detail is the SSH brute force attack. a brute-force attack is performed by an attacker submitting many passwords or passphrases with the hope of eventually guessing correctly. The attacker systematically checks passwords and passphrases from the database until the correct one is found. Also, if a user tries to connect via SSH using a random username, they will be considered to have attempted an attack and that alert will be recorded. Data processing on the Wazuh manager is in real-time and a potential attack is detected and alerted almost immediately. Table I provides very detailed information about the alerts when a potential attacker tried to connect as a non-existent user ‘dunja’.

The basic geo locations based on the source IP address are followed by information about the user trying to connect and the name of the decoder that analyzes the data. This is followed by a description of the full log and an abbreviated name as well as the original log file location.

A. *System performance*

The Wazuh manager described in this paper is installed on an Ubuntu virtual machine which is assigned 8GB of RAM (Random Access Memory), 4 cores and 30GB of storage. It aggregates data from a total of 5 servers in the network. Of the allocated resources, the system uses about 4.7GB of RAM, a

 ISBN 978-86-7466-930-3

negligible percentage of CPU load, and about 11G of storage is filled. The system uptime is 2 months.

V. Conclusion

The aim of this paper is to present the functionality of the Wazuh tool in detecting attacks demonstrated on web servers. Web servers are components that are very exposed to the Internet and if they are not well protected, they are very susceptible to attacks of various kinds. In order to prevent attacks, they must first be detected and that is why Host Intrusion Detection systems are used. One of the solutions that can help is Wazuh. It is a powerful tool that displays all detected attacks in great detail and in real-time. Although this paper demonstrates the analysis of detected attacks on web servers, Wazuh is a tool used to analyze attacks across the entire infrastructure. This paper presents the basic principle of operation of Wazuh tools based on the agent-manager system. Agents installed on hosts send the log data for processing to the manager. Statistics of different types of attacks are presented and special attention is paid to details concerning some well-known attacks such as SSH brute force. The attack was successfully detected and shown almost immediately. As further work, the installation of agents on all infrastructure devices is proposed, without limiting on the type of device. It would be desirable to integrate the Wazuh tool with an antivirus software in order to get deep inspection on viruses, worms trojans and other malicious content. Some security issues are most successfully detected by inspecting a server's actual network traffic, which is generally not accounted for in logs. This is where a Network Intrusion Detection System can provide additional insight into security. One of those systems is Suricata. Because Suricata is capable of generating JSON (JavaScript Object Notation) logs of events, it has very good integration option with Wazuh, so this is also a proposal to future work.

ACKNOWLEDGEMENT

Infrastructure for Simulating n-Dimensional Simplicial Complexes

Dušan Cvijetić, Nenad Korolija, and Marko Vojinović

***Abstract*—We present an infrastructure for simulating simplicial comple es. The classes for storing the structure of simplicial comple es and simplices are e plained in detail, for arbitrary dimension.**

The implementation is tested using functions for seeding simplicial comple es and for printing them on the screen. eside these functions, the supporting classes and the function for assigning unique identifiers and screen coordinates is also e plained.

esults of simulation show that there are potentials for the simulator to be used for big data problems, although appropriate e perimental results are still being collected. uture wor includes parallelizing the e ecution of the simulator using supercomputing architectures.

***Index Terms*— implicial comple ; triangulation; manifold; algebraic topology.**

I. Introduction

A manifold is one of the fundamental concepts in mathematics [1], and its importance in applications in physics, technology and engineering cannot be overstated. Virtually all modern physics describes the world using *field theory* [2], in which all physical quantities (fields) are represented as functions over some manifold (for example, spacetime). In technology, manifolds appear in all forms and guises, whenever one needs to deal with curved surfaces --- from civil engineering to graphics in video games.

While most of the interest in science and engineering revolves around *smooth* manifolds, for the purpose of studying manifolds using numerical techniques, the attention focuses on the so called *piecewise-linear* manifolds [3], which can intuitively be imagined as a structure made out of small flat cells called *simplices,* arranged like bricks into a structure which models a manifold. The procedure of approximating a smooth manifold with a piecewise-linear one is commonly called *triangulation,* see Fig. 1.

Within the framework of algebraic topology, the formal mathematical structure which describes piecewise-linear manifolds is called a *simplicial comple* . For the purpose of this article, we provide an informal descriptive definition of a simplicial complex, without mathematical rigour. A simplicial complex is a combinatorial structure, containing the information about *simplices* of various dimensions that make up a complex, and the information about how simplices are connected to each other. A *k-simple* is an elementary building block of a simplicial complex. It is an elementary geometrical "cell" of dimension k, which is being used to build simplices of higher dimension, and the entire simplicial complex. For k = 0, the simplex is called a *erte* , it is represented geometrically as a single point, and has no internal structure. The k = 1 simplex is called an *edge,* geometrically represented as a single straight line, having two vertices at its boundary. For k = 2, the simplex is a *triangle,* having three boundary edges and three vertices. The case k = 3 describes a *tetrahedron*, having four boundary triangles, six edges and four vertices. One can go further into higher dimensions: k = 4 represents a simplex called *pentachoron* – it is a 4-dimensional figure, having five boundary tetrahedra, 10 triangles, 10 edges and five vertices. In general, one can introduce a k-simplex for arbitrary dimension k, also called *le el*.

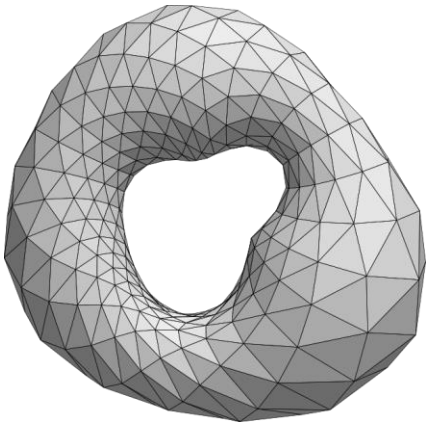

Fig. 1. Simplicial complex of a torus (source: Wikipedia).

Given a set of simplices, one can "glue them up" into a bigger geometrical structure, called simplicial complex. In order to describe a manifold of dimension D, a simplicial complex is constructed by gluing a set of D-simplices by identifying their common boundary (D-1)-simplices. Naturally, this implies the identification of all corresponding sub-simplices of level k < D-1 as well. The resulting simplicial complex is homeomorphic to a piecewise-linear manifold of dimension D.

The most important information about the simplicial complex, aside from its dimension D, is the data that tells one

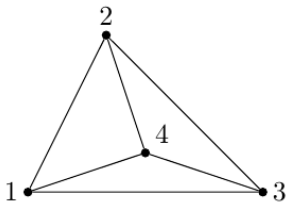
 ISBN 978-86-7466-930-3

which simplices are glued to which. This gives rise to a notion of a *neighborhood* of a k-simplex, which is a set of all simplices which contain a given simplex as its sub-simplex (called super-neighbors) and simplices which are contained in a given simplex (called sub-neighbors). Each k-simplex (for $0 \leq k \leq D$) in the complex has its set of neighbors, where by definition a simplex is not a neighbor of itself (this is convenient to avoid infinite loops when traversing a complex). The neighborhood structure of the entire complex determines the *topology* of the corresponding manifold.

While manifolds of various topologies are important in their own right in mathematics, the applications in physics and engineering typically introduce functions over manifolds, such as distances, areas and volumes, temperature, electric and magnetic fields, etc. In the language of simplicial complexes, these functions are commonly called *colors*, and are assigned to simplices of various level k within the complex. Given a k-simplex, one can assign to it multiple colors, representing the value of a given function when evaluated on the k-simplex. A prototype example of colors is the geometry of a simplicial complex: each k-simplex is assigned its "size" according to its geometry --- each 1-simplex (an edge) is assigned a real number representing its length, each 2-simplex (a triangle) is assigned a real number representing its area, tetrahedra are assigned volumes, and so on. Other examples are abound --- vertices can be assigned a temperature, edges can be assigned vectors of electric field, and so on. Depending on the problem at hand, one may or may not impose relationships between various colors, such as that the area of a triangle is consistent with the length of its edges, or similar. These relationships are collectively called *constraints*.

In most everyday applications, one is interested in manifolds of dimension 1 and 2 (curves and surfaces). However, within the context of theoretical physics, one often needs to deal with manifolds of higher dimension – most commonly 3, 4, 5, 10, 11 and 26, while more sporadically anything in between and above. One of the typical scenarios is *uantum gra ity* [4,5], a vast research area of fundamental theoretical physics, where the notion of spacetime is described as a piecewise-linear manifold of dimension D=4 or higher [6,7]. In order to apply numerical techniques to study the manifolds in such research disciplines, it is necessary to formulate and implement structures and algorithms which describe colored simplicial complexes of arbitrarily large dimension, in a uniform and optimal way. In what follows, we describe one such implementation, which is purposefully designed to mimic the mathematical structure of a simplicial complex as close as possible, while simultaneously providing efficient numerical techniques for the manipulation and study of such structures.



I. N-Dimensional Simplicial Complexes

This section describes the structure of simplicial complexes, and explains an example C++ implementation of classes for storing simplicial complexes.

Simplicial complexes consist of k-simplices at different levels. Given a simplicial complexes of dimension D, these elements include k-simplices for each level from zero to D. Elements at level zero are vertices, elements at level one are edges, elements on level two are triangles, etc. Finally, there are elements of highest level D. The representative source code of class for simplicial complexes is given in Algorithm 3 from the Appendix. The source code is pruned from comments and unnecessary functionalities for the presentation of the simulator.

K-simplex stores the level it has, the dimension of the simplicial complex it belongs to, neighboring elements and colors assigned to it.

Neighboring elements of a k-simplex are defined as k-simplices that this k-simplex is touching. Since these can be on various levels, the structure of neighbors is the same as for the simplicial complex. Therefore, the two main classes are mutually connected.

```
Printing SimpComp tetrahedron, D = 3
Simplices k = 0:
1, 2, 3, 4
Simplices k = 1:
(1-2), (1-3), (1-4), (2-4), (2-3), (3-4)
Simplices k = 2:
(1-2-3), (1-3-4), (1-2-4), (2-3-4)
Simplices k = 3:
(1-2-3-4)
```

Fig. 2. Tetrahedron and a corresponding output of the simplicial complexes simulator.

One possible implementation of the neighboring elements is to store only neighbors from one level above, and one level beneath (first sub-neighbors and first super-neighbors). The lower- and higher-level neighbors can be deduced following the structure of the first neighbors. However, we have opted for storing neighbors from all levels, giving us the opportunity to divide the structure onto multiple computing nodes and run the code in parallel. At current state, the simulator is running on a single CPU.

The instructions a CPU is executing are repeated over and over again, which makes this simulator suitable for acceleration using the dataflow paradigm [8,9]. The effort required for programming such architectures is higher than for conventional von Neumann architectures [10], but the simulator is suitable for transforming the C++ source code automatically [11]. Executing multiple simplicial complex operations in parallel requires appropriate scheduling

 ISBN 978-86-7466-930-3

techniques [12].

Each k-simplex (including all vertices, edges, triangles, etc.) can be colored with different types of color. Example colors include:

- k-simplex name,
- unique identifier of k-simplex,
- boundary color of k-simplex,
- screen coordinates.

These colors are included in our simplicial complex simulator, but the structure of the simulator allows adding additional user defined colors.

The representative source code of the class for k-simplices is given in Algorithm 4 from the Appendix. Just like it is the case with simplicial complexes, this source code is pruned for better clarity.

For simulation purposes, we have developed functions for seeding simplicial complexes at various levels, as it will be explained in the following section. In addition, coloring and printing simplicial complexes is also implemented. Pretty printing (or compact printing) prints k-simplices at all levels, where k-simplices of level higher than zero are printed as tuples consisting of unique identifiers (IDs) of their vertices. Fig. 2 shows an example tetrahedron (i.e. simplicial complex of dimension D = 3 consisting of a single 3-simplex and its sub-simplices) whose vertices are colored with unique identifiers that auto-increment after each assignment of the unique color to a vertex. Details of the implementation of compact printing is also explained in this manuscript.

Screen coordinates can be attached to vertices of the tetrahedron. Therefore, it can be drawn on the screen. However, there is no need to assign coordinates. They are just a convenient way to show an object on a screen. Similarly, there is no need to assign unique ID to any vertex. In the previous example, if a vertex with unique ID four would not have a unique ID assigned to it, the tetrahedron could still be printed out, but with word “Simplex” being printed out in place of number four.

II. Seeding Simplicial Complexes

This section describes seeding simplicial complexes using C++ implementation of function *seed single edge* . The example source code for seeding a single edge is used for demonstrating purposes.

The process of seeding simplicial complexes will be explained using the source code shown in Algorithm 1. The source code is pruned from comments and unnecessary statements. Seeding a simplicial complex consists of the following steps, and statements in Algorithm 1 follow the same principle in the same order:

- creating an empty simplicial complex of given dimension,
- creating k-simplices for storing vertices and simplices of higher levels,
- connecting vertices at each level with vertices on higher and lower levels.

Adding a neighbor to a k-simplex is a symmetric operation. This means that both k-simplices (the calling one and the one given as an argument) are neighbors to each other. All functions of the simulator are written in a robust manner, checking the validity of input parameters.

Note that multiple colors can be assigned to each k-simplex, which is left out of consideration in this algorithm for better clarity.

III. Coloring and Pretty Printing K-simplices

This section describes coloring and pretty printing simplicial complexes. These functions might work in pair, but are not necessarily connected.

A. Coloring -simplices

Coloring k-simplices will be explained using Algorithm 2 by coloring vertices of an edge with boundary colors. First, vertices have to be created as k-simplices of level zero. Then, colors have to be created for all vertices. Finally, colors need to be pushed back to the vector of colors that each k-simplex has.

Algorithm 1: Seeding a single edge.

```
SimpComp* seed_single_edge(string name){
    SimpComp *edge = new SimpComp(
            name, 1);
    KSimplex *v1 =
            edge->create_ksimplex(0);
    KSimplex *v2 =
            edge->create_ksimplex(0);
    KSimplex *e1 =
            edge->create_ksimplex(1);
    v1->add_neighbor(e1);
    v2->add_neighbor(e1);
    return edge;
}
```

Algorithm 2: Coloring vertices with boundary color.

```
KSimplex *v1 =
        edge->create_ksimplex(0);
KSimplex *v2 =
        edge->create_ksimplex(0);
Color *c1 = new BoundaryColor(true);
Color *c2 = new BoundaryColor(true);
v1->colors.push_back(c1);
v2->colors.push_back(c2);
```

Following colors are currently available:

- unique ID colors
- boundary colors
- screen coordinate colors.

Additionally, user is allowed to construct a custom color and use it within the simulator. The source code of the simulator is organized as a library, and user is allowed to extend it by using the library.

Unique ID colors are predominantly used for pretty printing simplicial complexes. They are implemented by a class inherited from the basic color class. Two main fields include

 ISBN 978-86-7466-930-3

static integer number, and an integer number. The first represents the current maximum of a unique color ID that is in use, and the second one is the color of a given k-simplex.

Unlike unique ID colors, boundary colors have special meaning. Each k-simplex may contain boundary color, but it does not have to. A simplicial complex can have boundaries on k-simplices of one level lower than the dimension of the simplicial complex. For example, a triangle can have edges as boundaries.

Screen coordinate colors are used for drawing simplicial complexes on a screen. The basic graphical user interface is under development.

B. Pretty Printing -simplices

Printing k-simplices includes printing of all of the fields that *Simple* class contains. This includes printing all of the neighborhood elements the k-simplex has. This is usually overwhelming for a user. Therefore, pretty printing is designed to print unique ID colors of each k-simplex in most readable way authors could think of.

Function *Simple print compact* is responsible for pretty printing. It assigns to the pointer to the unique ID a value returned by a function *get uni ueI* that returns either nullptr if a k-simplex doesn't have a unique ID, or a pointer to the color.

If there is no unique ID color assigned to a k-simplex, the output consists solely of word "Simplex". Otherwise, *print compact* function is called for a color that the pointer points to. Further, the following procedure is repeated, if level k is greater than zero and there are neighboring elements for all neighbors. A set of integer values is constructed, and then function *print ertices in parentheses s* is called for neighbors, adding unique IDs to the set. This way, printing sorted values is achieved, along with avoiding duplicate values. Sample output of a simplicial complex pretty printing is shown in Fig. 1.

IV. Conclusion

We have demonstrated how one can implement in code the structure of a simplicial complex of arbitrary dimension, in a way that is faithful to its combinatorial definition, and perform the most basic operations on it, like instantiating, coloring and printing.

The implementation of the basic classes of the code described in this work represents a fundamental basic building block for a more versatile software collection that aims to construct, manipulate and study the properties of simplicial complexes of arbitrary dimension. Future extensions of the software library will include the functions which implement attaching additional simplices to a boundary of a complex, performing Pachner moves [13] which transform a given complex into a different one without changing its topology, and functions for manipulating the colors and evaluating various mathematical constructions that include them. Note that the experimental data regarding the parallelization is yet to be collected (see the accompanying paper [14]).

The resulting software collection will feature the generality and versatility that aim for applications both in pure mathematics (algebraic topology research) and theoretical physics (quantum gravity, field theory), but also with potential applications in other disciplines of engineering and industry, wherever the analysis and the study of geometry of manifolds and curved surfaces may be relevant.

Appendix

Algorithm 3: Declaration of SimpComp class.

```
class SimpComp{
public:
    SimpComp(int dim);
    SimpComp(string s, int dim);
    ~SimpComp();
    int count_number_of_simplexes(
            int level);
    void print(string space = "");
    bool all_uniqueID(int level);
    void collect_vertices(set<int> &s);
    void print_set(set<int> &s);
    void print_vertices_in_parentheses(
            set<int> &s);
    void print_compact();
    // Creating new KSimplex at level k:
    KSimplex* create_ksimplex(int k);
    void print_sizes();

    string name;
    int D;
    // An element at each level
    // is a list or vector
    // of KSimplex pointers
    // to KSimplex on that level:
    vector< vector<KSimplex *> >
            elements;
};
```

Algorithm 4: Declaration of KSimplex class.

```
class KSimplex{
public:
    KSimplex();
    KSimplex(int k, int D);
    ~KSimplex();
    bool find_neighbor(KSimplex *k1);
    void add_neighbor(KSimplex *k1);
    void print(string space = "");
    UniqueIDColor* get_uniqueID();
    void print_compact();

    int k; // level
    int D; // dimension
    SimpComp *neighbors;
    vector<Color *> colors;
};
```

Possibilities for Parallelizing Simplicial Complexes Simulation

Dušan Cvijetić, Nenad Korolija, and Marko Vojinović

***Abstract*—This manuscript presents potentials for parallelizing simulation of simplicial comple es. The implementation of most important fields and methods of classes for storing simplicial comple es and -simplices is followed by wrapper classes for simplicial comple es and -simplices respectively. Infrastructure for communication between essage Passing Interface (PI) processes along with helper functions is e plained further in the manuscript. nce multiple data are prepared to be sent from each PI process to other PI processes, sending and receiving is performed in the bac ground. ecause of the stall introduced by using PI directives, the amount of data to be transmitted is ma imized by processing multiple operations over simplicial comple es in parallel. This requires the method for loc ing simplicial comple es and -simplices by the owner PI process until all the requests are processed. oc ing mechanism and supporting simplicial comple class actions regarding loc ing is not in the scope of this manuscript.**

***Index Terms*— implicial comple ; -simple ; triangulation; manifold; PI; parallelization.**

I. Introduction

In modern theoretical physics, a lot of problems are too complicated for study using analytical methods, and one needs to resort to numerical techniques. Among those problems, an especially important class deals with evaluation of functions over simplicial complexes. A simplicial complex [1] is a piecewise-linear approximation of a smooth spacetime manifold [2] and is typically 4-dimensional or higher. Functions over a simplicial complex represent physical fields on spacetime, and one commonly employs path integral evaluations of such structures to extract expectation values of observables. For example, in Lattice Quantum Chromo-dynamics, one employs such numerical techniques to predict the theoretical values for the masses of elementary particles called hadrons [3]. Also, in Causal Dynamical Triangulations approach to quantum gravity [4,5], one uses these techniques to evaluate spectral dimension of spacetime, and study various properties of phase space of triangulated manifolds. Finally, in the Regge Quantum Gravity approach [6,7,8] one can study the entanglement properties of matter fields and gravity described by the Hartle-Hawking wavefunction [9,10], again using the techniques of numerical evaluation of path integrals over simplicial complexes.

It goes without saying that all such calculations are exceptionally expensive in computation time. Typically, one develops custom-made code, heavily optimized to solve precisely one specific problem, and executes it over months-long periods on hardware dedicated for high performance computing (HPC), usually clusters with thousands of work nodes. Such enormous calculational efforts are usually unavoidable due to the nature of the problems that need to be solved.

Nevertheless, at least for one class of such problems, it may be possible to construct a more general algorithm and structures which would provide a common basis for solving an all-encompassing class of problems using the same underlying software, while intrinsically exploiting the parallelization possibilities of the code itself and the distributed nature of the underlying hardware. Our aim is to develop such a generic software library, which could be used to solve a whole host of physics problems in the same way and optimize it for parallelized HPC environments. In this work we present the first steps towards the construction of such a library. This approach of developing common code for a whole class of problems has not been attempted so far because research teams are usually concentrated on solving only one specific problem and opt to construct custom code for that problem. However, in our opinion, a generic software library, which would provide support for a whole class of problems simultaneously, would open new avenues for numerical research, since one could use the same code to study new, yet unexplored problems as well as old well-known ones.

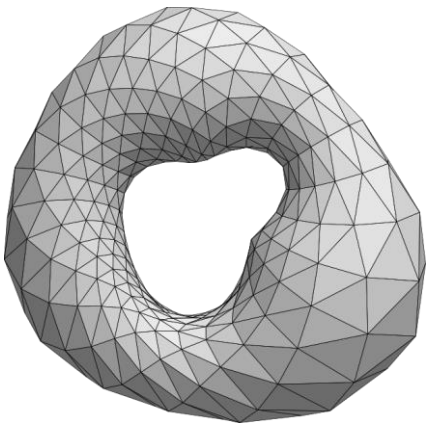

Fig. 1. Simplicial complex of a torus (source: Wikipedia).

The fundamental structure which lies at the core of the whole numerical method is the notion of a *simplicial comple* . A simplicial complex is a combinatorial structure which is easiest to understand as a generic lattice-like mesh,

 ISBN 978-86-7466-930-3

whose cells are called *simplices*, and are connected to each other along their boundaries to form the simplicial complex of a given dimension. The purpose of the whole structure is to approximate the smooth spacetime manifold with a discrete structure which is more convenient for numerical methods.

The most elementary simplex is a simplex of level zero, often called *0-simple* or *erte* – it is just a dimensionless point with no structure. Next is the *1-simple* , also called an *edge* – it is a one-dimensional line with two vertices at its boundaries. At level two we have the *2-simple* or *triangle*, whose boundary are three edges and their vertices. The *3-simple* , also known as the *tetrahedron*, has the boundary made of four triangles and their edges and vertices. The procedure of constructing simplices can be done for arbitrary dimension, giving rise to the notion of a *k-simple* , whose level (i.e. natural dimension of space in which it is defined) is equal to any positive integer k. The most commonly used example is the *4-simple* , also called *pentachoron* – a 4-dimensional figure whose boundary consists of 5 tetrahedra, 10 triangles, 10 edges and 5 vertices. In most applications in physics, the spacetime manifold is considered to be 4-dimensional, and it is cut into a lattice-like structure made of 4-simplices, which are glued together along their boundary tetrahedra. The resulting structure is a simplicial complex of dimension 4. Fig. 1 depicts an intuitive example of a 2-dimensional simplicial complex of a torus.

Given a simplicial complex, one typically wants to introduce functions that are evaluated on it. These are commonly called *colors* and are assigned via their values to each k-simplex within in the complex. In other words, some colors live on vertices, some on edges, some on triangles, and so on. The colors are a natural discretization of the notion of a *field* over a manifold. For example, just like electric and magnetic fields have a value at each point of a smooth spacetime, analogously the colors have values at each k-simplex in the simplicial complex.

Depending on the type of the problem at hand, algorithms that are used to evaluate required quantities on a simplicial complex can vary in complexity, from conceptually simple Monte Carlo integration techniques, to vastly complicated traversal and ray-tracing algorithms, to various methods for solving functional partial differential equations. Due to the variability of the complexity of all these algorithms, dictated by the nature of the problem at hand, it is helpful to develop the underlying software simulator to exploit the parallelization avenues that are intrinsic to the simplicial complexes and k-simplices themselves, so that the simulator can exploit parallel hardware environments even for algorithms that are themselves hard to parallelize. This helps the code developer with overall optimization and application to HPC hardware architectures. In what follows, we shall demonstrate a set of possible approaches to these intrinsic parallelization techniques.

II. N-Dimensional Simplicial Complexes

This section describes data structures used in the simulator of simplicial complexes from the point of view of their suitability for parallelizing the simulator execution. Data demanding structures are of main interest for optimizing the communication between processing units. Along with those, data that describes the structure and needs to be updated on multiple processing units will be described in detail. Further, the amount of data that needs to be exchanged and the frequency of expected changes will be compared to the pyramid, where top elements demand less memory, but require more often communication.

The parallelization is simulated using the MPI framework. The simulator is implemented in C++, and, as a result, the parallelization framework is built on top of the simulator. As improving the simulator of simplicial complexes is an ongoing process, the possibility for accelerating the computation is simulated based on the requirements.

Simplicial complexes are formed out of k-simplices at various levels. Simplicial complexes at level zero represent vertices. The structure of each vertex is stored in *Simple* class. Simplicial complexes at level one represent edges. Each edge consists of two vertices. As it is the case with vertices, information about edges are also kept in a *Simple* class. However, while vertices can be independent of other vertices, representing separate simplicial complexes, each edge must have at least two vertices defined as neighbors. Neighbor of an k-simplex is defined also as a k-simplex that the first k-simplex relies on. Neighboring relation is symmetrical. Therefore, if two vertices are neighbors of an edge, edge is also the neighbor of both vertices. Further, edges can form a triangle. By analogy, neighbors of triangle are three edges, but also the triangle is neighbor of these edges. The neighboring relation spans more than one level up or down. The triangle has also three vertices as neighbors and the opposite.

Simplicial complex representing a triangle consists of a k-simplex representing a triangle along with all neighbors of the triangle. Simplicial complex class is used for storing information about simplicial complexes. As it has elements field that is a pointer to pointer of k-simplices, it is also used for keeping neighbors of each k-simplex.

III. Parallelizing Simplicial Complexes Simulation

Parallelizing operations over simplicial complexes is implemented by splitting the structure over multiple MPI processes. First, we can consider a single simplicial complex system, as the most general approach. If no screen coordinates for k-simplices are assigned, we can artificially assign this type of color, so that we can present k-simplices in 2D space. Further, we can imagine multiple planes, where each plane is responsible for keeping k-simplices of one dimension. This way, we can consider n-dimensional simplicial complex as a pyramid that we observe from the bird's eye view. Now we could have a bottom-up approach, where k-simplices of dimension zero are divided onto MPI processes based on their screen coordinates. Going up, each MPI process would store higher dimensional k-simplices that have those that are one level below as their neighbors. When a k-simplex has neighbors on one level below that belong to multiple MPI processes, this k-simplex gets copied to all MPI processes involved. Finally, all MPI processes would keep the highest-level k-simplex. In the case of multiple simplicial complexes, they could be split over MPI processes based on the same bottom-up approach.

 ISBN 978-86-7466-930-3

The notion of determining the MPI process where a k-simplex is located is hidden by using wrapper functions, so that the calculation operations are performed as if all k-simplices would have been on the same MPI process, i.e. as if the simulation was executed serially. Each wrapper function can keep either a pointer to the structure, if it exists on the same MPI process, and the ID used for finding the structure on the owner MPI process.

Algorithm 1 describes the most important aspects of simplicial complex classes. First, a basic *SimpComp* class is given, followed by the wrapper class *irtualSimpComp* used for parallelization.

Algorithm 1: Declaration of simplicial complex classes.

```
class SimpComp{
public:
    SimpComp(int dim);
    SimpComp(string s, int dim);
    ~SimpComp();
    // Creating new KSimplex
    // at level k:
    VirtualKSimplex* create_ksimplex(
        int k);
    void update_owner(int owner);

    string name;
    int D;
    vector< vector<
        VirtualKSimplex *> > elements;
};
class VirtualSimpComp{
public:
    SimpComp *find_simpcomp;

    int id;
    int ownerRank;
    SimpComp *simpComp;
};
```

Algorithm 2 describes the most important aspects of k-simplices classes. A basic *Simple* class is followed by the wrapper class *irtual Simple* used for parallelization.

Algorithm 2: Declaration of k-simplex classes.

```
class KSimplex{
public:
    KSimplex();
    KSimplex(int k, int D);
    ~KSimplex();
    bool find_neighbor(
            VirtualKSimplex *k1);
    void add_neighbor(
            VirtualKSimplex *k1);

    int k; // level
    int D; // dimension
    VirtualSimpComp *neighbors;
    vector<Color *> colors;
};
class VirtualKSimplex{
public:
    KSimplex *find_ksimplex();
    int id;
    int ownerRank;
    KSimplex *ksimplex;
};
```

In both algorithms, wrapper functions store a pointer to the base class object, if such exists on a local MPI process. Otherwise, the value is *nullptr*, and the data is searched for on the so called *owner ank* based on unique identifier called *id*. Owner of this k-simplex can issue multiple requests while it holds a lock.

IV. Infrastructure for Communication Between MPI Processes

The communication between MPI processes is organized as follows. Each MPI process is preparing the data to be sent to other MPI processes. Order of operations prepared for other MPI processes is not important. All requests to other MPI processes for processing are packed in to_rank vector of vectors of unsigned char.

Each type of primitive data is serialized into the array of unsigned characters as it will be explained in the following section. Each prepared byte is pushed to the back of the vector of unsigned characters. Once all the data is prepared, the data is sent to other MPI processes in the background using *MPI Isend* directive. If a reference to the vector of array of unsigned characters is called *ec*, the pointer to the array is obtained by calling member function *data* of vector class from standard template library. After issuing all *MPI Isend* directives, waiting for each of sending to finish is achieved using *MPI Wait*.

Similarly receiving the data from other MPI processes is implemented in the background using *MPI Irec* , followed by *MPI Wait*, once the data is needed for the processing. The data is received into array of unsigned characters, that is further packed into vector of vectors of unsigned characters called from_rank for simple processing.

V. MPI Supporting Functions

As already mentioned, variables are serialized into the array of unsigned characters using the following syntax:

```
*( (__typeof__ (variable) *) (array + nArray) ) = variable;
nArray += sizeof(variable);
```

Here, *array* is array of unsinged characters where the data stored in the variable is serialized, and *nArray* is the number serialized bytes in the array.

Similarly, a variable is read and prepared into the to_rank using the following syntax:

```
__typeof__ (variable) temp_var = variable; \
int nBytes = sizeof(temp_var); \
for(int iByte = 0; iByte < nBytes; iByte++) \
  to_rank[rankNumber].push_back(
      ((unsigned char *) &temp_var) [iByte] );
```

This can be further optimized, but the optimization is out of the scope of this research.

 ISBN 978-86-7466-930-3

The communication between MPI processes is continued for as long as any MPI process requires further communication with other MPI processes. This is achieved using the following source code, where the MPI process that requires further communication sets variable *to_send* to one:

```
int to_receive = 0; // A rank required communication
MPI_Allreduce(&to_send, &to_receive, 1, MPI_INT,
      MPI_SUM, MPI_COMM_WORLD);
```

After *MPI Allreduce* is executed, all MPI processes will have the information whether they have to communicate further in *to_receive* variable.

VI. Parallelization Possibilities Using Dataflow Paradigm

This simulator issues the same set of computer architecture instructions repeatedly. As in majority simulator of physical phenomena, the number of instructions is dependent on the precision of the model and is limited by the computing resources and the total simulation time requirement. These conditions are exactly what is required for a program to be suitable for acceleration using the dataflow paradigm [11]. Programming dataflow architectures requires programming skills that are higher than those needed for programming conventional von Neumann architectures. One of the possibilities is to write a program in a VHDL. More suitable solution to most of the programmers would be to exploit the framework that enables writing source code in a Java-like language, which gets automatically translated into the FPGA image [12,13]. Even in this case, the effort needed for programming such architectures is higher [14]. Besides programming dataflow architecture for the simplicial complex simulator, appropriate scheduling scheme is also needed for efficient running of multiple jobs simultaneously [15].

As the number of operations that can be applied to simplicial complexes can lead to several days' simulation time or even more, having in mind the aging and the probability of failure of supercomputing nodes [16], we have decided to write restarts after given number of simulations defined by the user, so that the calculation can continue from the last stored state.

VII. Conclusion

In this work we have presented the basics of the paralellization techniques that can be applied to the structure of a simplicial complex, which underlies a host of research problems in theoretical physics (see also our accompanying paper [17]). These problems tend to be computationally extremely expensive, and the common underlying software that enables parallelization at the level of the basic data structure can possibly go a long way towards optimization of code for numerical study using heavily parallel hardware platforms such as HPC clusters. In particular, the simplicial complex naturally allows for various aspects of parallelization, and we have described the basic classes, corresponding MPI communication infrastructure, supporting functions and the dataflow paradigm employed for the construction.

One should note that our work represents just a first step towards a full working software implementation, and much more effort is needed to properly implement, optimize and test the resulting code in real world environments. All that is the topic for future work. In particular, the data regarding the experimental evaluation, which would compare the proposed parallelization method to ordinary sequential methods still needs to be gathered and analyzed. Nevertheless, this first step is fundamental, and it is conceptually important since it represents a paradigm in which parallelization is implemented dominantly at the level of the simplicial complex as the underlying data structure, rather than at the level of the particular algorithm that aims to solve some particular problem using these data structures.

Finally, we note that our code, once properly developed, may possibly find applications not just in theoretical physics, but also in other disciplines of science, technology and engineering.

The Evolution of Big Data Analytics Solutions in the Could

Danko Miladinović, Jovan Popović, and Nenad Korolija

***Abstract*— ig data analytics is a very important topic both for enterprises, science, and government institutions. The amount of data that is generated is e ponentially increasing and the need to analyze data is more important every year. ig data analytics evolved over the past decade from a large on-premises infrastructure for storing and processing data to modern cloud environments. In this paper we discuss how big data analytics evolved over the years and what are the future trends in this area.**

***Index Terms*— ig data; cloud; analytics; machine learning; databases.**

I. INTRODUCTION

BIG data analytics is one of the most important topics in the IT industry. There is a well-known "Data is the new oil" expression that points out the importance of data analytics that can have a huge effect on modern businesses and economy.

Most of the enterprises either leverage information from their data or plan to extract information from the data they own. Data science and analytics became more important for strategic growth of many organizations.

The organizations and software systems are continuously increasing the amount of data that is generated. Relatively big organizations must face the large amount of data that contains the information important for business decisions. Globally, we are now talking about the Exabyte to Zettabyte scale of data that needs to be processed. The global estimates are that the amount of data to be processed would reach multiple Zettabytes in this decade [1].

In this paper we discuss the industry trends and standards for big data analytics with a focus on data analytics in the cloud. This manuscript describes the solutions offered by the open-source community and the biggest commercial data analytics vendors that pave the way that will be followed by companies. The rest of the document is organized in the following sections:

- In the first section, we will talk about the main problems that impact big data analytic solutions.
- The cloud analytics section describes what are the main benefits of the cloud environments for big data analytics.
- Data analytic solutions section describes the two mainstream approaches for storing and analyzing data: Datawarehouse and Datalakehouse solutions.
- In the data format section, we will discuss the most important aspect of big data analytics – the format that is optimized for storing data.
- The conclusion section summarizes the trends for modern big data analytics.

Nenad Korolija is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: nenadko@etf.bg.ac.rs), (https://orcid.org/1234-1234-1234-123X).

II. PROBLEM STATEMENT

The main problem in big data analytics is the size of data. There are many problems that can be solved by analyzing data stored in files and spreadsheets containing gigabytes of data, or even the relational or NoSQL databases that can contain and process terabytes of data. However, there are many domains where the data contains petabytes of data that cannot be stored in a limited set of files or classic database systems.

The researchers and engineers tried to solve the problem of big data processing using the following approaches:

- Datawarehouses that try to stretch the capabilities of the relational databases by applying distributed processing over large data.
- File-based processing systems that try to build an infrastructure for storing a large amount of data. One of the most widely used solutions is Hadoop with HDFS file system [2].

The big data analytic solutions must ensure that users can store Exabyte scale data and ensure that there is enough compute power to process the data when needed. The infrastructure teams must ensure that they have enough hardware (processors and disk storage) to fulfil the user needs, but at the same time to ensure that the resources are not underutilized or constantly over-provisioned.

Solving the problem of ensuring the required resources for big data analytics, but at the same time not over-provisioning them, appeared to be too hard for the on-premises infrastructure. Planning for the resources could not be both cost effective and ensure enough capacity that will be utilized for most of the time.

Therefore, most of the organizations tried to solve this resource management problem in the cloud making the cloud analytics the mainstream in the big data analytics space.

III. THE CLOUD ANALYTICS

Over the past years, the clouds became a very important

 ISBN 978-86-7466-930-3

choice for modern big data analytics. There are three main benefits of cloud infrastructure that make them important for big data analytics:

- Large amount of storage that could be used to store any amount of data. The "Data Lake" [3] is a commonly used term for virtually unlimited storage where the organizations might store petabytes of data. As the amount of data rapidly rises, the organizations need to have an infrastructure that will guarantee that they can easily store Exabytes of data, and with the possibility to scale to Zettabytes in the future.
- Large amount of available compute power that could be used for data processing [4]. The compute power needed to analyze data is proportional to the data size and might easily span to the thousands of CPU cores needed to complete the data analytic tasks.
- Cloud resources can be used on-demand and released when they are not needed. This is one of the main reasons for choosing the cloud environment. Most of the data analytic jobs are not continuously processed and might require thousands of CPU cores for data processing, and then suddenly release all the resources. Cloud providers solve this problem using the economy of scale – with the large number of customers there is a high probability that someone will use them once others release them.

We should note that the could environment is not an absolute requirement to have an infrastructure for storing a large amount of data and use thousands of computer cores to process the data. The organizations might use their own data centers, supercomputers, and any custom-built architecture that will organize hundreds or thousands of computers that process the data. This was a common solution for the organizations who built their own Hadoop/HDFS infrastructure [2] for in-house analytics. However, the cost of management includes the need to maintain and replace the hardware, ensure that the infrastructure has enough compute power to satisfy the peak processing, but also to make sure that the capacity is not too underutilized during the period when nobody is executing analytic jobs.

The current trend is that most of the organizations are deciding to delegate the resource management to the cloud providers and utilize the resources on-demand when they need to run some analytics.

The data analytics solutions should not be misguided with the infinite scale claims of the cloud vendors. Cloud environments are built as many computers that are working together to process tasks. The applications see the sum of the compute power, memory, and storage allocated to the computers that are executing the tasks. In many scenarios, this setup can provide "the infinite scale" promise for a variety of applications such as web applications, easily parallelizable functions or jobs, or the classic databases that might not require a constant compute power of up to 128 cores. This kind of infrastructure is the ideal choice for scaling out the large number of small compute units such as microservices, functions that might need to quickly replicate to. These kinds of solutions made of a large number of micro-compute units are perfect for the cloud environments where each unit can be deployed on some available compute node in the cloud [5]. However, these solutions will rarely require an atomic compute unit between 64 and 128 cores. The big data analytics solutions with the demand to store and process petabytes of data might require compute power that can challenge the infinite scale promise of the clouds. In the big data analytics solutions, we can see the impact of the physical infrastructure where the components that process data might require a large amount of CPU or memory needed to decompress the large files and process the information. Therefore, migrating data to cloud and running the analytical functions in the compute provided by the cloud are not enough. In practice, data analytics solutions require specialized services such as cloud Datawarehouse [6] or cloud Datalakehouse [7] solutions, that are able to efficiently combine the physical resources in the cloud and optimally process data.

IV. THE DATA ANALYTIC SOLUTIONS

Data analytics solutions provide infrastructure and tools for the analysts and the business users that enable them to store and analyze data. There are two main classes of data analytic solutions:

- The Datawarehouse solutions that represent centralized data storage with API for analyzing data and implementing the business intelligence solutions [6].
- The Lakehouse solutions represent the analytical solution running on the storage that is detached from the analytical engine [7].

Both classes of the solutions are aware of the underlying infrastructure and designed to optimally process large amounts of data. The main differences between Data Warehouse and Data Lakehouse solutions are given in Table I.

TABLE I
THE KEY DIFFERENCES BETWEEN DATA WAREHOUSE AND DATA LAKEHOUSE

	Warehouse	Lakehouse
Data format	Proprietary and highly optimized.	Based on open specifications.
Data location	Internal – data is ingested from the external source.	External – data is placed on the original locations.
Data access	Through the predefined API or protocol (SQL)	Direct file access using the storage API

The main trade-off between Datawarehouse and Data Lakehouse solutions is the choice between the interactive and the real-time analytics. The Datawarehouses store data in the data format optimized for analytics, which enables them to

 ISBN 978-86-7466-930-3

complete the queries in second-to-minute time span. However, they require data engineers to load data from the actual locations into the Datawarehouse, meaning that the data analysts work with the snapshot of the data taken at the load time. The Lakehouses reference original data in the lakes without a need to ingest the data. However, the raw format of the data cannot guarantee sub-second or even sub-minute performance. Despite the differences, both Datawarehouse and Datalakehouse solutions are used in practice. The following sections describe the main characteristics of these solutions.

A. Warehouse solutions

The traditional database systems containing data used for the analytics are Datawarehouse solutions. Datawarehouse solutions have existed for decades, have well defined techniques for designing Datawarehouse schema [8, 9], and a variety of tools available for advanced data analytics. For a very long time, Datawarehouses were the mainstream solutions for storing and analyzing huge data volumes. The top vendors such as Oracle, Teradata, and Exadata are still enabling enterprises to store and analyze large amounts of data.

The main idea with the Datawarehouse solution is that the data required for analytics must be ingested into the internal data format that is highly optimized for analytics. The advantage of this approach is the performance. Internal and in many cases proprietary format contains optimizations that are not available in the open-source solutions. In the past, the proprietary format gave the Datawarehouse performance advantages compared to other analytic systems.

The main issues in the Datawarehouse solutions are the facts that the underlying infrastructure must enable Datawarehouse to store all required data, which puts a burden on the administration teams, and the cost of the solution that includes the resources that are always allocated to the Datawarehouse system even if it is not used. The Datawarehouse solutions were the first choice for most of the analytic teams who need interactive analytics, but the total cost of ownership (TCO) in many cases does not justify the solution.

Amazon made a breakthrough in the Datawarehousing technology with the release of Redshift [10] – a cloud-native Datawarehouse service that provides full data warehousing experience exposed as a cloud service. The customers got the ability to provision the Datawarehouse service, load the data, and define the compute needed to analyze the data. The biggest advantage of cloud Datawarehouse is the resource elasticity that solved the main drawback of the classical Data warehousing solutions – the TCO. Unlike the on-premises Datawarehouse that had pre-build resources, the cloud Datawarehouse enabled organizations to scale up and down the resources depending on the needs. The organizations could load a large amount of data without worrying about the underlying storage capacities, scale-up the compute power of the Datawarehouse when needed, and scale it down to reduce the cost when there is no need for processing the data. The cloud Datawarehouse provided by Amazon fulfilled the main requirements of the classical warehouses and added elasticity. Other vendors followed this approach and now we have many cloud data warehousing solutions such as Azure Synapse Datawarehouse [11], Google BigQuery [12], Snowflake [13], etc. All vendors are trying to combine all the benefits of the classical Datawarehouse with the elasticity and scale of the cloud.

The modern cloud Datawarehouses solve the problem of elasticity and scale on-demand that cannot be easily solved in the on-premises Datawarehouses. However, there is still one downside – the data must be ingested from the external data sources into the Datawarehouse internal data format, which causes a lag between the latest data and the data available for the analytics.

B. akehouse solutions

In cloud environments the data is stored in the Data lakes. The Data lake is a logical storage space where the organizations can store the exabytes of data, get the best throughput for reading raw files, ensure redundancy that can span across multiple geographical regions and data centers. The Data lake seems like a perfect solution for storing data. The only drawback of Data lake is that they do not provide the ability to analyze the data in the lake.

The first successful attempt to provide analytic capabilities over large storage was Hadoop – a distributed system that enabled the analyst to analyze a large amount of data stored in the distributed system called Hadoop file system (HDFS). This setup enabled the analyst to analyze data, but the performance of Hadoop is far from interactive. Apache Spark [14] is one of the most popular platforms that enabled analysts to do efficient analytics on the lake. Apache Spark became mainstream in the data lake solutions. One of the most common query engines used to implement the Lakehouse pattern is Apache Spark. Apache Spark is an open-source distributed query system licensed under Apache License 2.0. Spark enables advanced data analytics, management, and updates, and provides a rich and powerful set of APIs to analyze data.

The main idea of Lakehouse architecture is the separation of compute and storage. The compute is a query engine or data processing engine that is detached from the storage, and the data is placed in Data lake where it can be accessed by any query. The compute engine fetches data from the remote Data lake and return data to the analysts once the processing is completed.

Many commercial vendors offered their own implementation of Data Lakehouse services. Nowadays, we have many Lakehouse-type solutions that are offered on different clouds such by Databricks (proprietary version of Apache Spark code implemented by the founders of Spark), Azure Synapse, etc. The main characteristics of these solutions is that they are always referencing the externally stored data, and don't require data to be ingested to start analytics. This enables real-time insight into the latest version of data without the need to wait for the daily data loads to

 ISBN 978-86-7466-930-3

finish before starting the analytics.

One of the main concerns in the Lakehouse solution is whether they would be able to match the performance of Warehouse solutions. Traditionally, the proprietary format used in Datawarehouse solutions was the main competitive advantage compared to the original data formats stored in Data lake. Databricks announced that they have set a new world record in 100TB TPC-DS, the gold standard performance benchmark for data warehousing [15]. The test was performed in Barcelona supercomputing center and officially submitted as TPC-DS result that outperformed the previous record by 2.2x. This was the first Lakehouse-class solution that set the record in an official Datawarehouse benchmark and proved that the Lakehouse architectures can compete with the modern Datawarehouse solutions. One of the key reasons for this kind of success of Lakehouse solution is that they are using the optimized storage file format that matches the proprietary internal formats used in the Datawarehouse solutions.

More insights into data lake solutions and current trends can be found in the literature, including what steps are needed to adopt the cloud concept in data analytic solutions [16].

V. DATA FORMAT

One of the most important design decisions that will impact the efficiency of the data analytics is the choice of the file format that will be used to store the data. Most of the data used for analytic purposes is stored in a plain textual format represented as a delimited text (for example comma separated values – CSV, tab-separated values – TSV, etc.). The documents containing tabular data are represented as Open Office or Microsoft Office formats. Although these data formats are very common, they are inefficient for big data analytics.

There is an additional class of plain textual data represented in JSON format. The JSON format is the standard format in many Internet of Things (IoT) applications where the IoT devices send the messages in JSON format, or the messages that will be eventually stored in JSON format [17]. JSON format provides flexibility for changing the structure of data but complicates the analytics because it requires a parser that is more complex than the plain delimited text parser.

In the practice, the data analysts could analyze data stored in CSV, JSON and other commonly used formats. However, since these formats are not optimized for analytics, it was very hard for data analysts to extract valuable information with performance that matches performance of database systems.

The proprietary data formats that are used to store data in Datawarehouse solutions were the biggest competitive advantage of the Datawarehouse systems compared to the open-source solutions. The optimized formats with high compression, columnar organization of data, and vectorized processing was the main reason why the data analytics teams used the Datawarehouse solutions.

In the open-source community multiple advanced formats are proposed that are designed to optimize the storage format and improve the performance of analytics. Examples are Row Columnar (RC)[18] or Optimized Row Columnar (ORC)[19] file format. The idea of these formats was to define binary representation of data prepared for analytics and optimize access for the analytical jobs. However, the open-source format that took most of the market share became Parquet format [19]. Parquet format is an open-source format that introduces most of the benefits that exist in the proprietary Datawarehouse formats, such as:

- Column organization – the data is physically separated into column segments instead of rows. The column segments contain all cell values from the same column. The columnar organization enables the analytical queries that read 2 columns out of 100 columns to read only 2% of data on average. Since the analytical queries aggregate the measures and summarize them by few columns, the columnar organization introduces most of the performance benefits for the analytical queries.
- Row-groups – columns are divided into row–groups (for example 100.000 rows represent a row group that will be split into the columns) The column segments within the row groups contain some statistical information about cells such as min/max values.
- Compression – There are some compression techniques such as run-length encodings (RLE) [20] that can be applied on the Parquet files to achieve excellent 10-100x compression, which matches the compression in the proprietary Datawarehouse formats. The main impact is not just storage savings. Compressed storage decreases IO requests sent to the storage and improves data throughput that analytical tools can use to fetch the data.
- Non-relational types – Parquet is not limited to strongly defined types and enables storing objects and arrays. The organization of complex types in Parquet format is described in [21].

The Parquet format became the mainstream in data analytics. Although there are other formats that are used in practice, the Parquet format is getting the highest market share and we can expect that the majority of data will be stored in the Parquet format. Therefore, any modern big analytical solution must be based on the Parquet format, or some enhancement based on Parquet. Even if the new file format arrives in the future, there is a high chance that most data will be stored in the Parquet format.

Although the Parquet format is designed to store analytical data that should be read-only (or append-only), there is a need to enable data engineers to make updates to the data. There are several updateable formats (such as Delta Lake [22]), that combine the excellent storage format for analytics and provide ACID guarantees of the operations that managed data. Another possible advancement includes parsing big data using the dataflow paradigm [23] by transforming automatically the parsing software [24] and using appropriate scheduling techniques [25] for the dataflow supercomputing architecture.

 ISBN 978-86-7466-930-3

VI. Conclusion

Big data analytics solutions evolved from the original on-premises based big Datawarehouse solutions to modern cloud based Datawarehouse solutions. The original on-premises Datawarehouse solutions enabled organizations to store large amounts of data and analyze data with acceptable performance. However, these kinds of solutions failed to enable scalability and elasticity. Cloud computing can scale resources on-demand. Data lake that can store Exabytes of data with guaranteed replication, and advances in the opensource file formats disrupted the Datawarehouse solutions in big data analytics. Although Datawarehouse solutions evolved and have been adapted for the modern cloud environments, architectures with full separation of compute power and storage, where the compute can scale when needed, have a direct access to the latest version of data in the lake, and the performance that match modern Datawarehouses. In addition to matching all features that were historically considered as the advantage of Datawarehouse, the Lakehouse solves the issue that fundamentally cannot be solved with Datawarehouse solutions – data ingestion. Lakehouse solutions are able to access the original data in the Data lake and don't require an explicit process to load external data. Without performance degradation compared to internal data formats used in Datawarehouse solutions, direct access simplifies data management process by avoiding the additional processes that constantly move the data and also enable analyst to get the data without any delay.

By looking at the modern trends, we can conclude that the future of big data analytics will be based on the cloud environments and Lakehouse architectures. The cloud Data Lakehouse solutions leverage all benefits of the cloud and match performance of the Datawarehouse solutions. The cloud Data Lakehouse solutions can be considered as a primary solution for most of the future research and as the mainstream and preferred technology for development projects.

Hybrid Manycore Dataflow Processor

Danko Miladinović, Miroslav Bojović, Vladisav Jelisavčić, and Nenad Korolija

Abstract— **This wor addresses high performance computing architectures, presenting a hybrid processor that includes multiple computing architectures on a single chip die.**

eside commonly used multicore processor, a personal computer might include manycore graphical processor. This wor advocates for a combination of these two architectures along with a dataflow processor that usually appears in the form of a PGA chip able to perform parallel tas s at the same time.

A quic overview of these computer architectures and appropriate programming paradigms is followed by the comparison based on fle ibility and speed, price and development time, and speed and power consumption. inally, the proposed hybrid processor is analyzed against computationally demanding algorithms that are often e ecuted on high performance computing architectures.

uture wor will include the comparison of the proposed computer paradigms and the comparison of the proposed hybrid architecture with e isting ones.

Inde Terms— **igh performance computing; manycore processors; dataflow programming**.

I. Introduction

Many high performance computing algorithms are scalable, and as such, suitable for execution using:

- computer architectures the include graphical processing units capable of executing algorithms,
- dataflow computer architectures.

Both of these exist in the form of:

- personal computers,
- computer clusters,
- cloud computers.

Besides the differences in dataflow and conventional computing architectures, their computing paradigms also differ, as well as their suitability for executing high performance computing algorithms.

This work presents recently exploited computer architectures from the point of view of their usability for executing high performance computing algorithms. These architectures are compared based on programming flexibility that they offer, algorithm execution speed, scalability, software development effort, constraints of each of architecture type, price, and power consumption. The presentation of the work is based on the proposed method for presenting the results [1].

Danko Miladinović, Miroslav Bojović, and Nenad Korolija are with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mails: danko @ etf.bg.ac.rs, mbojovic @ etf.bg.ac.rs, and nenadko @ etf.bg.ac.rs).

Vladisav Jelisavčić is with the Mathematical Institute of the Serbian Academy of Sciences and Arts, Kneza Mihaila 36, Belgrade 11001 (e-mail: vladisavj @ gmail.com).

Following sections describe these computer architectures in a uniform manner. A brief overview is followed by the estimation of effectiveness. Each computing architecture is subjected to the following criteria:

- order of number of transistors per number of instructions that can run in parallel,
- speed of the hardware,
- suitability for high performance computing algorithms,
- independence from other computer architectures,
- price performance ratio,
- power consumption performance ratio,
- required space for computer architecture per performance ratio.

On the top of the work, authors propose a hybrid processor that includes multiple computing paradigms on a single chip.

II. Multicore architectures

Most of personal computer architectures are based on von Neumann paradigm. Programs written in programming languages are compiled and linked, and the resulting instructions are stored on the disk. Once a program starts, instructions are loaded into the RAM memory, from where they get copied into the cache memory, so that they could be read faster.

The processor is responsible for executing instructions. Long ago, processors included a single arithmetical logical unit (ALU) for performing arithmetical and logical operations. The speed of processors was increasing for decades by approximately doubling each second year. However, once the speed reached around 3GHz, the trend stopped. The constraint was and still is that the wave length became around 10 cm. Given the fact that the clock cycle must be stable during the whole instruction execution, and the signal has to travel with the speed of light multiple times in different directions, options for further acceleration were:

- to decrease the size of the chip,
- to decrease the size of transistors,
- to decrease the number of transistors per logical gates,
- to implement multiple ALUs that would work in parallel.

Decreasing the size of the chip die implies reducing the number of transistors, leading to deteriorating performances. Reducing the size of transistors would affect their functions considerably (i.e. more failures would appear). Logical gates are already optimized so that further reduction in the number of transistors would affect their capacities for producing output to multiple logical gates.

As a result, both research community and the industry opted for multiplying ALUs on a single chip die.

Multicore architectures can execute an order of 10

 ISBN 978-86-7466-930-3

operations simultaneously. The transistor count is around 1 billion. Clock cycle is order of GHz. As such, their usability for high performance computer algorithms is limited in terms of utilizing algorithms in the real time applications. One of the most important characteristics of multicore architectures is their independence from other computer architectures. As a result, personal computers usually contain only one processor of this type. Typical power consumption is around 500 watts. When used in computer clusters, a single node could include multiple processors of this type.

III. MANYCORE ARCHITECTURES

Graphical processing units are often referred to as manycore computer architectures, as the number of processing units is larger than those of multicore processors.

So-called manycore architectures are logical successor of multicore processors. Certain fields, like computer graphics, require more instructions per second than multicore architectures produce, so that the picture can be refreshed many times per second (e.g. 60 times). With shading effects and full-hd or even 4k resolutions this implies updating millions of pixel colors based on performed operations with appropriate matrices. As a result, companies started producing chips for graphical cards that include thousands of cores that have lower number of available instructions supported by their architectures but are capable of executing more instructions per second. Soon after, utilization of the processing power of new graphical cards started. Many algorithms are implemented using the CUDA programming model.

Manycore architectures have an order of 10 billion transistors with an order of 1000 processor cores, and an order of 1000 instructions that can run in parallel. The clock cycle has an order of 1 GHz. This makes it suitable for high performance computing algorithms. Although each core is based on von Neumann paradigm, being capable of executing any instruction defined by the architecture at any given moment, it relies on the multicore processor as the one that assigns jobs to cores. The manycore architectures proved to be efficient for high performance computing algorithms, including data mining and coin mining. Power consumption is of the same order of magnitude as of multicore processors, while manycore processor offer superior performance. They usually come in the form of a PCIe card that attaches to the mainboard.

IV. DATAFLOW ARCHITECTURES

Dataflow architectures are based on a separate programming paradigm called dataflow paradigm. Data flows through a hardware in terms of electrical signals, resulting in transforming an input to the output [2, 3]. One of the main advantages over the previously mentioned computer architectures is that there is no need for an order of 1 billion transistors to execute only around 10 instructions in parallel. Dataflow hardware can execute even 1000 instructions simultaneously. As such, it is capable of accelerating many algorithms [4, 5]. The main disadvantage is that the multicore processor is needed for preparing the data to be processed using a dataflow hardware and for handling results.

The order of number of transistors is comparable to previously mentioned computer architectures, while the number of instructions that can run in parallel can be much higher. The speed of the hardware is around 0.1 GHz. Since they do not support executing any instruction defined by the architecture at any given moment, they are suitable for only a portion of high performance computing algorithms and more programming effort is needed for creating programs [6]. A mitigating circumstance is that there is a way to automatically translate certain algorithms from the control-flow into the dataflow paradigm [7]. Having significantly lower space occupation and power consumption per instruction, dataflow hardware has good price performance ratio.

V. HYBRID ARCHITECTURES

While each of the available computer architectures has its own advantages and disadvantages, it is a logical step but also a challenge to try to merge multiple programming paradigms into a single computer architecture. The task is even harder to achieve if they are to be put on the same chip die. However, the need for computing justifies the effort needed to merge existing computing paradigms.

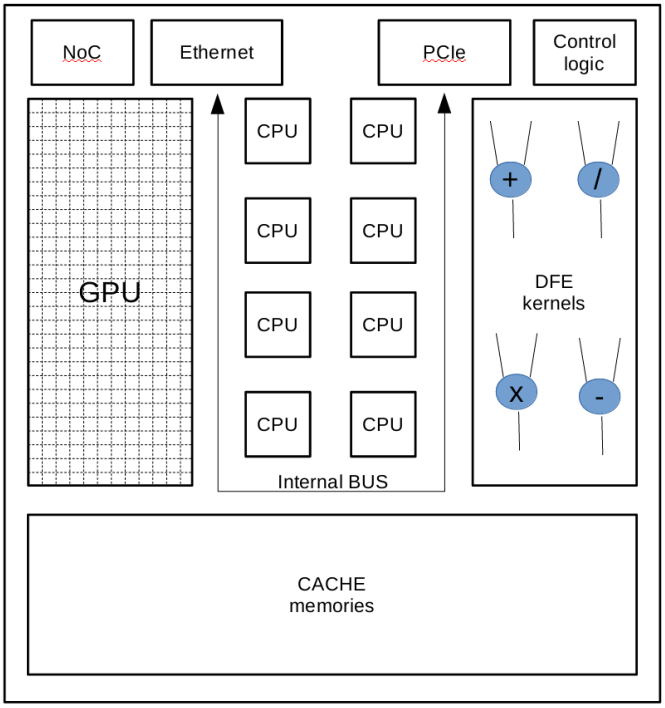

Fig. 1. Hybrid control-flow dataflow architecture.

Fig. 1 depicts a hybrid control-flow dataflow architecture on a single chip. Compared to the typical multicore processor architecture, the proposed hybrid architecture includes graphics processing unit (GPU) cores and dataflow kernels beside central processing unit (CPU) cores and cache memories. Additionally, network on chip (NoC) is suggested as a good way of handling the communication between GPU

 ISBN 978-86-7466-930-3

cores. Compared to the Maxeler dataflow hardware PCIe cards, proposed dataflow engine (DFE) kernels are connected directly to the slowest internal cache memory, because of the necessity for dataflow hardware to execute at the same speed. Constraint that has to be taken into account is that cache locking mechanism has to be implemented for cache memory connected to the dataflow, which would enable granted access to DFE kernels, but also to GPU if it is required by the application that is executed using both computing paradigms.

This architecture offers the best that any of the paradigms offer. On the other side, the complexity is equal to the sum of complexities of incorporated architectures. As such, the proposed hybrid architecture is suitable for executing multiple jobs simultaneously, where some of them are suitable for executing using the dataflow paradigm, while others achieve better performance when executed using manycore architecture. Finally, there are software applications that are not based on scalable algorithms, making them suitable solely for the multicore processor.

The emerging problem on heterogeneous computer architectures that include both dataflow and control-flow hardware is scheduling program execution. Authors have presented their novel algorithm for optimal scheduling of both dataflow and control-flow jobs [8]. The algorithm is general but is limited in number of jobs it can schedule due to the computational complexity. Based on this optimal algorithm, two heuristic algorithms for optimizing the throughput and minimizing total execution time are derived, producing near-optimal schedules for both dataflow and control-flow jobs at large job counts at the cost of negligible scheduling penalty. The heuristic algorithms performance gain decreases slightly as job count increases and only at the beginning, proving that the performance of existing cluster structures with appropriate dataflow accelerators can be considerably improved.

The drawback of combining multiple computing architectures on a single chip is that it increases the probability of failure. However, the probability is relatively high at the very beginning, and once a chip enters the so-called wear-out phase, and is relatively low in the meanwhile [9].

The order of number of transistors per number of instructions that can run in parallel depends on the type of job. If a job is suitable for dataflow architectures, the acceleration would be similar to those of dataflow architectures, while the number of transistors would be around three times higher, assuming that included architectures consume the same number of transistors. The same applies for jobs suitable for manycore architectures, and jobs that cannot be efficiently accelerated using neither manycore architecture, nor a dataflow architecture. However, this applies solely to scheduling a single job that can be executed using one of these three types of architectures. If we combine multiple jobs, those suitable for dataflow architectures would be executed there, based on their hardware requirements and on acceleration they achieve using the dataflow architecture. Jobs suitable for manycore architectures could run in parallel, while jobs that are based on algorithms that are not scalable could run in parallel on the multicore processor. Therefore, achieving fair comparison of the number of instructions that can be run on the proposed architecture is not a straightforward task. As a result, new benchmarks are needed to compare the proposed architecture to the existing ones. For now, one could consider the worst-case scenario, where the acceleration of a job is the same as for the best suited architecture for the job, and the number of transistors is equal to the sum of the number of transistors included on each part of the proposed hybrid processor [10].

The speed of the proposed hardware is also hard to define. As the processor includes different architectures that naturally run on different clock rates, the proposed processor would have a clock speed for the multicore processor that is a multiple of the clock speed of a dataflow architecture and manycore architecture. Therefore, the multicore would be able to efficiently communicate with other parts of the processor using input and output communication buffers.

The proposed computer architecture is not only suitable for high performance computing algorithms, but it is more efficient that aforementioned architectures, as it offers the most suitable hardware type for any particular job. The proposed processor includes multicore processor on the same chip die, making the architecture independent from other computer architectures. The price performance ratio for any given job is lower than those of the best suited of the aforementioned architectures. However, given a set of jobs, where each is suited for one particular architectures, the proposed architecture exploits advantages of all three types of architectures and could achieve the best speed-up in all categories of jobs. The price performance ratio is also lower for a particular job suited for a single computer architecture but is better than any of the aforementioned architectures if there are jobs that could approximately equally occupy all resources of the proposed processor. If completely utilized, the power consumption performance ratio is better than any of the three underlying architectures. For a single job, it is around three times lower, as it is estimated that this processor would consume as much electrical power as all three underlying architectures combined. The space required for the proposed computer architecture is one of its main advantages. Having in mind that it would be able to execute any type of jobs that any of the three computer architectures can, the space per performance ratio cannot be outperformed by any of the existing architectures.

This is not the unique case of proposing combination of manycore and dataflow architectures. Similar tries have been by researchers in the past [11, 12, 13].

VI. COMPARISON

This section summarizes the advantages and disadvantages of described computer architectures and compares them based on various criteria. For each of the given criteria, the proposed hybrid computer architecture is compared to all three underlying computer architectures.

The research [2] summarizes in their Table 2 the achieved

 ISBN 978-86-7466-930-3

speedups of algorithms implemented using the same type of the dataflow hardware that includes a memory on a chip comparing to the control-flow implementations of the same algorithms. The Lattice-Boltzmann algorithm is presented in detail, along with the dataflow code. Authors have compared execution time of Lattice-Boltzmann algorithms using the MAX2 card with 6GB of RAM and using Intel i5 650 processor with the clock speed of 3.2GHz. The computer used 4GB RAM memory at the speed of 1333MHz. The conclusion that can be drawn is that the speed-up of all observed dataflow algorithms ranges from 25% up to the multiplication factor of 150. Based on the comparison of these algorithm implementations for control-flow and for dataflow paradigms, we can summarize the advantages and disadvantages of both programming paradigms.

Table I presents a comparison of computing architectures in terms of flexibility to execute any instruction at any given moment and the speed of execution measured in number of instructions per second. As it can be seen, the multicore computing paradigm offers the highest flexibility by being able to execute any type of job, as it can execute any instruction defined by the architecture at any given moment. Although manycore architectures work on the same principle, they are considered to be utilized if many processing units may work in parallel. Therefore, their flexibility is limited to scalable algorithms suitable for manycore architectures. Dataflow architectures introduce new constraints by not being able to adapt to new needs before re-configuring the hardware. Hybrid architectures offer the advantages of both paradigms.

The speed of execution measured in number of instructions is lowest for the multicore architectures, as they are limited to processing up to an order of 10 instructions simultaneously. Any other of presented computer architectures can execute two or three orders of magnitude more instructions simultaneously.

TABLE I
FLEXIBILITY AND SPEED COMPARISON OF VARIOUS COMPUTING ARCHITECTURES

Type of architecture	Flexibility	Speed
Multi core	+++	+
Many core	++	++
Dataflow	+	++
Hybrid	+++	++

Table II presents a comparison of computing architectures in terms of price and the development time measured by effort needed for producing the software. The price raises as we lean towards more optimized computer architectures. The same applies to software development time. The only exception is that hybrid computer architecture, which is suitable for executing any of the given type of software, which means that the development time depends on the type of software being executed on the architecture.

As dataflow architectures are not as utilized as multicore and manycore computer architectures, the price tag of dataflow architectures is higher that it would be if each personal computer would include dataflow engines as well.

TABLE II
PRICE-DEVELOPMENT TIME COMPARISON OF COMPUTING ARCHITECTURES

Type of architecture	Price	Development time
Multi core	+	+
Many core	++	++
Dataflow	+++	+++
Hybrid	++++	+ - +++

Table III shows a speed to power consumption comparison of these computing architectures. The speed of the multicore computer architecture is slower than others, as it can run a smaller number of instructions in parallel.

When it comes to power consumption, it is similar for all types of architectures, which leads us to the following conclusion. The power consumed per a single instruction is the highest in the case of the multicore computer architecture, while it is the lowest for dataflow and hybrid computer architectures, assuming that they are not underutilized.

TABLE III
SPEED-POWER CONSUMPTION COMPARISON OF COMPUTING ARCHITECTURES

Type of architecture	Speed	Power consumption
Multi core	+	++
Many core	++	++
Dataflow	+++	++
Hybrid	+++	++

Based on these comparisons, we could conclude that the proposed architecture has the potential for achieving better results in terms of speed, flexibility, and power consumption comparing to the existing computer architectures, while the programming effort might be higher in the case of the algorithms implemented using the dataflow paradigm.

Comparing to the research available in the open literature, the proposed architecture is more high performance computing oriented than the Ultimate dataflow processor [12], while it doesn't support internet of things. Authors of SambaNova [14] also recognized the potentials of dataflow computing paradigm. Their Reconfigurable Dataflow Unit (RDU) enables accelerating algorithms with the flexibility to build custom dataflow pipelines as well as large memory capacity to run big models such as Natural Language Processing (NLP) and high-resolution computer vision efficiently. However, it is dedicated to algorithms that consist predominantly of the source code that can be most efficiently accelerated using the dataflow paradigm.

Research [15] exploits the opportunities from digital Processing-in-memory (PIM) bit-serial processing and in-memory customization, to tackle the above challenges by co-designing sparse algorithm, multiplication dataflow, and PIM

 ISBN 978-86-7466-930-3

architecture.

VII. Conclusion

Along with a multicore processor, a personal computer might include manycore graphical processor and a dataflow processor on the same chip die. This work advocates for a combination of these two architectures in order to create the type of the computer architecture that is able to execute jobs suitable for any of these three types of architectures in parallel.

Presented comparison between computing architectures suggests what kind of algorithms are suitable for execution using existing computing paradigms.

The proposed hybrid processor is analyzed against computationally demanding algorithms that are often executed on high performance computing architectures. As it includes multiple computing architectures on a single chip die, it could achieve the best acceleration for a job suitable for any of aforementioned computer architectures. At the same time, if the amount of jobs suitable for these three computer architectures matches the amount of resources of the proposed processor, the proposed processor with appropriate job scheduling can achieve the performance of combined architectures.

Future work includes the simulation comparison of the paradigms and the comparison of the proposed hybrid architecture with existing ones.

Service-Oriented Communication Between ADAS and IVI Domains in Automotive Solutions

Dušan Kenjić and Marija Antić, *Members, IEEE*, Dušan Živkov

***Abstract*—As the complexity of automotive systems has grown, it has become necessary to cluster various vehicle components into several domains, based on a specific function they perform. This approach has facilitated the development of domain-specific features, as it allows to create communication standards and common libraries that meet the requirements of the particular domain. On the other hand, it has created the redundancy in the resource consumption required to perform similar tasks in different domains, which leaves the room for further optimizations. This is most notable if we analyze the functionalities of the two fastest growing domains: autonomous driving assistance (ADAS) and in-vehicle infotainment (IVI), which are both developing simultaneously, and may benefit from the option of providing features and services to each other. This paper will examine and propose a solution for interconnection between ADAS and IVI domains by utilizing state-of-the-art mechanisms of the service-oriented architecture (SOA) paradigm. The examination of SOA utilization rationale will be presented, as well as the crucial challenges and limitations of the possible approaches, derived mainly from the discrepancy of service-oriented architecture implementation and mapping in different standards. Various features and use-cases will be discussed, that would be good candidates for cross-domain implementation.**

***Index Terms*— in-vehicle domains, ADAS, IVI, interconnection, SOA in automotive.**

I. Introduction

The transition to centralized domains in the automotive system design and development was necessary due to the increasing number of Electronic Control Units (ECUs) in the modern vehicle. With this approach, the system is organized into several domains based on the features and the tasks ECUs within the domain perform. By splitting the whole system into a set of specialized domains, it was possible to create standards and abstractions that facilitate the development of features specific to the particular domain, without the need for developers to constantly solve the problems of connectivity and resource sharing. Two domains which are constantly improved and require powerful resources are ADAS - Advanced Driver System Assistant domain and IVI - In-vehicle Infotainment domain. The ADAS domain is responsible for safety-critical features and algorithms using various types of sensors in order to enable safe, comfortable and cost-effective driving. On the other hand, the IVI domain is oriented towards passenger entertainment, as well as towards providing useful information about the driving conditions and the state of the vehicle. Although these two domains perform different tasks, there is a set of features and sensors of the same type which are commonly used in both of them. However, in the current architecture of modern vehicle, these two domains do not share any of the hardware resources nor results of the data processing algorithms. This creates an implementation overhead, as similar functionalities need to be implemented in both of the domains, and the hardware cost is constantly increasing. This represents the main motivation to design an approach for resource sharing between domains as a first step towards the unified platform which shall control the entire system.

In this paper, we will present the results of the initial phase of a research project aiming to create the solution for the inter-domain communication and resource sharing in the automotive solutions. First, we will present the summary of the state-of-the-art research and commercially used approaches for the inter-process communication and service-oriented architecture in automotive industry. Then, we will propose the architecture of the solution connecting ADAS and IVI domains, provide some practical details and discuss the examples of the use-cases which would benefit from the resource sharing between these two domains. Finally, we will discuss the implementation challenges of the proposed approach.

II. IPC and SOA in Automotive Systems

A. Service-Oriented Middleware in Automotive

Traditionally, automotive systems use a conventional signal-based communication approach, which provides a deterministic data transfer, and enables the processes to run in the predefined schedule [1][2]. However, such an approach does not support the desired scalability of the system, which is required to satisfy the requirements of emerging applications and scenarios. Therefore, in order to provide the flexibility and a more dynamic and scalable system, service-oriented architecture (SOA) was introduced to the automotive system design. Service-oriented communication approach has been adopted from the domains of web applications, cloud and information systems, where it has already proven its flexibility for functional services implementation [3]. SOA represents an efficient way to encapsulate the job done by the specific component into a service. This way, resources can be

Dušan Kenjić is currently working toward the Ph.D. degree with the University of Novi Sad, Serbia, (e-mail: dusan.kenjic@uns.ac.rs).

Dušan Živkoc is with the RT-RK Institute for Computer based Systems, (e-mail: dusan.zivkov@rrt-rk.com).

 ISBN 978-86-7466-930-3

distributed to the clients interested in the information which the service provides, the service implementation can remain obscured from the clients and modularity and repetitiveness can be achieved. Additionally, the unified communication mechanism facilitates the interoperability between heterogenous system components, which otherwise represents a time consuming and challenging problem that needs to be solved during the application development.

The first step towards the integration of SOA principles within an automotive system is to create a platform and define a protocol which can support this integration. Such platform must be compatible with other automotive solutions and protocol must be suitable with the automotive requirements [4]. Scalable service-Oriented Middleware over IP (SOME/IP) is a Remote Procedure Call (RPC) mechanism [5] specialized for the usage in the automotive systems. It consists of three modules: SOME/IP, SOME/IP Service Discovery (SD) and SOME/IP Transformer. SOME/IP fundamental module is managing the serialization and deserialization of transmitting data, SD module enables the connection establishment and service discovery procedure and the Transformer module specifies automotive/embedded data serialization [4].

There are multiple protocols which can be used for in-vehicle cross-domain communication such as DDS, HTTP, MQTT, web sockets, etc. Besides the abovementioned fact that the SOME/IP is created for the automotive industry there are several functional benefits that made it our choice for such use-case. First, the mandatory configuration of the communication over SOME/IP enables somewhat more deterministic behavior in contrary to another protocols and mechanisms used to implement SOA in the web and cloud computing such as the HTTP for example. Additional benefit is that SOME/IP provides multiple types of communication. Comparing to the HTTP, which allows only request-response communication initiated from clients, SOME/IP provides both request-response and publish-subscribe approaches. Furthermore, SOME/IP does not require communication establishment for each data exchange, but only for initial client-service connection and it can rely on both, TCP and UDP protocols in contrary to the communication implementing Representational State Transfer (REST) principles.

Although having different architectures, diverse software platforms use the SOME/IP communication stack based on the similar concept as depicted in Fig. 1.

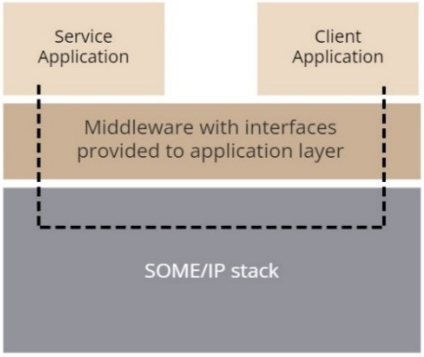

Fig. 1. Concept of SOME/IP implementation in automotive platforms

Usually, the middleware which provides the applications with the particular interfaces based on the determined configuration parameters is implemented by the standard. Depending on whether it is event, method or field that is defined by the configuration the data exchange would be performed by publishing the information to subscribed client when a logic on the service side determines so, client requesting the execution of a method on service side and getting the response if needed and getting, setting or notifying about the changed state of a field, i.e. attribute on the service side respectively.

Services in automotive SOA need to meet strict requirements regarding the service discovery and startup latency time [6]. Authors in [3] even propose dividing and isolating secured and exposed subnetworks in order to accomplish more reliability, since the service discovery mechanisms cannot guarantee that the service will be provided at the needed time. However, this aspect will not be examined in this paper, but another one instead – how SOA is implemented within available architectures and how it can be used for inter-communication between ADAS and IVI domains.

B. IPC Standards in IVI Domain

Modern vehicles are currently competing to meet the requirements driven by the consumer technology, especially in the infotainment domain. Inside the vehicle, the passengers expect the experience they have when using everyday portable devices, such as tablets and mobile phones. They are used to being able to install and use various types of applications developed by different vendors. In order to meet these requests, it is necessary to utilize the globally accepted standards for building scalable and portable platforms.

1) GENIVI approach

The former GENIVI (currently COVESA) alliance drives the development of open standards and technologies used in automotive systems. Their goal is to address the challenges which the in-vehicle infotainment components are facing when reaching to the outside world (cloud services, other vehicles, etc.) and communicating with other in-vehicle infotainment components as well. They offer the CommonAPI [8] – an inter-process communication middleware based on the FRANCA framework, which provides service-oriented mechanisms. It is designed to split the applications implementation apart from the communication mechanisms used between the implemented application components.

Since the only purpose of this middleware is to provide interfaces between lower (platform services and protocols) and upper (applications) layers, its implementation is generated mainly from the FRANCA Interface Definition Language (FIDL) to make its utilization easier. Applying the specified interface definition language – FIDL, it enables flexible deployment models. This way, the dynamic behavior of an API is specified by defining client/server interaction interfaces, states and transitions between them [7]. The communication itself is performed by using the generated Stub and Proxy classes relying on the CommonAPI middleware within the Service and Client applications respectively. This way, the concept from Fig. 1 is kept since the entire CommonAPI stack

 ISBN 978-86-7466-930-3

including the Stub and Proxy provides applications with interfaces for usage of the SOME/IP mechanisms.

Additionally, COVESA semantically differentiates between the two realms: Common-API Core, which does not depend on the communication protocol itself, and CommonAPI Binding which is protocol-specific [8]. Currently, the CommonAPI support two RPCs, D-Bus and the SOME/IP. In order to set deployment parameters for chosen protocol, the FRANCA Deployment (FDEPL) files are used along with the FIDL.

2) Android approach

Android is an open-source operating system mainly utilized for mobile devices. It enables deployment on wide range of hardware platforms and supports third-party applications development [9]. Currently, the automotive industry is facing a similar requirement for the possibility for third-party application development and utilization, therefore the automotive community is more interested in the Android platform [10].

Android platform has the mechanisms for feasible handling of the Inter-Process Communication (IPC) via its proprietary interface definition language called AIDL. It provides a programming interface utilized by both the client and the service using the IPC to communicate with each other [11]. Although AIDL has similar functionality as other IDLs, its utilization does not rely on the same paradigm as it is the case with the FIDL and COVESA's Common-API service-client communication model. Additionally, the SOME/IP had not been supported in Android until vsomeip version 3 was released. The possible correlation between CommonAPI and Android and more details about the AIDL paradigm and its communication mapping to other mechanisms will be addressed in the Section 4.

C. IPC standards in ADAS domain

The previously described standards are used for the implementation of the application for the in-vehicle infotainment part of the automotive system. On the other hand, ADAS domain is faced with the challenges driven by different requirements, as it considers safety-critical algorithms and modules. Nevertheless, ADAS domain implies the integration of functionalities provided by machine vision and sensor fusion. Lots of these algorithms are used in consumer technologies, i.e., in the IVI domain also. Therefore, the benefit of exchanging resources between two mentioned domains is obvious, since there is a set of functionalities they share. A standard that has become a convention for the implementation of ADAS domain functionalities is AUTOSAR.

The AUTOSAR standard considers both safety host and performance host implementations. Safety hosts are referring to ECU's cores with safety and security control features specialized for the automotive industry. Classic AUTOSAR platform is designed for the fully deterministic, deeply embedded standardization of safety hosts. Furthermore, the Adaptive AUTOSAR platform is offering more flexibility by addressing operability and communication mechanisms more suitable for high-performance computing devices called performance hosts. Since the performance host resources and algorithms complexity are more similar to the ones in the IVI domain, we will focus on the sharing resources and features of the Adaptive AUTOSAR platform.

User applications are running on the top level, right on top the AUTOSAR Runtime Environment for Adaptive Applications (ARA). The main component of ARA is ara::com, a middleware controlling the communication within a system. It provides the interfaces to the user applications which allow data exchange with both local and remote applications and ARA services [12].

Equivalent to the FIDL, ara::com interfaces in ARA-API are defined by the ARXML. Interfaces are provided to applications with the exact same purpose as it is the case with CommonAPI, to decouple the applications development from the communication mechanism. It is done by utilizing two artifacts - Skeleton and Proxy which implement the SOA paradigm, i.e., the service-client communication, likewise it is the case with the Stub and Proxy in CommonAPI. Skeleton represents the generated instance which provides service calls functionalities. On the other hand, Proxy is a generated instance which provides the client calls functionalities.

III. CURRENT CROSS-DOMAIN RESOURCE SHARING SOLUTIONS

Most of the research in the field of interconnecting different automotive domains focuses on the modelling and implementation of multi-ECU system using a single standard. Since meeting the safety and latency requirements for ADAS is critical, it dictates the approach to use Adaptive AUTOSAR for both the ADAS and IVI realm. This way, for the sake of connectivity between different domains, neither the CommonAPI nor Android are used, although they are a better fit for IVI domain, since the development is forced to a single standard approach which must fit ADAS requirements. The authors then try to deal with the shortcomings that the AUTOSAR standard provides in terms of UI as an important aspect of in-vehicle infotainment [13]. Authors in [14] presented challenges of modelling ADAS components for camera resource sharing. However, it is needed to perform further research on the most suitable communication channel for the transmission of sensing data and data streams along with the research on the most suitable communication mechanisms by considering the entire, end-to-end communication context for such resources sharing between domains in automotive, the SOME/IP is not the most effective solution for such use-cases. Furthermore, taking into consideration the variety of operating systems on the other side, such implementation cannot be taken "as is".

COVESA alliance recognized this challenge and tried to attain the adaptation between Adaptive AUTOSAR and the CommonAPI by creating FARACON generator [15]. This generator is used to translate the interface definition files from one standard to another. This can be considered as a first step towards the mapping of the features between standards. However, it does not solve the cross-domain heterogeneity issue, which is somewhat more complex.

There are not many papers that provide the actual proposition for interconnection between ADAS and IVI domains utilizing different standards. i.e., following AUTOSAR on ADAS and CommonAPI or Android on IVI side. The existing solutions have recognized the need for such

 ISBN 978-86-7466-930-3

binding, but are also typically reduced to simple utilization of socket-based communication with no actual research background on the available protocols and state-of-the-art SOA principles [16]. Additionally, the inter-process communication paradigms diversity when considering the various platforms standards is not actually covered even in papers which provide the extensive solution for heterogenous in-vehicle environments [17]. Hence, there is no comprehensive project dealing with all aspects of this topic.

Since this topic is substantive and our project is still in the development, some of the challenges will not be covered by this paper but will be addressed in future work instead.

IV. Proposed Solution

In this section, we will discuss the possible approaches that allow remote procedure calls and exchange of data between ADAS and IVI domains of the vehicle. Our goal is to provide the connectivity, without compromising the functionality of the IVI domain offered by the CommonAPI or Android, or the safety features provided by the AUTOSAR in ADAS domain. We will design our solution using the service-oriented architecture principles, which fit perfectly into the scenarios we want to support. Our focus is on allowing IVI domain applications to use raw measurement data from ADAS sensors, as well as the results of some of the algorithms that run on the ADAS side. The opposite direction of integration is not possible, due to potential safety issues.

There are several examples of use-cases where the proposed cross-domain inter-connection can be beneficial. For example, inputs from cabin camera which is commonly used for driver monitoring on ADAS side can be shared for video calls and other applications using camera in IVI domain. This way, the cost of providing redundant hardware components would be avoided. On the other hand, data from sensors monitoring tire pressure, engine temperature and other crucial components of the vehicle could be easily transferred and handled by the applications in the IVI domain. These applications could then not only inform the driver, but also provide the better user experience by searching for the recommendations and manuals on the Internet, or help by finding the route to the nearest mechanic service. The results of the data processing algorithms such as traffic sign detection and recognition or driver drowsiness monitoring could also be used by the IVI domain applications, to propose rest stops, provide tourist information, etc.

To connect the components of the two domains in the proposed solution, Ethernet-based communication will be used. Recently, Ethernet has taken on the role of the vehicle communication backbone because of its bandwidth, scalability, flexibility and prevalence. In all of the aforementioned terms, Ethernet is generally superior to other in-vehicle buses, which are designed and optimized to fit only specific use-cases. For example, CAN provides the reliability which Ethernet cannot achieve because of the different transmission media access strategies. On the other hand, CAN is the automotive specific technology which means that Android, as a standard that was not created solely for the automotive industry, does not support CAN bus module natively. Similarly, other in-vehicle buses are created to meet

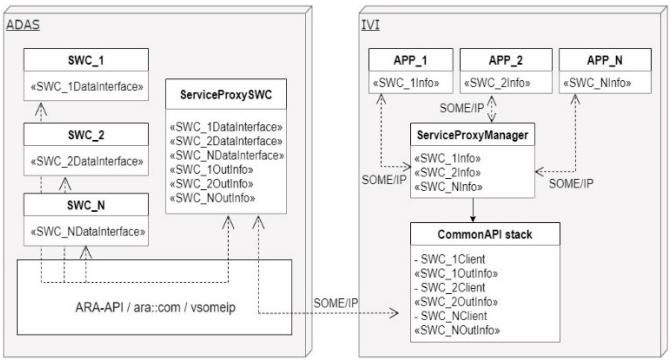

Fig. 2. Centralized interconnection approach with POSIX OS on IVI side

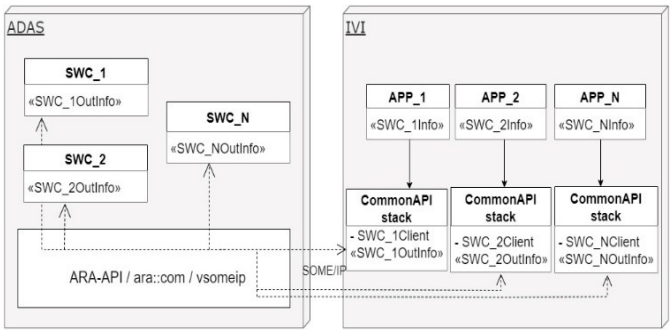

Fig. 3. Distributed interconnection approach with POSIX OS on IVI side

the requirements of automotive signal-based communication, where priority is the price and the determinism of the communication mechanism, not the bandwidth itself. On the other hand, Ethernet is widely used technology which makes it suitable for interconnection of different domains. To exchange data between the domains, we will use SOME/IP, from the reasons already discussed in Section 2, and it can be used over the Ethernet network.

Typically, IVI solutions can either run on Linux operating system and use CommonAPI mechanisms for the inter-process communication, or they can be Android-based. For both of these cases, we will propose the solution architectures in the following sections.

Since Adaptive AUTOSAR and CommonAPI both implement the SOME/IP communication interfaces, this is the easiest way to establish the communication between the two domains in the SOA manner. The ADAS side is implemented by following Adaptive AUTOSAR standard and the IVI domain uses the CommonAPI middleware running on the native operating system such as Linux. This scenario is depicted in Fig. 2 and Fig. 3. Communication in Adaptive AUTOSAR is handled by ara::com which natively supports vsomeip as a library that implements SOME/IP standard. The same vsomeip implementation is utilized in CommonAPI SOME/IP stack. This means that serialization and deserialization of data shall be handled in the same way, so both sides will be able to interpret data properly.

Information from components on ADAS side are initially given to the Service Proxy SWC via SOME/IP implemented within the ara::com module. This data is furtherly forwarded to the corresponding CommonAPI clients grouped together on the IVI side in a single Service Proxy Manager instance (Fig. 2). Such inter-domain transfer is performed over SOME/IP on

 ISBN 978-86-7466-930-3

demand of IVI applications or when the event/change is captured.

The type of communication between the ADAS and the IVI does not necessarily have to match the communication between the ADAS Service Proxy and other SWCs which means that IVI applications can request the data through the Service Proxy Manager instance over method mechanism, but the sharing information on the ADAS side can be sent to the Service Proxy SWC from the actual service component as an event for example.

Another approach is to implement separate services for each CommonAPI client (Fig. 3) so the Service Proxy components on both sides are unneeded and the information will be provided from ADAS ara::com services to the IVI CommonAPI clients included in particular application. The first approach is easier to scale and can be used with the variable number of application instances. Also, it can be favorable from the safety perspective since it can contain mechanisms to protect from other SWCs from being jeopardize by IVI applications. On the other hand, the second is superior in terms of reliability, because there is no single central node which distributes the data between the applications. This way, the malfunction of one service does not affect the operability of others. Furthermore, the monolithic design is harder to maintain, as even minor changes require the entire integration cycle. The speed of access to information is also one of the factors that is on the side of the distributed approach.

As already said, Android has recently become the operating system of choice for IVI applications, as most of the users are familiar with it and it is available on a very large variety of hardware. The interconnection of the ADAS domain with the IVI domain running on the Android platform is a bit more challenging for the implementation. Namely, Android itself does not have mechanisms to implement SOME/IP client which can communicate with ADAS side. Therefore, the CommonAPI must also be used in this scenario in the exact same way it was the case when non-Android OS was examined, as it is presented in Fig. 4 and Fig. 5.

The CommonAPI clients are included within an Android native service and provided information can be transferred to both, custom applications and HAL modules over AIDL. The entire CommonAPI stack can be built within an AOSP (Android Open Source Project maintained by Google) with the soong build system. Still, the vsomeip itself has some dependencies, such as boost library, which can cause issues while building within the AOSP. Further options are to build CommonAPI client beyond the AOSP, with the Native Development Kit – NDK, or even to use another implementation of SOME/IP standard instead of vsomeip, which would eliminate the dependencies such as the afore-mentioned boost library. Nevertheless, CommonAPI clients must be included in Android services so the data from ADAS can be provided to applications or other services in IVI domain.

Additionally, the mapping of SOME/IP service-client communication paradigm from CommonAPI/AUTOSAR to Android represents a challenge. Namely, AIDL files used for

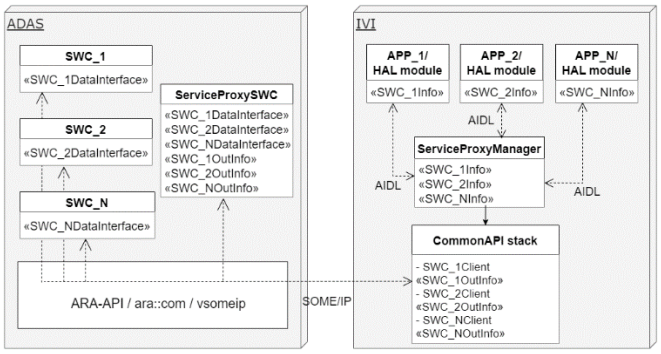

Fig. 4. Centralized interconnection approach with Android on IVI side

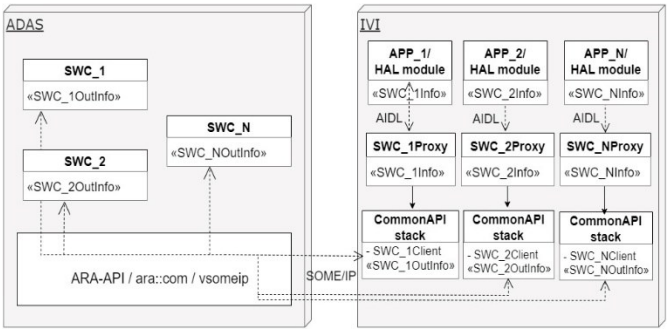

Fig. 5. Distributed interconnection approach with Android on IVI side

interface generation provide the inter-process communication by marshaling the object instances through the binder. This is not suitable for the event-triggered traffic. Event-triggered communication from service to clients within a SOA is performed in a way that the client itself is only subscribed to the events from service. This specific case cannot be covered by using regular AIDL, because AIDL always assumes that the communication is initiated from the client side

Our approach was to incorporate the receiving (client) side for broadcasts and events in the Android native service, and further distribute this information to the interested applications. The easiest way to achieve this is to set properties based on the information received by the Android native service. The interested applications can then read that particular property. This approach has a big limitation since the data can only be used to transfer flags and states since properties do not exist to be used as IPC mechanisms.

We went for the another, a slightly more demanding way for implementation. It assumes the creation of a helper AIDL, which will pass the interface object as a parameter from the applications to Android native service, in order to enable the Android native service to react on event-trigger signals from CommonAPI by invoking methods from the passed object like it is a client to the application. Furthermore, in order to avoid forming a list of registered applications which methods will be invoked when event-triggers we created additional helper service in Java with which it will be communicated via that helper AIDL and which will furtherly provide Intents to the applications. Additionally, it is even possible to have stand-alone Java service which will use the CommonAPI via Java Native Interface – JNI. JNI is necessary in this scenario to enable inter-operability between Java and C/C++ code, since the COVESA provides CommonAPI middleware in C++

 ISBN 978-86-7466-930-3

programming language.

V. Conclusion and Further Work Directions

This paper presented both, the theoretical and the practical aspects of proposal for service-oriented communication between ADAS and IVI domains. Background and motivation for such binding are provided, along with the key challenges and limitations as it is summarized in Table 1. Several approaches were elaborated in order to satisfy system heterogeneity. Additionally, the beneficial use-cases are discussed in order to emphasize the value of bonding itself.

TABLE I
Major challenges and limitations

Challenges	Limitations
SOA paradigm mapping	Implementing broadcast/events with AIDL principles
Centralized or distributed approach	Prioritization, robustness, bandwidth
Data transfer channel	Performance evaluation
Safety	Enable safety solution for Android
Generation of inter-communication	Verification and tool qualification

In our future work, we will focus on the evaluation of the latency, bandwidth and robustness in order to present comprehensive comparison of the centralized service proxy manager approach with the distributed approach, to determine the optimal design.

The performance of data transfer channel shall be furtherly examined too by considering the Audio Video Bridging (AVB) and other mechanisms for big data integration. It is needed to determine the exact use-cases where the data shall be transferred only within SOME/IP request/response, and where it is more suitable to open additional channel for data transfer. Several aspects regarding data size and safety shall be analyzed in order to define the optimal approach.

Safety requirements are maybe the most complex of all challenges that we plan to address. Safety analysis implies the detail examination on the system level too. It is not enough only to implement mechanisms for Android native service to control which applications can use it based on the given permissions and to properly handle dead listeners and multiple registrations which is done by now. Hazard analysis on the system level involves hardware and OS safety competence and certain communication determinism (Time-Triggered Ethernet or Time-Sensitive Networking). Android itself currently cannot have any Safety integrity level but QM [18]. From that reason, it is mandatory to involve the hypervisor if the communication must be initiated from the Android [19].

The final challenge will be to automate the entire process of providing resources from ADAS to IVI. This means that our goal will be to generate the translation between ARXML, FIDL and AIDL, as well as the generation of Android service along with the code that is responsible for providing resources from service on ADAS side to the IVI realm.

Утврђивање сличности софтверског кода

Захарије Радивојевић, Милош Цветановић

***Апстракт*—Утврђивање сличности софтверског кода представља област истраживања у оквиру софтверског инжењерства. Поред великог броја домена у којима налази примену оно представља кључни елемент за утврђивање постојања софтверских клонова, а самим тим утиче на софтвер током читавог његовог животног циклуса, током дизајна, развоја и одржавања. У овом раду је, на основу искустава аутора, дат преглед домена и карактеристике кодова који се у датим доменима пореде. Описане су и технике које се примењују у овој области независно од домена примене, као и карактеристике кодова које се датим техникама пореде. Такође је изложено пет сукцесивних поступака које су аутори развили за примену у домену откривања неовлашћеног коришћења лиценци. Поступци обухватају описе техника за утврђивање сличности бинарног кода, утицаја архитектуре рачунара на утврђивање сличности бинарног кода, утицаја трансформација преводиоца на утврђивање сличности бинарног кода, могућности за коришћење неуралних мрежа за утврђивање сличности бинарног кода, као и коришћење секвенци операција за утврђивање сличности бинарног кода.**

***Кључне речи*—Софтверски клонови, сличност кода, бинарни код, софтверске метрике, неуралне мреже.**

I. Увод

Анализа изворног кода програма има широки спектар примена, које укључују од рангирања и категоризације програма [1], преко откривања преписивања у домаћим задацима [2], до откривања недостатака у програмима [3]. У овој анализи као један од важних корака јесте утврђивање сличности делова кода. Постоје домени примене код којих је утврђивање сличности кода од пресудног значаја. Ови домени обухватају откривање злонамерног кода [4], реверзно инжењерство софтверских закрпа [5], откривање неовлашћеног коришћења лиценци [6], и слично. Ова анализа се у већини случајева обавља над изворним кодом програма, али се у неким случајевима може обављати и над асемблерским кодом програмима као и директно над бинарним записом извршног кода програма. Без обзира да ли се ради анализа изворног или извршног кода, као и без обзира на домен примене поступак се заснива на откривању софтверских клонова.

Овај рад има за циљ да представи област истраживања која се бави анализом сличности софтверског кода. Рад даје сажетак истраживања у овој области и нема за циљ да да систематичан преглед литературе у овој области. Рад је организован тако да ће у другој глави бити представљени домени примене утврђивања сличности кода. У трећој глави објашњене постојеће технике утврђивања сличности кода, док ће у четвртој глави бити представљени резултати истраживања у области анализе софтверског кода датог у бинарном облику које су аутори спровели током више година. Последња, пета, глава представља закључак овог рада.

Захарије Радивојевић, доктор електротехнике и рачунарства – Електротехнички факултет, Универзитет у Београду, Булевар краља Александра 73, 11000 Београд, Србија (e-mail: zaki@etf.bg.ac.rs).

Милош Цветановић, доктор електротехнике и рачунарства – Електротехнички факултет, Универзитет у Београду, Булевар краља Александра 73, 11000 Београд, Србија (e-mail: cmilos@etf.bg.ac.rs).

II. Домени примене одређивања сличности кода

У овој глави ће бити описани карактеристични домени у којима се може применити утврђивање сличности софтверског кода. За сваки од домена биће наведена сврха са којом се утврђивање сличности користи. Такође, за сваки од домена биће наведен и угледни примерак алата и описан његов начин функционисања. Преглед основних карактеристика појединих домена је дат у табели 1.

A. Детекција клонова

У домену детекције клонова упоређивање сличности кода се користи са циљем упаривања делова кода који могу потицати од сличног изворног кода или од сличног бинарног кода који потиче од истог изворног кода. Два дела кода која представљају софтверски клон поседују исту семантику, али се разликују по нивоу синтаксне сличности и на основу ње су класификовани у четири типа. Два синтаксно идентична кода се класификују као клонови типа 1, а могу се разликовати само по форматирању и пратећим коментарима. Уколико између два кода постоји и разлика у називима литерала онда се класификују као клонови типа 2. Убацивање малог броја додатних инструкција или промена редоследа инструкција која не утиче на резултат извршавања кода се класификује као клон типа 3. Све остале промене које чувају семантику али у већој мери мењају синтаксу оригиналног кода се класификују као клонови типа 4 [7].

Један од алата који се може користити у поступку откивања софтверских клонова је ACD алат [8]. Овај алат покушава да упари секвенце инструкција највеће могуће дужине. За упаривање инструкција потребно је да редослед упарених инструкција буде идентичан у оба кода који се упарују и да се утврди да се инструкције нису раније упариле. Као додатни услов се користи да је циљна адреса скокова иста у односу на остале упарене инструкције. Ако се током упаривања секвенци деси да се мали број инструкција не може упарити оне се игноришу. За сваке две упарене секвенце израчунава се тежина. Сваки пут, када су две инструкције упарене, тежина се

 ISBN 978-86-7466-930-3

ТАБЕЛА 1. ПРЕГЛЕД ДОМЕНА ПРИМЕНЕ

Домен	Тип кода	Тип клона	Циљ потраге	Узрок разлика
Детекција клонова	Изворни	1, 2, 3, 4	Сличне процедуре	Програмер
Откривање неовлашћеног коришћења лиценци	Изворни/Бинарни	1-Изворни, 4-Бинарни	Еквивалентне процедуре	Преводилац
Откривање злонамерног кода	Бинарни	1, 2, 3	Сличан код	Програмер/Преводилац
Откривање рањивости кода	Бинарни	1, 2, 3	Сличан код	Програмер

повећава за одређену вредност. Када се у некој од секвенци наиђе на инструкцију која се занемарује, да би се наставило упаривање, тежина се умањује. Процес упаривања две секвенце почиње са две инструкције које се могу упарити и наставља се све док тежина претходно упарених секвенци не буде једнака нули. Након тога, покушава се са побољшањем упаривања две секвенце откривањем нових инструкција које се могу упарити унутар ових секвенци а које би могле повећати укупан број упарених инструкција.

B. Откривање неовлашћеног коришћења лиценци

Све већи број кршења ауторских права у софтверској индустрији доводи до огромних економских губитака за носиоце ауторских права [9]. Једна од ситуација у којој може доћи до кршења је лиценцирање софтвера са двоструком лиценцом. Овај тип пословног модела се обично користи да би се подржао софтвер отвореног кода у комерцијалне сврхе. У таквом пословном моделу, власник ауторских права софтвера нуди изворни код бесплатно за некомерцијалну употребу, али остварује профит продајом ауторских права компанијама које желе да користе изворни код у својим производима. Повреда настаје када се изворни код власника користи у производу без лиценце добијене од власника. За разлику од домена откривања клонова, где је изворни код углавном доступан, одређивање сличности кода се у домену кршења лиценци примењује углавном над извршним кодом. Разлике које у извршним кодовима постоје последице су употребе различитих преводиоца над истим изворним кодом.

Један од алата који се може користити у поступку откивања кршења лиценце је BAT алат који је заснован на приступу описаном у раду [10]. Приступ користи три технике за ублажавање негативних ефеката потенцијалних разлика између кодова који се пореде. Прва техника прикупља стринг литерале који се појављују у коду који се пореди. Након тога, покушава да пронађе исте литерале у коду за који се сумња да крши лиценцу. Друга техника претпоставља да ће алгоритам компресије података успети да компримује боље два кода заједно ако међу тим кодовима постоје исте секвенце инструкција. Успех се мери односом између величине архиве, која се састоји од два кода, и укупне величине архива које се појединачно састоје од само једног од два кода које се пореде. Што је однос мањи, то се очекује већа сличност између упоређених кодова. Трећа техника се заснива на израчунавању бинарних разлика између кодова. Што су разлике мање, вероватноћа да посматрани код крши лиценцу је већа. Алат BAT користи се за откривање да ли посматрани код крши лиценцу неког од кодова из репозиторијума, а за ту сврху користи само прву технику.

C. Откривање злонамерног кода

Злонамерни код је сваки код који има могућност да оштети било који рачунарски систем [4]. Количина злонамерног кода се сваке године све брже повећава и представља озбиљну безбедносну претњу. Отуда је откривање злонамерног кода критична тема у рачунарској безбедности. У оквиру комерцијалних антивирусних програма откривање злонамерног кода је засновано на поређењима отисака метода са познатим отисцима метода. Недостатак овог начина откривања злонамерног кода је да не успева да открије нове варијације већ познатог злонамерног кода. У циљу превазилажења тог недостатка може се употребити одређивање сличности злонамерног кода са циљем откривања дела кода који показује слично понашање као што је понашање које има код из већ познате колекције злонамерног кода.

Један од алата који се може користити у поступку откивања злонамерног кода који користи одређивање сличност кодова је алат који упоређује секвенце кодова операција [4]. Током поређења посматрају се низови кодова операција фиксних дужина и узима се у обзир да различити кодови операција имају различиту релевантност током поређења. Код овог алата се најпре обавља анализа великог броја злонамерног кода и регуларног кода и утврђује се релевантност кодова операције. Затим се израчунавају фреквенције појављивања свих секвенци изабране дужине у кодовима који се упоређују. За сваки од кодова формира се вектор чије су компоненте бројеви појављивања појединачних секвенци. Свака од компоненти вектора се затим множи са производом релевантности свих кодова операција који се појављују у посматраној секвенци како би се елиминисао шум који уноси ирелевантан код. На крају сличност између кодова који се пореде се израчунава коришћењем косинусне сличности ових вектора. Приступ такође предлаже комбинацију добијених резултата за неколико различитих дужина посматраних секвенци.

 ISBN 978-86-7466-930-3

D. Откривање рањивости кода

У домену рањивости софтверског кода могу се разматрати анализа рањивости и откривање рањивости. Анализа рањивости има за циљ да формалним методама потврди или оповргне хипотезу да је софтвер рањив. Приступи анализи рањивости се могу класификовати у три категорије: статичка анализа, динамичка анализа и хибридна анализа кода. Откривање рањивости има за циљ да мање формалним поступцима лоцира конкретну рањивост у коду. У овој области постоји више различитих приступа који између осталог обухватају: тестове пенетрације софтвера, насумично тестирање, и статичку анализу токова података [11]. За разлику од претходно разматраних домена у овом домену се одређивање сличности софтверског кода користи за откривања разлика између две различите верзије истог кода.

Један од алата који се може користити за потребе откривања рањивости је алат који покушава да упари делове кода односно процедура које су скоро идентичне [12]. Први предуслов за упаривање процедура је да су идентичне према свим датим критеријумима (тзв. селекторима): броју основних блокова, броју ивица у контролном графу тока и броју позваних потпрограма. Други предуслов за упаривање је да не постоји друга процедура која је идентична са процедурама које се пореде на основу коришћених критеријумима. Да би се смањило ограничење другог предуслова у свим корацима алгоритма, посматрају се подскупови процедура из кодова који се пореде а који су дати у бинарном облику. Приликом формирања првих парова, подскупови се формирају издвајањем процедура које задовољавају неку карактеристику. Неке од карактеристика које се користе су број улазних и излазних грана процедура у графу позива, исти називи процедура, референце на исте стрингове и број пута када су се неке од инструкција појавиле. Када даље упаривање по датим карактеристикама више није могуће, формирају се нови подскупови процедура које се позивају из упарених процедура. Подскупове такође формирају процедуре које позивају упарене процедуре. Алгоритам се понавља за сваке две упарене процедуре све до тренутка када даље упаривање више није могуће. Унутар упарених процедура врши се даље упаривање основних блокова и инструкција.

III. Технике утврђивања сличности кода

У овој глави ће бити описане најзаступљеније технике утврђивања сличности софтверског кода описане у прегледним радовима [7], [13], [14], [15], [16], [17]. За сваку од техника биће наведен кратак опис, применљивост, могућности проширења, као и на које типове софтверских клонова се најчешће примењује. Такође, биће наведен и угледни примерак алата и описане његов начин функционисања за сваку од техника. Поред техника које су описане у наставку постоје и хибридне технике код којих се може јавити синергистички ефекат тако да могу детектовати додатне типове клонова у поређењу са типовима клонова који се могу детектовати било којом од коришћених техника детекције одвојено.

A. Технике засноване на поређењу текста

Технике засноване на поређењу текста посматрају секвенцу линија изворног кода. Како би се пронашла секвенца истоветних линија, стрингова или лексема пореде се делови два изворна кода или њихови отисци. Када се у датим деловима кода открије да су поједини делови слични они се проглашавају за клонове одређене класе. Ове технике се углавном користе за откривање клонова код виших програмских језика и развијени алати често подржавају више од једног програмског језика. У случају да их је потребно проширити тако да подрже неки нови програмски језик или није потребно ништа додатно имплементирати или је потребно имплементирати лексички анализатор. Ова техника се углавном може применити за откривање клонова типа 1 и типа 3, а може се применити и за откривање клонова типа 2. Ова техника се у имплементацијама показала као техника средње сложености.

Један од алата који користи технику засновану на поређењу текста је SimCad алат [18]. Овај алат подржава више програмских језика и то: C, C#, Java, Python. Процес откривања клонова се заснива на техникама откривања скривеног знања и рударења података и користи алгоритам за груписање података као и претрагу података засновану на вишенивојским индексима. Овај алат извршава три фазе обраде: прелиминарну обраду, откривање клонова и генерисање резултата. У фази прелиминарне обраде користећи Simhash алгоритам се генеришу отисци кода, након чега се обавља индексирање формирањем вишенивојски индекси за потребе брже претраге. У другој фази се обавља откривање клонова тако што се фрагменти кода групишу у кластере користећи Хемингово растојање између генерисаних отисака који одговарају тим фрагментима кода. Парови фрагмената који не прелазе одговарајући ниво сличности бивају елиминисани из кластера, а такође мора постојати и одређен број фрагмената кода у кластеру. У трећој фази се врши чишћење добијених резултата као и њихов приказ у одговарајућем формату.

B. Технике засноване на поређењу токена

Технике засноване на поређењу токена посматрају секвенцу токена издвојених из изворног кода. Издвајање токена се обавља у поступку лексичке анализе изворног кода. Секвенца токена се формира као скуп токена на одређеном нивоу гранулације. Срж ове технике представља поређење токена који припадају суфиксним стаблима или суфиксним низовима састављених од секвенци токена. Ова техника откривања користи посебан објекат који представља апстракцију конкретних вредности идентификатора и литерала и који води рачуна о очувању њиховог међусобног редоследа. Ове технике се углавном користе за откривање клонова код виших

програмских језика, али је за разлику од техника заснованих на поређењу текста зависност од програмског језика већа. У случају да је потребно проширити их подршком за нови програмски језик неопходно је имплементирати лексички анализатор. Ова техника се углавном може применити за препознавање клонова типа 1, 2 и 3, и представља једну од најцитиранијих техника за одређивање сличности. Ова техника се у имплементацијама показала као техника мање сложености.

Један од алата који користи технику засновану на поређењу текста је CCFinder алат [19]. Овај алат подржава више програмских језика и то: C/C++, C#, Cobol, Java, VB. Обрада коју спроводи овај алат се извршава у четири фазе: лексичка анализа, трансформација међурезултата, одређивање сличности и форматирање добијених резултата. У фази лексичке анализе се свака линија изворног кода дели у низ токена у складу са лексичким правилима датог програмског језика. У другој фази се обавља трансформација добијених низова токена користећи правила трансформације и правила замене одређених типова токена. У трећој фази се обавља упоређивање свих подстрингова како би се идентификовали парови клонова. На крају, у четвртој фази, се препознати клонови пресликавају на линије изворног кода из кога потичу.

C. Технике засноване на метрикама

Технике засноване на метрикама посматрају карактеристике изворног програма издвојене користећи скуп метрика. Издвајање карактеристика се обавља полазећи од кода који је трансформисан у одговарајућу структуру. Метрике се могу израчунавати на основу имена, размештаја елемента, израза, контроле токе функција, и сличних елемената структуре кода. Одређивање сличности се обавља израчунавањем удаљености између одговарајућих чланова у формираном метричком простору. Ове технике се углавном користе за откривање клонова код виших програмских језика и зависност од програмског језика је велика, али се такође могу примењивати и код нижих програмских језика. У случају да је потребно проширити их подршком за нови програмски језик неопходно је имплементирати не само лексички анализатор, већ и одговарајући парсер. Техника се може применити за препознавање свих типова клонова. Ова техника се у имплементацијама показала као техника средње сложености.

Један од алата који користи технику засновану на метрикама је CLAN алат [20]. Овај алат подржава програмске језике C/C++. Обрада коју спроводи овај алат се извршава у четири фазе: препроцесирање директива, парисирање и идентификација фрагмената, екстракција метрика и идентификација клонова. Како је алат намењен језицима C/C++ у првој фази се обавља препроцесирање директива датог језика како би се добио изворни код који се даље може обрађивати. У другој фази се обавља екстракција декларација и дефиниција самих функција користећи наменски парсер. У трећих фази се издвајају метрике коју укључују бројање функција, локалних променљивих, дељених и глобалних променљивих, параметара, исказа скокова и петљи. У четвртој фази се обавља идентификација клонова у поступку квантизација метрика коришћењем прагова за елиминацију шума и спектралне анализе резултата.

D. Технике засноване на апстрактним синтаксним стаблима

Технике засноване на апстрактним синтаксним стаблима трансформишу изворни код у структуру стабла које се касније може упоређивати. За поређење стабала, или њихових подстабала, се може користити више различитих метода које укључују хеширање, трансформацију у префиксна стабла, одређивање најдуже заједничке секвенце употребом динамичког програмирања. Ове технике се углавном користе за откривање клонова код виших програмских језика и зависност од програмског језика је велика, али се такође могу примењивати и код нижих програмских језика. У случају да је потребно проширити их подршком за нови програмски језик неопходно је имплементирати одговарајући парсер. Ова техника се углавном може применити за препознавање клонова типа 1, 2 и 3. Ова техника се у имплементацијама показала као техника средње сложености.

Један од алата који користи технику засновану на метрикама је DECKARD алат [21]. Овај алат подржава програмске језике: C, Java, Php. Обрада коју спроводи овај алат се извршава у пет фаза: генерисање парсера, формирање стабла, генерисање вектора, кластеровање вектора и додатна обрада. У првој фази се на основу формалне граматике језика генерише парсер који се користи и даљој обради. У другој фази се на основу генерисаног парсера и улазног изворног кода формира апстрактно синтаксо стабло које ће се даље обрађивати. У

 ISBN 978-86-7466-930-3

трећој фази се обрађује синтаксно стабло како би се формирали вектори карактеристика фиксне дужине. У овој фази се додатно може обавити и спајање делова који имају заједничко подстабло. У четвртој фази се обавља груписање вектора у кластере користећи еуклидско растојање са циљем одређивања клонова. На крају се као додатна, пета, фаза обавља додатна обрада како би се користећи одређене хеуристике елиминисали погрешно идентификовани клонови.

E. Технике засноване на коришћењу графа зависности

Технике засноване на коришћењу графа зависности које постоје у графу тока контроле и у графу тока података. Графовска репрезентација изворног кода се дели на мање делове у зависности од понашања фрагмента изворног кода. За деобу и поређење се може користити неки од постојећих алгоритама за рад са подстринговима и откривање сличности. Ове технике се углавном користе за откривање клонова код виших програмских језика и зависност од програмског језика је велика. У случају да је потребно проширити их подршком за нови програмски језик неопходно је имплементирати одговарајући парсер. Ова техника се, као и рад са метрикама, може применити за препознавање свих типова клонова. Ова техника се у имплементацијама показала као техника велике сложености.

Један од алата који користи технику засновану на коришћењу графа зависности је PDG-DUP алат [22]. Овај алат подржава програмске језике C/C++. Обрада коју спроводи овај алат се извршава у четири фаза: формирање графа зависности, проналажење парова клонова, уклањање обухваћених клонова и груписање клонова у веће групе. У првој фази се формира граф зависности код кога чворови представљају наредбе програма и предикате, а ивице представљају зависности података и контроле. Друга фаза се обавља у неколико корака. На почетку се обавља деоба свих чворова графа зависности у класе еквиваленције на основу синтаксне структуре исказа и предиката који ти чворови представљају, занемарујући имена променљивих и литерале. У наредном кораку се обавља најбитнији део, срж, алгоритма који проналази изоморфне подграфове коришћењем технике одсецања уназад (*backward slicing*) која датом програмском сегменту додаје претходни повезани део. Поред повратног одсецања користи се и техника одсецања унапред која додаје наредни повезани део. У трећој фази се обавља уклањање свих парова клонова који су већ садржани у неким другим паровима клонова идентификованим у претходном кораку. У четвртој фази се обавља груписање идентификованих парова у веће групе користећи особину транзитивности.

IV. Доприноси утврђивању сличности кода

Откривање неовлашћеног коришћења софтверске библиотеке је проблем детекције клонова који у случају комерцијалних производа има додатну сложеност због чињенице да је код доступан само у бинарном облику. Циљ аутора је био да предложи приступ за процену нивоа сличности између процедура који потичу из различитих бинарних кодова. Основна претпоставка у истраживањима је била да клонови у бинарним кодовима потичу од употребе заједничке софтверске библиотеке, односно истог изворног кода, која се може преводити користећи различите алате. За потребе истраживања бинарни код је дисасемблиран, а за потребе коришћења других алата и декомпајлиран. Детаљан преглед различитих приступа у препознавању сличности бинарног кода дат је у прегледном раду [17] док ће у овој глави бити описана истраживања аутора овога рада спроведена стремећи ка наведеном циљу у области утврђивања сличности бинарног кода. За свако од спроведених истраживања биће наведен кратак опис истраживања, кораци предложеног приступа а потом дати и остварени резултати. Преглед основних карактеристика појединих истраживања је дат у табели 3.

A. Утврђивање сличности бинарног кода

Прво истраживање је имало за циљ да утврди применљивост постојећих техника и алата описаних у претходним поглављима за утврђивање сличности бинарног кода [6]. Имајући у виду да су постојеће технике и алати превасходно намењени раду са вишим програмским језицима у овом истраживању су нека одабрана решења прилагођења раду са бинарним кодом ради евалуације. У истраживању је такође предложен нови приступ који је заснован на метрикама.

Предложени приступ за процену нивоа сличности између две процедуре које се пореде је процес који се обавља у четири фазе: издвајање метрика, упоређивање метрика, трансформације метрика, израчунавање нивоа сличности. У првој фази се спроводи статичка анализа процедура и издвајање метрика тако да се за сваку процедуру формира вектор метрика, при чему елементи тог вектора могу бити скаларне или векторске вредности. Ове метрике укључују одређивање броја и учестаности свих инструкција, појединих типова инструкција (аритметичких, логичких и трансфер података), скокова (условних и безусловних скокова, позива процедура и петљи) и које се представљају скаларним вредностима. Поред скаларних вредности метрика коришћене су и нескаларне, векторске, метрике која укључују бројање сваке појединачне инструкције, сваке адресе доскока, и сваке адресе позива процедуре. У другој фази се обавља поређење сваке о издвојених метрика користећи одговарајући функције за поређење. У трећој фази се обавља трансформација и нормализација добијених резултата поређења на основу претходног знања. У последњој, четвртој, фази комбинују се одабране метрике користећи одговарајућу формулу за формирање једне вредности која представља сличност између две процедуре.

Резултати истраживања су дали одговоре на три истраживачка питања и довела до следећих закључака. Прво питање се односило на разматрање додавања нове

 ISBN 978-86-7466-930-3

ТАБЕЛА 3. ПРЕГЛЕД РЕЗУЛТАТА ИСТРАЖИВАЊА

Приступ	Метрике	Архитектура	Мера сличности	Одзив
1.	Скаларна(13) векторска(6)	ARM	Формуле (7)	35,8%-73,1%
2.	Скаларна(3) векторска(1)	x86	Тежинска сума	37,6%-63.0%
3.	Скаларна(13) векторска(6)	ARM	Формуле (7)	52,7%-81,8%
4.	Векторска(1)	ARM	Неуралнa мрежа	49,2%-82,8%
5.	Векторска(1)	ARM	Левенштајнова удаљеност	57,9%-88,9%

метрике у скуп метрика предложних у постојећим решењима и утврђивање доприноса приликом рангирања процедура. Резултати спроведеног експеримента показују да увођење нових метрика доприноси рангирању процедура за све посматране позиције приликом рангирања. Штавише, са новим метрикама предложени приступ је постигао 1,44 пута бољи одзив (*recall*) за прву посматрану позицију у поређењу са случајем када се користе само постојеће метрике. Друго питање се односило на проверу да ли рангирање процедура обављено предложеним приступом зависи од преводиоца, нивоа оптимизације програма и контекста проблема. Према резултатима експеримента утврђено је да постоји значајан утицај изабраног преводиоца на рангирање процедура који је остварен у предложеном приступу. Међутим, контекст проблема и опције превођења имају мањи утицај на резултате. Треће питање се односило на проверу да ли предложени приступ постиже боље резултате од постојећих алата у смислу прецизности, одзива и F2 мере. Одговарајући експеримент је показао да предложени приступ постиже други најбољи резултат у смислу прецизности и најбољи резултат у смислу одзива. У случају посматрања F2 мере, предложени приступ постиже резултате боље од осталих алата када се посматра до првих шест позиција, док се максимална вредност постиже када се посматрају само прве две позиције при рангирању.

B. Утицај архитектуре рачунара на утврђивање сличности бинарног кода

Друго истраживање је имало за циљ да утврди применљивост приступа предложеног у првом истраживању на другу архитектуру [23]. С обзиром да је у првом истраживању коришћена ARM архитектура, за потребе другог истраживања је коришћена x86 архитектура. Имајући у виду разлике у архитектури било је потребно поновно креирање скупа података на коме ће се обавити тестирање. Овом приликом је коришћен сличан скуп програмских преводилаца, али не потпуно исти, јер ниси сви преводиоци подржавали обе архитектуре.

У оквиру другог истраживања је предложен нови приступ који представља подскуп приступа предложеног у првом истраживању. У овом новом приступу број различитих корака који су спровођени током испитивања у појединим фазама је редукован, и такође је редукован број фаза. Предложени приступ уместо четири фазе има само три фазе. У првој фази је смањен број издвојених метрика, тако да су коришћене метрике које одређују дужину процедуре, број скокова, број позиваних процедура и броје инструкција. Иако је смањен број метрика сачувано је постојање и скаларних и векторских метрика. У другој фази се обавља поређење сваке о издвојених метрика користећи одговарајући функције за поређење, на истоветан начин као и првом истраживању. Трећа фаза се може посматрати као обједињење треће и четврте фазе из првог истраживања и у њој се израчунава сличности користећи хармонијску средину, тежинску суму и наивни Бајес.

Резултати за x86 архитектуру показују да је најбољи одзив постигнут користећи приступ заснованим на тежинској суми. Одзив се креће од 37% до 63% када се посматра прва односно првих десет позиција. Поређење резултата остварених на x86 и ARM архитектурама показује да су постигнућа добијена за првих десет позиција на обе архитектуре упоредива.

Ово показује да се технике поређења бинарних кодова у извесној мери могу користити за поређење кодова који су преведени за исту архитектуру рачунара. Истраживања која су спровели други истраживачи након овог истраживања, почев од 2016. године а која се баве поређењем сличностима бинарног кода између архитектура рачунара [17], су показала да се технике за поређење могу примењивати не само на једној архитектури рачунара, већ се могу примењивати и на кодове код којих су једни преведени за једну архитектуру рачунара а други за други архитектуру рачунара. Овиме се проширује оно што је другим истраживањем утврђено а то је да се технике поређења бинарних кодова у извесној мери могу посматрати независно од архитектуре рачунара.

C. Утицај трансформација преводиоца на утврђивање сличности бинарног кода

Као што је претходно описано, резултати првог истраживања су показали да постоји значајан утицај изабраног преводиоца на рангирање процедура. Из тог разлога треће истраживање је имало за циљ да детаљније испита утицај трансформација програмског преводиоца на утврђивање сличности бинарног кода [24]. У истраживању је такође предложен и нови приступ који дефинише нове технике за смањење утицаја процеса превођења на перформансе поступка утврђивања сличности бинарног кода.

У односу на приступ предложен у првом истраживању у овом приступу је у првој фази, у којој се спроводи

 ISBN 978-86-7466-930-3

статичка анализа, додато пет техника које се спроводе као независни кораци. Прва техника предлаже игнорисање инструкција за рад са стеком. Ова техника је уведена је уведена зато што је приликом анализе уочено да различити преводиоци на различите начине интерагују са стеком и да инструкције које том приликом користе не носе информације о семантици кода. Друга техника предлаже игнорисање инструкција за трансфер података. Ова техника је уведена из сличног разлога као и прва техника јер различити преводиоци користе различите приступе приликом алокације регистара и трансфера између њих или меморијске локације на којој се неки податак налази. Трећа техника предлаже измену неких од разматраних векторских метрика. Овде се уместо посматрања статистике о појединим инструкцијама посматра статистика о секвенцама инструкција одређене дужине. Четврта техника предлаже уграђивање позваних процедура у оквиру позивајуће процедуре. Ова техника је уведена како би се елиминисала разлика између бинарних кодова која може настати усред одлуке преводиоца да обави аутоматско уграђивање у време превођења. Пета техника предлаже увођење прага сличности између процедура. Ова техника је уведена како би смањила број лажно позитивно идентификованих клонова, с обзиром да преводиоци могу различиту логику да имплементирају користећи сличне инструкције.

Резултати истраживања су дали одговоре на три истраживачка питања и довела до следећих закључака. Прво питање се односило на одређивање постигнућа постојећих решења зависе од тога да ли се користи произвољни преводилац и произвољни ниво оптимизације. Према резултатима експеримента утврђено је да постоји значајан утицај изабраног преводиоца на рангирање процедура, и за разлику од првог истраживања овом приликом су тачно измерени утицаји који имају промена преводиоца и промена нивоа оптимизације. Друго питање се односило на проверу да ли додавање сваке од предложених техника једне по једне основном приступу повећава постигнуће ако се упоређене процедуре преводе са произвољним преводиоцима и нивоима оптимизације. Према резултатима експеримента утврђено је да све технике, изузев друге технике које филтрира инструкције трансфера података, доприносе побољшању резултата утврђивања сличности. Треће питање се односило на проверу да ли додавање свих предложених техника заједно основном приступу повећава постигнуће и да ли резултира синергистичким ефектима ако се упоређене процедуре преводе са произвољним преводиоцима и нивоима оптимизације. Резултати експеримента су показали да додавање свих техника има синергистички ефекат који доноси 6,7% до 9,3% повећања одзива за првих пет посматраних позиција приликом рангирања.

D. Коришћење неуралних мрежа за утврђивање сличности бинарног кода

Четврто истраживање је имало за циљ да испита могућност употребе неуралних мрежа за утврђивање сличности бинарног кода [25]. За разлику од приступа описаном у претходним истраживањима који се заснивају на посматрању метрика у овом истраживању су посматране само инструкције. За потребе евалуације је искоришћен исти скуп података који је коришћен у првом и трећем истраживању.

Предложени приступ обавља поређење процедура у пет фаза: издвајање инструкција, кодирање инструкција, коришћење једног првог слоја неуралне мреже, коришћење другог слоја неураллне мреже, поређење. У првој фази се спроводи издвајање токена који одговарају појединим инструкцијама. У другој фази се обавља кодирање инструкција у целобројну вредност. У поступку кодирања су примењене три технике: лексикографско кодирање, семантичко мапирање и мапирање засновано на класи. У трећој фази се полазећи од секвенце кодираних инструкција формирана секвенца карактеристика исте дужине користећи неуралне мреже. Коришћена је Дуготрајно-краткотрајна меморија LSTM (*Long Short-Term Memory*). У четвртој фази се обавља издвајање одређеног броја карактеристика користећи неуралну мрежу која занемарује одређен број улазних карактеристика DNN (*Dropout Neural Network*). У последњој, петој, фази комбинују се рачунање сличности између две процедуре користећи издвојене карактеристике и поступак агрегације и нормализације.

Резултати истраживања су дали одговоре на три истраживачка питања и довели до следећих закључака. Прво питање се односило на разматрање какве резултате даје предложени поступак у односу на поређење процедура само по њиховој дужини. Резултати спроведеног експеримента показују да предложени приступ даје бољи одзив на свакој посматраној позицији. Друго питање се односило на проверу да ли рангирање процедура обављено предложеним приступом зависи од преводиоца. Према резултатима експеримента утврђено је да постоји неки утицај изабраног преводиоца на рангирање процедура од 0,55% до 1,64% када се посматра одзив. Овај утицај је знатно мањи у односу утицај који је присутан код првог и трећег приступа. Треће питање се односило на проверу да ли предложени приступ постиже боље резултате од постојећих алата у смислу одзива. Одговарајући експеримент је показао да предложени приступ постиже незнатно боље резултате, просечно 1,14%. Овај приступ је дао бољи одзив на вишим позицијама, док у првих 9 позиција даје лошије резултате у односу на трећи предложени приступ.

E. Коришћење секвенци операција за утврђивање сличности бинарног кода

У првом истраживању је примећено да метрика која узима у разматрање секвенцу инструкција највише доприноси успешном одређивању сличности. Из тог разлога пето истраживање је имало за циљ да детаљније испита могућности те метрике и да је учини робуснијом на промене које чини преводилац. Сходно томе

 ISBN 978-86-7466-930-3

предложен је нови приступ заснован на испитивању секвенце кодова операција [26].

Предложени приступ обавља поређење процедура у четири фаза: издвајање инструкција, кодирање инструкција, одређивање Левенштајнове удаљености, рачунање релативне Левенштајнове удаљености. У првој фази се спроводи издвајање токена који одговарају појединим инструкцијама. У другој фази се обавља кодирање инструкција у целобројну вредност на истоветан начин ономе описаном у четвртом приступу. У трећој фази се обавља рачунање Левенштајнове удаљености користећи *Needleman–Wunsch* алгоритам. У последњој, четвртој, фази се коришћењем релативне Левенштајнове удаљености добија сличности између две процедуре.

Ово истраживање је требало да да одговор на једно истраживачко питање о томе какве резултате даје предложени приступ у односу на остале приступе које су аутори развили за ARM архитектуру. Резултати спроведеног експеримента показују да предложени приступ даје бољи одзив на свакој посматраној позицији од свих претходно разматраних приступа. У односу на приступ из четвртог истраживања даје од 3,59% до 9,45% бољи одзив, као и од 0,17% до 4,73% бољу прецизност када се посматрају првих 20 позиција. У односу на приступ из трећег истраживања даје од 3,45% до 9,53% бољи одзив, као и од 0,45% до 1,72% бољу прецизност када се посматрају првих 20 позиција.

V. Закључак

Утврђивање сличности кода представља област истраживања са дугом историјом, доста запажених резултата али и перспективом за даљи развој у будућности. Овај рад је имао за циљ да ову област приближи истраживачима и да да осврт на истраживања која су аутори спровели. У раду је најпре објашњен значај и домени у којима се резултати истраживања примењују. Након тога је дат сажет преглед најважнијих техника у овој области. На крају су изложена истраживања и резултати до којих су аутори дошли у претходним годинама.

Захвалница

Рад на овом пројекту је делимично био финансиран од стране Министарства просвете, науке и технолошког развоја Републике Србије (2022/200103), као и Фонда за науку Републике Србије (АВАНТЕС).

Softversko rešenje za akviziciju i vizuelizaciju moždanih talasa

Ivan Tot, Boriša Jovanović, Dušan Bogićević, Tamara Gajić, Jordan Atanasijević

***A stra t*— današnjem društvu veoma značajnu ulogu imaju sistemi za identifikaciju korisnika. Složeni bezbednosni zahtevi naterali su eksperte da istraže načine na oje se biometrijs i podaci mogu iskoristiti u utvrđivanju identiteta korisnika. U ovom radu je prikazano softversko rešenje za akviziciju i vizuelizaciju moždanih talasa (EEG) kao biometrijskih podata a.**

***Ključne reči*—biometrija; moždani talasi; akvizicija; vizuelizacija**

I. UVOD

Kontrola pristupa informacionim sistemima predstavlja jedan od najznačajnijih aspekata zaštite, posebno kod sistema koji sadrže bezbednosno osetljive podatke. Ona onemogućava osobama koja nemaju pravo da pristupe nekom sistemu i samim tim zloupotrebe podatke koje se nalaze u njemu.

Da bi se došlo do faze identifikacije korisnika, u smislu zaštite informaciono-komunikacionih sistema, neophodno je da se putem biometrijskih senzora prikupe biometrijski podaci koji će se uporediti sa već postojećim podacima registrovanim u samom sistemu [1] [2] [3]. Spajanje više biometrijskih podataka smanjuje stepen sistemske greške prilikom identifikacije korisnika. Samo prikupljanje podataka sa više biometrijskih senzora stvara kompletniju sliku o korisniku. Metod fuzije biometrijskih podataka uključuje sekvencijalnu obradu biometrijskih modaliteta dok se ne dobije prihvatljivo podudaranje u slučaju identifikacije korisnika [4] [5].

Ovaj rad daje prikaz softverskog rešenja koje omogućava akviziciju i vizuelizaciju moždanih talasa (EEG) koje predstavlja prvi korak u realizaciji rešenja za autentifikaciju korisnika.

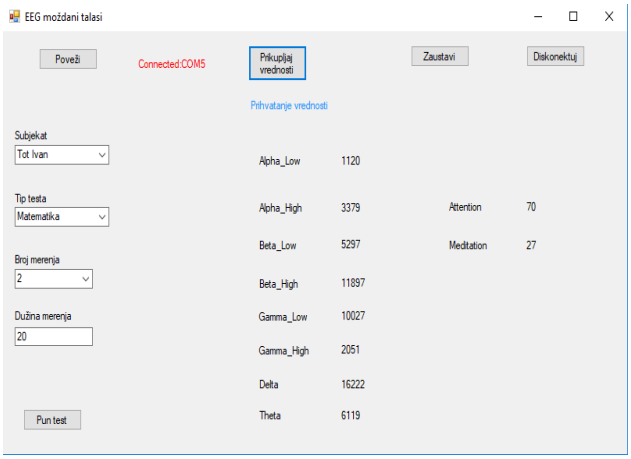
.

II. PRIMENJENI HARDVERSKI UREĐAJ

Akvizicija predstavlja prikupljanje podataka iz spoljašnje sredine u određeni električni uređaj, to jest senzor. Kada se govori o biometrijskom podatku, onda je potreban biometrijski uređaj za akviziciju takve vrste podataka [6]. Tako prikupljeni podatak može biti upotrebljen za identifikaciju ljudi. Pojedini biometrijski podaci su jedinstveni za svaku osobu i mogu služiti za identifikaciju osoba, kako u civilnom sektoru npr. u zdravstvu, obrazovnim ustanovama, firmama, tako i u vojnim, policijskim i državnim ustanovama u cilju zaštite sopstvenih resursa. Biometrijska autentifikacija (odnosno realna autentifikacija) se koristi u informacionim tehnologijama kao oblik identifikacije korisnika i kontrole pristupa zaštićenim resursima [7].

EEG autentifikacija koristi elektrofiziološki sistem za praćenje aktivnosti mozga. Ova tehnologija je vrlo popularna i može se koristiti bez ikakvih sporednih efekata na mozak. Do sada je izvršeno nekoliko istraživanja o mogućnosti primene EEG signala za autentifikaciju korisnika [8] [9].

Postoji nekoliko komercijalnih uređaja sa različitim brojem elektroda koje se koriste za prikupljanje EEG podataka. Neki od senzora koriste suve elektrode, a neki senzori koriste mokre elektrode. Moždani režnjevi emituju EEG signale kao odgovor na različite stimulanse i mentalna stanja. Pretpostavlja se da postoji promenljiva razlika uzoraka EEG talasa dok se vizuelizuje lozinku u mirnim uslovima u odnosu na prinudu, zbog različitih mentalnih stanja, mozak proizvodi različite obrasce analognog EEG talasa [10]. Na slici 1 prikazan je uređaj koji je korišćen u ovom radu.



Sl. 1. Neuro Sky Mind Wave 2-EEG biometrijski uređaj [11]

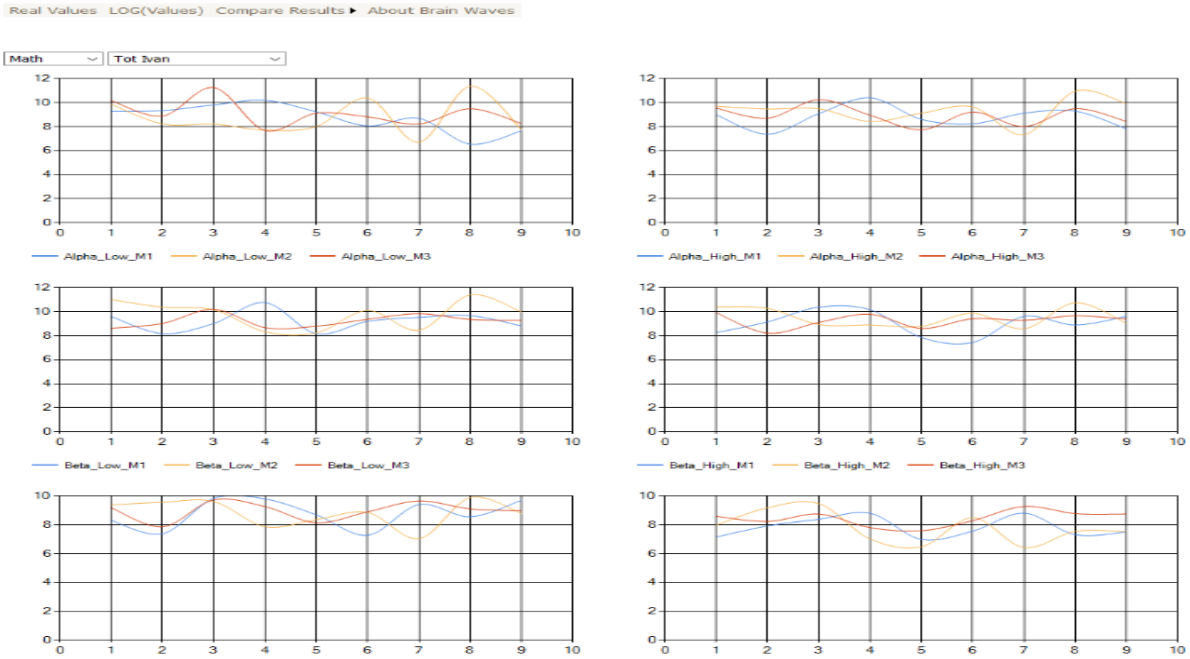
 ISBN 978-86-7466-930-3

Uređaj prikazan na slici 1 vrši merenje alfa, beta, gama, delta i teta moždanih talasa kao i trenutno stanje usredsređenosti – fokusa (attention) i opuštenosti (meditation) subjekta čiji se moždani talasi mere [12].

III. PRIKAZ SOFTVERSKOG REŠENJA

Izgled ekrana softverskog rešenja za akviziciju podataka sa senzora prikazan je na slici 2. Rešenje je razvijeno u alatu Microsoft Visual Studio 2017 korišćenjem programskog jezika C# i biblioteke ThinkGear.dll proizvođača uređaja. Sama biblioteka nudi funkcije za ostvarivanje komunikacije sa uređajem. Dalji rad je podrazumevao prihvatanje vrednosti koje dolaze sa uređaja u određenim vremenskim intervalima definisanim i samom programskom kodu softverskog rešenja. Radi usrednjavanja vrednosti korišćena je logaritamska funkcija. Tako izračunate vrednosti su čuvane u realizovanoj bazi podataka.

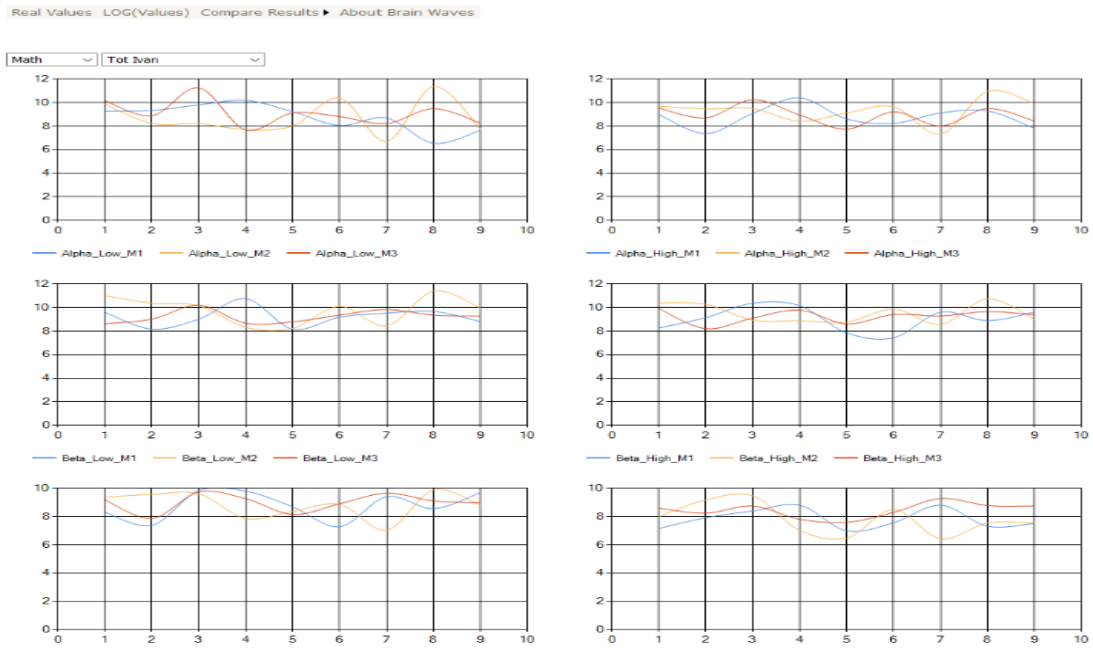
Sl. 2. Izgled ekrana za akviziciju podataka



Klikom na komandno dugme Poveži vrši se uspostavljanje bluetooth konekcije sa senzorom. Nakon uspešno ostvarene konekcije, klikom na dugme Prikupljaj vrednosti aplikacija će prihvatati vrednosti sa uređaja i prikazivati ih na ekranu. Komandno dugme Zaustavi privremeno prekida prihvatanje vrednosti sa uređaja, a komandno dugme Diskonektuj prekida konekciju sa uređajem.

Prihvaćene vrednosti mogu se čuvati u bazi podataka realizovanoj u Microsoft SQL Server Express 2014 klikom na komandno dugme Pun test svake 2 sekunde. U tom slučaju neophodno je izabrati subjekta čiji se moždani talasi mere, tip testa, broj merenja kao i zadati dužinu svakog testa u sekundama. Tip testa može biti:

1. *Opušteno* – subjekat se potpuno opusti i zatvori oči,
2. *Čitanje* – subjekat dobija tekst koji treba da čita u sebi,
3. *epe slike* – subjekat posmatra slike koje u njemu bude lepe emocije,
4. *Matematika* – subjekat dobija matematički zadatak koji treba da reši,
5. *Uznemiravajuće slike* – subjekat posmatra slike koje treba da izazovu ružne emocije (slike ratnih zločina, iskasapljenih životinja i slično).



U ovoj fazi istraživanja predviđeno je da se radi do 5 merenja svih navedenih testova u različite dane. Nad uzorkom od 60 testiranih lica (različitih polova, godina i nivoa obrazovanja) uočeno je da postoje određena poklapanja moždanih talasa naročito prilikom primene testa „Čitanje“. Takođe, uočeno je da prilikom primene testa „Uznemiravajuće slike“ značajan faktor imaju godine testiranih lica. Na mlađe osobe slike ratnih zločina slabije izazivaju ružne emocije, ali zato značajno reaguju na slike iskasapljenih životinja. U slučaju starijih osoba, reakcije su suprotne.

Za vizuelizaciju podataka razvijena ja web aplikacija u alatu Microsoft Visual Studio 2017 korišćenjem ASP.NET tehnologije. Na slikama 3 i 4 prikazane su delovi web stranica realizovane aplikacije koje omogućavaju poređenje dobijenih podataka.

Sl. 3. Web stranica za vizuelizaciju podataka za izvršena tri merenja

 ISBN 978-86-7466-930-3

Sl. 4. Poređenje moždanih talasa

Web stranica prikazana na slici 3 omogućava vizuelizaciju i poređenje podataka dobijenih iz uređaja za izabranog subjekta i izabrani tip testa. Za svako merenje se po kolonama prikazuje zbirni grafikon sa svim talasima (na x-osi su odbirci vremena, a na y-osi logaritamske vrednosti izmerenih talasa), a zatim i pojedinačni grafikon za svaki izmereni moždani talas.

Web stranica prikazana na slici 4 takođe omogućava vizuelizaciju i poređenje podataka dobijenih iz uređaja za izabranog subjekta i izabrani tip testa, ali po pojedinačnim talasima. Svaki grafikon prikazuje rezultate svih izvršenih merenja po vrstama talasa (na x-osi su odbirci vremena, a na y-osi logaritamske vrednosti izmerenih talasa).

IV. Zaključak

Bezbednost informacionih sistem je jedno od najaktuelnijih pitanja današnjice. Kontrola pristupa je pogotovo bitna jer služi da spreči korisnike koji nemaju prava da pristupe i koriste sistem. Pristup nepoželjnih korisnika je veoma opasan skoro kod svih sistema zbog postojanja velike mogućnosti zloupotrebe samog sistema i informacija koje se nalaze u njemu.

Zbog značaja utvrđivanja identiteta potrebno je stalno raditi na usavršavanju sistema za preciznu identifikaciju, odnosno na poboljšavanju njihovih performansi, bilo kroz razvoj biometrijskih uređaja, bilo kroz unapređenje metoda akvizicije biometrijskih podataka. Jedan od potencijalnih načina je i primena moždanih talasa za autentifikaciju korisnika.

Do sada su po ovom projektu razvijene dve aplikacije. Jedna za akviziciju podataka sa senzora i druga za vizuelizaciju podataka.

U daljem istraživanju planirana je detaljna analiza dobijenih podatka primenom MATLAB softverskog paketa i statističkih alata da bi se utvrdilo postojanje korelacije moždanih talasa na odgovarajući tip testa kao i testiranje značajno većeg broja lica kako bi rezultati planirane analize bili tačniji. Ukoliko bi se potvrdilo postojanje korelacije, onda bi se moždani talasi mogli koristiti pouzdano za autentifikaciju korisnika.

Zahvalnica

Rad je nastao kao rezultat rada na naučno-istraživačkom projektu “Upravljanje pristupom zaštićenim resursima računarskih mreža u Ministarstvu odbrane i Vojsci Srbije na osnovu multimodalne identifikacije korisnika”, pod brojem VATT/3/18-20, od 2018. do 2020. godine na Vojnoj akademiji Univerziteta odbrane u Beogradu.

ABSTRACT

Nowadays, user identification systems play a very important role in modern society. Complex security requirements have led experts to explore ways in which biometric data can be used to identify user identities. This paper presents a software solution for acquisition and visualization of brain waves (EEG) as biometric data.

Platforma za praćenje kvaliteta vazduha u gradu Čačak

Nikola Kukrić, Božidar Popović, Slobodan Lubura, Zorana Mandić

Elektrotehnički fakultet, Univerzitet u Istočnom Sarajevu, Istočno Sarajevo, Bosna i Hercegovina

***A stra t*—Izloženost PM2.5 česticama izdvaja se ao vodeći zdravstveni problem na globalnom nivou, a problem zagađenosti vazduha predstavlja jedan od glavnih uzro a smrtnosti na svijetu. Kako ovo predstavlja problem današnjice, zahtjevi da se mjerenje kvaliteta vazduha vrši što češće na što više lo acija, doveli su do razvoja nis obudžetnih senzora. Uz pomoć široko dostupnih senzora grade se senzorski čvorovi, koji pribavljaju podat e o trenutnim oncentracijama suspendovanih čestica, a ovi podaci roz asniju analizu dovede do asne informacije o valitetu vazduha pre o A I - indeksa zagađenosti vazduha. U ovom radu osim razvoja senzorskih čvorova, predstavljena je i realizacija jedinstvene web platforme za pri azivanje, arhiviranje i analizu kvaliteta vazduha, čime je realizovan jedinstven i potpun sistem za pri upljanje i obradu podata a o valitetu vazduha. Ia o je platforma realizovana za područje grada Čačka, gdje je izvršena integracija postojećih senzorskih čvorova sa novo realizovanim čvorovima, može biti prilagođena i drugim geografs im područjima te je široko upotrebljiva.**

***Ključne r eči*— valitet vazduha, suspendovane čestice, PM2.5, P 1**

I. Uvod

Kvalitet vazduha je jedan od vodećih problema u mnogim gradovima i ima direktan uticaj na kvalitet života. Izloženost suspendovanim česticama PM10 i PM2.5 (eng. *Particular Matter*) predstavlja jedan od vodećih uzroka smrtnosti u svijetu i prema podacima Svjetska zdravstvena organizacija (eng. *World ealth rgani ation* - WHO) na svjetskom nivou tokom godine dovede do između 4,2 i 8,9 miliona smrtnih slučajeva [1]. Suspendovane čestice su sastavni dio prašine i manje su od 10μm (PM10), odnosno 2.5μm (PM2.5) te predstavljaju smješu čađi, dima, kiseline, uz prisustvo teških metala, a izloženost PM2.5 česticama je prepoznat kao glavni globalni zdravstveni problem [2]. Podjela na osnovu izvora iz kojih potiču suspendovane čestice data je u Tabeli I, što predstavlja glavni kriterijum pri izboru lokacije senzorskih čvorova koji prate njihovu koncentraciju.

TABELA I
IZVORI PM2.5 ČESTICA [3]

Izvor	Procentualno (%)
Saobraćaj	25%
Neodređenog ljudskog porijekla	22%
Ogrjev u domaćinstvu	20%
Prirodna prašina i soli	18%
Industrijska djelatnost	15%

Dugoročnim praćenjem koncentracije suspendovanih čestica moguće je detektovati u kojim oblastima gradova je najveća koncentracija čestica te djelovati na izvore zagađenja kako bi se smanjenjem koncentracije čestica unaprijedio kvalitet života.

U gradu Čačku su ranije instalirana tri senzorska čvora za mjerenje zagađenosti vazduha, koji nisu bili povezani u jedinstvenu mrežu, niti su informacije o mjerenjima bile dostupne korisnicima tj. građanima. U pitanju su senzorski čvorovi *a is Air ink* kompanije *a is Instruments* [4]. Navedeni senzorski čvorovi mjere količine suspendovanih čestica PM1.0, PM2.5 i PM10 i u na osnovu njih izračunavaju indeks kvaliteta vazduha (eng. *Air uality Inde* - AQI).

U proteklom periodu, realizacijom projekta prekogranične saradnje „*Transport related Air Pollution and ealth impacts in the Čačak city – AI P ISCA"*, u decembru 2021. godine [5], ovi senzorski čvorovi su povezani na jedinstven server sa odgovarajućom bazom podataka gdje se čuvaju podaci o izvršenim mjerenjima kvaliteta vazduha, obezbijeđen je domen za Web aplikaciju i kreirana Web aplikacija za prezentaciju podataka. Na taj način, broj građana Čačka koji imaju pristup informacijama o kvalitetu vazduha nije ograničen.

U nastavku aktivnosti vezanih za proširenje mreže senzorskih čvorova za mjerenje kvaliteta vazduha u saradnji sa gradom Čačkom, zaključno sa 08.02.2022. godine postavljeno je osam novih senzorskih čvorova koji će biti predstavljeni u nastavku.

Grad Čačak je pokriven sa senzorskom mrežom od jedanaest senzorskih čvorova za prikupljanje podataka o koncentraciji suspendovanih čestica i pristup podacima u realnom vremenu je omogućen svima preko Web stranice https://cacak.vazduh.net.

U nastavku rada, poglavlje II, predstavljen je problem kvaliteta vazduha te standardi i referentne vrijednosti za ocjenu kvaliteta. Poglavlje III daje detaljnu analizu realizovanog senzorskog čvora, a prezentacija prikupljenih podataka je predstavljena u poglavlju IV.

II. Kvalitet Vazduha

Prema uredbi za monitoring i zahtjevima kvaliteta vazduha [6] kvalitet ambijentalnog vazduha se određuje pomoću koncentracije sumpor dioksida SO_2, azot monoksida NO i azot dioksida NO_2, ozona O_3, ugljen monoksida CO i masene koncentracije PM10 i PM2.5 čestica. Za mjerenje

 ISBN 978-86-7466-930-3

koncentracije navedenih čestica propisane su referentne metode i standardi koju su dati u Tabeli II.

TABELA II [6]
VRSTE MJERENJA I REFERENTNE METODE

Vrsta mjerenja	Metode/Specifikacije
Koncentracija sumpor dioksida SO2	EN 14212:2013 EN 14212/Cor1:2015 Ultraljubičasta fluoroscencija
Koncentracija azot monoksida NO i azot dioksida NO2	EN 14211:2013 Hemiluminiscencija
Koncentracija ozona O3	EN 14625:2013 Ultraljubičasta fotometrija
Koncentracija karbon monoksida CO	EN 14626:2013 Nedisperzivna infracrvena spektroskopija
Masena koncentracija PM10 i PM2.5	EN 12341:2015 Gravimetrijska metoda

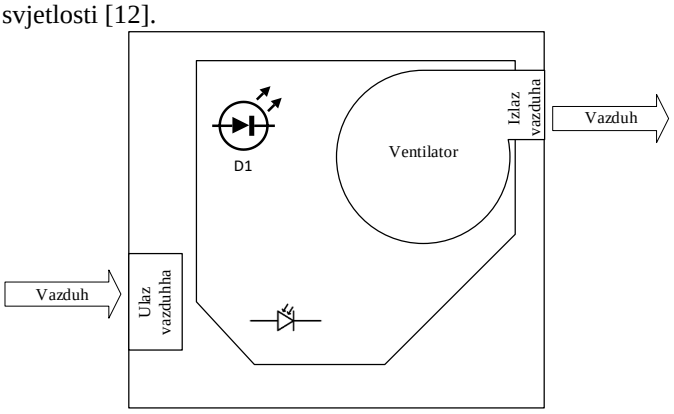
Ministarstvo zaštite životne sredine - Agencija za zaštitu životne sredine Republike Srbije je 2015 pokrenula projekat „Objedinjeni prikaz automatskog monitoringa kvaliteta vazduha u Republici Srbiji“ gdje se prate navedeni parametri [7]. Za ocjenu kvaliteta vazduha korišten je indeks kvaliteta vazduha EAQI (eng. *European Air uality Inde*), koji je 2017. godine usvojila Evropska agencije za životnu sredinu (eng. *European En ironment Agency*) zajedno sa Upravom za ekologiju Evropske komsije (*European Commission's irectorate General for En ironment*). Pomenuti indeks kvaliteta vazduha prikazan je u Tabeli III.

TABELA III
SKALA ZA OCJENU KVALITETA VAZDUHA

Oznaka	Zagađivač (satna koncentracija u µg/m^3)	
	PM10	PM2.5
Odličan	0 – 25	0 – 15
Dobar	25 – 50	15 – 30
Prihvatljiv	50 – 90	30 – 55
Zagađen	90 – 180	55 – 110
Izuzetno zagađen	>180	>110

S obzirom na to da je raspoređivanje i postavljanje akreditovanih stanica sa referentnim metodama za praćenje navedenih parametara vazduha veoma skupo te da najveći problem u gradovima uglavnom predstavljaju PM10 i PM2.5 čestice odlučeno je da se realizuju senzorski čvorovi za mjerenje PM10 i PM2.5 čestica. Za senzore koji prate koncentraciju suspendovanih čestica korišćeni su nisko budžetni (eng. *low ost*) laserski senzori.

Prema standardu EN 12341:2015 PM česticu su „čestice suspendovane u zraku koje su dovoljno male da mogu proći kroz otvor za odabir veličine sa 50% efikasnosti pri aerodinamičkom promjeru x µm.“ [8]. Referentna metoda je gravimetrijska motoda koja podrazumijeva prikupljanje prašine na uzorku u periodu od 24h te određivanje koncentracije u opsegu od 1 – 150 µg/m^3 za PM10 i 1 – 120 µg/m^3 za PM2.5 čestice.



III. SENZORSKI ČVOR

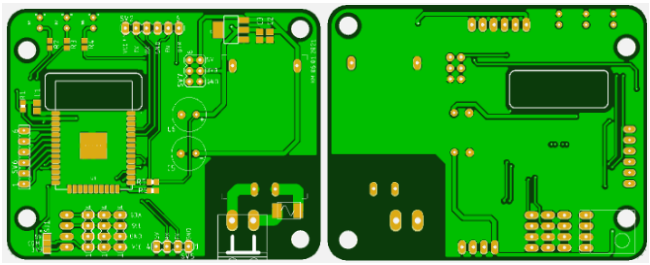
Tokom istraživanje korišćena su tri niskobudžetna laserska senzora i to: SDS011 od proizvođača *No a Fitness Co*., PMS5003 i PMS7003 od proizvođača *Beijing Plantower Co., td, China*. Pregled karakteristika senzora dat je u Tabeli IV.

TABELA IV
PREGLED KARAKTERISTIKA POJEDINIH NISKOBUDŽETNIH LASERSKIH SENZORA SUSPENDOVANIH ČESTICA [9,10,11]

Karakteristika	Senzori		
	SDS011	PMS5003	PM7003
Dimenzije (mm)	71x70x23	50x38x21	48x37x20
Napajanje (V)	4.7~5.3	4.5~5.5	4.5~5.5
Potrošnja (mA)	70 ± 10	<100	<100
Temperaturni opseg (°C)	-20 ~ +60	-40 ~ +80	-40 ~ +80
Opseg mjerenja čestica (µg/m^3)	0 – 999.9	0 – 500 efktivno, >1000 maks	0 – 500 efktivno, >1000 maks

Navedeni optički senzori mjere intenzitet svjetlosti koja se raspršuje pod uticajem prašine koja se uvlači u senzor. Senzori se sastoje od svjetlosne diode (eng. *ight Emitting iode* – LED), fotodiode, ventilatora koji uvlači vazduh sa česticama prašine i većeg broja sočiva za fokusiranje snopa svjetlosti [12].

Sl. 1. Struktura optičkog senzora suspendovanih čestica



Prilikom realizacije senzorskog kao najbolji omjer kvalitet/cijena odabran je senzor PMS7003.

Senzorski čvor se sastoji od mikrokontrolerske jedinice, senzora i jedinice za napajanje. Mikrokontroler korišćen u realizaciji senzorskog čvora je ESP-WROOM-32, koji

 ISBN 978-86-7466-930-3

pomoću *A T* modula komunicira sa PMS7003 senzorom i pomoću *Wi-Fi* modula prenosi očitane podataka sa senzora brzinom do 150 Mbps, sa snagom signala od 20 dB. Za napajanje je korišćen Hi-Link naponski modul. Navedeni modul ima naponsku konverziju sa 90-245 VAC na 5VDC sa maksimalnom izlaznom snagom od 3W [13]. Napon od 5VDC je potreban za napajanje senzora PMS7003. S obzirom da je za napajanje mikrokontrolera potrebno 3.3V korišćen je naponski regulator AMS1117-3.3V koji za ulazni napon u opsegu 4.8VDC – 6.5VDC daje na izlazu 3.3VDC.

Za crtanje šeme i realizaciju štampane ploče korišćeno je programsko okruženje *Eagle*. Izgled štampane ploče senzorskog čvora sa prednje i zadnje strane prikazan je na Sl. 2.

Sl. 2. Izgled štampane ploče senzorskog čvora

Tokom realizacije senzorskog čvora realizovano je kućište u kojem se smještaju pomenute elektronske komponente, koja treba da omogući protok vazduha prema senzoru PMS7003 te da elektronske komponente budu zaštićene od vremenskih uslova. Izgled senzorskog čvora i sastavljene ploče sa senzorom PM10, PM2.5 prikazani su na Sl. 3.

Sl. 3. Izgled senzorskog čvora i sastavljene ploče

Tokom instalacije senzorskog čvora, potrebno je senzoru proslijediti parametre za pristupnu *Wi-Fi* tačku preko kojeg će senzor slati očitane podatke. Za te potrebe kreirana je Android aplikacija *a duhNet* koja omogućava jednostavno prosljeđivanje pristupnih podataka i praćenje očitanja sa svih dodatih senzora. Prilikom dodavanja uređaja svakom se dodjeljuje jedinstveni *Token* koji omogućava autorizaciju prilikom slanja podataka, a na osnovu *MAC* adrese i lokacije uređaja radi se autentifikacija senzorskog čvora.

IV. PREZENTACIJA SENZORSKIH OČITANJA

A. Za administraciju senzorskih čvorova i prezentaciju očitanih vrijednosti kreirana je Web aplikacija koju možemo podijeli na administratorsku i klijentsku.

Administratorska aplikacije je kreirana pomoću *ii2* okruženja, a njene osnovne funkcionalnosti su: administracija senzorskih čvorova (dodavanje, brisanje, izmjene), prijem podataka od senzorskih čvorova, obrada podataka, tabelarni prikaz svih očitanja i generisanje izvještaja koji sadrže očitane podatke. *ii2*, čiji naziv potiče od kineske riječi *ii* - "jednostavan i evolucijski", je PHP okvir visokih performansi, baziran na komponentama za brzi razvoj modernih web aplikacija [14]. Komunikacija između senzorskih čvorova i web aplikacije se odvija preko programskog interfejsa aplikacije (eng. *Application Programming Interface* – API). Pristup administratorskoj aplikaciji je dozvoljen samo autentifikovanim korisnicima.

B. lijentska aplikacija

Klijentska aplikacija je dostupna svim korisnicima i omogućava korisnicima da prate zagađenost vazduha. Prilikom otvaranja Web stranice prvo se prikazuje poruka o trenutnom kvalitetu vazduha na području grada i odgovarajući „emitikon“ u zavisnosti od kvaliteta vazduha. Prikaz kvaliteta u slikovnoj formi sa emotikonima omogućava korisnicima jednostavnije i brže dobijanje informacija. Takođe uz emotikone stoje i preporuke građanima i informacije o uticaju kvaliteta vazduha na zdravlje stanovništva.

Sl. 4. Emotikoni i preporuke građanima u zavisnosti od kvaliteta vazduha

Na stranici je omogućeno mapiranje senzora pomoću biblioteke *eaflet*. *eaflet* je vodeća JavaScript biblioteka otvorenog koda za interaktivne mape prilagođene mobilnim uređajima. Težak je samo oko *32 B*, i ima sve funkcije za rad sa mapama koje će većini programera biti potrebne, a ako postoji potreba za dodatnim stvarima tu su i razni dodaci i efekti [15]. *eaflet* je dizajniran za jednostavnu upotrebu, brzinu i kvalitet. Radi lako i efikasno na gotovo svim desktop i mobilnim platformama, postoji i mogućnost ekstenzija sa dosta dodataka. Podaci o mapama koje se koriste su dobijeni od strane *penStreetMap* platforme. Svaki senzor na mapi je obojen odgovarajućom bojom u zavisnosti od trenutne zagađenosti. Klikom na jedan od senzora na mapi otvara se novi prozor na kojem se prikazuju detalji kvaliteta vazduha odnosno trenutni kvalitet, tačne koncentracije PM10 i PM2.5 čestica i vrijeme posljednjeg mjerenja, dok klikom na naziv senzora otvaramo grafik kvaliteta vazduha u vremenskom rasponu od montiranja senzora pa do posljednjeg mjerenja. Na dnu Web stranice nalazi se i sumirani grafik kvaliteta vazduha svih senzorskih čvorova i dodatne informacije šta prestavljaju PM10 i PM2.5 čestice. Izgled mape prikazan je na Sl. 5.

 ISBN 978-86-7466-930-3

Sl. 5. Mapa sa označenim senzorskim čvorovima

V. ZAKLJUČAK

U radu je prezentovan senzorski čvor sa mogućnošću praćenje količine PM10 i PM2.5 čestica. Realizovana je platforma za praćenje, koja omogućava jednostavnu prezentaciju podataka grafički, prikaz na mapi i tabelarno. U narednom periodu je planirano da se dobijena mjerenja upoređuju sa mjerenjima koja su dobijena referentnim metodama i da se odredi koeficijent kalibracije. Takođe, planirano je unapređenje mobilne aplikacije da pomoću lokacije korisnika ispisuje poruku kvaliteta vazduha.

ZAHVALNICA

Zahvaljujemo se gradu Čačak, koji je obezbijedio novčana sredstva za realizaciju projekta praćenja kvaliteta vazduha.

ABSTRACT

PM2.5 exposure stands out as a leading health problem globally while the problem of air pollution is one of the leading causes of death in the world. Due to the poor air quality, the requirement for frequent measures in as many locations as possible has led to the development of low-cost sensors. Sensor nodes are being developed by utilizing widely accessible sensors, their use is to acquire the current concentration of particle matters. This raw data is later processed and used to calculate the air quality index – AQI. This paper presents the development of sensor nodes, as well as the development of a unique web platform. The web platform is equipped with a graphic representation of the date and history of archived data that had been collected. While this platform has been developed for the city of Čačak, it can be adapted to other geographical areas and it can be broadly used.

Mobile robot decision-making system based on deep machine learning

Aleksandar Jokić, Milica Petrović and Zoran Miljković

***Abstract*— ne of the major aspects of Industry 4. is enabling the manufacturing entities to operate in the dynamical systems autonomously. Therefore, to be autonomous, manufacturing entities need to have sensors to perceive their environment and utilize that information to ma e decisions regarding their actions. aving that in mind, in this paper, the authors propose a mobile robot decision-ma ing system based on the integration of visual data and mobile robot pose. obile robot pose (current position and orientation) is integrated with two images gathered by two cameras and utilized to predict the possibility of gripping the part to be manufactured. A decision-ma ing system is created by utilizing the deep learning model esnet1 with an additional input for the mobile robot pose. The model is trained end-to-end and e perimental evaluation is performed by using the mobile robot ACI (obot with Artificial Intelligence based C gnition).**

***Index Terms*—Decision-ma ing system, mobile robots, deep learning.**

I. Introduction

Enabling mobile robots to operate in the manufacturing environment autonomously represents one of the fundamental requirements regarding Industry 4.0 concepts [1]. To fulfill this requirement, mobile robots need to localize themselves within the environment and use sensors to perceive the current state of the manufacturing system. In this paper, the authors propose to include both visual information and mobile robot pose in the make-decision process regarding future mobile robot actions. Mobile robot pose (Fig. 1), represented by position (x and y) and orientation (θ), is combined with image data to make a decision regarding the probability of successful gripping of the manufacturing part. The mobile robot's task is to move relatively close to the machine (marked with red color in Fig. 1) and decide if the current pose is adequate for a part (presented with a blue color in Fig. 1) picking process.

Aleksandar Jokić, teaching assistant, University of Belgrade - Faculty of Mechanical Engineering, Department of Production Engineering, Laboratory for industrial robotics and artificial intelligence (ROBOTICS&AI), Kraljice Marije 16, 11120 Belgrade 35, The Republic of Serbia (ajokic@mas.bg.ac.rs).

Dr. Milica Petrović, Associate Professor, University of Belgrade - Faculty of Mechanical Engineering, Department of Production Engineering, Laboratory for industrial robotics and artificial intelligence (ROBOTICS&AI), Kraljice Marije 16, 11120 Belgrade 35, The Republic of Serbia (mmpetrovic@mas.bg.ac.rs).

Dr. Zoran Miljković, Full Professor, University of Belgrade - Faculty of Mechanical Engineering, Department of Production Engineering, Laboratory for industrial robotics and artificial intelligence (ROBOTICS&AI), Kraljice Marije 16, 11120 Belgrade 35, The Republic of Serbia (zmiljkovic@mas.bg.ac.rs).

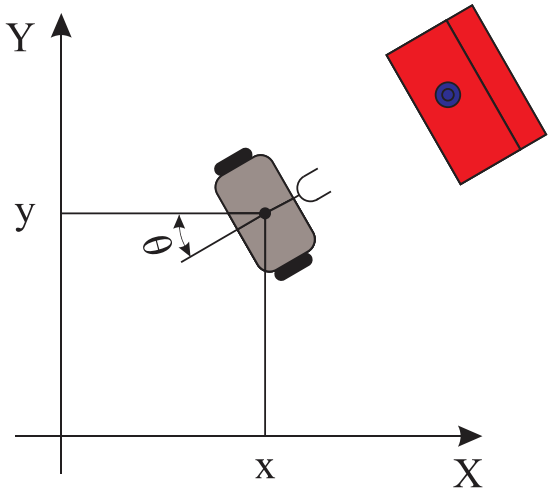

Fig. 1. Mobile robot in the environment with machine tool and part.

The related work regarding the mobile robot decision-making system is as follows. The determination of the next-best-view for environment exploring and mapping algorithm is proposed in [2]. The multi-objective decision criterion for a mobile robot with a 360° laser scanning sensor is proposed and evaluated in simulation. The proposed strategy showed superior performance compared to the other two strategies from the literature. The reinforcement learning approach for developing a mobile robot decision-making system is proposed in [3]. The mobile robot was equipped with an RGBD camera utilized to detect the obstacles. The learning approach was divided into three subtasks (i) reaching the target pose as fast as possible, (ii) obstacle avoidance, and (iii) not losing the target. According to the learned policy, a mobile robot can decide between five actions to reach the desired goal. The proposed system is verified within four simulation studies, and the results show that the proposed system achieves better results compared to the three state-of-the-art strategies.

The learning approach used for mobile robot navigation in both unknown and known environments is proposed in [4]. The model utilized for the mobile robot decision-making system is based on Developmental Networks. An incremental learning paradigm is implemented, allowing mobile robots to learn as they move in the new environment. Experimental results show that the proposed system enables mobile robots to utilize already learned cognitive functions in new environments.

A mobile robot decision-making system for outdoor path planning is proposed in [5]. The mobile robot utilizes the

 ISBN 978-86-7466-930-3

information gathered by the lidar sensor to obtain the optimal path in the uneven and obstacle-rich hill environment. In the offline stage, the robot learns in simulation the correlation of a good path with lidar data and utilizes that information in the online stage. The simulation results show the applicability of the proposed methodology for the path selection process.

Different from other approaches, in this paper, the authors propose the end-to-end trainable deep learning model capable of integrating image information and current mobile robot pose to predict the accuracy of the gripping process.

II. THE DEEP LEARNING-BASED DECISION-MAKING SYSTEM

The everlasting challenge within the deep learning-based robotic research domain is developing an adequate methodology for adapting heterogeneous data into deep learning models [6]. Examples of such data are different sensor measurements with uncertainty, a priory logical conclusions, or a mobile robot pose.

In this paper, the authors present deep learning-based decision-making system developed by modifying Resnet18 architecture [7]. The first input in the Resnet model is an image created by combining images generated by two mobile robot cameras. Images are stacked on top of each other to produce an image with the same width and height dimensions. Afterward, the additional vector input is added to the network utilized to represent the mobile robot pose (1):

$$= \begin{bmatrix} & y & \theta \end{bmatrix}^{\mathrm{T}}. \tag{1}$$

The change in mobile robot pose is calculated with (2):

$$\begin{bmatrix} \cdot \\ \dot{y} \\ \dot{\theta} \end{bmatrix} = \begin{bmatrix} \cos\theta & 0 \\ \sin\theta & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \omega \end{bmatrix}, \tag{2}$$

where v represents mobile robot translation velocity, and ω is mobile robot angular velocity.

The deep neural network architecture is presented in Fig. 2. Additional input is represented as one pixel in the image. When the feature maps are flattened just before the classification layer, the unchanged value of the mobile robot pose (from the input layer) is concatenated with the rest of the features and utilized in the classification process. The utilized Resnet18 model is created with basic and bottleneck blocks of layers with skip connections after each one; details regarding the implementation of this model can be found in [8].

Dataset for mobile robot training is generated as follows. The mobile robot is positioned to the predefined pose in the laboratory model of the manufacturing environment. Afterward, the mobile robot is set in motion until it reaches the pose close to the machine. The achieved pose is measured according to the data gathered by two wheel encoders. Then, the achieved pose is saved in the text document and two images are generated, combined, and saved. The gripping procedure is initiated, and if the mobile robot manages to grip the part, all the saved data is moved to the "successful grip" category and vice versa.

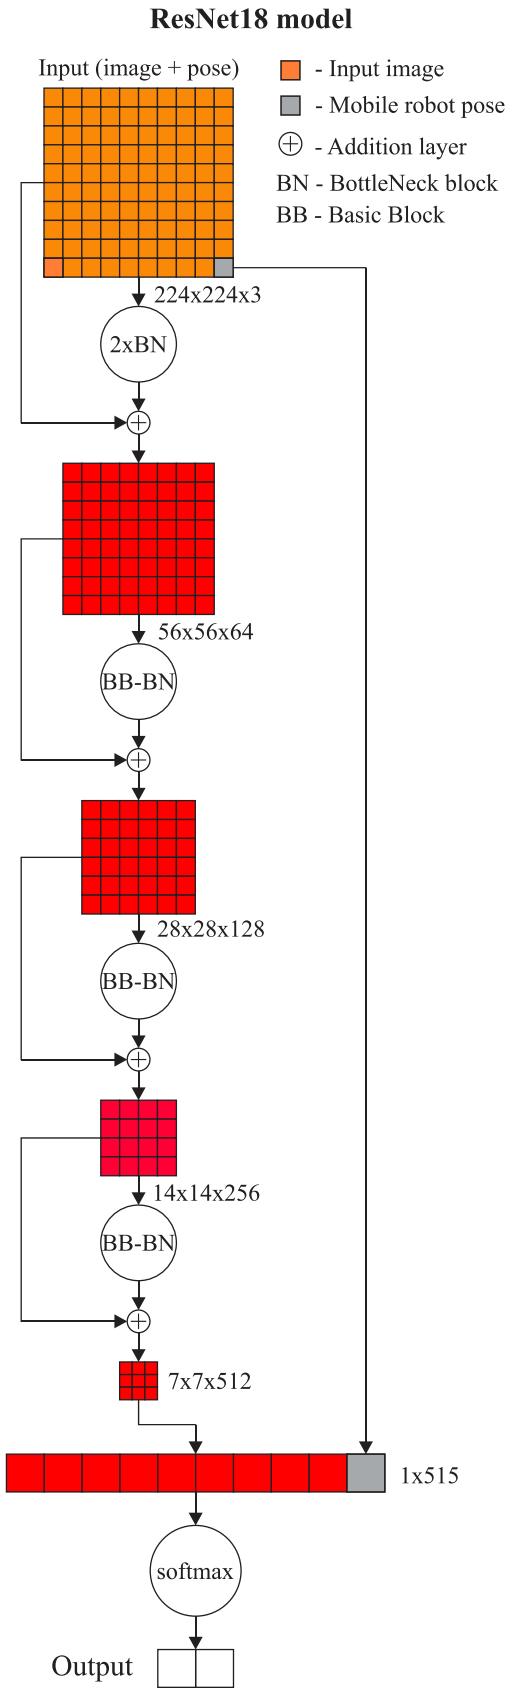

Fig. 2. Graphical representation of the proposed CNN model.

After the dataset is acquired, the training process begins. This problem belongs to the category of the binary classification process, with two outcomes "successful grip"

 ISBN 978-86-7466-930-3

and "unsuccessful grip". The classification is performed with softmax fitness function (3), and the loss function is defined with (4):

$$s_i = \frac{e^{y_i}}{\sum_{i=1}^{N} e^{y_i}} \tag{3}$$

$$\ell(\mathbf{s},\mathbf{c}) = -\sum_{i}^{N} c_i \log(s_i) \tag{4}$$

Where **y** represents the output of CNN model, *i* represents the *i*-th element of the output vector, *N* is a number of classes, **c** represents one-hot class vector.

The training is performed by stochastic gradient descent with momentum training algorithm with a batch size of one. Initial experiments are performed to determine the best training parameters for Resnet18 model. The learning rate varies from 0.0001 to 0.001, and the momentum is set to range from 0.7 to 0.9. The best performance on the training set is achieved with a learning rate of 0.0005 and momentum of 0.9.

III. Experimental results

The experimental evaluation is done by using the mobile robot RAICO (Robot with Artificial Intelligence based COgnition). RAICO is set to an initial pose in the laboratory model of the manufacturing system, and the movement command is activated. The pose RAICO achieves is relatively close to the machine where the part needs to be picked up; however, the pose is never the same due to slight differences in both the initial pose and movement process. Afterward, the final pose is calculated and integrated into the combined image generated using images from the right and left cameras. Then, the whole input is passed through the CNN network. The output represents the class (i.e., *grip* or no_*grip*) and the confidence in the class prediction. The gripping process is activated, and the outcome (successful or unsuccessful grip) is recorded. The experiment is repeated 10 times, and the results can be found in Table I.

TABLE I
THE EXPERIMENTAL RESULTS OF THE DECISION-MAKING MODEL

Exp. No.	Prediction	Confidence [%]	Successful gripping?
1	Grip	76	No
2	Grip	93	Yes
3	No_grip	83	No
4	No_grip	84	No
5	Grip	95	Yes
6	No_grip	85	No
7	Grip	85	No
8	No_grip	83	No
9	Grip	80	No
10	Grip	97	Yes

As shown in Table I, the mobile robot decision-making system adequately predicts the outcome of the gripping process in 70% of cases. Moreover, in all the cases where the prediction accuracy of the deep learning model for successful gripping is over 93%, the mobile robot actually manages to grip the part. Therefore, the high prediction confidence is highly correlated to the gripping success. Images generated by a mobile robot with prediction accuracy are shown in Fig. 3.

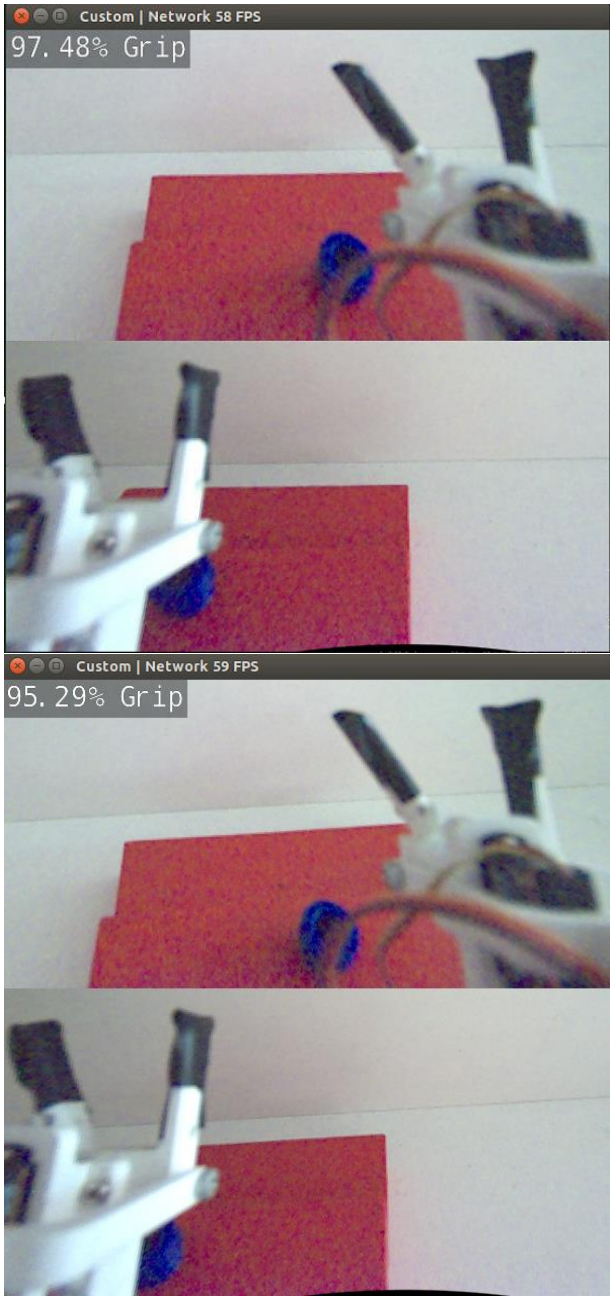

Fig. 3. Two input images for mobile robot decision-making system.

One more important piece of information that can be seen in Fig. 3 is the inference time of the developed deep learning model. Even though the proposed model has more layers and parameters than the original Resnet18, it can be used in real-time (around 60 FPS).

 ISBN 978-86-7466-930-3

Moreover, the images of the mobile robot RAICO in the laboratory model of the manufacturing system during the testing of the decision-making system are presented in Fig. 4.

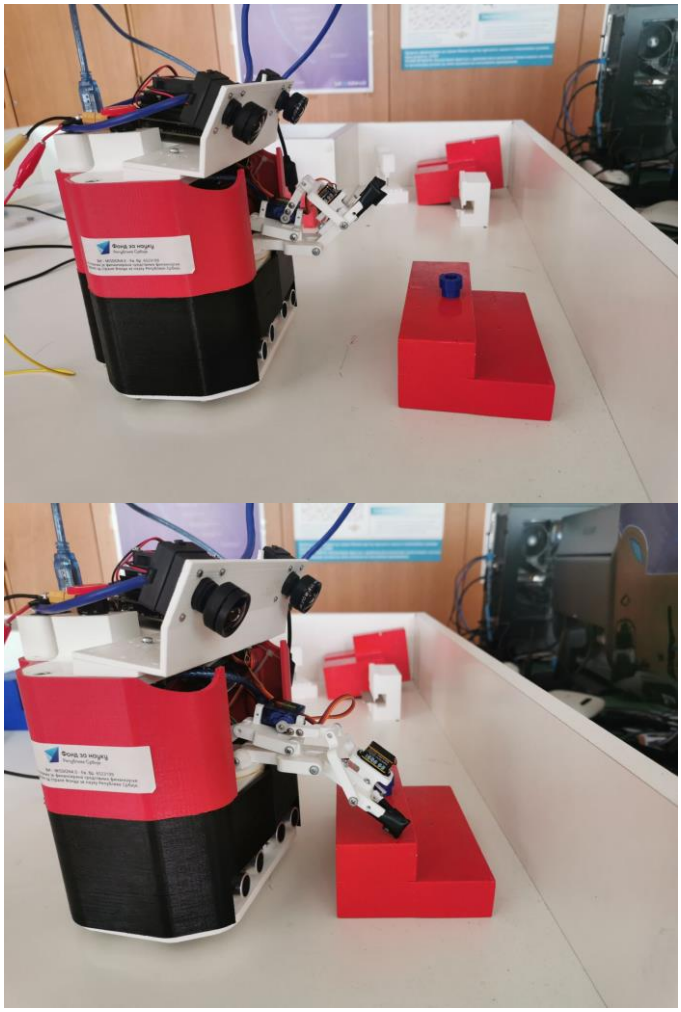

Fig. 4. Mobile robot RAICO in the pose close to the machine tool during the unsuccessful gripping process.

IV. Conclusion

In this paper, the authors propose a decision-making system based on the Resnet18 deep learning model. The input represents the images from the stereo camera pair and the pose of the mobile robot. The Resnet model is trained on the custom dataset to produce the binary classification output regarding the success of the griping process. The experimental results show that the model accurately predicts gripping success in 70% of cases. Moreover, it is experimentally verified that high confidence (93%+) in the prediction of accurate gripping has a strong correlation to the real-world successful griping process. The future research directions will include the extensive testing of the processed system with different state-of-the-art deep learning models that will enable a higher level of accuracy.

Method for Configuring Virtual Robot as an Integral Part of the Control System

Nikola Slavković, Saša Živanović, Zoran Dimić, and Nikola Vorkapić

***Abstract*—The development of integrated computing environments provides opportunities for the development of virtual production. Virtual simulation is crucial when the robot performs tasks that include some manufacturing processes. Virtual robots are used for program verification before sending it to the real robot and enable collision checking between robot segments themselves and the robot and its environment. Virtual models of industrial robots could be configured in different environments and ways. This paper presents the method for configuring virtual robots as an integral part of the control system. The virtual robot's configuration is realized under the LinuxCNC software environment and relies on OpenGL and several interface classes written in Python programming language. Developing a robot kinematic model to implement a virtual robot integrated with an open-architecture control system is necessary. Models of robot segments were imported in ASCII STL format and connected according to the robot kinematic model, and then the virtual robot was integrated within the LinuxCNC control system. The method for configuring a virtual robot as well as its kinematic model is presented in the example of the BiSCARA robot. Verifying the robot control system, virtual model, and kinematic model has been performed through several examples of drawing contours on the configured virtual robot.**

***Index Terms*—Virtual robots; Control system; Robot simulations; Kinematic modeling;**

I. Introduction

Sudden changes in production programs, product short life cycle, as well as further progress in the development of integrated computing environments for the development of new products provide opportunities to achieve the paradigm of virtual production [1]. The use of industrial robots in manufacturing and assembly lines is continuously increasing due to the need for high efficiencies, high accuracy, high production rates, and repeatability [2]. The use of robots for pick and place, welding, subtractive and additive manufacturing has been spreading in the last years with the concept of industry 4.0 [3]. In addition to performing these tasks, the application of industrial robots has been extended to laser engraving, laser and plasma cutting, robot milling, etc. Designing and testing a robotic cell is one of the essential modern manufacturing engineering tasks, especially when the robot does not just handle materials but also performs manufacturing processes [4]. To save time and verify the robot cell for performing these tasks before its production, virtual environments, i.e., virtual robots have a key role.

The notion of a virtual industrial robot is broad and includes complete models of robot structure, kinematic subsystem, tasks process, the environment, etc. All these models are integrated into a single software system, enabling some part of the virtual production.

Virtual industrial robots, that are included in the production engineering environment, could be configured in the different environments such as CAD/CAM systems, MatLab/Simulink environment, specialized CAM software for robot programming (RobotStudio, Robotmaster, …), LinuxCNC as an integral part of robot control systems, virtual reality system, etc.

This paper presents the configured virtual robots in different software environments using a five-bar, i.e., dual SCARA or BiSCARA robot. Robots based on the five-bar mechanism are widespread in academic institutions because they are suitable for experimental work. This base mechanism is almost always improved with the additional translatory and rotary axis to develop 3- or 4-axis robots. The developed virtual robot can simulate robot tasks such as laser engraving, 3-axis milling, 3D printing, etc. The first such robot, Fig. 1, is described in a US patent in 1934 [5, 6]. In 1978, Prof. Hiroshi Makino invented the well-known SCARA robot [7], while in 1985, Donald C. Fyler came up with the idea of using a five-bar mechanism as a robot [5, 8].

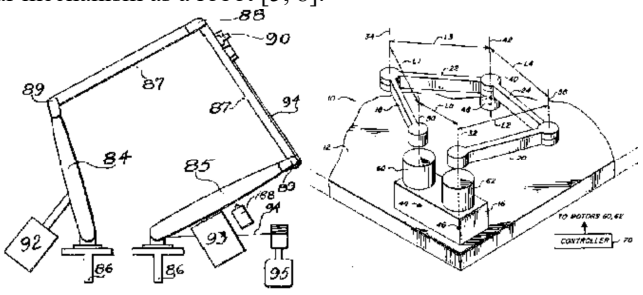

Fig. 1. Concept of five-bar, i.e., dual SCARA or BiSCARA, robot [1]

Mitsubishi Electric was the first company that commercialized the robot, MELFA RP-1A, based on this mechanism [5]. An example of a developed industrial prototype is the DexTAR robot (Dextrous Twin-Arm Robot) [9].

II. VIRTUAL INDUSTRIAL ROBOTS

A virtual industrial robot is a digital description of a robot, usually with simplified geometry, and is used for computer simulations of robot tasks.

To configure a virtual robot in a CAD environment [10], first, all elements of the robot structure are generated. These elements are then connected to the kinematic structure of a real robot. To be able to model a robot used in the simulation, one member of the robot mechanism must be fixed, and the moving components of the robot should be connected with appropriate kinematic connections (pin and/or slider). After this, in the next step, it is necessary to connect the coordinate systems of the workpiece and end-effector (EE) with the robot's coordinate system. In CAD/CAM environment, PTC Creo, the robot's coordinate system is defined as MACH_ZERO, while TOOL_POINT presents the end-effector's coordinate system. Coordinate systems with the same names have both an EE and a workpiece. The virtual EE is placed on the virtual robot by matching these coordinate systems. After the successful connection of the virtual workpiece and EE, a virtual industrial robot simulation according to a given program can be run. The model of the BiSCARA robot configured in the PTC Creo environment is shown in Fig. 2. The simulation of movement of the virtual robot tooltip is shown in the example of drawing a circle and a rectangle inscribed in a determined workspace of the robot.

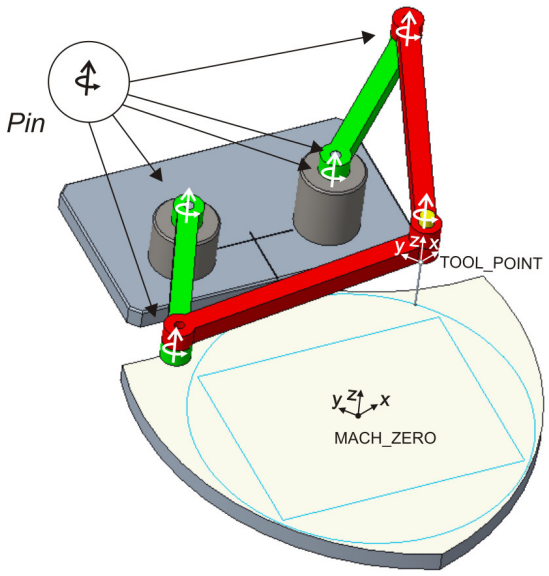

Fig. 2. Configuring of virtual robot in CAD/CAM environment

As described in the previous work [11], configuring the virtual robot in the MatLab/Simulink environment considers the development of the program for the joint space trajectory generation in the MatLab environment and configuring of the virtual robot in the Simulink environment. The structure of configured virtual robot in Simulink is presented in Fig. 3a.

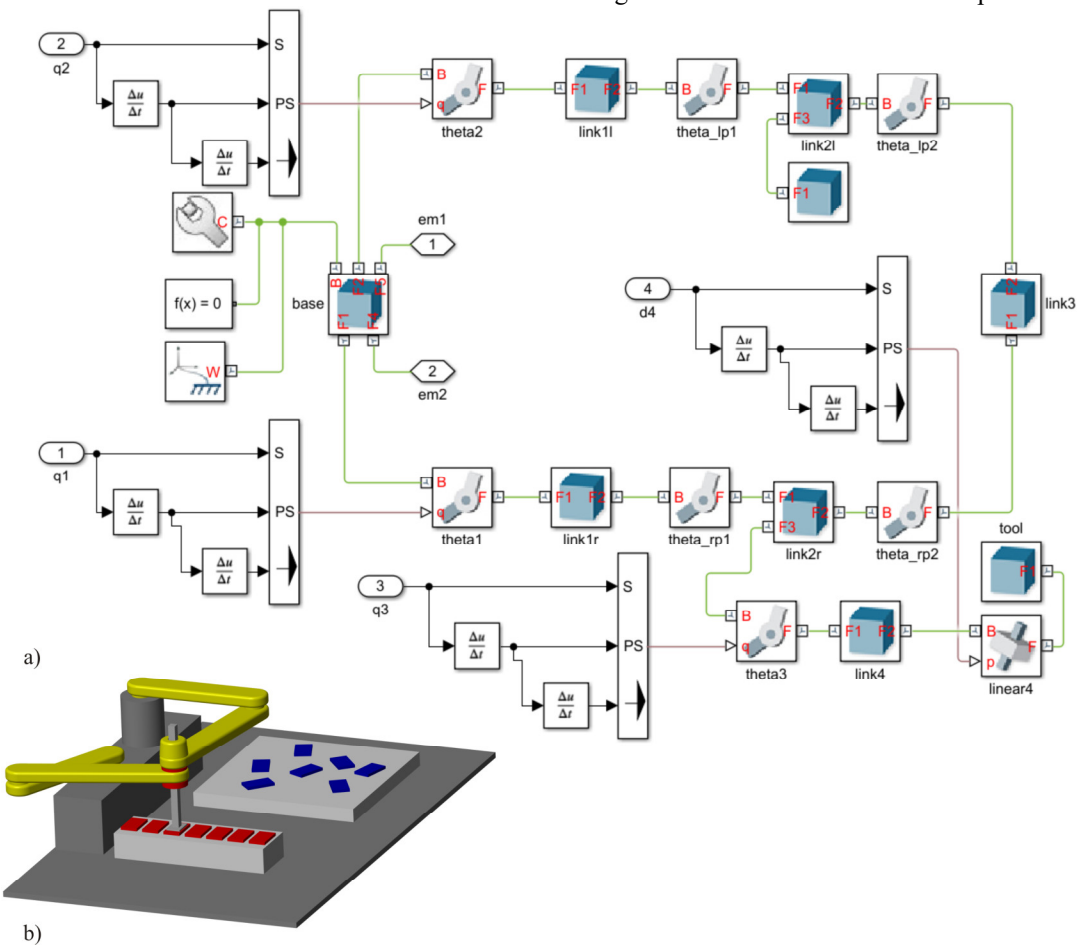

Fig. 3. Configuring of virtual robot in MatLab/Simulink environment

 ISBN 978-86-7466-930-3

It consists of a base and three kinematic chains. The base is represented with the Brick Solid element connected with World Frame, Solver Configuration, and Mechanism Configuration elements. Any kinematic chain consists of Brick Solid elements and appropriate Revolute Joint and/or Prismatic Joint elements. The active joints in these kinematics chains have to be actuated by joint time series generated in MatLab consisting of joint angle, velocity, and acceleration [11]. The model of the BiSCARA robot configured in MatLab/Simulink environment is shown in Fig. 3b.

Virtual robots, as well as virtual machines, have a significant role when developing a control system where it is necessary to integrate solutions of inverse and direct kinematics. In this way, it is possible to develop a control system even before the realized physical prototype, which is of great importance because it allows virtual testing during development, known as virtual commissioning [12, 13, 14].

This paper considers the method for configuring virtual robots in the LinuxCNC control system. Virtual robots in the control system are significant during the robot exploitation and the configuring of the control and before the realization of the robot. Program verification using virtual robots is significant because it enables:

- testing the kinematic model during the development of the control system,
- visual detection of collisions between the moving parts of the robot and between the tool, workpieces, and fixtures in the workspace,
- checking if the robot can execute the specified toolpath within the limited workspace, joints ranges, and speeds,
- training and education for robot programming, etc.

III. KINEMATIC MODEL OF ROBOT

To realize the virtual robot as an integral part of the control system, it is necessary to perform a kinematic analysis of the considered robot [11, 15]. A Parallel BiSCARA robot can be viewed as a planar manipulator with two degrees of freedom. The kinematic analysis embraced solving direct and inverse kinematic problems, determination of Jacobian matrix, and workspace analysis [11]. The kinematic model of the BiSCARA robot is shown in Fig. 4.

The robot consists of a base, a platform, and two kinematic chains with struts lengths l_1 and l_2. All mechanism elements are connected by a joint with one rotary degree of freedom. The frame {B} represents the base frame, while the platform is represented by point P because the struts of length l_2 are connected at the point P.

As it can be seen from Fig. 4, the world coordinate vector is defined as

$$ {}^{B}\mathbf{p}_P = \begin{bmatrix} x_P & y_P \end{bmatrix}^T \tag{1} $$

while joint coordinate vector is represented as

$$ \boldsymbol{\theta} = \begin{bmatrix} \theta_1 & \theta_2 \end{bmatrix}^T \tag{2} $$

Besides another unit vector, the unit vector ${}^{B}\mathbf{a}_i$ is defined as

$$ {}^{B}\mathbf{a}_i = \begin{bmatrix} \cos(\theta_i)\cos(\gamma_i) \\ \sin(\theta_i) \end{bmatrix} \tag{3} $$

where i=1, 2 represents the number of the kinematic chain and γ_i represents the angle that defines the arrangement of kinematic chains and is introduced in order to generalize the solution of the inverse kinematic problem and parallel determination of joint coordinates during the solving an inverse kinematic problem.

Observing one kinematic chain, the following vector equations can be derived

$$ \begin{aligned} {}^{B}\mathbf{p}_p &= {}^{B}\mathbf{b}_i + k_i \cdot {}^{B}\mathbf{w}_i \\ k_i \cdot {}^{B}\mathbf{w}_i &= l_1 \cdot {}^{B}\mathbf{a}_i + l_2 \cdot {}^{B}\mathbf{z}_i \end{aligned} \tag{4} $$

from which inverse and direct kinematic problems can be solved in analytic form.

The authors' previous work represents the complete solution of inverse and direct kinematic problems, as the determination of Jacobian matrix and workspace analysis [11]. Here are presented only the solutions of the inverse kinematic problem that is crucial for developing a virtual robot integrated with a control system. The joint coordinates can be determined using the following equations

$$ \theta_i = A\tan 2(t_{i1/2}) \tag{5} $$

where

$$ t_{i1/2} = \frac{y_P \pm \sqrt{A_i^2 + y_P^2 - B_i^2}}{A_i + B_i} \tag{6} $$

and

$$ \begin{aligned} A_i &= (x_P - b_{ix})\cos(\gamma_i) \\ B_i &= \frac{l_1^2 + (x_P - b_{ix})^2 + y_P^2 - l_2^2}{2l_1} \end{aligned} \tag{7} $$

 ISBN 978-86-7466-930-3

IV. METHOD FOR CONFIGURING VIRTUAL ROBOTS IN CONTROL SYSTEM

The basic concept of a configuring virtual robot in the control system is shown in Fig. 5. The virtual robot's configuration is realized under the LinuxCNC software environment and relies on OpenGL and several interface classes written in Python programming language. Python is an interpreted programming language suitable for scripting tasks, such as developing and configuring virtual environments [12].

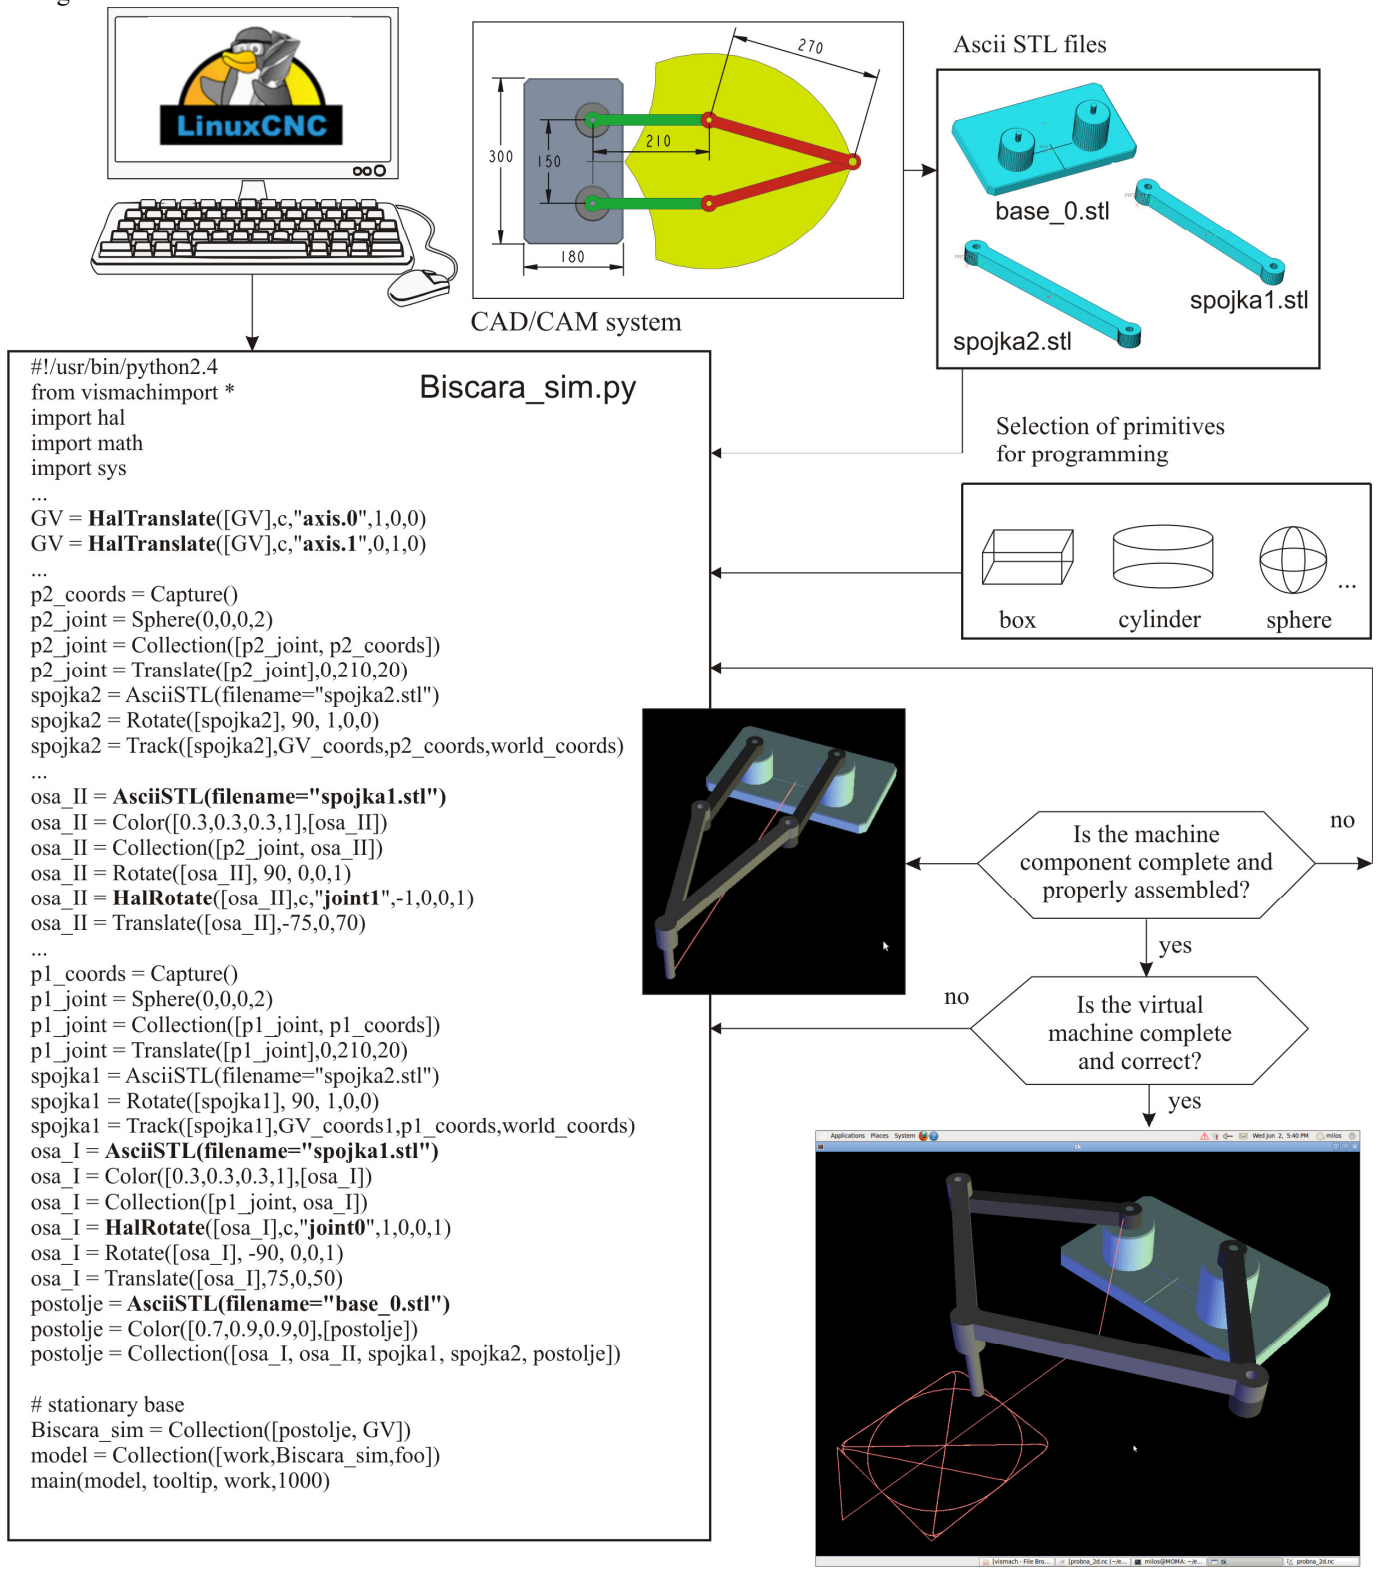

Fig. 5. The basic concept of a configuring virtual machine in a control system realized under the LinuxCNC software environment

 ISBN 978-86-7466-930-3

Models of robot components were imported in ASCII STL format and connected according to the robot kinematic model. The ASCII STL files of the robot components were obtained from the CAD/CAM system.

After the virtual robot is configured, it is integrated within the LinuxCNC control system. During the program execution for a robot in G-code, the virtual robot components are moving in real-time, according to identical control signals as for the real robot.

The modeling procedure of the virtual robot starts by defining the geometric primitives as parts of the robot assembly in CAD/CAM system. Defining only the essential and functional parts of the robot 3D model may simplify the development of the virtual robot. Basic geometric primitives, e.g., boxes, cylinders, spheres, etc., can be used to form robot parts. The positions of the geometric primitives, as well as the robot parts, are programmed according to the adopted reference frame. The robot parts are connected to form the robot base, and the moving parts of the robot, in this case, are connected via rotational joints.

Step by step programming, testing, and error correction is the only way of configuring an error-free virtual robot. Besides the manual approach, using basic geometric primitives, a CAD system can be used for preparing 3D models of robot components, which are exported as separate files ASCII OBJ or ASCII STL code. In this paper, the virtual BiSCARA robot was configured using PTC Creo. The robot components were converted into an ASCII STL format and then loaded into the Axis GUI through appropriate Python calls, Fig. 5.

Afterward, the imported components are oriented and placed in the virtual environment, resulting in a fully functional virtual robot, as shown in Fig. 5. The virtual robot is placed in a separate window and allows drawing the toolpath within the limitations of the virtual robot elements' movements.

V. Simulation and Verification

The developed virtual two-axis BiSCARA robot, integrated with the LinuxCNC control system, is suitable for drawing tool paths and laser engraving [15].

The programming system for the considered robot is entirely conventional and the same as for all machine tools which can perform milling or laser engraving. Programs for testing configured virtual robots are generated in the CAD/CAM system using trajectory milling or a special CAM system that can convert drawing in DXF format into G-code.

During the program's execution written in G-code, the virtual robot components are moving in real-time, according to the tool path, thanks to the kinematics built into the control system.

Figure 6 shows the first of the experiments on a virtual robot integrated with the control system, which represents the drawing of the programmed tool path consisting of regular geometric figures of squares with diagonals and inscribed circles.

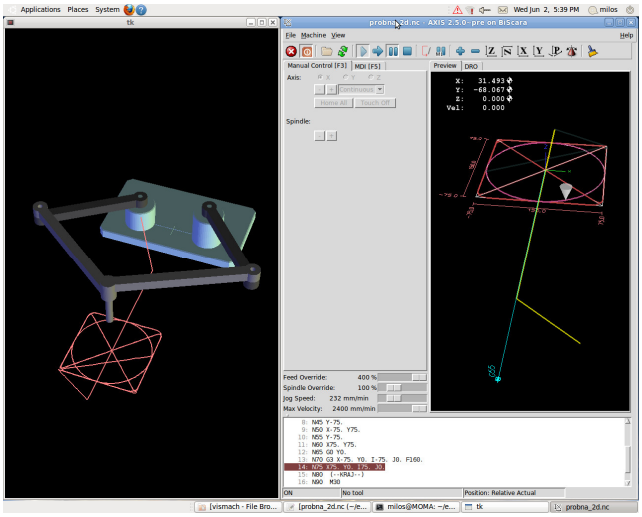

Fig. 6. Simulation of programmed tool path on virtual BiSCARA robot in LinuxCNC control system

Figure 7 shows one of the experiments on a virtual robot integrated with the control system, representing the drawing of the programmed tool path in the shape of the lion drawing. This experiment was used to test systems for programming complex 2D contours, which were programmed, based on DXF drawings and their conversion into G-code.

Some of the details during the virtual trial simulation of the BiSCARA robot are as follows: (i) the appearance of the programmed contour confirms the realized kinematic model, (ii) realized control system is correct, (iii) the used programming system gives correct G-code, (iv) positioning within the robot workspace was correct.

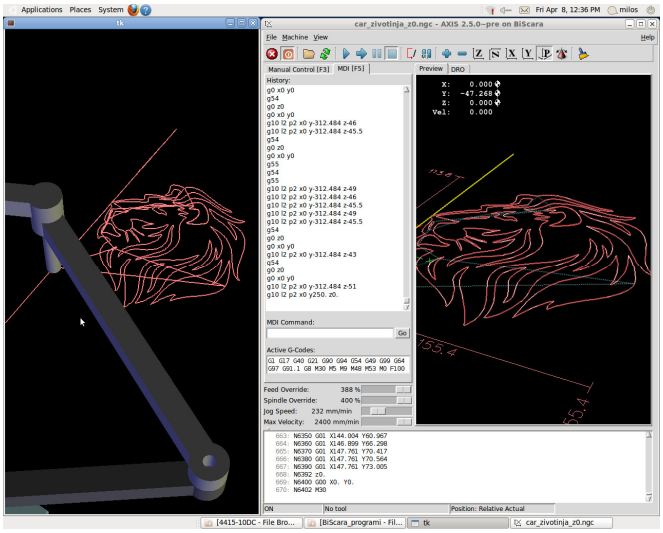

Fig. 7. Simulation of programmed tool path based on lion drawing on virtual BiSCARA robot

 ISBN 978-86-7466-930-3

VI. CONCLUSION

Testing and verifying the robotic cell before its realization through virtual environments is one of the modern manufacturing engineering tasks. Configuring a virtual environment that includes virtual robots is of crucial importance to verify the programmed trajectory, collision detection, etc.

The paper presents the configuration of a virtual robot in the CAD/CAM and MatLab/Simulink environments on the example of the BiSCARA robot. The virtual CAD and complete kinematic models are used to implement robots in the LinuxCNC software according to a presented method for configuring virtual robots as an integral part of the control system. Configuring virtual robots relies on OpenGL and several interface classes written in Python programming language. First, robot segments were imported in ASCII STL format and connected according to the robot kinematic model, and then the virtual robot was integrated.

Further research will encompass the realization of a virtual prototype of a 4-axis robot by adding on the presented base mechanism one translatory and one rotary axis. Also, the development of a laboratory prototype of a 4-axis robot will be covered in further research.

Low-cost real-time human motion capturing system

Milutin Nikolić, Lazar Milić, Milutin Studen, Mirko Raković

***Abstract*— In recent years motion capturing technology found numerous applications in industry and research areas li e human-robot interaction, medical applications, etc... Those systems can be very e pensive and might require a lot of setup time. In this paper, leveraging the advances in deep learning and computer science, the low-cost real-time motion capturing system is presented. The system was designed to use off-the-shelf ine pensive cameras, freely available software, and a gaming laptop. The system design, underlying math principles, reconstruction pipeline, and reconstruction results will be discussed in the paper. The presented motion capturing system can reconstruct a human pose with eypoints in real-time at 1 z. The whole setup costs less than 25 including the price of the dedicated PC.**

***Index Terms*— otion capturing, uman pose estimation, uman-robot interaction, Deep learning**

I. Introduction

Motion capture or "MoCap", for many years now, has been recognized in the majority of industries as the highly advanced technique of recording movements and transferring the results of such recording into digital data. It is widely used in various fields from science, through the film industry, to gaming and video game development, which makes it broadly applicable and remarkably alluring for use in different professional spheres [1].

In medicine and biomedicine, motion capture is used to conduct scientific research and analyses with regard to the understanding of human physiology, particularly the bipedal locomotion. This knowledge can contribute to understanding the effects of injuries and required rehabilitation [2]. In addition, MoCap havs the ability to record facial expressions of humans, which can help us in further understanding of human emotions. In robotics MoCap is used for constructing dynamically stable humanoid movement and for capturing motion trajectory of a human [3, 4].

Furthermore, the filmmaking and video games industry uses motion capture to record the physical actions of the live actors participating in the movies, enabling the real-life movie characters to be "transcribed" into the computer animations, i.e., digital characters. Nonetheless, the MoCap is often used for the creation of special effects in different animated content such as movies, video games, etc.[5] Also, in human-robot interaction, the MoCap is used to record, evaluate and classify human behavior patterns. Also, MoCap is extensively used to record and evaluate human behavior, and modify robot behavior based on recognized human behavior pattern [6].

Milutin Nikolić, Lazar Milić, Milutin Studen and Mirko Raković are with Faculty of Technical Sciences, University of Novi Sad. Trg Dositeja Obradovića 6, 21000 Novi Sad, Serbia (email: {milutinn, miliclazar, studen, rakovicm}@uns.ac.rs)

It may be easily concluded that, from its beginnings, motion capture has been a significant addition to the technical processes throughout the diverse industries. However, although many excellent systems leading to the outstanding results are currently present on the market, such as the Vicon Motion[1]

Capturing System, the main setback of motion capture as an asset able to simplify the variety of industrial processes is the fact that its application and practical use are conditioned upon expensive hardware and software. Furthermore, some solutions such as [7] include complex offline postprocessing following the collection of the movement data. For instance, the basic equipment, without any upgrades and advancements, that is necessary for the Vicon setup amounts to approximately $40.000, which is noticeably expensive for the SME.

Although there are many types of motion capture, optical MoCap is most commonly used technology. Optical MoCap use multi-camera setup and triangulation to determine position of markers in 3D world. There are two types of optical motion capture reflective and pulse LED. First technique has reflective markers which are placed on actor's body and because of their reflection it becomes easy for software to determine the position of markers. On the other hand, pulse LED technique has active markers that emission LED light which cameras can capture. Both techniques required 50 plus markers on actor's body for motion to be captured. This process requires a lot of time for markers to be placed on predefined part of body and also markers restrict actor's movement.

Regardless of that, the rapid development of the technology has through the years led to the possibility of the development of low-cost MoCap systems. In addition, the introduction of new methods that can extract the pose from image sequence by using artificial neural networks lowered the cost of new budget MoCap systems. Furthermore, the decrease in the prices of usable equipment for the motion capture processes, including personal computers and cameras, has affected the realization of the more affordable MoCap systems with non-equal but satisfying results [8]. Having in mind all previously mentioned, we are now able to construct budget MoCap system for less than $2500, including all hardware and software, without any markers which minimize required time for preparation, allows actor's to move freely and eliminates location restrictions. Tha low cost would enable further expansion of use of MoCap. Also, removal of required markers and long setup time, enables recording in places where we can't interfere with the subjects, e.g. recording athletes during sport events, behavioral studies of people in pubic spaces, interaction of workers with the robot

 ISBN 978-86-7466-930-3

on the factory floor, etc ... The design and implementation of such a low-cost system is the main topic of this paper.

The paper is organized as follows: in Section II we will describe the hardware components of the system and how it is layed out. In Section III the process for calibrating the system will be described. Section IV describes the whole reconstruction pipeline, while Section V gives experiment results. The paper is concluded in Section VI.

II. System setup

In this section, we will describe the complete system architecture, calibration process, and video acquisition. The video acquisition and recording system consists of three Intel RealSense D415 cameras, which are connected to a PC via a USB interface. The placement of the cameras in the room is so that each camera is oriented towards the center of the room. Since Intel RealSense D415 has narrow field of view, the coverage of the visible area is relatively small. This could potentially disrupt pose estimation. But as shown later in section results this was not a problem.

A. Intrinsic camera calibration

Because of the camera manufacturing process nature, there is a high possibility for it to be assembled imperfectly. This imperfection brings distortions to the image. There are two major distortions, and those are radial and tangential distortions.

Radial distortion has stronger effect on further points in the image and is reflected in such a way that straight lines appear curved. Similarly, tangential distortion occurs when camera lens is not perfectly aligned with image plane.

To describe radial and tangential distortion these five coefficients are used: k_1, k_2, k_3, p_1, p_2, where k_1, k_2 and k_3 are used to represent radial distortion, while p_1 and p_2 describe tangential distortion [9].

Additionally, during camera calibration, intrinsic camera parameters are calculated and these are focal length (f_x, f_y) and optical centers (c_x, c_y). Intrinsic camera and distortion parameters are calculated using OpenCV library. Process of calibration consists of multiple image captures, where each image is showing black and white chessboard with known square size. Images are then processed with the help of OpenCV functions which return all necessary parameters as the end result. Fig 1. shows example of detected chessboard and its corner points during calibration process.

B. E trinsic camera calibration

After finding intrinsic camera parameters, it is necessary to determine camera positions in real world, also known as extrinsic camera parameters, using chessboard as a reference. Again, we are using OpenCV library to calculate these transformations and Fig **2.** shows example of images containing chessboard and its estimated location in the world.

III. Reconstruction pipeline

In order to reconstruct the pose of the human in 3D space the images coming from cameras have pass through a several processing stages. The flow chart of the raw data obtained from cameras to the final reconstructed pose is illustrated in Fig. 3. Each stage of the reconstruction pipeline will be described in detail in subsequent sections.

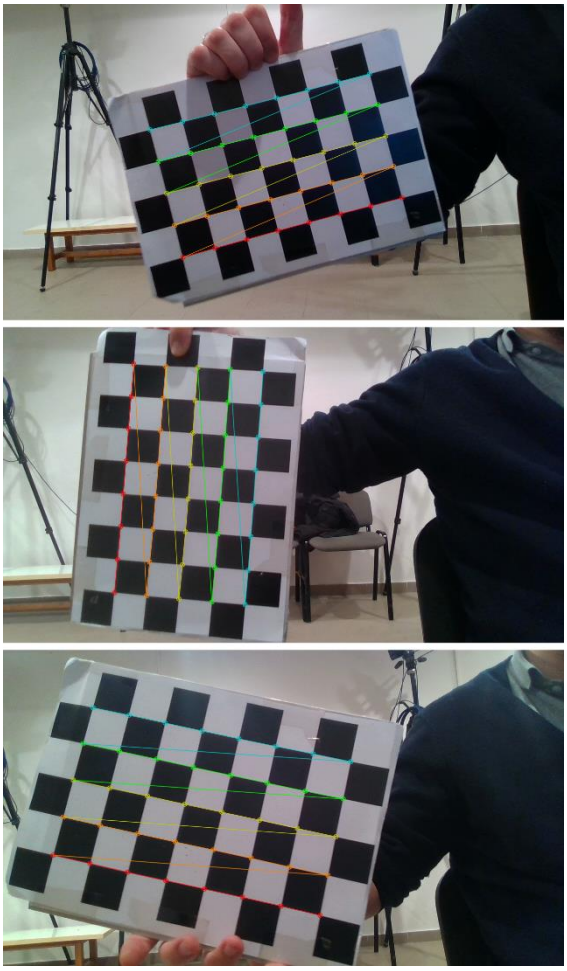

Fig 1. Images acquired for camera calibration with detected chessboards

Fig 2. Images used for extrinsic camera calibration displayed with system origin

A. Image ac uisition

The first block in the processing pipeline is image acquisition from the camera. This operation is the simplest one, and the image data from the camera is retrieved by using API provided by the camera manufacturer, in this case python library `pyrealsense2` provided and maintained by Intel.

 ISBN 978-86-7466-930-3

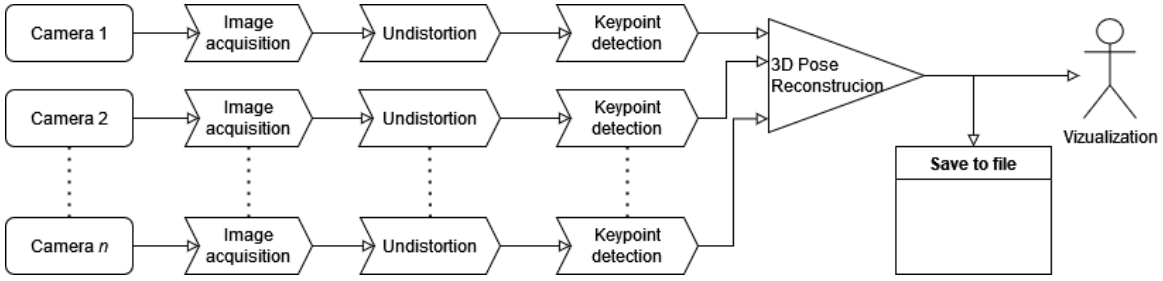

Fig 3. Processing pipeline

[10] Before retrieving the image, user has to provide camera serial number, and desired framerate.

B. ndistortion

The obtained image contains some distortion due to lens imperfection and assembly errors. Such a distortion will introduce errors in the reconstructed pose, so it is extremely important to correct it. In section III we have described the camera calibration process, and result of it is the distortion parameters. In this block, those distortion parameters will be used to undistort the obtained image.

C. uman pose detection

After obtaining distortion-free images the next step is the detection of the human keypoints on the image. Until very recently, without special clothing or markers, accurate detection of body keypoints was almost impossible. In year 2017 OpenPose was developed as a first convolutional neural network based human pose detection framework.[11] It was trained using COCO dataset and it can detect 25 keypoints on the human body. Also, it can detect multiple humans captured by the camera.

Unfortunately, OpenPose, although very accurate, is very computationally demanding. In order to run OpenPose real time, dedicated GPU is required which would significantly increase the total system cost.

Alternative was found in MediaPipe [12] developed by Google as an open-source cross platform, customizable machine learning solution set for live and streaming media. One of solutions provided is used for human pose detection and tracking. It can infer 33 3D keypoints and background segmentation mask on the whole body from RGB video frames utilizing BlazePose [13]. The detected keypoints are given in Fig 4. The MediaPipe can be set up to detect even higher fidelity mode, with total 543 keypoints, with 33 keypoints on the body, 21 on each hand and 468 on the face. To be able to reconstruct face and whole body, the higher resolution and quality camera is required, and for that reason we decided to reconstruct only 33 body keypoints. One limitation of this framework compared to OpenPose is that it can detect only one human in the scene. Multiple humans would inevitably produce detection errors.

3D poses are given relative to pelvis, whose 3D pose is unknown, and, if just one camera is used, can suffer from unknown scale, leading to wrong 3D pose estimation. Hence, we still need multi-camera setup to obtain full 3D position of the keypoints.

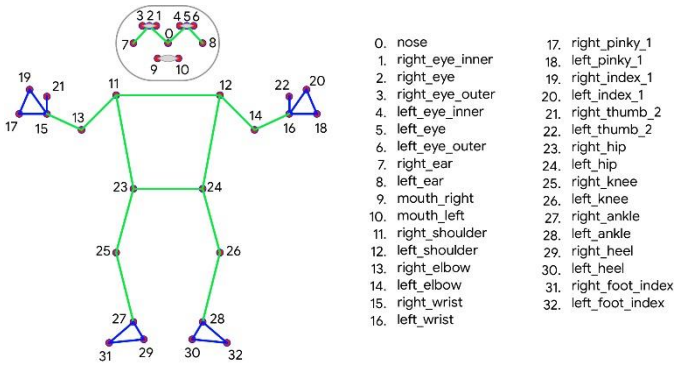

Fig 4. Keypoints detected by BlazePose

. 3 reconstruction

After getting positions of all keypoints on all cameras, the last step is to reconstruct their positions in a 3D space. To do so, let's assume that we have *n* cameras. The keypoint in space can be seen on camera *i* at the location $\mathbf{q}_i$ given in pixels. The position and rotation matrix of camera *i* are given with $\mathbf{T}_i$ and $_i$. The intrinsic camera matrix is $_i$. These vectors and matrices are the result of the calibration process described in section IIIA. The setup is illustrated in Fig. 5. Now, having all the camera positions, rotation matrices and location of the keypoint on all images, the goal is to compute the position of the point in the 3D space.

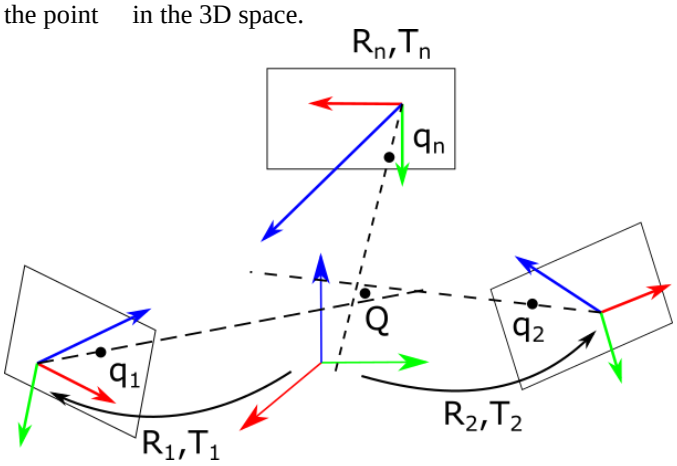

Fig. 5 Setup with multiple cameras observing the same point.

To derive equations, we will start from pinhole camera model, and projection rule:

$$\mathbf{q}_i = s_i \mathbf{M}_i \mathbf{R}_i^{\mathrm{T}} (\mathbf{Q} - \mathbf{T}_i) . \quad (1)$$

 ISBN 978-86-7466-930-3

Where s_i is positive scalar and $_i$ is intrinsic camera matrix projecting points from the space to pixels in image. From that equation we can deduce :

$$\mathbf{Q} = \mathbf{T}_i + w_i \mathbf{R}_i \mathbf{M}_i^{-1} \mathbf{q}_i = \mathbf{T}_i + w_i \mathbf{u}_i, \quad (2)$$

where we w_i is again positive scalar equal to $1\ s_i$. The physical meaning is that a point lies on the ray starting from center of camera i $\mathbf{T}_i$, that passes through point $\mathbf{q}_i$ and follows direction $\mathbf{u}_i$.

Obviously, this is the ideal case, where cameras are perfectly calibrated and keypoint is perfectly detected. In the real world we can't achieve that, so the mentioned ray will pass close, but will not contain the point . Including that observation we can rewrite equation (2):

$$\mathbf{Q} = \mathbf{T}_i + w_i \mathbf{u}_i + \boldsymbol{\varepsilon}_i, \quad (3)$$

where $\boldsymbol{\varepsilon}_i$ represents the deviation of point from ray going from $\mathbf{T}_i$, in a direction $\mathbf{u}_i$.

The position of the point Q will be obtained by minimizing the deviation from ideal rays. It is the result of the following optimization problem:

$$\min_{\mathbf{Q}} \sum_{i=1}^{n} \left\| \boldsymbol{\varepsilon}_i \right\|^2. \quad (4)$$

The meaning of this optimization problem is that the point that is the detected on n images at location $\mathbf{q}_i$ is the point in space whose total squared distance to all rays starting at $\mathbf{T}_i$, and passing through point $\mathbf{q}_i$ is minimal.

By expressing inserting $\boldsymbol{\varepsilon}_i$ from equation (3) and inserting it into (4) and some matrix manipulation we can the optimization problem as:

$$. \min_{\mathbf{Q},\, w_i} \left\| \begin{bmatrix} 1_{3x3} & -\mathbf{u}_1 & 0_{3x1} & \dots & 0_{3x1} \\ 1_{3x3} & 0_{3x1} & -\mathbf{u}_2 & \dots & 0_{3x1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1_{3x3} & 0_{3x1} & 0_{3x1} & \dots & -\mathbf{u}_n \end{bmatrix} \begin{bmatrix} \mathbf{Q} \\ w_1 \\ w_2 \\ \vdots \\ w_n \end{bmatrix} - \begin{bmatrix} \mathbf{T}_1 \\ \mathbf{T}_2 \\ \vdots \\ \mathbf{T}_3 \end{bmatrix} \right\|^2 \quad (5)$$

Such an optimization problem has a well known solution:

$$. \begin{bmatrix} \mathbf{Q} \\ w_1 \\ w_2 \\ \vdots \\ w_n \end{bmatrix} = \begin{bmatrix} 1_{3x3} & -\mathbf{u}_1 & 0_{3x1} & \dots & 0_{3x1} \\ 1_{3x3} & 0_{3x1} & -\mathbf{u}_2 & \dots & 0_{3x1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1_{3x3} & 0_{3x1} & 0_{3x1} & \dots & -\mathbf{u}_n \end{bmatrix}^{+} \begin{bmatrix} \mathbf{T}_1 \\ \mathbf{T}_2 \\ \vdots \\ \mathbf{T}_n \end{bmatrix} = \mathbf{A}^{+} \begin{bmatrix} \mathbf{T}_1 \\ \mathbf{T}_2 \\ \vdots \\ \mathbf{T}_n \end{bmatrix} \quad (6)$$

where we introduced substitute **A** for shorter notation and plus (+) represents a MP-inverse matrix.

It is important to note that matrix **A** has 3n rows and 3+n columns and for it to be tall, guaranteeing unique solution n has to be at least 2, meaning that we need to see the waypoint at, at least two cameras to be able to reconstruct the pose. Detecting the same waypoint on more than 2 cameras will produce more accurate result. Also, matrix **A** is different for each keypoint, so in order to reconstruct model with e.g 33 keypoints, we need to construct 33 different matrices and solve 33 different optimization problems.This process has to be performed for each recorded frame.

E. ata post processing

At this point in pipeline, we have already fully reconstructed the 3D pose of all the keypoints. The last basically depends on the usage of MoCap system. We can either save data for later use, or directly stream it to dedicated video/gaming production software, medical application, etc …

IV. RESULTS

Complete process of image acquisition, undistortion, pose estimation and 3D reconstruction is done on laptop with Intel Core i7 10750H, 6 physical & 12 logical core 10th generation CPU with 16GB of RAM and Nvidia GeForce 1660TI GPU. Even so, we were able to achieve stable 20 FPS. The code has been implemented on Ubuntu 20.04 Focal Fossa in Python3 with extensive use of `multiprocess` library, enabling parallelization. Separate process responsible for image acquisition, undistortion and pose estimation was spawned for each camera, with one additional process tasked with 3D reconstruction, and data post processing.

Fig 6. A frame from all 3 cameras taken at the same time with detected keypoints drawn over

 ISBN 978-86-7466-930-3

In Fig 6, the images from all three cameras taken at the same time are shown. The keypoints detected by MediaPipe are overlaid on top of the undistorted images. I can be noted that not all markers are detected on all 3 images, e.g right arm is not detected on first image. Nevertheless, as seen in Fig 7 it can be observed that the system was able to reconstruct the full human pose, with all keypoints. That comes from the fact that for 3D reconstruction we need a keypoint to be detected at minimum 2 cameras. Detection of a keypoint is more than 2 cameras, increases estimation accuracy. It can be noted that the reconstructed full body pose closely matches the one shown in undistorted images.

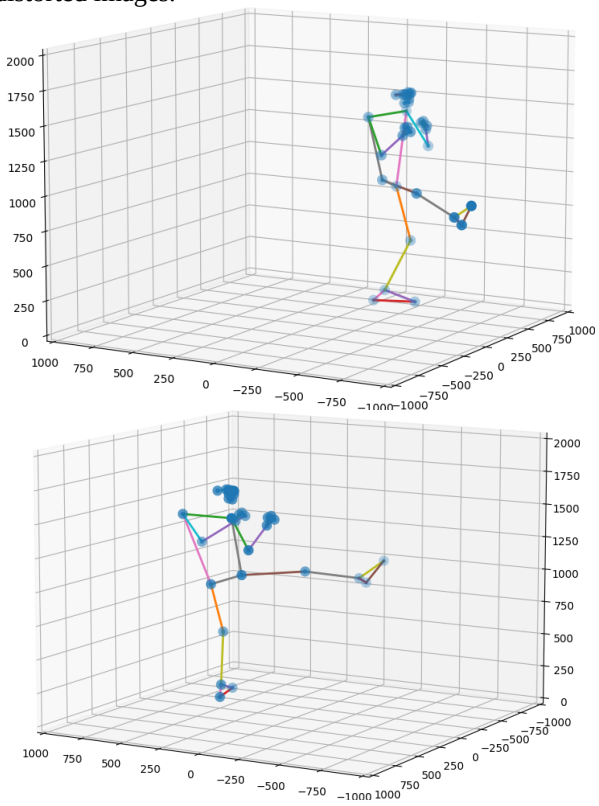

Fig 7. Full body pose reconstructed from images shown in Fig.6

However, during pose estimation some problems occurred. We can observe several frames with incorrectly detected human poses as shown in Fig. 8. Those bad reconstructions can be a result of several issues. Firstly some body parts can go out

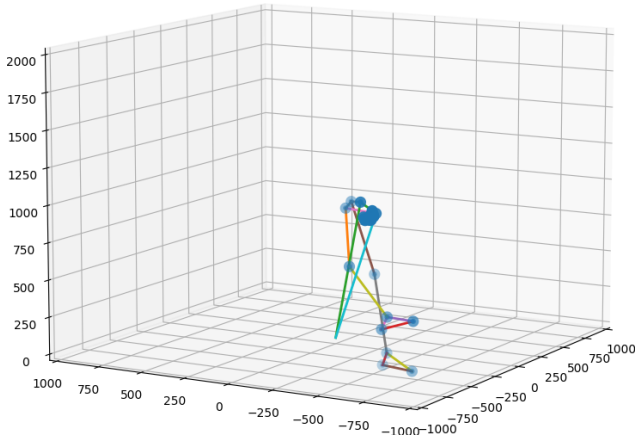

Fig 8. Incorrectly reconstructed human pose

of recording volume or be occluded by objects in the scene, thus preventing MedaPipe to detect keypoints successfully. Other issues can come out of just wrong detection pose detection as shown in the middle of Fig 9. These images show MediaPipes' inability to estimate human pose in non-standing positions. That is a result of MediaPipe being trained on dataset which consists mostly of humans in standing position. That introduces strong bias in the CNN, which expects the torso to be upright. In Fig 9. that was not the case, and MediaPipe has detected a chair in the background as humans face and shoulders. That frame prevents successful reconstruction.

V. Conclusion

In this paper we have presented a budget MoCap system. The system uses inexpensive of-the shelf cameras with a middle-range gaming laptop. Used libraries and software are all open source, with licenses allowing commercial use. Hence, most of the price of the system comes from gaming laptop. The price of the full system was under $2500, but uses common hardware that we had at our disposal, so the MoCap didn't cost us any money. The framerate that we could have achieved was 20FPS. The reconstructed poses closely matched the pose of the actor that was recorded and were stable as long as the actor was within recording volume.

Except low price, the system doesn't require any markers, which significantly reduces setup time. There is no need for

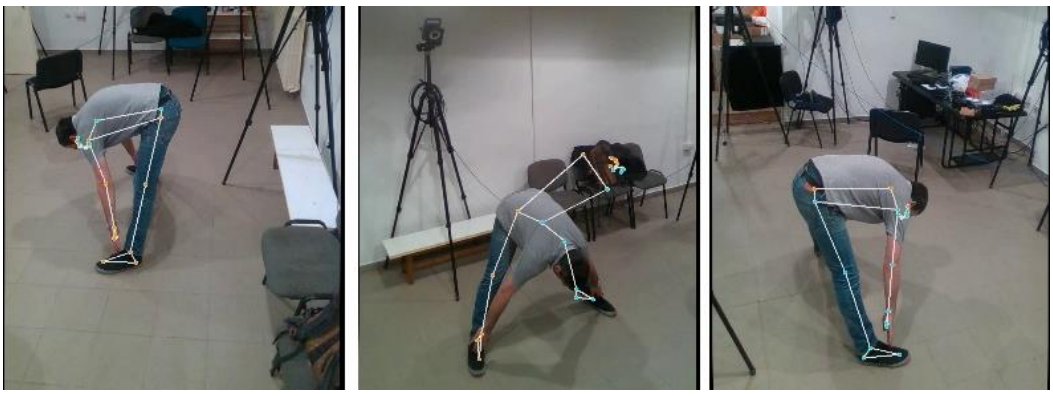

Fig 9. A frame from all 3 cameras taken at the same time with detected keypoints drawn over with incorrect human pose detections

 ISBN 978-86-7466-930-3

tedious process of attaching markers to the actor. The other benefits from this is that people can be recorded while performing their task without interference. That means, the person's motion isn't modified by the fact that there are markers attached to it's body. For behavioral studies, person's motion can be recorded subject's knowledge, reducing the chance for the person to unconsciously alter the behavior. This makes developed MoCap, extremely potent for studies in sport science and behavioral studies with potential HMI application.

Although presented MoCap has a lot of potential there are a few issues that would be the topic for the future research. The current approach doesn't include the temporal continuity of the recording, but each frame is considered independently. The system doesn't consider human model, which would make detection more accurate and more robust to false detections and outliers. Finally, current deep learning backend, MediaPipe can detect only one person. OpenPose, can be used instead, but that comes at the cost of framerate and ability to run system in real time or at the price of higher performance and higher price hardware.

GAN-based Data Augmentation in the Design of Cyber-attack Detection Methods

Dušan Nedeljković and Živana Jakovljević, *Member, IEEE*

***Abstract*—The advent of the Industry 4.0 paradigm that relies on the concepts of Cyber-Physical Systems (CPS) and the Industrial Internet of Things (IIoT) leads to the transition from centralized to distributed control. In this approach, interconnected smart devices (sensors, actuators, etc.) as the key enablers achieve system control through coordinated work. Introduction of IIoT leads to ubiquitous communication between smart devices, thus opening up a vast area for potential malicious threats and attacks which can cause serious consequences, take to system dysfunction or even endanger human lives. Therefore, security mechanisms have to be developed to provide timely detection of different cyber-attacks and to keep the system safe and protected. Since industrial processes are often very complex and their analytical model is very difficult to determine, deep learning based methods for cyber-security mechanisms development are imposed as a technique of choice. Successful employment of data-driven solutions, particularly based on deep learning approaches usually requires a big amount of data. However, due to various limitations in the acquisition of data from the real process, its availability is still a major challenge. For instance, the Industry 4.0 factory implies frequent reconfiguration which reduces the time intervals available for experimental procedures such as data acquisition. One of the ways to deal with this issue is called data augmentation. In this paper, we apply data augmentation in the design of cyber-attack detection methods in Industrial Control Systems (ICS). In particular, we explore the possibilities for utilization of Generative Adversarial Networks (GAN) to generate the necessary amount of data for deep learning based modeling using a relatively small number of available samples on input.**

***Index Terms*—Data augmentation; Cyber security; Generative Adversarial Networks; Deep learning; Convolutional Neural Networks.**

I. Introduction

IMPLEMENTATION of Cyber-Physical Systems (CPS)-based smart devices at industrial plants represents the basis for the digitization of manufacturing processes and leads to the next step in industrial evolution known as Industry 4.0 [1]. Industrial Control Systems (ICS) embrace Industrial Internet of Things (IIoT) and go through significant changes. In addition to enormous benefits, introduction of IIoT at shop-floor has a number of drawbacks, where the ubiquitous wired or wireless communication between smart devices and connection of ICS to Internet can be singled out. Since ICS are no longer isolated, communication links between IIoT devices become vulnerable for the attacks by different malicious adversaries (Fig. 1). To address this issue specially designed systems for ICS cyber-attacks detection and communication links protection are necessary.

Considering the real-time operation of ICS and safety related issues such as catastrophic damages or even threat to human lives that cyber-attacks can bring about, the requirements for cyber-security systems in ICS differ from general information technologies (IT). Opposite to general IT where the data confidentiality is paramount, in ICS data availability, along with its integrity, is the most important [2, 3]. Another key aspect of ICS is that expected lifetime of ICS components (at least 10-15 years) is significantly longer than in general IT (3-5 years) [4] and that, as a result, ICS contain a large number of devices that use legacy communication protocols that do not even utilize the basic protection mechanisms such as authentication [5]. In addition to multilayered protection mechanisms based on network segmentation and segregation, one of the key concepts for cyber-security in ICS is Defense-in-Depth. This concept implies the ability of the devices within ICS to recognize an attack if it bypasses previous layers and that the device should do this before the attack achieves the desired effects [6]. For these purposes host based (installed on the device) Intrusion Detection Systems (IDS) are developed.

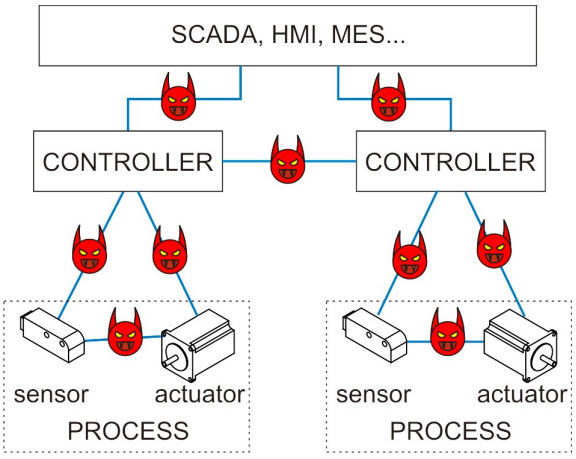

Fig. 1. Cyber-attacks on communication links in ICS within Industry 4.0

Generally, IDS within ICS are based on the model of the system behavior or the data communicated between system

Dušan Nedeljković, MSc (ME) is with the Faculty of Mechanical Engineering, University of Belgrade, 16 Kraljice Marije, 11000 Belgrade, Serbia (e-mail: dnedeljkovic@mas.bg.ac.rs).

 ISBN 978-86-7466-930-3

elements, and the attack is detected as the discrepancy between modeled and exhibited behavior of the system or as the discrepancy between modeled and data received through communication links. Depending on the approach for the model generation, IDS within ICS can be classified in two high level categories: design based and data based. In the design based approaches the model of the system/data is obtained in a mathematically formalized way using analytical models or different formal methods depending on the system type [7, 8].

Data based approaches, on the other hand, use the data obtained during system operation to create the model usually using different machine learning (ML) techniques. These approaches can be supervised, semi-supervised and unsupervised [9]. Supervised methods use labeled datasets containing data obtained during normal system operation and during system operation under attacks to generate detection mechanisms [10, 11]. Unsupervised methods, on the other hand, generate IDS using unlabeled data again containing the data obtained from the system performing with and without attack, and ML techniques find the structure within data themselves. The main shortcoming of the considered classes of methods is that they show low generalization properties when attacks not present during IDS creation are exhibited on the system.

Finally, semi-supervised methods use only the data obtained during normal system operation, i.e., from the system that was not subject to the attacks. They generate the model of the system behavior/communicated data during normal operation and the attack is recognized as the discrepancy between exhibited and the values estimated using the developed models. This class of approaches is most commonly utilized and shows better generalization to different kinds of attacks [12, 13, 14].

In our previous work [14] we have proposed a method for the development of IDS on communication links within ICS that is based on Convolutional Neural Networks (CNN). The proposed method, as well as the other data driven methods, requires significant amount of data from the real-world ICS that cannot be always easily obtained. In this paper we explore the possibility of augmentation of real-world data using Generative Adversarial Networks (GAN) and utilization of thus obtained dataset for IDS creation.

The reminder of the paper is structured as follows. Section 2 briefly describes GAN, whereas Section 3 refers to the utilized method for the development of IDS in ICS. Performance of IDS created using the data generated with a GAN and its comparison with IDS created based on real-world data are shown in Section 4 using an example of electro-pneumatic positioning system based on smart devices. Finally, in Section 5 we provide conclusions and future work guidelines.

II. Generative Adversarial Networks

Generative Adversarial Networks (GAN) represent a method for creation of generative model using adversarial process [15]. GAN consists of two players:

- Generator G that has the goal to generate data with the distribution close to the distribution of training data (Fig. 2.a), and
- Discriminator D with the goal to recognize if the data is created by generator or comes from the original dataset through classification of input as real or generated (fake) data (Fig. 2.b).

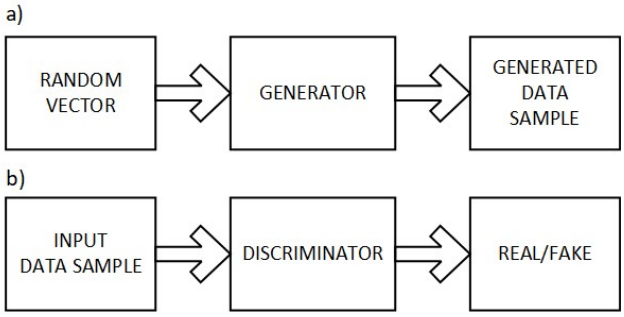

Fig. 2. Generative Adversarial Network: a) Generator, b) Discriminator

GAN training is a two player adversarial game in which generator generates fake data and tries to force discriminator to make a mistake and to recognize this data as real [16, 17]. As a rule, at the generator input is a vector of random numbers (vector of latent variables) and at its output is multidimensional vector that represents the generated data (Fig. 2.a). This data is at the input into discriminator, whereas at the discriminator output is a scalar which represents the probability that the input data is real and classifies the input accordingly (Fig. 2.b).

Generator and discriminator are trained simultaneously, where generator creates a batch of fake samples that are along with a batch of real samples from training dataset put to discriminator to classify them [16]. Based on the quality of discriminator's classification, the generator is updated to create "better" fake data and discriminator is updated to perform better classification. This adversary game repeats for a predefined number of iterations.

Generator and discriminator can be in the form of different ML based models. In our approach we will use deep neural networks (DNN), in particular CNNs and fully connected neural networks – Multilayer Perceptron (MLP).

III. CNN-based Method for the Development of IDS in ICS

The CNN-based method for the development of IDS in ICS that we have proposed in our previous work [14] belongs to the class of semi-supervised data driven methods and consists of the offline and online phase. During offline phase it generates the CNN based model of signals transmitted between IIoT devices using the data acquired during normal system operation. The model is based on auto-regression of the transmitted signals where the current value of the signal is estimated using a buffer of previously received v values. The

 ISBN 978-86-7466-930-3

main characteristic of this method is that it is designed to autonomously find the CNN with relatively small number of parameters that models the training data with good accuracy, opposite to alternative approaches that are as a rule based on manual trial and error.

IDS offline development consists of three main steps (Fig. 3). The first step represents signal preprocessing that performs FIR filtering, data structuring in ordered pairs prepared for training and data shuffling. CNN hyper-parameters (number of CNN layers, size and number of filters within them, number of pooling layers and their parameters, number of dense layers and number of neurons within them, etc.) are varied in the second step, and for each combination a CNN model is created. Finally, in the third step the generated model is selected as appropriate if it satisfies the following criteria:

1. The variance between real and estimated values should be similar for test and training data; this insures that the model is not prone to overfitting or underfitting.
2. The simulation of online performance of the IDS based on the developed model should show good performance in terms of false positive attacks detection; this insures the robustness of IDS to false attack detection online which is very important for smooth operation of ICS.

Once the model that meets given criteria is encountered, the offline procedure stops and this model is put to online detection of attacks. During online phase, the attack is detected based on the discrepancy between estimated and signal values received through communication links. If this discrepancy is higher than threshold automatically calculated from training data for z consecutive signal samples, the attack is detected.

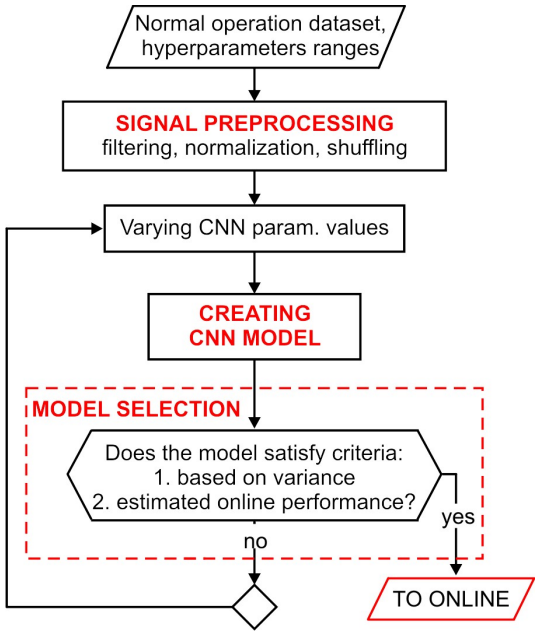

Fig. 3. Overview of the method for IDS development – offline phase

As can be observed from the presented short overview of the method, as all DNN based methods, it is highly dependent on the quality and quantity of the training data and it requires a large amount of this data at input. Acquisition of the data from the system in normal operation requires that the system is operated in isolated conditions without possibility for the attacks. Here the question arises if it is possible to operate the system long enough in such conditions to get sufficient amount of data. Another important issue that is present in Industry 4.0 factory is frequent reconfiguration of resources which leaves little room for experimenting with it. So the acquisition of appropriate amount of data from the system can be hardly feasible in some situations. For this reasons in the following section we explore the possibilities to use relatively small amount of data from real process and to augment it with data obtained using GAN.

IV. The Development of IDS for Electro-Pneumatic Positioning System based on Data Generated using GAN

In this paper we will develop IDS using GAN generated data for experimental electro-pneumatic positioning system – DisEPP (Fig. 4) that consists of:

1. Smart pneumatic cylinder, based on rodless cylinder driven by electro-pneumatic pressure regulator (EPR) that regulates pressure in 2-6 bar range on one and by mechanically controlled pressure regulator (MR) set to 4 bar on the other side, that is controlled by local controller LC1;
2. Smart encoder based on magnetic linear encoder controlled by LC2.

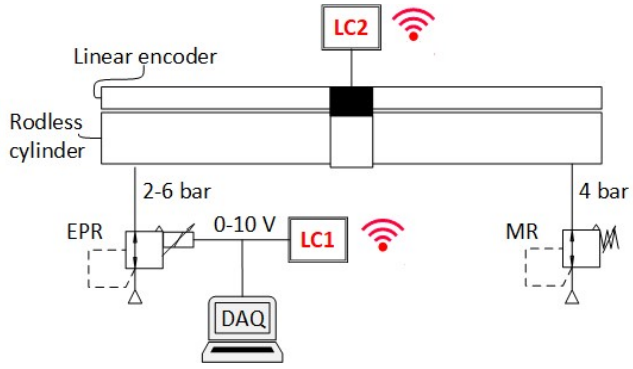

Fig. 4. A schematic representation of electro-pneumatic positioning system DisEPP

Both, LC1 and LC2 represent “mbed” devices based on ARM Cortex-M3 running at 96 MHz [18] augmented by IEEE 802.15.4-compliant wireless transceiver Microchip MRF24J40MA [19] that is used for communication between devices. The control task given in the form of desired piston positions is distributed between LC1 and LC2 in such way that: (i) LC2 has desired trajectory at input and calculates the corresponding pressure on electro-pneumatic regulator using PID and sensory signal; (ii) LC2 communicates PID output to

 ISBN 978-86-7466-930-3

LC1 using IEEE 802.15.4; (iii) LC1 converts received PID output to the 0-10 V range and puts it to electro-pneumatic pressure regulator which finally sets the pressure to 2-6 bars (proportional to the received voltage) and invokes the piston movement.

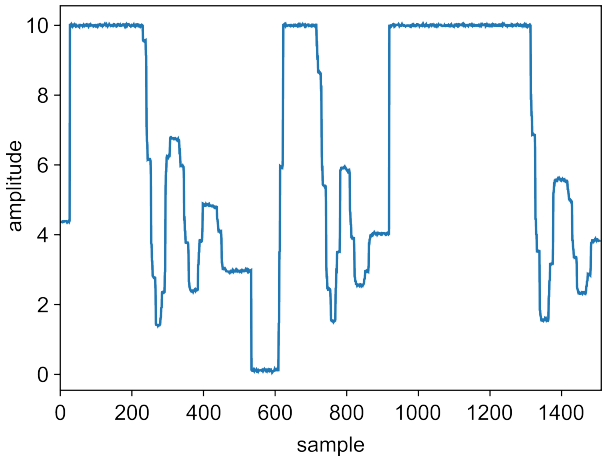

Fig. 5. An excerpt of signal acquired from DisEPP

IEEE 802.15.4 communication link between LC1 and LC2 represents vulnerable point for cyber-attacks and should be protected using IDS. The first step in IDS design using method from section III is generation of dataset representing signals obtained during normal system operation. For this purpose, we have acquired the voltage put to electro-pneumatic pressure regulator using National Instruments Data Acquisition (DAQ) system operating with 100 Hz sampling rate. A total of 399,000 samples x_i, $i \in [1, 399{,}000]$ were acquired and an excerpt of 1,500 samples is presented in Fig. 5.

A. Data Augmentation using GAN

To augment the data acquired from DisEPP we have developed a GAN with the following elements. The discriminator (Fig. 6) has the following architecture:

1. Two blocks of: (i) convolutional layer with 30 filters, each containing 10 samples, with ReLU (Rectified Linear Unit) activation function, followed by (ii) dropout layer with 0.2 dropout rate;
2. Flattening layer;
3. Output layer with one neuron.

At input of discriminator is a generated/real signal with length of 1,500 samples and estimation if this signal is generated or real (0/1) is at output.

The generator (Fig. 7), on the other hand, has the following architecture:

1. Input latent vector of 1,000 random numbers;
2. One dense layer with 100 neurons and sigmoid activation function;
3. Fully connected output layer with 1,500 neurons.

The generator generates 1,500 samples based on 1,000 random numbers.

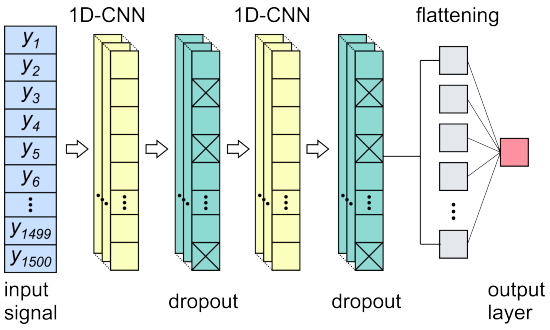

Fig. 6. The architecture of discriminator

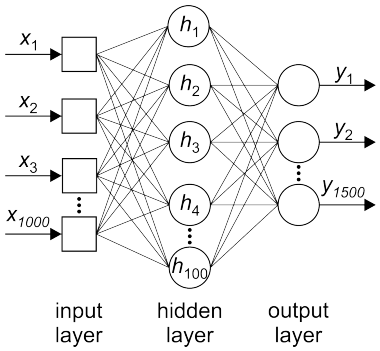

Fig. 7. The architecture of generator

For GAN training a batch of 2,000 real signals $\boldsymbol{s_i}$, $i \in [0, 1999]$, with length of 1,500 samples each, are extracted from training dataset in the following way:

$$\boldsymbol{s_i} = [x_{50i+1}, x_{50i+2}, \ldots x_{50i+1500}] \quad (1)$$

exploiting a total of 101,450 samples acquired from DisEPP. During training 500 epochs were employed.

Figure 8 presents an example of signal obtained using the trained generator. This signal is similar to the excerpt of signal obtained from real process (Fig. 5).

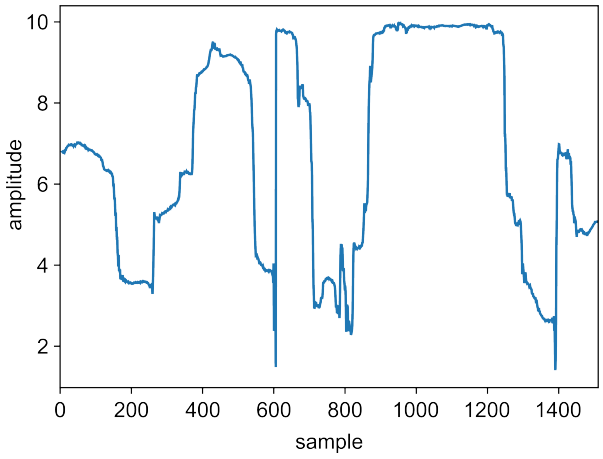

Fig. 8. An example of signal obtained using the generator

 ISBN 978-86-7466-930-3

B. *IDS creation using generated and acquired signals*

Following the procedure presented in Section III, two IDS were created: one using generated signals, and the other using real signals obtained from DisEPP. The same preprocessing procedure is applied to both signals, where the buffers of v=16 samples were used. The employed FIR filter in signal processing has pass band of [0, 0.11π], stop band of [0.35π, π], transition region in between. The filter is composed of 11 coefficients ([0.020243, 0.023017, 0.054189, 0.10397, 0.12557, 0.12344, 0.12557, 0.10397, 0.054189, 0.023017, 0.020243]) that are generated by the Parks-McClellan algorithm. After applying the filter, the signal is normalized by its maximum value. During models training, the whole datasets (signals structured into ordered pairs) are divided into training, validation and test part, with a share of 70/10/20%, respectively. Model training was performed through 5 epochs with Adam optimizer (learning rate of 0.001) and the mean squared error (MSE) cost function.

Following the procedure presented in Section III, two CNN models were developed:

1. based on signals generated using GAN where a total of 266 signals with 1,500 samples containing a total of 391,818 ordered pairs;
2. based on real signal from DisEPP that contains 399,000 samples corresponding to 398,973 ordered pairs.

For both signals (real and generated) the models with the same architecture were obtained. This architecture is composed of the following layers:

- 1D-CNN (4 filters, kernel size=2)
- 1D-CNN (8 filters, kernel size=2)
- Max pooling (pooling rate=2)
- 1D-CNN (16 filters, kernel size=2)
- 1D-CNN (16 filters, kernel size=2)
- Max pooling (pooling rate=2)
- Flattening
- Dense (30 neurons)
- Dense (1 neuron).

and it has a total of 2865 trainable parameters. The model was trained in Python v3.8.5 using a Spyder with TensorFlow v2.3.0 in the background.

In the online part of the algorithm, the detection threshold is calculated as a sum of the mean (μ) value and the triple standard deviation (σ) of discrepancies between received and estimated values over the testing data:

$$T=\mu+3\sigma \tag{2}$$

and it was T=0.00941 for the IDS based on generated and T=0.00956 for IDS based on real-world data.

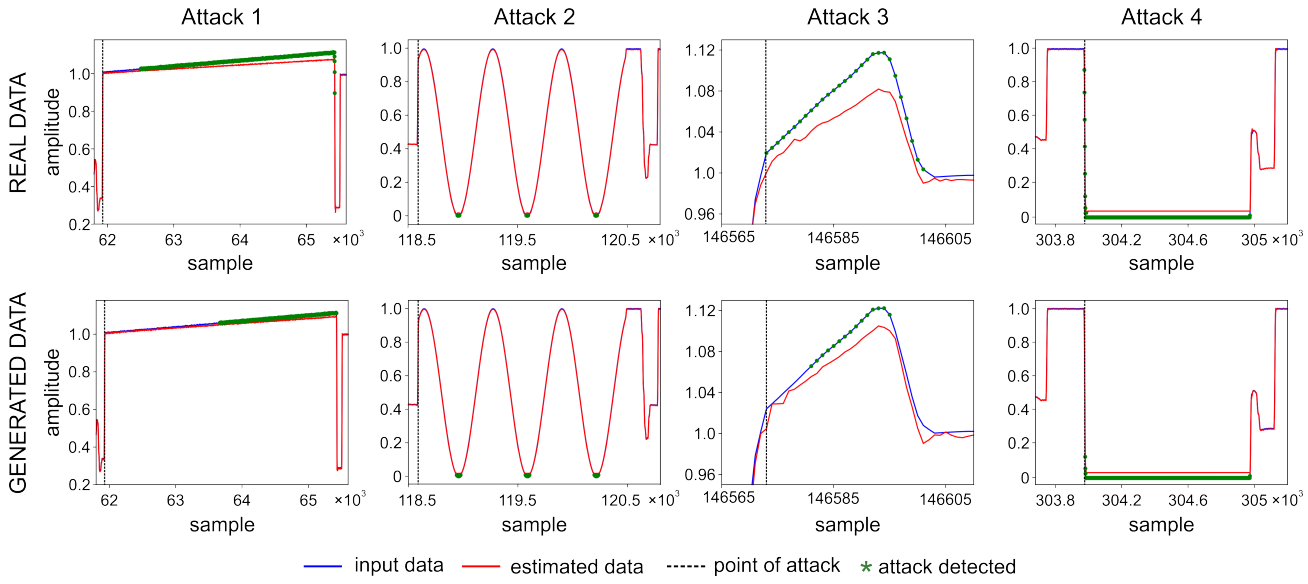

Fig. 9. Detected cyber-attacks

If the discrepancy between real and estimated value is higher than the threshold for z=15 consecutive signal samples, then the attack is detected.

To test the performance of the developed IDSs they were simulated using in Python using a number of the designed attacks. In this paper, we present and compare the performances of IDSs using four attacks with different shapes and duration. Attacks 1 and 3 increase signal value linearly by 0.00003 and 0.005 per sample, respectively, where in attack 1 random noise was introduced as well. Attack 2 utilizes sine function to generate signal value, whereas in attack 4 the signal value is set to 0 for predefined time period.

The results of attacks detection using IDSs obtained based on generated and real data are presented in Fig. 9. In this Figure input data and their estimation are shown in blue and red lines, respectively, the start of the attack is represented with a black dashed line, whereas the moments when the attack was detected are marked with green markers. Both

 ISBN 978-86-7466-930-3

models proved to be equally effective and successfully detected all attacks without false positives.

It can be noticed from the Fig. 9 that the model based on the real data detected attack 1 earlier than the model that used GAN-generated data for training. On the other hand, for attacks 2, 3, and 4, the difference between the detection moments is negligible.

V. Conclusion

In this paper, we have explored the possibilities for utilization of GAN based data augmentation in the design of IDS for ICS using an example of electro-pneumatic positioning system DisEPP based on smart devices. Using a limited number of real signal samples obtained from the DisEPP, an amount of data sufficient for deep learning based generation of IDS was generated. Using the previously developed attack detection method based on CNN, two IDS were created: one using generated signals, and the other using real signals obtained from DisEPP. To evaluate the performance of the created IDSs, a number of attacks have been created, of which four are presented in the paper. As presented in the paper, the IDS based on generated data was able to successfully detect all cyber-attacks without false positives. It presented the similar performances as IDS based on original data not only in terms of a number of detected attacks, but also in terms of attack detection latency, thus confirming that GAN augmented data can be successfully utilized for the generation of semi-supervised data based IDS in ICS.

In the future, we plan to extend our work to additional datasets that contain a higher number of signals and attacks. Furthermore, our research efforts will be directed to the application of different types of GAN and a comparison of their performances.

Comparison of SLAM algorithms on omnidirectional four wheel mobile robot

Slaven Petković, Lazar Milić, Milutin Nikolić, Dragiša Mišković, and Mirko Raković

***Abstract*—In this article we present a comparative analysis of various SLAM algorithms. We compared robot trajectories computed by three ROS-based SLAM algorithms to a reference trajectory obtained from Vicon motion capture system. For data acquisition purposes we used mobile robot with four omnidirectional (*mecanum*) wheels. Our mobile platform was equiped with following sensors: 3D lidar, a RGB-D camera and motor encoders. Experiments were conducted indoor in an office environment. Acquired dataset was used as an input data for all algorithms that we tested. Following algorithms have been taken into account: Livox Mapping, RTAB-Map and Cartographer.**

***Index Terms*—Simultaneous Localization and Mapping, SLAM, ROS, Mobile robot**

I. Introduction

ONE of the most important tasks for autonomous mobile robots is to create a consistent map of unknown environment and to determine its location inside that map. This problem is known as Simultaneous Localization and Mapping (SLAM) and it is considered a difficult problem, because robot needs good estimate of its location in order to create a valid map, but at the same time robot needs consistent map to determine its location.

Problem was first defined back in 1986 [1]. There are two main approaches for solving SLAM problem: probabilistic approach and non-probabilistic approach. The probability methods are based on Bayesian estimation method. Many methods were developed, such as SLAM based on Kalman Filter, Extended Kalman Filter [2], Particle Filter [3], Rao-Blackwellized Particle filter [4], etc.

Nowadays there are many different methods for solving SLAM problem. In this article we focus on SLAM algorithms that are available as an *open-source* ROS (Robot Operating System) [5] package and that have support for 3D lidar and/or RGB-D camera. For purpose of acquiring data, mobile robot with four omnidirectional wheels was used and all experiments were done indoor.

II. Related Work

In this section, we provide an insight into papers that deal with the comparison of SLAM algorithms. Paper [6] provides benchmark for two popular SLAM algorithms: RTAB-Map and RGBD SLAM. Paper [7] shows comparison results of three different mapping approaches. Comparison between three modern VSLAM approaches : RTAB-Map, ORB-SLAM3 and OpenVSLAM is presented in [8]. In article [9] authors show comparison of trajectories computed by various ROS-based SLAM systems in office environment. This article presents a different approach to comparing SLAM algorithms.

S. Petković, L. Milić, M. Nikolić, M. Raković are with the Faculty of Technical Science, University of Novi Sad, (e-mail: rakovicm@uns.ac.rs). D. Mišković is with the Institute for Artificial Intelligence Research and Development of Serbia, Novi Sad, Serbia

III. Compared SLAM algorithms

A. RTAB-Map

RTAB-Map (Real-Time Appearance-Based Mapping) [10] is an open-source library released in 2013 and is still in the development. It is a graph-based SLAM approach with memory management available as *rtabmap_ros* ROS package. RTAB-Map is very flexible SLAM approach because it supports wide range of input sensors such as odometry from any source, RGB-D or stereo cameras and optionally 2D/3D lidar data. Package consists of main *rtabmap_ros/rtabmap* node, two nodes for visual odometry (*stereo_odometry* and *rgbd_odometry*) and lidar odometry node (*icp_odometry*). As RTAB-Map supports inputs from multiple different sensors, data obtained from these sensors needs to be synchronized in order to create a valid map. There are two types of synchronization in RTAB-Map: exact synchronization and approximate synchronization. RTAB-Map can be configured with large number of parameters whose description can be found in [11].

B. Cartographer

Google's Cartographer is lidar graph-based SLAM approach. Cartographer is used for indoor mapping and it supports 2D and 3D lidar data as well as odometry data. In the process of creating map Cartographer uses lidar scans or point cloud to create sub-maps and when loop-closure is detected it runs pose optimization in order to minimize error. First part of this process is managed by Cartographer's local SLAM subsystem (also called frontend), while optimization is done using Cartographer's global SLAM subsystem (also called backend). Detailed description of Cartographer can be found in [12]. On official web page [13] one can find algorithm explanation, description of all parameters and tips for parameter adjustment.

C. Livox Mapping

Livox mapping is a SLAM algorithm developed for creating a map using only Livox lidars. It is available as *livox_mapping* ROS package which supports multiple Livox 3D lidars. Algorithm also uses odometry data, for example wheel odometry. In the development of this package, authors reference to [14]-[16].

 ISBN 978-86-7466-930-3

IV. System setup and Data set acquisition

In this section, we will present the hardware and software used to conduct the experiment. Experiment consists of three main modules: (1) Vicon system for motion capture, (2) a mobile robot for acquiring sensor data and (3) a notebook for running and comparing SLAM algorithms.

A. Vicon system

Vicon system is a highly accurate motion capture system. This system can be used in multiple applications, like robot tracking, human motion capture, etc. In our experiment, the main task of this system was to capture robot's motion and compute trajectory of the robot. This trajectory was used as a reference trajectory to compare and evaluate different SLAM algorithms. Our indoor testing environment with Vicon system and mobile robot is shown in Figure 1. In this experiment Vicon system consisted of (1) seven Vicon MX T-20S cameras, (2) Vicon MX Giganet and (3) desktop computer with Vicon Nexus software used for data processing. Calibration of cameras is done using Vicon Active Wand calibration device and Vicon Nexus software. In this experiment, the operating frequency of Vicon cameras was set to 200 Hz.

Fig. 1: Experimental setup with Vicon cameras and mobile robot

In order to record the movement of the mobile robot, it was necessary to place reflective markers on the mobile robot, which can be tracked by motion capture system. Position and orientation of these markers defines coordinate system of tracking object created in Vicon Nexus software. The orientation of the coordinate system depends on the order in which the markers are selected in Vicon Nexus software. Figure 2 shows three markers placed on the mobile robot. To make it easier to compare data later, the position and orientation of the markers on the mobile robot is chosen to match *base_link* coordinate system defined in robots URDF model (*Unified Robot Description Format*).

B. Mobile robot

Mobile robot used in this experiment was a four wheel omnidirectional mobile robot (Figure 3). This construction with

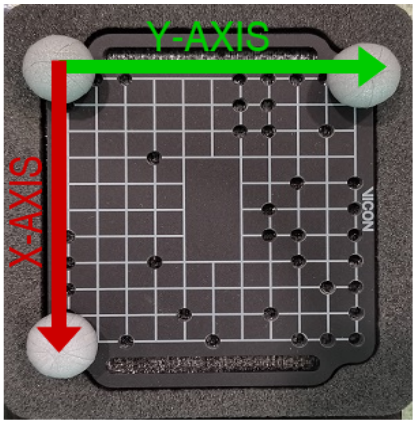

Fig. 2: Reflective markers used to track robot motion by Vicon system. Position of markers determines position and orientation of coordinate system of tracked object

omnidirectional wheels (*mecanum wheels*) enables it to move in multiple directions and change direction rapidly. Mecanum wheel consists of k rollers made of rubber positioned at 45 degrees angle offset from the wheel rotation around its circumference. Paper [17] describes geometry and kinematics of mecanum wheels. Main problem with this type of mobile robots is that robot's wheels slip, and odometry based on encoders from wheels can not be considered as reliable.

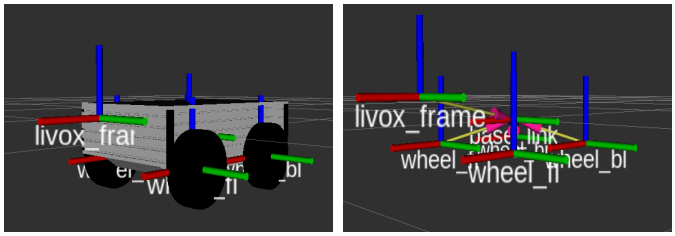

Fig. 3: Omnidirectional four-wheeled mobile robot

Running SLAM algorithms on ROS requires a file that describes robot's physical state to ROS. Creating robot model was done using URDF. URDF is an XML file format used to describe all components of a robot. Figure 4 presents model of our mobile robot and positions of coordinate systems presented in RViz.

Robot's software runs on Ubuntu 18.04 operating system and ROS Melodic. Following sensors were mounted on mobile robot in this experiment: 3D lidar, RGB-D camera and wheel

C. Data processing

In order to get the most valid comparison results, the goal was to record data from robot sensors to one file, so every SLAM algorithm tested in this experiment could use the same input data. For this reason we run offline all the SLAM algorithms that are evaluated. Detailed information about computer configuration that was executing SLAM algorithms is shown in II.

V. Metrics and data comparison

In this section, we give an insight into how the Vicon system and ROS represents robot pose. We also present metrics for analyzing performance of SLAM algorithms by comparing trajectories and robot poses generated by each SLAM algorithm to a ground truth trajectory and robot poses computed by Vicon system. We did not compare generated maps. The idea was to compare predicted robot pose to an actual robot pose in every moment in time. As robot pose in plane consists of three components, x and y coordinate and rotation around z-axis, we compared each component of robot motion separately. Then the error for all three components of robot motion was calculated.

A. Data representation

1) Vicon system: Vicon Nexus software is able to export data in number of different formats. We have chosen to work with *.csv* file. Table III shows an example of *.csv* file generated by Vicon Nexus software. Values *RX*, *RY* and *RZ* represent rotation of robot's base coordinate frame around x, y and z axis respectively, while *TX*, *TY* and *TZ* represent position of robot's coordinate frame in x, y and z direction respectively with respect to the reference frame. All values are expressed in relation to the origin of the coordinate system defined by the position of the Vicon Active Wand during calibration. Frame column was used to calculate timestamp.

Frame	Sub Frame	RX	RY	RZ	TX	TY	TZ
number	number	[deg]	[deg]	[deg]	[mm]	[mm]	[mm]

TABLE III

2) SLAM algorithms: The ability of Robot Operating System to record data from any available topic was used for generating data set. Recorded data was saved to *.bag* file. ROS represents robot pose as *geometry_msgs/Pose* ROS message and it also enables us to export in *.csv* file. Unlike Vicon system, ROS uses Quaternion to display robot rotation.

B. Data comparison

Comparing two trajectories requires them to consist of same number of points (robot poses) and to be synchronized in time. In our case, neither of these two conditions was met.

As previously said, we collected data from sensors mounted on mobile robot and run algorithms offline using collected data to generate test data set. Reference trajectory was computed by Vicon system. These systems are not synchronized in time.

First problem was how to equalize the beginnings of two compared trajectories in time. In order to do that, we decided to find moment in time in which robot made a movement for 1 mm in x or y direction.

Second problem was that every ROS algorithm publishes messages about robot pose at different rate and Vicon system frequency was 10 to 20 times greater than frequency at which ROS algorithms publish messages. In order to deal with this problem, there were two possibilities: to reduce the size of reference data set or to expand test data set. We opted for the latter and decided to do an interpolation over data generated by SLAM algorithms.

C. Metrics

Interpolation was done by time for every component of robot motion: $x(t)$, $y(t)$ and $\theta(t)$. Figure 5 shows example of interpolation in case of function $x(t)$.

 ISBN 978-86-7466-930-3

As previously sad, SLAM algorithms publish messages about robot pose less frequently than Vicon system. In this paper interpolation was used to calculate new value in test data set for every moment in time of reference data set. Let's observe point (t_i, x_i) from the reference data set. In order to calculate new value we decided to find two points in the test data set which were closest in time to the observed point. On figure 5 points A(t_j, x_j) and B(t_{j+1}, x_{j+1}) represent two closest points. Equation of line connecting points A and B was calculated. Inserting value of t_i into new equation, interpolated value x_{interp} is calculated.

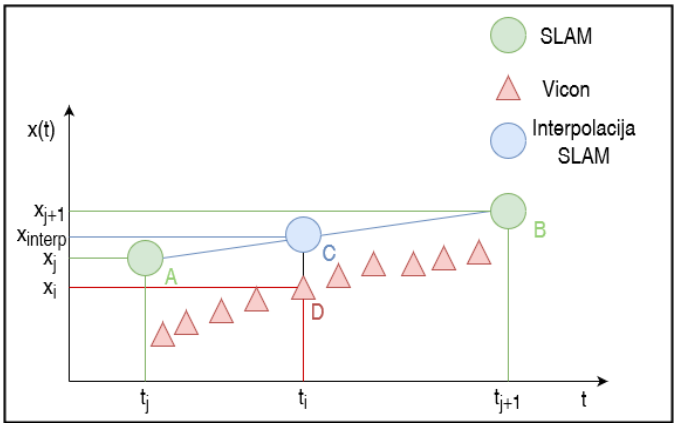

Fig. 5: The figure illustrates an example of interpolation used to generate new data in test data set

Data processing and comparison was done using the Python 3 programming language and the *NumPy* library, as one of the best open-source tools for working with data and numerical calculations.

VI. Results and Analysis

In this section we present results of our experiment. Results are presented graphically and numerically. For visualizing results, we used Python programming language and *Matplotlib* library. Results are presented in four graphs for each tested SLAM algorithm. First figure contains estimated trajectory (shown in red) computed by SLAM algorithm and reference trajectory computed by Vicon system (shown in green). Other three figures show comparison of *x(t)*, *y(t)* and $\theta(t)$ functions respectively. Table IV presents numerical results of our experiments. Error is represented as RMSE (*Root Mean Square Error*), standard deviation, mean absolute error and maximum absolute error.

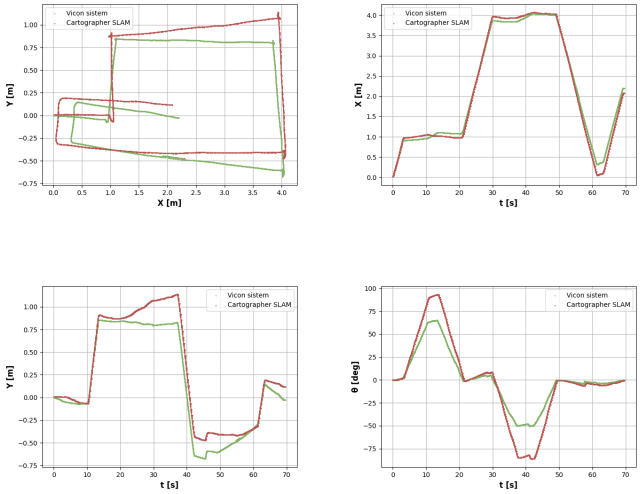

Fig. 6: Trajectory recovered from Cartographer SLAM (red) vs Vicon system reference trajectory (green)

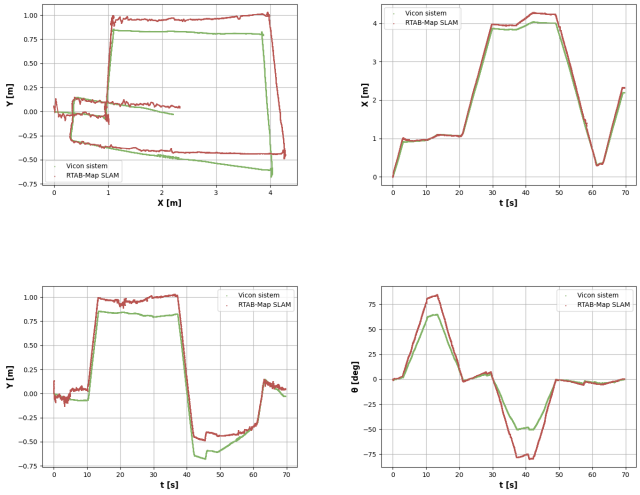

Fig. 7: Trajectory recovered from RTAB-Map (red) vs Vicon system reference trajectory (green)

VII. Conclusion

In this paper, we have presented a method for analyzing performance of ROS-based SLAM algorithms that compares trajectories computed by SLAM algorithm to a reference trajectory obtained from motion capture system. We proposed a metric for calculating error in estimated trajectory. This approach allows us to compare algorithms that use different sensor information.

Since omnidirectional wheels are slipping during the motion of robot, the localisation of the robot has to be based on sensory system that is not measuring motion of wheels directly. Therefore, the robot is build with 3D Lidar and RGB-D camera as sensors for localisation of the robot and mapping of the environment. To better determine what algorithm is the best for sensory system that our robot has, we evaluated three

Natural Non-Invasive Human-Machine Interface Based on Hand Gesture Recognition

Jelena Rodić, Darko Golubović, Nikola Knežević, Kosta Jovanović

***Abstract*— In recent years human-machine interfaces have been identified as an important aspect for enabling safe and efficient human-robot collaboration. In the same period of time, deep learning has made great progress in image classification problems with the evolution of convolutional neural networ s This paper presents a hand gesture classification module as a non-invasive natural human-machine interface that e ploits deep learning technology. There were various approaches for this tas in the past, such as loo up tables, detection of ey-point positions of fingers, classic neural networ s, etc. This paper implements GG1 convolutional neural networ to solve the tas of hand gesture. To capture an image, we use leap motion sensor which is cheap and can wor in challenging light conditions, because it uses infra-red emitters to lighten the object. Thus, this approach is useful for factories and production lines. Another contribution of this paper is an e tensive database consisting of 2 images.**

***Index Terms*— uman-machine interface; and gesture; Convolutional eural etwor s; eap motion sensor; GG1**

I. Introduction

Enhanced by developments in technology, numerous jobs are being transferred into the domain of robots and sophisticated machines [1, 2, 3]. These production lines perform various tasks. However, because market requirements are changing daily, there is a need for quick adaptation of these lines. Therefore, some manufacturers have developed flexible robotic cells that can serve multiple types of processes [4]. On the other hand, humans can adapt to changes in requirements quickly. This quality makes them valuable considering the dynamic of market needs. Combining human flexibility and robot reliability and consistency could give us a solution to the challenge the market sets without sacrificing the output volume.

The application of such a system is displayed in assembling fiscal cash registers. The process itself requires human involvement because the parts needed for assembly are small and the assembly process is delicate (mounting flat cables, soldering capacitors for PCBs, inserting tape for thermal printers). This process could be significantly less demanding for the operator by using novel technologies.

Firstly, it is possible to show the operator instructions for assembling a specific device using adaptive screens. Secondly, collaborative robots can be used to deliver the right part for the current production phase on time, which would increase the overall speed of production.

Thirdly, it is possible to gain an insight into worker performance (focus, monotony, fatigue) during tasks using EEG headphones. With this approach, the worker could switch assignments occasionally, and stay interested and productive.

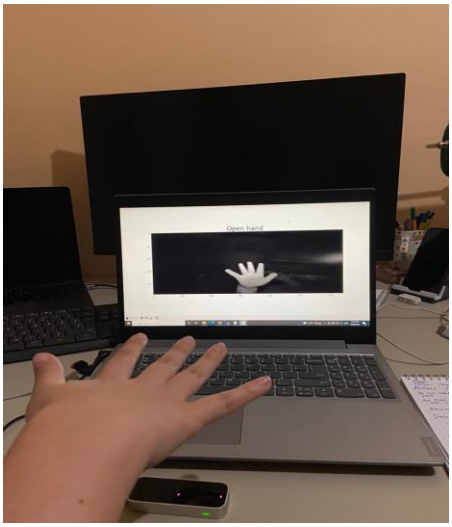

Fig. 1. System setup. Leap Motion sensor connected to PC for classification of hand gestures.

Also, if a person is engaged in dangerous work, this approach can prevent injuries from occurring when their focus is low and fatigue high. In addition to assistive devices, it is necessary to enable intuitive communication between humans and the rest of the system. For this purpose, a Leap Motion sensor is used (Fig. 1).

This sensor can detect hand gestures and provide human-machine interaction. There were a couple of solutions providing the human-machine interface but, some of them were invasive (wearing sensor gloves) or non-intuitive (complex system of buttons and taskbars). Using this type of sensor non-invasive method of human-machine interface is introduced. In this way communication between humans and machines is alleviated and it is more receptive to humans.

In this paper, we present a system for classifying human hand movements. For this purpose, it was necessary to collect the appropriate database, select the neural network architecture that will perform the classification, and finally test and implement the application that works in real-time.

II. Previous work

Paper [5] from the University of Padua implements hand movement recognition. The classification was done over ten basic hand gestures. Also, the paper focuses on static gesticulation using leap motion controllers and kinetic devices. Microsoft's Kinect camera provides 3D images, while leap motion provides only key points in 3D. Here the authors explain that the images from ordinary cameras are 2D variants of the 3D position of the hand, so there is a loss of information.

 ISBN 978-86-7466-930-3

By providing 3D finger positions leap sensor can give more meaningful measurements. With the introduction of Time-of-Flight cameras for widespread use, 3D representations of objects have become more accessible to use. However, recognizing any movements that are not the most basic is still too complex for this type of sensor (leap motion), the paper states. The authors decided to unite these two types of controllers and try to get a more accurate classification. The problem is to calibrate these two devices. They achieved this by combining the fingertips from leap motion and the peaks on the depth camera that represent the fingers. Attributes used are the number and position of the fingers, the center of the palm and the orientation of the hand, angles at which the fingers stand, and the distances between the fingers. The problem occurs when the fingertips touch because sometimes they are detected as one finger. Furthermore, rings, bracelets, etc. can spoil the accuracy too. After PCA analysis, features were input into a multiclass SVM classifier with a Gaussian kernel. The best accuracy authors achieved is 80.9%, using only the leap sensor. After they inserted the data from Kinect, the accuracy jumped to 96%.

Paper [6] deals with the recognition of dynamic hand movements. The attributes used in this paper can be divided into two categories: static and dynamic. Static ones are based on the positions of the fingers and palms, ie. at the relative distances between them. Distances between the tips of adjacent fingers, and between the center of the palm and the tip of the finger are defined as attributes. For example, the Ok symbol is represented by the distance between the thumb and forefinger as a good attribute. Dynamic attributes are defined by finger and palm speeds to detect moving patterns. Those patterns are complicated, but the velocities of the essential points are given by the sensor itself, which makes the job easier. Examples of dynamic attributes used here are the translation of the whole hand (when the palm and fingers move at the same speed along some axis, without rotation), rotation of the hand (when the palm rotates), the precession of the hand (when the palm moves in a circle), swipe index finger, etc. The results of this work show that when the controller detects fingers accurately, the classification methods themselves work accurately. The authors noticed that tracking the fingertips of the middle and little fingers is not very stable. This can cause some problems in inference.

Paper [7] deals with the application of leap controllers to realize a virtual museum for free. Interaction with the virtual world using hand gestures has been suggested. It is necessary to classify the positions of the hand to prevent unwanted moves. First, data based on x, y, and z coordinates of fingertips was obtained, and then attribute extraction was performed. The authors used information on how far the fingertips are above the plane of the palm. They also used information on angles between the fingers and the palm. The classification method used was K nearest neighbors (KNN). They state that the accuracy obtained in other papers is about 80% for the same subjects and about 70% for new ones. The exact accuracy they obtained was 99%, but it was not said how they chose the test set.

Paper [8] was done at the University of Malaysia and deals with the control of drones based on hand movements read from leap sensors. The idea is that leap motion reads the gesture, sends it to the Arduino for recognition, and then sends the command to the drone to control. Three throttle commands are classified - lift, pitch, and roll. The idea was to simplify communication with the drone, which is currently complicated since there are numerous handles, buttons, etc. Therefore, the new commands were up and down, tilt back and forth, and tilt left and right. It is said that the drone worked well when the commands were given clearly. No accuracy or classification methods were stated.

In [9] authors implemented automation of design commands in CAD, Solidworks, and Catia software. It is stated that there is a lack of tools for some very intuitive modifications. The authors wanted to replace the commands given by the mouse and keyboard. For example, the review mode requires translation, rotation, and scaling. The scaling command is the distance between two index fingers. The rotation command is rotating the fist. In the end, a grab, and release command for translation are performed based on the distance between the index fingers. Paper does not use machine learning for classification but only distance mapping. If a command cannot be mapped to the table, then it is omitted. The accuracy they get is 80%.

Paper [10] dealt with a slightly different task. They wanted to recognize handwritten symbols in the air based on the movement of the hand. The key points were sampled at a rate of 100 frames per second. The attributes taken are the positions and velocities of the key points, the angles at which the fingers stand, etc. Finally, the classification was performed using convolutional neural networks. The accuracy they obtained is 92.4%.

Paper [11] deals with the dynamic movements of human hands. Motion information is converted to color images. The conversion of movement into an image is done by tracking the finger position in time. Each finger is assigned to a distinct color, and the intensity of the color changes depending on the time. The authors used the ResNet-50 for the classification. The accuracy they get is about 80%.

III. METHOD

First, we need to define the problem we want to solve. Namely, for the needs of working on the production line in factories, it is convenient to use only commands that do not include pressing the screen and buttons when worker's hands are dirty, or the screen can't detect users' input caused by wearing the safety gloves or other equipment. For our case, it was necessary to select 4 hand commands that could be classified with high precision using the leap motion sensor. Some crucial steps in solving this problem were:

- Obtain or form an adequate dataset that has different commands given by hand movements. We decided to work on images because they are more reliable than the detection of key points from Leap sensors. Also, convolutional neural networks are powerful in image

 ISBN 978-86-7466-930-3

classification, so this method should give promising results.

- Choose 4 distinct commands, which will be able to be easily distinguished from the images returned by the Leap sensor.
- Choose the adequate architecture of the convolutional neural network and tune the hyperparameters. Assess the probability of misclassification on the test set.
- Eventually do a live simulation with a real sensor where after the first detection of the hand in the frame three frames would be captured at 0.33s interval. Then each of these three frames would be passed through a neural network for classification, and finally, a final decision would be made based on a majority vote.

A. eap Motion Sensor

There are several sensors on the market that handle motion detection. The Leap Motion sensor [12] stands out for its price (it is cheap) and accuracy. Leap Motion Controller is an interactive device specializing in detecting hand movements and finger location based on infrared light emitters and two cameras that receive reflected IR waves. The Leap Motion architecture can be seen in Fig. 2.

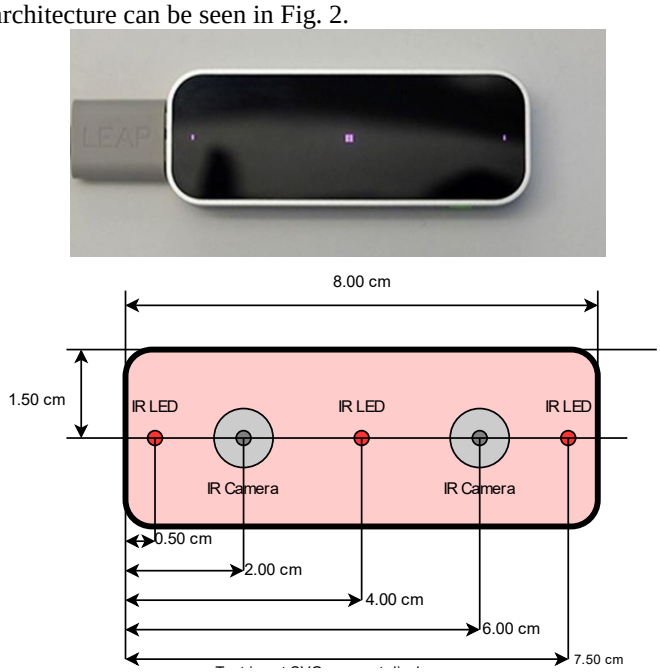

Fig. 2. Leap motion sensor, from [14]

Its field of vision is up to 1m away. There is also a skeletal model of the human hand, which represents five fingers divided into phalanges. We can also obtain a raw image from the sensor, which is the one we used.

B. atabase

First approach was to try to train the network on different publicly available datasets. The best result we got was with the database [15]. The problem with this database is that it did not contain various heights or angles on which the hand can be, thus making this network prone to errors once the hand is not perfectly positioned. Considering the application of this paper, we wanted to develop a system that is able to work in real life conditions, thus making this database inadequate for our task. On our versatile test dataset, this network had the accuracy of 91.5%.

After realizing that publicly available databases are not extensive enough to meet our needs, we decided to develop our own dataset using the Leap Motion sensor. Our training set consists of four classes of hand gestures. Each class consists of 5000 images. There is an equal part of men and women in the hand dataset. Also, there are 50% left-hand images in the database. Furthermore, images were obtained at various lighting conditions, angles, and heights. The last two turned out to be important for the network to generalize well. We trained our network on one publicly available data set which had only photos of hands perpendicular to the sensor. Also, all the pictures were formed with a constant distance between the hand and the sensor. This plays a key role because the camera on the leap sensor is in a wide range. That slight change in the distance of the camera results in a tremendous change in the size of the object in the final image. As a result, the same architecture performed significantly worse than when it was trained on our custom dataset. This shows us the importance of a well-rounded dataset, which achieved accuracy of 99.3%. We will compare these results in detail in the section Results.

In the end, we used an unseen person to obtain the test set. Also, the test set contains images taken from different angles and heights. Here are examples from the dataset (Fig. 3):

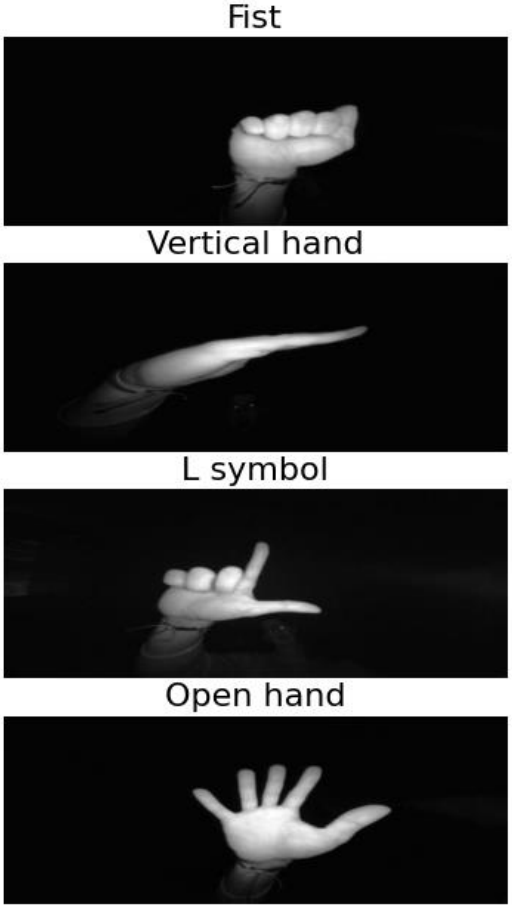

Fig. 3. Example of each hand gesture in our database.

 ISBN 978-86-7466-930-3

C. Model Architecture

VGG16 is a deep convolutional neural network pre-trained on the ImageNet dataset. The VGG16 Architecture was developed and introduced by Karen Simonyan and Andrew Zisserman. The VGG16 model achieved 92.7% accuracy on the classification task, which earned its authors second place in the competition. On the localization task, VGG16 earned first place. This model is widely used both because it is easy to implement and because it is still extremely competitive.

During training, the input to the CNN is a 224 x 224 RGB image. Subtracting the mean RGB value computed on the training set from each pixel is the only pre-processing done here. The image is passed through a stack of convolutional layers, where filters with a small radius are used (Fig. 4). The convolution stride and the spatial padding of convolutional layer input is fixed to 1 pixel. This ensures that the spatial resolution is preserved after the convolution. Five max-pooling layers, which follow some of the convolutional layers, help in spatial pooling. Max-pooling is performed over a 2×2-pixel window, with stride 2. Here is the architecture:

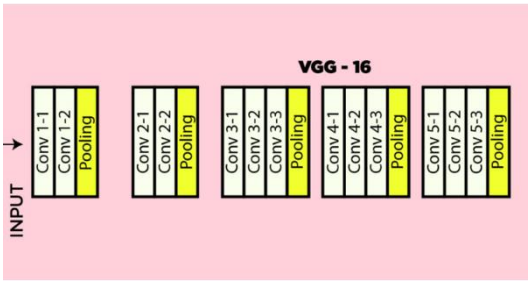

Fig. 4. VGG16 architecture, from [13].

On top of the CNN, we put a classification head that consisted of 2 dense layers. The first one was size 512 with ReLU activation function, and the second one was size 4 with Sigmoid activation function.

. yper-parameters

In this section we will mention some hyper parameters as well as optimizers we used. Firstly, we used an RMS prop optimizer. This is a gradient-based optimizer that deals with vanishing and exploding gradients very well. It uses the moving average of squared gradients to normalize the gradient. This normalization decreases steps for large gradients and increases steps for small gradients. Effectively this means that the learning rate is adjusted based on previous magnitudes of gradients. For the loss function we opted for cross entropy loss.

E. Training

We trained our model during 5 epochs, with batch size 64 and learning rate 0.0001. Train-validation split ratio is 80:20. Another way to stop overfitting of the network was using regularization with L1 and L2 losses combined. Also, we used dropout layer in classification head.

IV. Results

Results of the network which was trained on the small database [11] (the one that did not contain various positions and scales of the hand), has considerably lower accuracy on the versatile test dataset. This can be seen in the confusion matrix below (Fig. 5). The accuracy of this model is 91.5%.

After training our network for five epochs on 20000 images (our database), loss reaches saturation both on validation and training set.

Further, this model has 99.3% accuracy on test data. The confusion matrix is very concentrated around the main diagonal (Fig. 6).

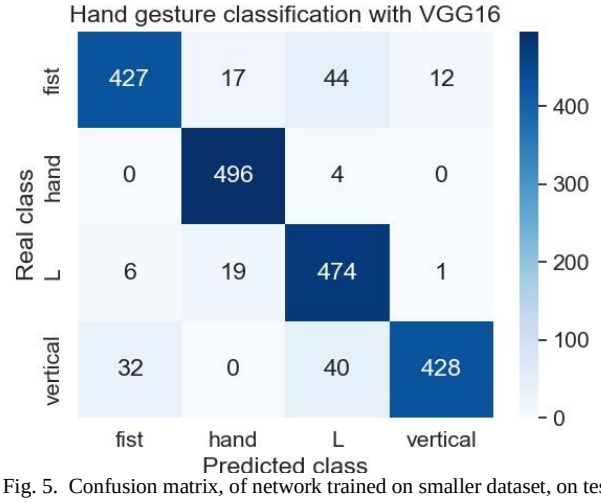

Fig. 5. Confusion matrix, of network trained on smaller dataset, on test data

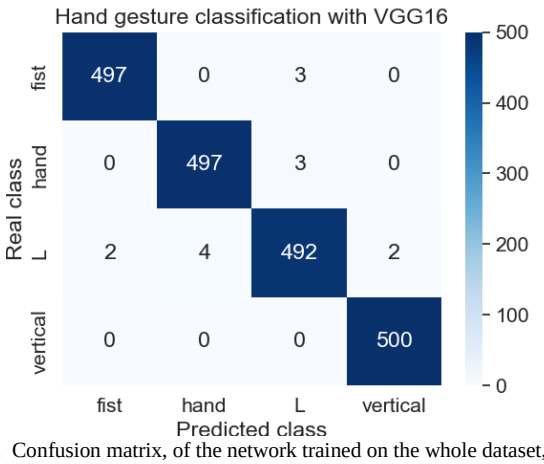

Fig. 6. Confusion matrix, of the network trained on the whole dataset, on test data

We can see that there is no significant difference in these precisions, which suggests that our model is not biased towards any class. This is because our dataset is balanced, and the network can learn the features of each class equally well. However, the L symbol has the highest number of misclassified examples. This could be because it is visually somewhere between the fist and the open hand. Two fingers extended like in the open hand, and three fingers flexed like in the fist
Next, we will show some misclassified instances:

- Fist mistaken for L shape: This could be because of

 ISBN 978-86-7466-930-3

the angle between the forearm and the fist. Therefore, this calls for a more well-rounded database that will contain lots of these examples in the training

- L shape is mistaken for fist: This could be because the index finger is too thin in the image.

In the end, it is important to notice that our system works in real-time. Also, the accuracies are even greater in real-life use because the decision is made using a majority vote from three shots of the subject's hand.

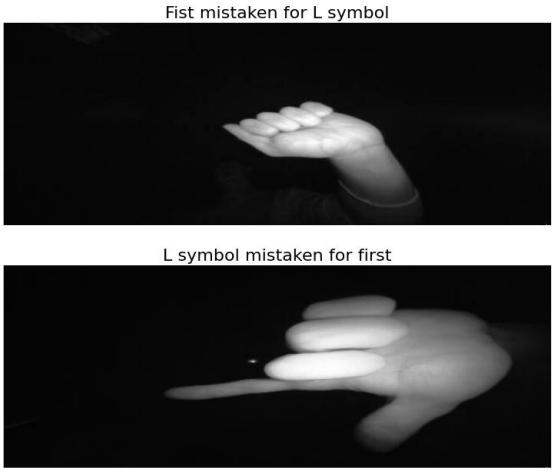

Fig. 7. Examples of failure cases.

V. Conclusion

In this paper, we developed a system for natural and non-invasive human-machine interface using a leap motion sensor. The aim was to classify four hand gesture commands with high precision in real-time. This was done by using deep convolutional network VGG16 and a custom classification head. The inference time per image is 0.23s. To trigger a decision, a hand must be detected by the leap sensor. After that, our system takes three shots at 0.33-second intervals. This setup enables us to use this system in real-time efficiently. The decision is made based on the majority vote of those three shots. This approach gives an accuracy of 99.3% on the test set. Further, our system is robust in terms of distance from the hand to the sensor, and orientation of the hand with respect to the sensor. This is important because in real-life situations workers will approach this device from different angles and heights.

I. Uvod

Roboti su brzo poslali sastavni deo proizvodne industrije. Roboti se koriste na različite načine u različitim industrijama i imaju izuzetno veliki uticaj kada je u pitanju industrijska automatizacija.

Tradicionalni industrijski roboti su fizički odvojeni od ljudi, izvršavaju zadatke koji su odvojeni od ljudi zaposlenih u proizvodnji, kako bi obezbedili njihovu bezbednost. Sa druge strane, kolaborativni roboti su napravljeni tako da imaju ograničene brzine, i momente, kao is senzore koji im omogućavaju da budu bezbedni za ljude i da ljudi mogu biti u blizini, kao i da rade sa njima zajedno. [1,2]

Kolaborativni roboti nude nove potencijale za poboljšanje načina na koji radimo. Oni su se brzo razvili ubrzanim uvođenjem industrije 4.0 i razvojem novih robotskih tehnologija. Pre samo deset godina, prema robotima su se odnosili sa nepoverenjem, a danas je oblast industrijske robotike ona koja se najbrže razvija. Kolaborativni roboti brzo postali sastavni deo proizvodne industrije.

Ovim robotima je potrebna ljudska pomoć kada vrše manipulaciju materijala ili sklapanje nekih komplikovanih delova. Kolaborativni roboti su dizajnirani da rade i pomažu ljudima, umesto da im oduzimaju posao. Oni su programirani da obavljaju ponovljive zadatke tamo gde su ljudi potrebni, ali ne i njihova stručnost. Dakle, koriste se za jednostavne, ponavljajuće zadatke koji su opasni ili teški za ljude, kao što su operacije na proizvodnoj liniji, održavanje mašina, elektro lučno zavarivanje, rukovanje opasnim materijalima, laboratorijsko testiranje i drugi proizvodni zadaci.

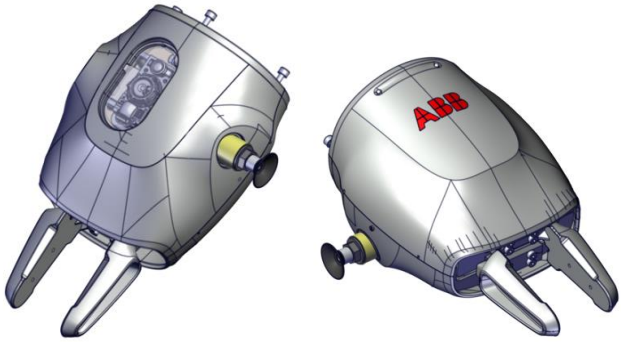
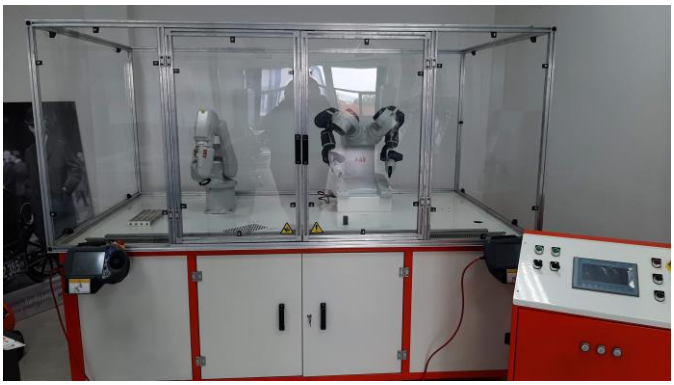
.

II. Laboratorijska Postavka



U ovom istraživanju je korišćena oprema postavljena u laboratoriji Naučno tehnološkog parka u Čačku čije opremanje je finansirano od strane Ministarstva prosvete , nauke i tehnološkog razvoja Republike Srbije. U ovoj laboratoriji instalirana su dve robotske ćelije. Jedna ćelija je industrijski robot ABB IRB 120, multifunkcionalni robot sa šest stepeni slobode, koji je detaljno opisan u radu [3]. Drugi robot je ABB IRB 14000 YuMi kolaborativni robot koji je prikazan na slici 1.

Slika 1. ABB IRB 14000 kolaborativni robot [4]

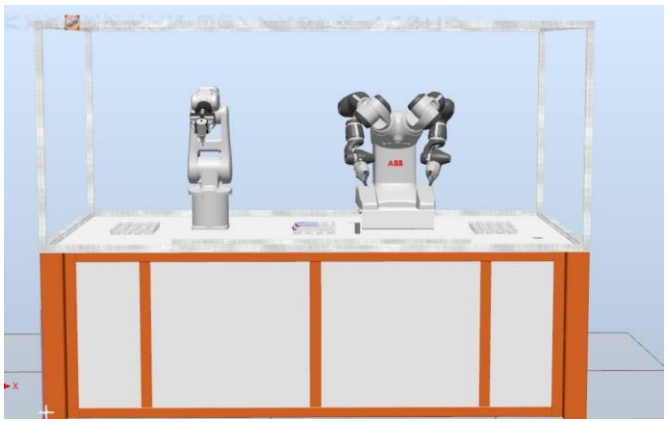


Ovaj robot je dvoručni robot koji je napravljen za zajednički rad sa čovekom na istom poslu. Robot poseduje sedam stepeni slobode u jednoj ruci koje mu daju veliku fleksibilnost i agilnost u proizvodnji. Ponovljivost robota je 0.02mm. Robot ima domet od 559mm i nosivost od 500g po ruci. IRB 14000 poseduje Smart Gripper kao end efektor sa manipulaciju i sklapanje. Griper ima servo prste kao podrazumevani modul, dok su vakuum hvataljka i kamera opcioni. U ovom slučaju leva ruka ima servo prste i vakuum modul. Desna ruka poseduje servo, vakuum i kameru (Cognex AE3) [4].

 ISBN 978-86-7466-930-3

Slika 2. Desni i levi Smart Gripper [4]

Oba robota su smeštena na radni sto sa zaštitnom zonom od pleksiglasa. Na radnom stolu nalaze aluminijumski profili za montažu dodatne opreme, senzora, pribora… Kontroleri robota i ostale komponente povezane su na komandni pult u kome se nalazi PLC kontroler i HMI tač panel. Na ovoj laboratorijskoj postavci sa opremom koja se na njoj nalazi moguće je testirati različite industrijske aplikacije. Izgled laboratorijske postavke prikazan je na slici 3.



Slika 3. Izgled laboratorijske postavke

III. Virtuelno Okruženje

Jedan način za programiranje ABB robota je korišćenje softverske platforme ABB RobotStudio. Softver poseduje virtuelni kontroler za programiranje robota. Dobar je za simulaciju rada robota kao i drugih pokretnih mehanizama. Ovaj softver omogućava programiranje robota i promene programa bez ometanja ili zaustavljanja proizvodnje. RobotStudio se koristi kao virtuelna laboratorija i programiranje robota van mreže (offline). Ova softverska platforma sastoji se od četiri glavna dela: modeliranje, simulaciju, kontroler i RAPID [5, 6].

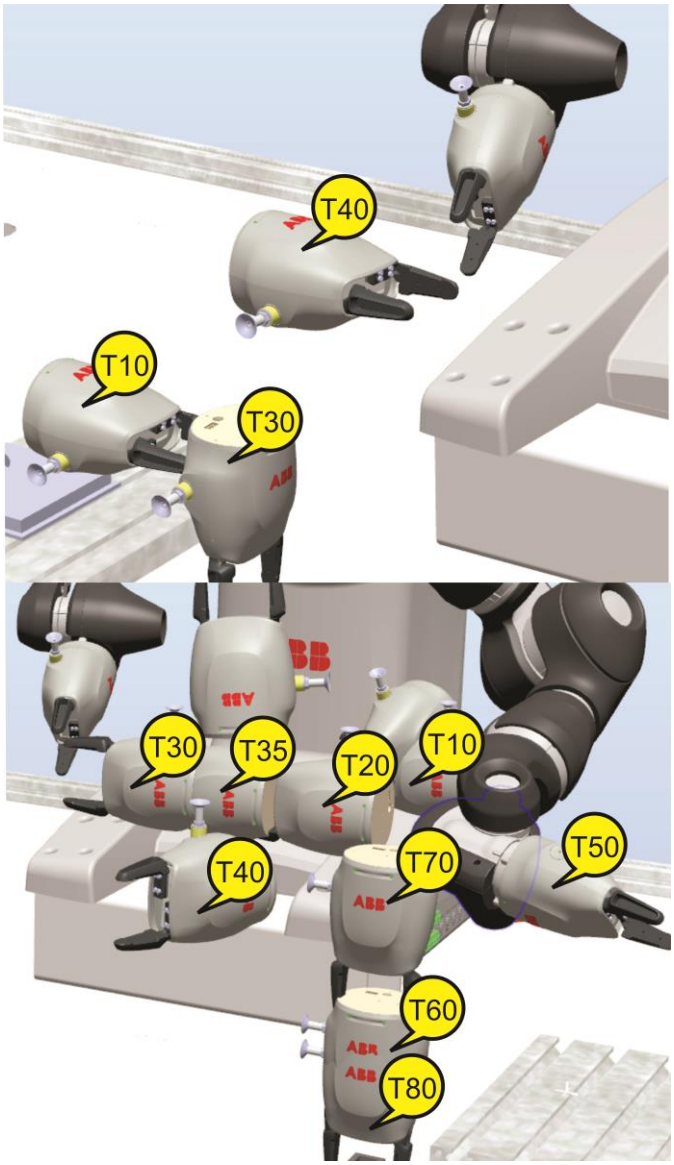
Modeliranje omogućava kreiranje virtuelnog okruženja izradom ili uvozom 3D modela mehaničkih delova i mašina u proizvodnoj liniji. Virtuelno okruženje je korisno za izbegavanje mehaničkih sudara između robota i drugih delova proizvodne linije. Kreiranje virtuelne laboratorije počinje kreiranjem nove prazne stanice. Sledeći korak je uvoz mehaničkog 3D modela radnog prostora sa sigurnosnom zonom iz softvera za 3D modeliranje. Ovaj korak je detaljno opisan u [3]. Nakon dodavanja radnog stola, robot mora biti postavljen na radni sto. ABB IRB 14000 je dodat iz biblioteke. Položaj robota je podešen (pozicija (x, y, z): 1604, 900, 853, orijentacija (x, y, z): 0,0, -90). Sledeći korak je dodavanje Smart Gripper-a na levu i desnu ruku. Leva ruka ima servo prste i vakuum, dok desna ima servo prste, vakuum i kameru. Hvataljke moraju biti pričvršćene za svaku ruku. Nakon postavljanja hvataljki potrebno je dodati 3D model radnog komada da bi se kompletirao mehanički model virtuelne laboratorije. Kompletan mehanički virtuelni model je prikazan na slici 4.

Slika 4. Izgled virtuelne laboratorije [3]

Nakon dodavanja svih potrebnih mehaničkih delova u virtuelni model, virtuelni kontroler se mora dodati. Dodat je kontroler sa RobotWare verzija 6.11.01 za IRB 14000 0,5kg 0,5m.

IV. Programiranje Kretanja Robota

Program koji će biti napravljen je da se sa jedne (desne) strane podigne predmet sa jednom (desnom) rukom, prebaci u drugu (levu) ruku i spusti na drugu stranu radnog prostora. Pre preuzimanja predmeta sa desnom rukom, kamera na hvataljci skenira prostor i vrši orjentaciju hvataljke u zavisnosti od orjentacije predmeta koji se prenosi.



Programiranje ABB robota počinje definisanjem *Target-a. Target* je specifična tačka u radnoj zoni robota u koju robot treba da dođe. Jedan od najbitnijih *Target-a* je *Target* u inicijalnom (*ome* položaju ruke. Za svaku ruku potrebno je podesiti inicijalnu poziciju. Svaka ruka ima svoje *Target-e*

Desna ruka mora da ode iz početnog položaja u položaj iznad predmeta, poziciju za snimanje kamerom, Target 10. Na poziciji Targeta 30, hvataljka mora biti zatvorena da bi se uhvatio predmet. Zatim ide do Targeta za razmenu – Target 40. Slika 5a prikazuje desnu poziciju Smart Gripper-a u definisanim Targetima. Od tih Targeta se mora napraviti putanja (Path_R). Ova putanja sadrži sve napravljene Targete i instrukcije za pomeranje *Mo e* (*-joint or -linear*) za prelazak sa jednog na drugi Target.

Leva ruka ima *Target-e* za približavanje tački razmene desnom rukom (Target 10, 20, 30), izvlačenje iz tačke razmene (Target 35), Target (40, 50, 60 i 80) služe za prebacivanje predmeta na drugu poziciju na radnom prostoru. Poslednji Target 70 je pomeranje od Targeta 80 da bi se

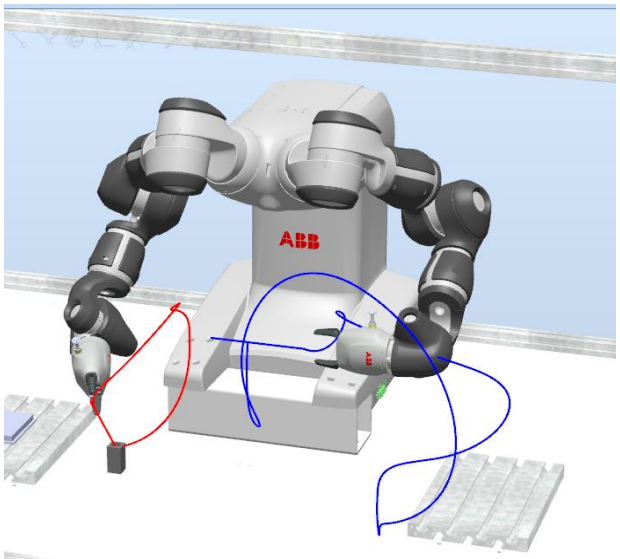
 ISBN 978-86-7466-930-3

izbegao sudar hvataljke sa predmetom. Slika 5b prikazuje položaj levog Smart Gripper-a u definisanim Targetima. Sa tim Targetima, napravljena je putanja do (Path_L).

Slika 5a. Desna hvataljka u definisanim Targetima, Slika 5b. Leva hvataljka u definisanim Targetima

Nakon kreiranja programa, moguće je izvršiti simulaciju rada. Kada simulacija počne, robot ide od Targeta do Targeta, praveći pokrete definisane putanjama. Prva simulacija pokazuje da ruke nisu sinhronizovane, pa se program mora modifikovati. Promene koje se moraju izvršiti su:

a) Desna ruka mora da sačeka dok leva ruka ne preuzme predmet.
b) Leva ruka mora da sačeka dok se desna ruka ne pomeri iz zone hvatanja.
c) Desna ruka može ići u početni položaj, a leva ruka može da nastavi da prenosi predmet na željenu pozuciju.
d) Sačekati da obe ruke budu u početnoj poziciji.



Program mora imati promeljive za sinhronizaciju ruku:

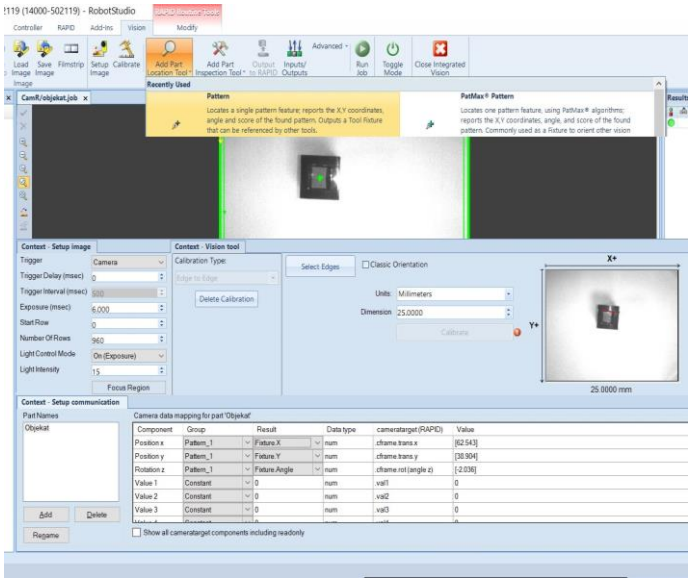
PE S tasks task list 2 T B , T B

A syncident sy01 A syncident sy02 A syncident sy03

Definisane promeljive se koriste u fukncji za sinronizaciju WaitSyncTask\InPos,sy01,task_list; i dodaju se u program za obe ruke na mestu gde je potrebno da ruke jedna drugu čekaju.

Nakon dodavanja delova za sinhronizaciju simulacija kretanja robota sa putanjom kretanja ove ruke data je na slici 6.

Slika 6. Simulacija kretanja robota sa prikazanim putanjama kretanja



V. Podešavanje Vizijskog Sistema

Za pozicioniranje robota na osnovu vizijskog sistema koristi se desna ruka robota koja u sebi ima integrisanu kameru (Cognex AE3). Pre podešavanja opcije *Inegrated ision* potrebno je desnu ruku robota postaviti u poziciju za snimanje objekta i modifikovati Target_30. Nakon toga se može odabrati opcija *Integrated ision* u kojoj je potrebno izvršiti sledeće korake:

1. Opcija *Setup Image* gde se podešavaju parametri ekspozicije i osvetljaja podloge.
2. Opcija *Calibrate* kojom se definiše koliko piksela na slici je dimenzija predmeta (predmet je dimenzije 25x25 mm).
3. Opcija *A Part ocation Tool Patern* kojom se definiše oblik predmeta kome treba podesiti poziciju.
4. Opcija *utput to API* gde se definiše šta će sa slike RAPID program preuzeti od podataka.
5. Opcija *Sa e ob* kojom se definisani parametri snimaju na kontroleru robota.

Definisanje parametara u okviru *Integrated ision-a* dat je prikazano je na slici 7.

 ISBN 978-86-7466-930-3

Slika 7 Podešavanje vizijskog sistema

Po završetku definisanja parametara u okviru *Integrated ision* potrebno je u RAPID programu napisati kod kojim se poziva rad kamere i vrši upis pozicije hvatanja predmeta na osnovu slike. Deo koda koji vrši pozicioniranje na osnovu slike je:

```
CamSetProgramMode Cam ;
Cam oad ob Cam , amera
CamSet unMode Cam
Cam e Image Cam
CamGet esult Cam , Target po icija sa kamere
wobj0.oframe Target po icija sa kamere.cframe
```

Nakon implementacije programa izvršeno je testiranje programa, finalno podešavanje pozicija za razmenu predmeta, robot je pušten u rad. Robot u radu prikazan je na slici 8

Slika 8. Robot ABB IRB 14000 YuMi u radu

VI. ZAKLJUČAK

Opremanjem nove laboratorije opremljene sa dva ABB robota u okviru Naučno-tehnološkog parka u Čačku otvorilo je nove mogućnosti za razvoj robotike na Fakultetu tehničkih nauka u Čačku. Virtuelna laboratorija sa ABB IRB 120 i ABB IRB 14000 je formirana korišćenjem softvera RobotStudio. Ovo omogućava programiranje robota od kuće koristeći virtuelno okruženje, kao i primenu u izvođenju laboratorijskih vežbi sa studentima.

Program za kretanje robota napravljen je u virtuelnoj laboratorij nakon čega je proveren i podešen kroz simulaciju. Nakon toga je program ubačen u kontroler robota i na realnom robotu izvršena finalna podešavanja.

Nakon definisanja kretanja u program je ubačen vizijski sistem kojim se vrši pozicioniranje hvataljke robota bez obzira na poziciju i orjentaciju predmeta na podlozi.

Naredni koraci u istraživanju oblasti vizije i kolaborativne robotike su primena ovakvih sistema u radu sa čovekom, gde bi na osnovu slike robot mogao da odluči šta je naredno potrebno uraditi čime se postiže veća fleksibilnost.

Takođe je moguće koristiti viziju za inspekciju urađenog zadatka od strane čoveka ili nekog drugog robota i korigovanje u koliko je zadatak moguće ispratiti.

ZAHVALNICA

Istraživanja prezentovana u ovom radu su delimično finansirana sredstvima Ministarstva prosvete, nauke i tehnološkog razvoja RS, ugovor br. 451-03-68/2022-14/200132 čiji je realizator Fakultet tehničkih nauka u Čačku - Univerziteta u Kragujevcu.

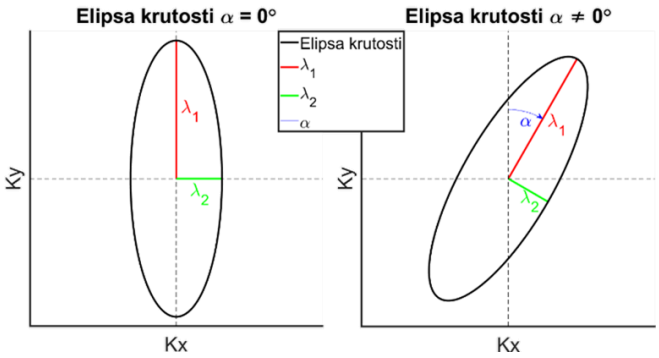
Upravljanje pasivnom krutošću završnog uređaja robota oblikovanjem elipsoida krutosti

Branko Lukić, Nikola Knežević i Kosta Jovanović

***A stra t*— Krutost završnog uređaja robota određuje ponašanje robota pri intera ciji sa o olinom. Krutost završnog uređaja je najčešće predstavljena preko matrice krutosti čije oblikovanje može da bude neizvodljivo jer roboti ne poseduju dovoljno stepeni slobode da bi se svi elementi u matrice rutosti podesili. To dovodi do primene optimizacije oja balansira između vrednosti elemenata matrice krutosti koji su od interesa za izvršavanje zadatka. U ovom radu je predložen pristup za „ *ne*“ obli ovanje matrice rutosti primenom elipsoida krutosti gde se podešavanjem orijentacije i dužina osa elipsoida obli uje rutost. bli ovanje elipsoida ima manje parametara oje je potrebno podesiti u odnosu na matricu krutosti. Predložene su dve kriterijumske funkcije za obli ovanje elipsoida rutost koje eksploatišu kinematičku redundansu robota. ptimalne vrednosti pozicija i rutosti zglobova izračunate su primenom algoritma zasnovanog na P (engl. *e ent a east are r ramm n*). a on dobijanja željenog obli a elipsoida krutosti završnog uređaja robota, pokazana je mogućnost promene volumena elipsoida na željenu vrednost skaliranjem krutosti u zglobovima.**

***Ključne reči*— lipsoid rutosti, krutost završnog uređaja, pasivna rutost.**

I. Uvod



Kod bezbedne fizičke interakcije između čoveka i robota (pHRI) [1, 2] ili robota i okoline, jednu od bitnijih uloga igra popustljivost robota. Pored aktivne popustljivosti [3, 4] koja se ostvaruje kroz upravljačku petlju, postoji i pasivna popustljivost koja se realizuje kroz elastične elemente ugrađene u prenosnom sistemu robota između aktuatora i segmenta robota [5]. Fokus ovog rada je na robote pogonjene aktuatorima sa promenljivom krutošću – VSA (engl. *ariable Stiffness Actuators*), koji imaju dve kontrolne varijable: pozicije i krutosti aktuatora.

Matrica krutosti završnog uređaja je u funkciji pozicija zglobova robota preko Jakobijeve matrice i krutosti zglobova (videti (4) i (5)). To znači da za kinematički redundantnog robota sa popustljivim aktuatorima, krutost završnog uređaja se može oblikovati promenom konfiguracije u nultom prostoru i/ili promenom krutosti zglobova. Za tipične robotske konfiguracije, matrica krutosti

Branko Lukić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: branko@etf.rs).

Nikola Knežević – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: knezevic@etf.rs).

Kosta Jovanović – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: kostaj@etf.rs).

Sl. 1. Elipsa krutosti je definisana dužinama osa λ_1.i λ_2, kao i uglom rotacije α. Levo: Ose elipse krutosti se poklapaju sa osama koordinatnog sistema. Desno: Pravac u kome je elipsa krutosti usmerena je zarotiran za ugao α.

je simetrična matrica dimenzija 6×6, što rezultuje sa 21 promenljivom. Kontrola matrice krutosti i svih šest pozicija završnog uređaja (3 rotacije i 3 translacije) [6, 7] rezultuje sa 27 promenljivih koje treba podesiti.), što je sa stanovišta kontrole veoma zahtevno budući da postoji suviše promenljivih i fizičkih ograničenja (ograničen raspon pokreta zglobova i krutosti zglobova) i manjak kontrolnih ulaza. Za kontrolu svih 27 promenljivih veličina robota pogonjenog sa aktuatorima promenljive krutosti minimalan broj aktuatora bi bio 14 [6], ne razmatrajući fizička ograničenja koja postoje i da bi realan broj bio daleko veći i kompleksniji za realizaciju i upravljanje. Stoga, kontrola cele matrice krutosti nije laka, niti je potpuno opravdan cilj [8], već da je kontrola dijagonalnih elemenata matrice krutosti neophodna u većini aplikacija.

Matrica krutosti završnog uređaja ima nelinearnu zavisnost od konfiguracije robota preko Jakobijeve matrice, pa za tipičnog robota sa 6-7 stepeni slobode, nemoguće je pronaći analitički skup pozicija zglobova koji će zadovoljiti željeni položaj završnog uređaja i matricu krutosti. Stoga su neophodne tehnike optimizacije koje koriste nulti prostor [4, 9, 10].

Oblikovanje krutosti završnog uređaja robota računanjem optimalnog seta krutosti u zglobovima za konstantnu poziciju završnog uređaja, gde su krutosti zglobova predstavljen kroz linearni sistem jednačina, a gde je linearnost ostvarena izborom odgovarajuće norme dato je u [6]. Nadogradnja računanja optimalnog seta krutosti u zglobovima prikazana je [7]. U njemu se razmatra iterativna procedura za rešavanje nelinearnih sistema jednačina sa ograničenjima (radni opsezi pozicija i krutosti zglobova). Pristup optimizaciji kretanjem u nultom prostoru može

 ISBN 978-86-7466-930-3

dovesti do lokalno optimalnog rešenja. Kada se računa optimalna konfiguracija zgloba, projekcija nultog prostora će osigurati glatku putanju zgloba u poređenju sa metodama nelinearne optimizacije koji traže optimalno globalno rešenje koje se može značajno razlikovati od trenutne poze robota [11].

Pristup predložen u ovom radu se zasniva na „*offline*“ oblikovanju elipsoida krutosti u fazi planiranja trajektorije i krutosti završnog uređaja robota, čijim se oblikovanjem indirektno podešava i matrica krutosti završnog uređaja. Predložene su dve kriterijumske funkcije. Jedna koja ima labaviji kriterijum i jedna sa konzervativnijim kriterijumom.

Struktura rada je sledeća: Nakon uvodnog poglavlja sledi poglavlje II gde je modelirana i opisana priroda matrice krutosti. Poglavlje III opisuje grafičku prezentaciju krutosti preko elipsi i elipsoida krutosti. U poglavlju IV je opisan algoritam za offline planiranje krutosti i pozicije završnog uređaja robota sa simulacionim rezultatima, a u poglavlje V je diskusija i zaključak.

II. PASIVNA KRUTOST

Lokalna statička karakteristika krutosti zglobova robota se definiše kao negativni izvod momenta po uglu [6, 7]

$$K_j = -\frac{\partial \tau}{\partial q}, \tag{1}$$

gde je K_j matrica krutosti zglobova, τ je vektor momenata koji se razvijaju na zglobovima, a q je vektor pozicija zglobova. Važi relacija $\tau = J(q)^T F_{ekst}$, između Jakobijeve matrice ($J(q)$), eksterne sile koja deluje na završni uređaj robota (F_{ekst}) i momenta zglobovima (τ) koji se stvara usled delovanja sile, kao i to da je F_{ekst} proporcionalno matrici krutosti završnog uređaja K_C i otklona iz ravnotežnog položaja Δx nastalog usled eksterne sile $F_{ekst} = K_C \Delta x$, tako da izraz (1) postaje

$$K_j = -\frac{\partial (J(q)^T K_C \Delta x)}{\partial q} = J(q)^T K_C J(q) - \frac{\partial J(q)^T}{\partial q} K_C \Delta x, \tag{2}$$

gde je $\partial \Delta x / \partial q = J(q)$, K_C je $m \times m$ simetrična matrica, K_j je $n \times n$ dijagonalne matrice, $J(q)$ je $m \times n$ matrica i q je n-dimenzionalni vektor pozicija zglobova. Parametri m i n su dimenzije radnog prostora i broja zglobova robota. Kada nema otklona od ravnotežnog stanja, tada je $\Delta x = 0$, tako da izraz (2) postaje

$$K_j = J(q)^T K_C J(q). \tag{3}$$

Matrica pasivne krutosti zglobova (K_j) može da ima nedijagonalnu strukturu sa van dijagonalnim elementima kada se koriste biartikulisani aktuatori [12, 13], gde jedan aktuator pogoni više od jednog segmenta robota, a koji su mehanički veoma komplikovani za realizaciju. Fokus u ovom radu je na uniartikulisanim aktuatorima koji rezultuju da matrica K_j ima dijagonalnu formu.

Iz jednačine (3) se dobija statička relacija za mapiranje matrice krutosti završnog uređaja robota K_C u Dekartovim koordinatama (engl. *Cartesian space*) sa jedne strane i sa druge strane matrice krutosti zglobova K_j i konfiguraciji robota predstavljene kroz Jakobijevu matricu $J(q)$ [6, 7] kao

$$K_C = \left(J(q) K_j^{-1} J(q)^T\right)^{-1}, \tag{4}$$

odnosno

$$K_C = J(q)^{\dagger^T} K_j J(q)^{\dagger}, \tag{5}$$

gde je $J(q)^{\dagger}$ desna pseudo inverzija Jakobijeve matrice $J(q)$ za koju važi $J(q)J(q)^{\dagger} = I$, gde je I jedinična matrica. U opštem slučaju pseudo inverzija je definisana kao $J(q)^{\dagger} = Z^{-1}J(q)^{\mathrm{T}}(J(q)Z^{-1}J(q)^{\mathrm{T}})^{-1}$, gde je Z pozitivno definitivna matrica. Za pravilno mapiranje krutosti u zglobu i krutosti završnog uređaja metrički tenzor (Z) mora imati vrednost matrice krutosti zglobova $Z = K_j$ [6].

Jednačine (4) i (5) ukazuju da se na krutost i popustljivost završnog uređaja robota može uticati:

1) rekonfiguracijom robota kroz nulti prostor kinematički redundantnog robota,
2) promenom krutosti zglobova robota pogonjenih sa VSA,
3) simultanom rekonfiguracijom i promenom krutosti zglobova robota.

Svi nabrojani načini se mogu primeniti na robote pogonjene sa aktuatorima promenljive krutosti, dok samo rekonfiguracija robota kroz nulti prostor se može primeniti na robote pogonjene aktuatorima sa konstantnom krutošću. Zbog toga eksploatacija redundanse kod robota pogonjenog aktuatorima konstantne krutosti ima veliku važnost.

Česta aproksimacija je da se matrica krutosti podeli na četiri submatrice (K_T i K_R su translatorna i rotaciona krutost, dok su K_{RT} i K_{TR} matrice kuplovanja), gde su od interesa samo submatrice na glavnoj dijagonali (translatorna i rotaciona), dok se one na sporednoj dijagonali zanemaruju [6]

$$K_C = \begin{bmatrix} K_T & K_{RT} \\ K_{TR} & K_R \end{bmatrix}, \tag{6}$$

$$\widehat{K}_C = \begin{bmatrix} K_T & 0 \\ 0 & K_R \end{bmatrix}. \tag{7}$$

Treba imati na umu da je $\widehat{K}_C$ aproksimacija koja je lokalno validna.

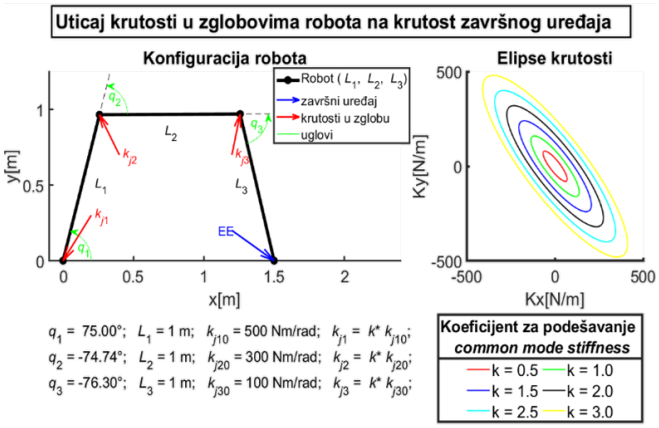
III. GRAFIČKA REPREZENTACIJA KRUTOSTI

Za robote koji imaju bilo aktivnu ili pasivnu popustljivost, moguće je sprovesti određene analize koje se tiču performansi robota i krutosti završnog uređaja [14, 15, 9]. Generalno, elipse i elipsoidi daju jednu vrstu aproksimacija koliko i u kom pravcu robot može da razvije krutost, što predstavlja koristan alat u fazi dizajniranja kao i u operativnoj fazi. Elipsoidi imaju veliku primenu u analizi i dizajnu matrica krutosti kod aktivne popustljivosti, gde se kod kinematički redundantnih robota mogu koristiti da se maksimizira radni prostor [14, 15], a da pri tome aktuatori ne budu u zasićenju i željeno ponašanje ne bude narušeno.

 ISBN 978-86-7466-930-3

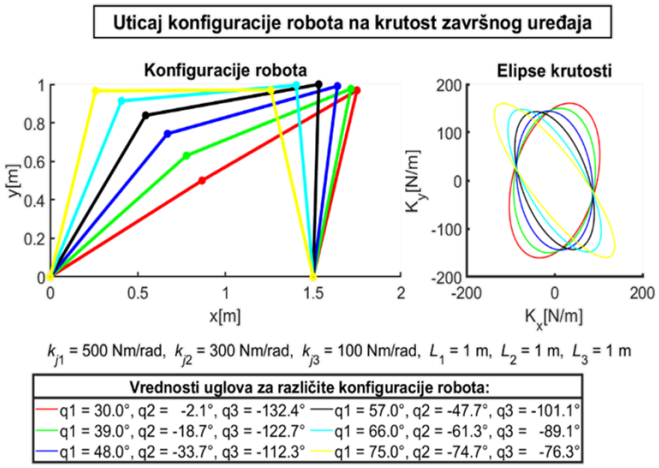
Kod aktivne krutosti osim samih elipsoida i politopa moguće je uvesti i region ostvarive krutosti (SFR – engl. *Stiffness Feasibility egion*) koji predstavlja oblik sa ne-politopskim granicama [14].

Kod sila interakcije, bez obrtnih momenata, koje deluju na završni uređaj, ulogu igraju samo elementi matrice translatorne krutosti K_T koji se odnose na sile odnosno na translatorna kretanja. To je kvadratna simetrična matrica koja ima dimenzije 3×3 za trodimenzionalni prostor, ili 2×2 u ravanskom prostoru (2D). Kada je u pitanju trodimenzionalni prostor, matrica krutosti se može predstaviti pomoću elipsoida krutosti, ili u slučaju dvodimenzionalnog prostora pomoću elipse krutosti. Radi intuitivnijeg razumevanja na slici 1 je dat prikaz elipse krutosti. Parametri koji opisuju elipsu krutosti su ose elipse λ_1 i λ_2 (u slučaju elipsoida postoji i λ_3) međusobno normalne, i ugao orijentacije elipse α (u slučaju elipsoida postojaće dodatni ugao orijentacije u odnosu xy ravan). Pravac orijentacije elipse i elipsoida je u pravcu najduže ose elipse/elipsoida. Na levoj strani na slici 1 prikazana je elipsa kada se ose elipse poklapaju sa osama koordinatnog sistema, dok na desnoj strani je prikazana elipsa koja je ukošena za ugao α. Kada se ose elipse/elipsoida poklapaju sa osama koordinatnog sistema, tada nema kuplovanih elemenata i matrica krutosti ima dijagonalni oblik.



Dužine osa i ugao orijentacije elipsoida se dobija dekompozicijom matrice (SVD – engl. *Singular alue ecomposition*) krutosti kao

$$K_T = USV^T, \qquad (8)$$



Kolone ortogonalnih matrica U i V predstavljaju sopstvene vektore, a elementi na dijagonali dijagonalne matrice S predstavljaju sopstvene vrednosti. Sopstvene vrednosti matrice S predstavljaju intenzitete krutosti duž osa elipsoida, a vrednosti kolona matice V predstavljaju sopstvene vektore koji određuju pravac orijentacije osa elipse/elipsoida.

Oblikovanje krutosti završnog uređaja može se podeliti na krutost zavisnu od konfiguracije (CDS – engl. *Configuration ependant Stiffness*) i krutost koja zavisi od krutosti zglobova (CMS – engl. *Common Mode Stiffness*) [16]. CDS potiče od redundantne konfiguracije robota i koristi se za usmeravanje elipse ili elipsoida krutosti, dok CMS utiče na veličine osa elipse ili elipsoida. CMS predstavlja dodatni parametar koji se može uključiti u oblikovanje krutosti. Krutost završnog uređaja robota pogonjenog sa aktuatorima konstantne krutosti može se promeniti samo rekonfiguracijom kada je robot kinematički redundantan.

Na primeru planarne konfiguracije robota sa 3 stepena slobode (segmenti L_1, L_2 i L_3) koja je ilustrovana slici 2 (levo) prikazan je uticaj CMS na elipsu krutosti (slika 2 desno). Pozicije zglobova (q_1, q_2 i q_3) su konstantne i samim tim pozicija završnog uređaja (EE) je konstantna. Krutost zglobova (k_{j1}, k_{j2} i k_{j3}) dobija se kao proizvod početnih vrednosti krutosti (k_{j10}, k_{j20} i k_{j30}) i parametra CMS-a (k) kao $k_{j1} = kk_{j10}$, $k_{j2} = kk_{j20}$ i $k_{j3} = kk_{j30}$. CMS ne utiče na oblik (odnos osa) i usmerenje elipse

Sl. 2. Uticaj *Common Mode Stiffness* -a na krutost završnog uređaja robota. Levo: Planarna konfiguracija robota koja se sastoji od tri segmenta – L_1, L_2 i L_3 (crno); pozicija završnog uređaja robota (plavo); krutosti u zglobovima k_{j1}, k_{j2} i k_{j3} (crveno); pozicije zglobova q_1, q_2 i q_3 (zelena). Desno – Elipsoidi krutosti za fiksnu konfiguraciju ($q_1 = 75°$, $q_2 = -74.74°$ i $q_3 = -76.30°$) različiti koeficijent CMS-a $k \in [0.5 - 3]$. Krutost u zglobovima se računa kao proizvod početnih vrednosti krutosti (k_{j10},k_{j20} i k_{j30}) i parametra common mode stiffness-a (k) kao $k_{j1} = kk_{j10}$, $k_{j2} = kk_{j20}$ i $k_{j3} = kk_{j30}$.

Sl. 3. Uticaj konfiguracije kinematički redundantnog robota na krutost završnog uređaja robota sa dužinama segmenata $L_1 = 1m$, $L_2 = 1m$ i $L_3 = 1m$, i krutostima u zglobovima $k_{j1} = 500\text{Nm/rad}$, $k_{j2} = 300\text{Nm/rad}$ i $k_{j3} = 100\text{Nm/rad}$. Levo: Različite planarne konfiguracije robota sa istom pozicijom završnog uređaja; Desno – Elipsoidi krutosti za različite konfiguracije robota.

krutosti, već samo na njen volumen odnosno samo linearno skalira elemente matrice krutosti.

Jedan od pristupa za oblikovanje matrice ili elipse (ili elipsoida u 3D prostoru) krutosti robota pogonjenog aktuatorima konstantne krutosti je kroz promenu kinematičke konfiguracije robota kada postoji kinematička redundansa. Promena konfiguracije se odvija u nultom prostoru. To omogućava da robot pored primarnog zadatka (praćenje trajektorije) izvrši i sekundarni zadatak koji je u ovom slučaju oblikovanje krutosti završnog uređaja robota. Na primeru planarne konfiguracije robota sa 3 stepena slobode (segmenti L_1, L_2 i L_3) koja je ilustrovana slici 3 (levo) prikazan je uticaj CDS na elipsu krutosti (slika 3 desno).

 ISBN 978-86-7466-930-3

IV. ALGORITAM ZA OFFLINE PLANIRANJE KRUTOSTI I POZICIJE ZAVRŠNOG UREĐAJA ROBOTA

Osim preko matrice krutosti, krutost završnog uređaja je moguće oblikovati preko elipse krutosti. U ovom radu predložen je offline pristup oblikovanja krutosti završnog uređaja robota, promenom optimizacionih algoritama, koji je predviđen za planiranje krutosti kada je zadatak u napred poznat, pa samim tim i trajektorija završnog uređaja. Primenjena su dva kriterijuma koji kombinuju oblik i grešku orijentacije elipsoida. Oblikovanje elipsoida krutosti se ostvaruje kombinacijom nultog prostora i krutosti u zglobovima. Optimizacioni algoritmi su primenjeni na simulacionom modelu KUKA LWR robota na primeru ravanskog kretanja u „xy" ravni, kada se završni uređaj robota kreće po krivoj putanji.

Optimizacioni algoritmi koji su korišćeni su zasnovani na SLSQP (engl. Sequential Least SQuare Programming) [10, 17, 18], a implementirani su Matlab-u. SLSQP je algoritam koji optimizuje vrednosti nelinearnih kriterijumskih funkcija sa linearnim i nelinearnim ograničenjima. Ograničenja koja postoje u predloženim optimizacionim algoritmima se odnose na ostvarive vrednosti pozicije zglobova robota i na definisani opseg krutosti koje robot može da ostvaruje. Nelinearna ograničenja koja moraju biti zadovoljena se odnose na kinematiku. Optimizacioni algoritam uvek mora da zadovolji željenu poziciju završnog uređaja robota.

Kako zbog prirode zadatka, pozicija zadnjeg zgloba ne utiče na položaj završnog uređaja, već samo na ugao orijentacije oko z ose, njegova vrednost je zaključana na 0°. Na taj način robot ima 6 stepeni slobode na raspolaganju za izvršavanje zadatak. Usvojen je da raspon krutosti zglobova bude 1-100 Nm/rad. Ovo se može usvojiti bez gubljenja opštosti, jer bitan je relativan odnos krutosti u zglobovima za orijentaciju i odnos osa elipsoida krutosti. Naknadno preko CMS-a se podešava i volumen.

Prvi predloženi kriterijum (f_1) usmerava elipsoid i maksimizira krutost duž pravca kretanja, zadavajući minimalni odnos dijagonala elipsoida. Drugi kriterijum (f_2) usmerava elipsoid duž pravca kretanja, ali zadajući tačan odnos dijagonala elipsoida. Predložene optimizacione metode imaju za cilj da doprinesu planiranju trajektorije i krutosti zglobova prilikom izvršavanja zadataka.

A. Maksimiziranje krutosti duž pravca kretanja

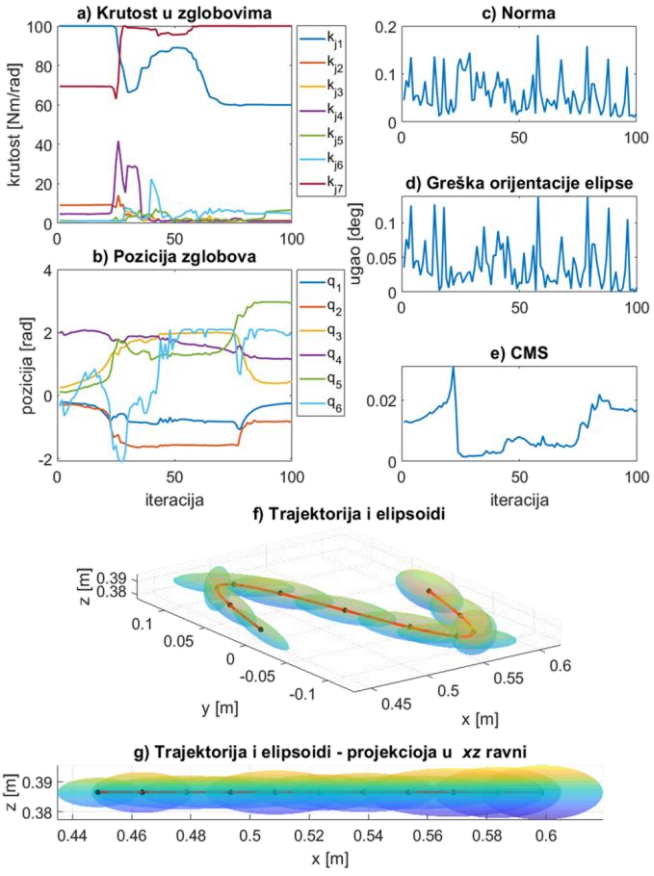
Oblikovanje elipsoida krutosti moguće je ostvariti primenom kriterijumske funkcije definisane kao

$$f_1 = \frac{|\alpha_{error}| + c}{min\left(\frac{r_{max}}{r_{min}}, r\right)/r}, \tag{9}$$

gde α_{error} označava grešku orijentacije elipsoida u stepenima, r je minimalni željeni odnos osa elpsoida, r_{max} i r_{min} su najduža i druga po dužini osa elipsoida, dok je c pozitivna konstanta koja omogućava optimizaciju kada je apsolutna greška orijentacije elipsoida $|\alpha_{error}| = 0°$, dok je željena orijentacija u smeru kretanja završnog uređaja robota. Usvojena je vrednost $c = 0.01$.

U svakoj iteraciji računaju se pozicije i krutosti zglobova koje minimiziraju vrednost funkcije f_1 kao

$$\begin{bmatrix} q[p] \\ k_j[p] \end{bmatrix} = \underset{\substack{q\in[q_{min},q_{max}] \\ k_j\in[k_{j_{min}},k_{j_{max}}]}}{argmin} f_1(q, k_j), \tag{10}$$



gde je p redni broj iteracije, a q_{min}, q_{max}, $k_{j_{min}}$ i $k_{j_{max}}$ su minimalne i maksimalne vrednosti pozicija i krutosti zglobova. Opseg vrednosti promenljivih u optimizacionom algoritmu se može dodatno suziti, i samim tim smanjiti prostor pretrage i ubrzati algoritam pretrage u svakoj iteraciji. Nove granične vrednosti varijabli (q^*_{min}, q^*_{max}, $k^*_{j_{min}}$ i $k^*_{j_{max}}$) u svakoj iteraciji se računaju uzimajući u obzir maksimalne brzine promene koje robot može da ostvari u okviru jedne iteracije (za pozicije zglobova - Δq, za krutost zglobova - Δk_j) i fizički ostvarive vrednosti kao

$$q_{min_iter}[p] = max(q_{min}, \quad q[p-1] - \Delta q), \tag{11}$$

$$q_{max_iter}[p] = min(q_{max}, \quad q[p-1] + \Delta q), \tag{12}$$

$$k_{j_{min_iter}}[p] = max\left(k_{j_{min}}, \quad k_j[p-1] - \Delta k_j\right), \tag{13}$$

$$k_{j_{max_iter}}[p] = min\left(k_{j_{max}}, \quad k_j[p-1] + \Delta k_j\right). \tag{14}$$

Sl. 4. Simulacioni rezultati za oblikovanje elipsoida krutosti na primeru krivolinijskog kretanja kada je zahtev da odnos osa elipsa bude minimalno 5:1: a) krutost u zglobovima; b) pozicija zglobova; c) norma (vrednost kriterijumske funkcije); d) greška orijentacije; e) CMS; f trajektorija i elipsoidi; g) trajektorija i elipsoidi- projekcija u xy ravni.

 ISBN 978-86-7466-930-3

To je računski zahtevan posao i nije ga jednostavno implementirati da radi u realnom vremenu, ali moguće ga je iskoristiti u fazi planiranja krutosti i trajektorije zglobova i završnog uređaja.

Simulacioni rezultati za primer krivolinijskog kretanja su prikazani na slici. Na slici 4a je prikazana krutosti u zglobovima, a na slici 4b pozicija zglobova. Slika 4c prikazuju vrednost (normu) optimizacione funkcije, dok slika 4d ilustruje grešku orijentacije. Slika 4e je CMS kojim su skalirane krutosti sa slike 4a da bi se dobili skalirani elipsoidi.

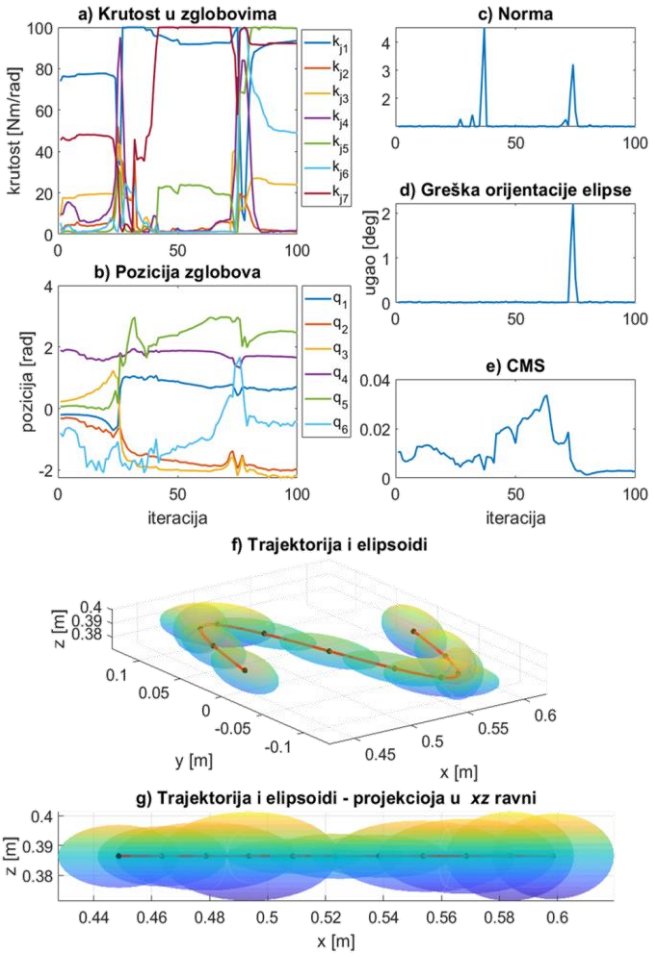
Primenjena optimizaciona funkcija i algoritam su ostvarili zadati cilj, da elipsoid ima željeno usmerenje i minimalni odnos osa. Dobijeni CMS skalira elipse da bi bile uporedive. Dobijene elipsoide moguće je dodatno skalirati da se dobije željena amplitude, ali samo po jednoj od osa. Da bi bilo moguće potpuno oblikovati elipsoid krutosti, potrebno je modifikovati kriterijumsku funkciju.

B. bliko anje elipsoida krutosti

Da bi se elipsoid krutosti potpuno oblikovala neophodno je da budu ostvareni sledeći zahtevi:

1) željeni pravac orijentacije elipsoida,
2) tačan odnos osa elipsoida,
3) magnitude osa elipsoida.

Kada su prva dva uslova zadovoljena, treći se ostvaruje primenom CMS-a na već oblikovanu elipsu. Da bi prva dva uslova mogla simultano da se optimizuju, predložena je modifikovana kriterijumska funkcija koja kombinuje grešku orijentaciju i odnos osa elipse



$$f_2 = (1 + |\alpha_{error}|)\left(1 + \left|r - \frac{r_{max}}{r_{min}}\right|\right). \quad (15)$$

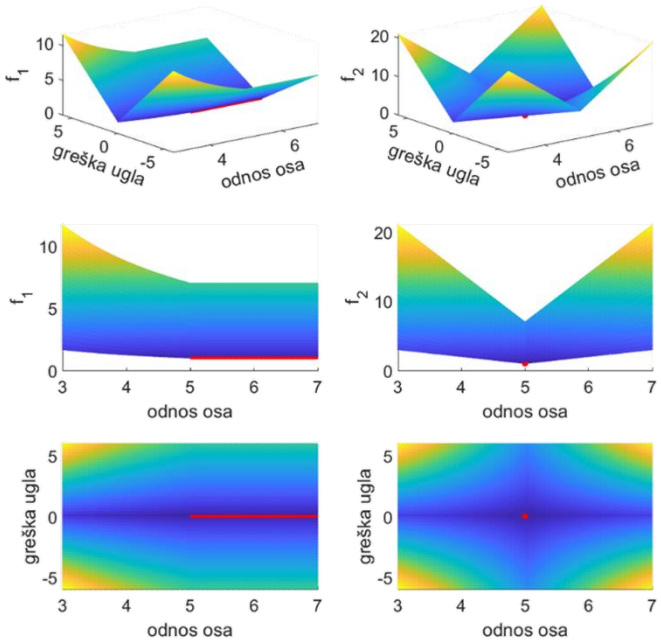
Pozicije i krutosti zglobova u svakoj iteraciji se računaju identično kao i u prethodnom primeru opisanom u jednačinama (10) – (14) samo je optimizaciona funkcija promenjena i definisana kao f_2.

Funkcija je modifikovana tako da penalizuje svaku grešku orijentacije, i svako odstupanje odnosa osa od željenog odnosa. Zadati su zahtevi da je greška orijentacije $\alpha_{error} = 0°$, dok je željena orijentacija u smeru kretanja završnog uređaja robota, a odnos osa elipse $r = 5$.

Simulacioni rezultati za primer krivolinijskog kretanja su prikazani na slici 5. Na slici 5a je prikazana krutosti u zglobovima, a na slici 5b pozicija zglobova. Slika 5c prikazuju vrednost (normu) optimizacione funkcije, dok slika 5d ilustruje grešku orijentacije. Slika 5e je CMS kojim su skalirane krutosti sa slike 5a da bi se dobili skalirani elipsoidi.

Primenjena optimizaciona funkcija i algoritam su ostvarili zadati cilj, da elipsoid ima željeno usmerenje i odnos osa. Dobijeni CMS skalira elipse da bi bile uporedive. Dobijene elipsoide moguće je dodatno skalirati da se dobije željena amplitude. Algoritam je ostvario zadati cilj da elipsa ima željeno usmerenje i odnos osa. Dobijeni CMS skalira elipsoide da bi bile uporedivi. Rezultati pokazuju da svi elipsoidi imaju željeni oblik ili oblik koji je jako blizak

Sl. 5. Simulacioni rezultati za oblikovanje elipsoida krutosti na primeru krivolinijskog kretanja kada je zahtev da odnos osa elipsa bude tačno 5:1: a) krutost u zglobovima; b) pozicija zglobova; c) norma (vrednost kriterijumske funkcije); d) greška orijentacije; e) CMS; f trajektorija i elipsoidi; g) trajektorija i elipsoidi- projekcija u xy ravni.



željenom. Dobijene elipsoide moguće je dodatno skalirati da se dobije željena amplitude osa.

Slika 6 ilustruje vrednosti funkcija u zavisnosti od greške orijentacije i odnosa osa elipse, a crvena boja označava minimum funkcije koji je u slučaju f_1 definisan kao prava, dok u slučaju f_2 kao jedna tačka. Samim tim je jasno da je optimalni set za f_2 koji je konzervativniji mnogo teže zadovoljiti nego u slučaju labavijih zahteva kriterijumske funkcije f_1. Ostvarivanje optimalnog rešenja u svakoj iteraciju uslovljeno je fizičkim ograničenjima samog robota.

V. DISKUSIJA I ZAKLJUČAK

U radu je uspešno implementiran pristup oblikovanja krutosti završnog uređaja robota pomoću grafičke reprezentacije krutosti preko elipsoida na modelu robota KUKA LWR. Krutost koja se analizira je zasnovana na modelu. Ilustrovano je da različiti kriterijumi daju rezultate različitog kvaliteta u skladu sa definisanim kriterijumima i fizičkim ograničenjima robota. Dobijeni rezultati uglavnom dobro ispunjavaju zadate zahteve, dok su ograničenja izraženija kod konzervativnije kriterijumske funkcije koja se ogleda u trenucima kada trajektorija ima najveće

 ISBN 978-86-7466-930-3

Sl. 6. Oblici kriterijumskih funkcija u zavisnosti od greške orijentacije i odnosa osa elipsi. Crvena boja označava minimum funkcije koji je u slučaju f_1 definisan kao prava, dok u slučaju f_2 kao jedna tačka

zakrivljenje, a samim tim i najveće promene orijentacije elipsoida. To pokazuje da su ostvarivi rezultati ograničeni izborom dela radnog prostora, kao i oblikom trajektorije. Klasična matrica translatorne krutosti ima 6 elemenata koje treba optimizovati, dok predložene kriterijumske funkcije koriste samo dva parametra, ugao greška ugla orijentacije elipsoida i odnos osa.

ZAHVALNICA

Rad je realizovan u okviru projekta Fonda za nauku Republike Srbije PROMIS, Grant #6062528, ForNextCobot i tokom istraživanja finansiranog od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije. Broj ugovora 2022/200103.

ABSTRACT

The stiffness of the robot's end-effector (EE) determines the robot's behavior when interacting with the environment. The stiffness of the EE is most often represented by a stiffness matrix whose complete design can be impossible because robots do not have enough degrees of freedom to adjust all the elements in the stiffness matrix. This leads to the application of optimization that balances the values of the stiffness matrix elements that are of interest for the task. In this paper, an approach for offline shaping of the stiffness matrix using stiffness ellipsoids is proposed, where stiffness is shaped by adjusting the orientation and axis length of the ellipsoid. The shape of the ellipsoid has fewer parameters that need to be adjusted relative to the stiffness matrix. Two criterion functions for shaping the ellipsoid stiffness have been proposed to exploit robot kinematic redundancy in shaping the stiffness ellipsoid. Optimal values of joint positions and stiffness were calculated using the algorithm based on SLSQP (Sequential Least SQuare Programming). Following the shaping of EE stiffness ellipsoid, adjustments or its volume based on variations in joint stiffness are highlighted.

Hijerarhijsko distribuirano upravljanje kolaborativnim industrijskim humanoidnim robotom podržano oblak-arhitekturom

Jovan Šumarac, Ilija Stevanović, Aleksandar Rodić

***A stra t*— vaj rad predstavlja jednu hijerarhijs u, distribuiranu upravljačku arhitekturu dvoručnog, olaborativnog, humanoidnog servisnog robota podržanom tehnologijom "računarstva u oblaku". va upravljačka stru tura dizajnirana je namenski za izvršavanje robots ih zadataka koji zahtevaju primenu složenijih manipulativnih i ognitivnih veština u o viru industrijs og proizvodnog tehnološkog procesa. Upravljačka struktura robota osmišljena je ta o da zadovolji potrebe tzv. pametne proizvodnje u o viru platforme Industrije 4. , odnosno da omogući i olakša kooperaciju čoveka i robota kao njemu komplementarnog inteligentnog sistema, neophodnog u industrijs im zadacima koje čovek ne može samostalno sprovoditi. Ovaj rad prikazuje strukturu i način funkcionisanja sistema hijerarhijskog distribuiranog upravljanja, organizovan na tri operativna nivoa a) strateškom, b) taktičkom i c) izvršnom. To je omogućeno zahvaljujući korišćenju arhitekture oblak-računarskog sistema. Hardver upravljačkog sistema uspostavljen je na tri nivoa fizičkom, komunikacionom i aplikativnom. Zahvaljujući distribuiranoj arhitekturi, sistem oblaka omogućava distribuirano izvršavanje pojedinačnih upravljačkih zadataka što rezultira uravnoteženim opterećenjem multiprocesorskog sistema i smanjenjem vremena odziva na stimuluse iz fizičkog okruženja robota.**

***Ključne reči*—upravljanje u obla u, olaborativni roboti, distribuirana inteligencija, pametna proizvodnja, Industrija 4.**

I. UVOD

Od kada je kompanija „General Motors" u Detroitu (SAD) 1961. napravila prvog industrijskog robota za manipulaciju (UNIMATE) i koristila ga u automobilskoj industriji za sklapanje delova, timovi naučnika, inženjera i tehnologa razmišljali su o tome kako da automatizuju ljudske manipulacione i kognitivne veštine što je više moguće i kako da robote učine bezbednim i kolaborativnim. Prethodne generacije industrijskih robota za manipulaciju, kao deo svojih kontrolera, koristile su algoritme za "imitaciju" ljudskih manipulativnih veština uz korišćenje petlji povratne sprege po poziciji ondosno brzini i po sili odnosno momentu. Ovo je uglavnom bilo dovoljno za obavljanje tehnoloških operacija u okviru proizvodnih procesa u visoko tehnološki strukturiranim infrastrukturnim okruženjima – tehnološkim proizvodnim linijama. Međutim, takav pristup je imao relativno nizak nivo fleksibilnosti i prilagodljivosti poremećajima i promenama u proizvodnim procesima.

Sa napretkom informacionih tehnologija, bežičnih komunikacija, "Interneta stvari", senzorskih tehnologija i mašinske vizije, otvorene su nove perspektive automatizacije tehnoloških procesa tako što je industrijskim robotima omogućeno da, sa svojstvenom preciznošću i brzinom, ostvare sofisticirane atribute ljudske mikro-manipulativne i taktilne veštine na visokom nivou kognitivne percepcije i sposobnosti rasuđivanja [1].

Cilj ovog rada jeste da predstavi kako se ljudske veštine i znanje kvalifikovanih radnika mogu sticati, čuvati i koristiti u bazi podataka na sistemu oblaka (ondosno "Cloud" sistemu), odakle se ovi podaci mogu analizirati i koristiti za obuku (tj. za učenje veština) industrijskog humanoidnog robota u izvođenju različitih manipulativnih i kolaborativnih zadataka u saradnji sa ljudima. U tu svrhu razvijen je originalni dvoručni kolaborativni robotski sistem (industrijski humanoidni servisni robot) koji omogućava implementaciju i verifikaciju različitih algoritama za automatizaciju ljudskih manipulativnih i kognitivnih veština u proizvodnim procesima [2]. Originalni robotski sistem sa svim hardverskim i softverskim komponentama razvijen je u Centru za robotiku Instituta "Mihajlo Pupin".

II. INDUSTRIJSKI HUMANOID

A. Mehanički dizajn prototipa robota

Industrijski humanoid je dvoručni (ili bi-manuelni) kolaborativni servisni robot namenjen industrijskim zadacima [3]-[7], koji po svojoj strukturi podseća na svoj biološki model – čoveka. U mehaničkom smislu industrijski humanoid ima sledeće module: (i) sistem podrške za sletanje montiran na mobilnu platformu (motorizovana kolica), (ii) segmentirani trup - torzo robota, (iii) dve industrijske robotske ruke sa odgovarajućim hvatačima (Sl. 1).

Humanoidni robot je montiran na motorizovana kolica sa diferencijalnim upravljanjem na par pogonskih (aktivnih) točkova. Kolica imaju i dva pomoćna (pasivna) točka, koja se okreću oko sopstvenih vertikalnih osa. Zahvaljujući takvoj strukturi, kolica robota imaju mogućnost da se kreću u tri koordinatna pravca: napred-nazad, levo-desno i da se okreću

 ISBN 978-86-7466-930-3

oko sopstvene ose u opsegu od 0 do 360 stepeni. Nosivi sistem bimanuelnog robota je tehnička varijanta (imitacija) ljudskih nogu. Mehanizam za noge robota može se savijati oko tri ose. Jedna osa rotacije prolazi kroz skočni zglob, druga osa kroz zglob kolena, a treća kroz zglob kuka. Na ovaj način se sinhronizovanim pokretima u pomenutim zglobovima može podesiti položaj (orijentacija) trupa humanoida u odnosu na površinu oslonca.

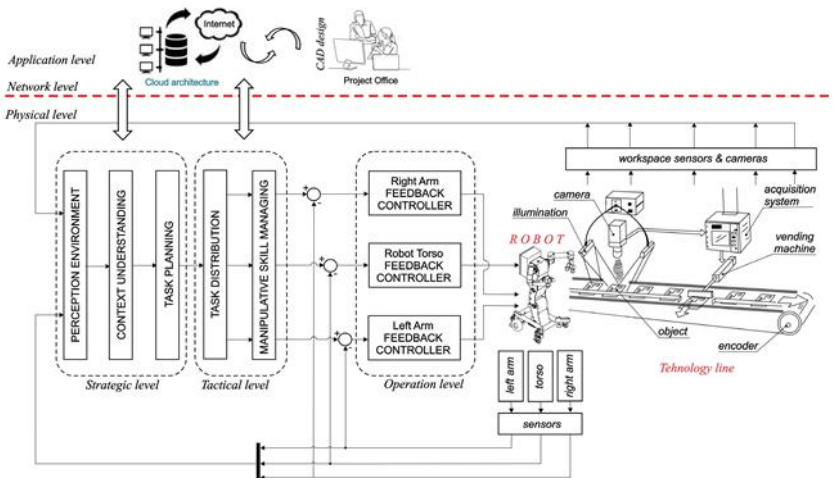
Gornji deo trupa robota (torzo) ima mogućnost savijanja oko sagitalnog pravca u frontalnoj ravni (levo-desno). Uz mogućnost promene nagiba trupa napred-nazad u sagitalnoj ravni (promenom konfiguracije nogu), ovo omogućava humanoidnom robotu da se prilagodi svom operativnom prostoru zadatka.

Kolaborativni dvoručni robot ima dve industrijske robotske ruke UR5 sa odgovarajućim hvatačima koje mu daju mogućnost različitih manipulacija objektima kao i fizičke interakcije sa okolinom. Takođe, svaka robotska ruka ima instaliran zglobni senzor sile/momenta na završnom uređaju.

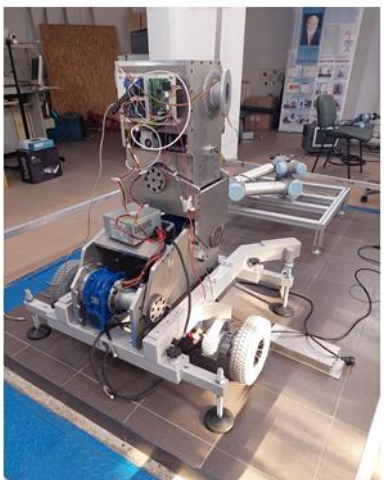
Sl. 1. 3D prototip modela industrijskog robota.

Visina ovog humanoida iznosi oko 175cm a njegov raspon ruku iznosi oko 2300 mm. Ideja iza projektovanja ovakvog sistema jeste da njegove dimenzije budu približne čovekovim kako bi robot mogao lako da zameni čoveka u određenim zadacima, ali i da bi mogao prirodno da obavlja zadatke u kojima postoji kolaboracija sa čovekom. Analiza njegovog radnog prostora pokazala je dobru manipulativnost ovog sistema u oblastima zajedničkog radnog prostora obe robotske ruke, pogotovo u zonama ispred samog torzoa robota [8].

Na Sl. 1. može se videti i ormarić koji je okačen na robotski torzo kao svojevrsni "ranac". U njemu se nalaze različite elektronske komponente neophodne za funkcionisanje celokupnog sistema (mikrokontroleri, uključujući i glavni mikrokontroler ondnosno "mozak" sistema, zatim napajanja, bezbednosne sklopke, releji i dr.).



B. Arhitektura hard era kontrolera robota



Hardverska struktura celokupnog sistema upravljanja industrijskog servisnog robota prikazanog na Sl. 1 je projektovana kao distribuirana računarsko-senzorska mreža [9] koja funkcioniše na tri funkcionalna nivoa (Sl. 2): (i) fizički nivo, (ii) nivo mreže i (iii) aplikativni nivo.

Na fizičkom nivou, postoji robot sa pripadajućim senzorima i kamerama, poseban kontroler trupa robota, kao i nezavisni kontroleri robotskih ruku i pridruženih robotskih hvatača. Globalno posmatrano, to je prilično složena struktura dizajnirana da omogući specifične sposobnosti robota. Takođe na fizičkom nivou, u okruženju robota postoje odgovarajuće mašine alatke sa svojim upravljačkim jedinicama i na kraju ljudi (radnici) koji zajedno sa dvoručnim robotom čine deo tehnološkog procesa.

Mrežni, odnosno komunikacioni nivo hardverske strukture "Cloud" kontrole, zadužen je za brzu i efikasnu međusobnu komunikaciju između sastavnih komponenti robotske ćelije i odgovarajućeg tehnološkog procesa. Uloga mreže je da obezbedi pouzdan prenos informacija i senzorskih podataka do svih i od svih konstitutivnih elemenata sistema. Komunikacioni nivo dakle obezbeđuje umrežavanje robota u lokalnu računarsku mrežu (LAN) korišćenjem Wi-Fi pristupa ili GSM-GPRS modema (u slučaju informaciono strukturiranog okruženja) i povezivanje robota na Internet.

Na nivou aplikacije postoji nekoliko računara koji međusobno komuniciraju i koriste zajedničku bazu podataka. Svaki, pojedinačni računar ima strogo definisane zadatke. Jedan obrađuje podatke koji se odnose na karakteristike objekata (delova) i njima manipuliše, obrađuje podatke koji se odnose na mašine alatke preuzete iz okoline, njihove dimenzije, prostornu lokaciju itd. Drugi računar je zadužen za

Sl. 2. Blok dijagram hardverske strukture robotskog kontrolera industrijskog humanoida (levo). Sastavljeni prototip robota (desno)..

 ISBN 978-86-7466-930-3

analizu, učenje i operacionalizaciju ljudskih manipulativnih i kognitivnih veština koje su karakteristične za tehnološke procese. Treći računar se bavi tehnikama i metodama formalizacije određenih industrijskih tehnoloških procesa (npr. obrada, montaža delova, fizička pomoć ljudskim radnicima, itd.) na način koji će biti razumljiv za mašinu (kontroler robota). Informacije koje se odnose na tehnološke operacije se uglavnom svode na podatke kojim redosledom i kojim alatima treba izvršiti određene tehnološke operacije, na koji način, u kojoj tački uhvatiti objekat, kojom silom ili momentom, kojom brzinom to učiniti, itd.

Zadaci koji se obavljaju na računarima, koji su deo aplikativnog nivoa, u velikoj meri se oslanjaju na baze podataka u vezi sa aplikacijama koje su operativni domen industrijskog humanoida. Baze podataka sadrže informacije koje se odnose na geometrijske atribute objekata koji su predmet tehnološkog procesa, zatim informacije od interesa o tehnikama ljudskih veština karakterističnim za iskusne radnike (stručnjake) i informacije o fazama ili redosledu izvođenja pojedinih tehnoloških operacija i detalje o tome kako se one izvode sa specifičnim numeričkim indikatorima (kompozitna brzina, pozicija, sila, obrtni moment, itd.).

Ljudskim operaterima "Cloud" arhitektura omogućava daljinsko upravljanje robotom pomoću pametnog telefona sa Android aplikacijom ili standardnog PC računara sa odgovarajućom aplikacijom sa grafičkim korisničkim interfejsom. Ovo pretpostavlja Wi-Fi hot spot ili GSM-GPRS modem na robotu koji donosi dodatnu funkcionalnost daljinske komunikacije sa ovlašćenim pristupom i mogućnošću praćenja parametara sistema i/ili daljinskog prenosa slike i zvuka.

III. UPRAVLJAČKI NIVOI

Za upravljanje dvoručnim kolaborativnim robotom prikazanim na Sl. 1, koristi se arhitektura upravljanja u oblaku (odnosno "Cloud" kontrola) prikazana na Sl. 2. Ova kontrolna konfiguracija podržava koncept takozvane hijerarhijski distribuirane kontrole implementirane na tri nivoa kontrole: (i) strateški, (ii) taktički i (iii) izvršni nivo. Svi navedeni nivoi upravljanja imaju precizno diferencirane kontrolne zadatke i postoji jasna podređenost operacija u sistemu.

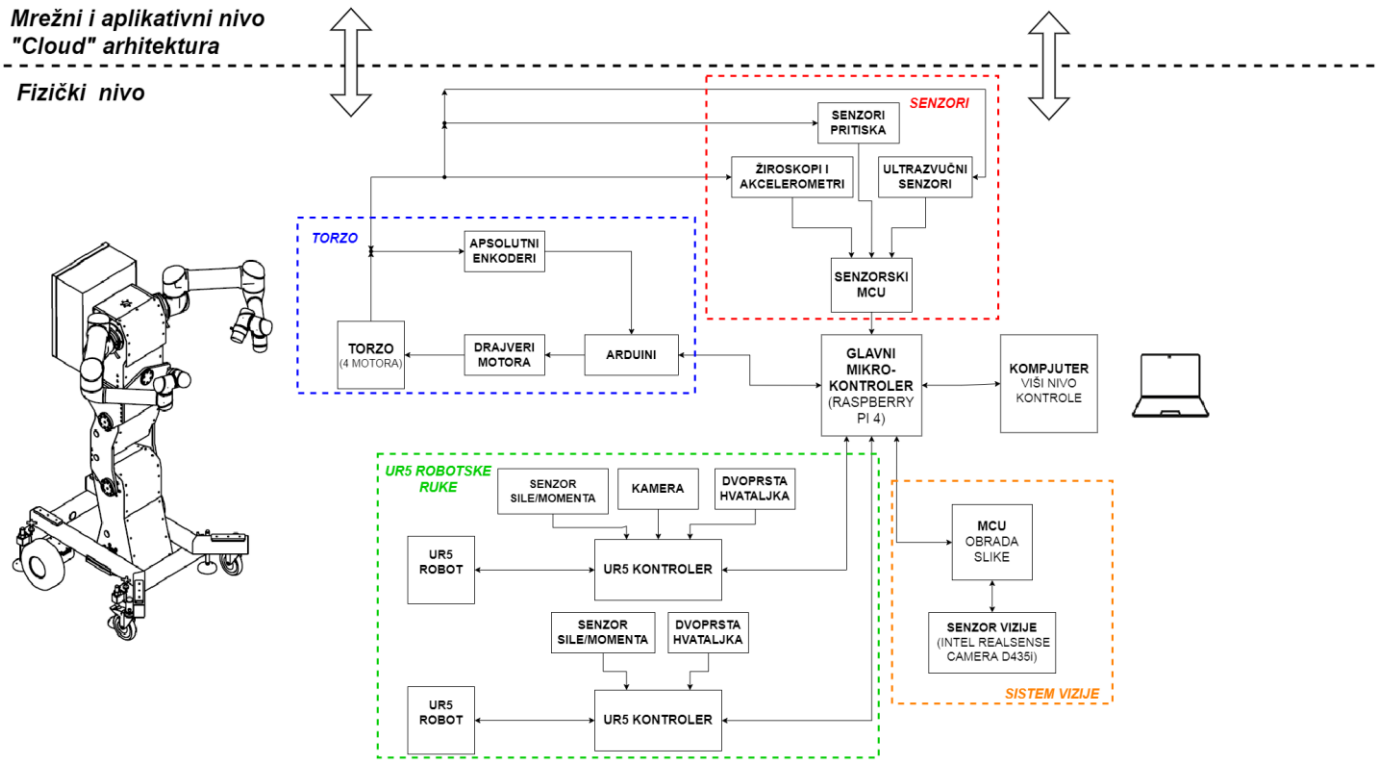
A. Strateški nivo

Na strateškom nivou upravljanja definišu se globalni ciljevi, planiranje procesa, tehnološke operacije koje robot treba da obavlja samostalno ili u saradnji sa čovekom ili mašinom, kao i manipulativne i kognitivne veštine koje robot treba da demonstrira dok obavlja svoje aktivnosti, poštujući redosled tehnoloških operacija i bezbednosne standarde. Strateška kontrola koristi informacije dobijene na fizičkom nivou (Sl. 2) kao i iz odgovarajuće baze podataka. U bazama podataka se čuvaju informacije relevantne za robota industrijske usluge koje se odnose na prepoznavanje geometrije objekata, informacije o fazama i tehnikama izvođenja određenih tehnoloških procesa u koje je robot uključen i na kraju informacije o manipulativnim i kognitivnim veštinama pretvorene u formu razumljivu mašini (robotski kontroler). U bazi se čuvaju i podaci o bezbednosnim standardima za obavljanje određenih robotskih zadataka, budući da je industrijski humanoid namenjen za kolaborativni rad sa ljudima. Takođe, na nivou strateške kontrole vodi se računa o ispunjavanju standarda kvaliteta izvođenja tehnoloških operacija. Rezultati ovog nivoa kontrole su jasno definisani ciljevi visokog nivoa i redosled ostvarivanja tehnološkog procesa, tehničko-tehnološka ograničenja, način izvođenja procesa, alati koji se koriste i odgovarajuće veštine, razvrstane na podciljeve koje treba postići na nižem, podređenom hijerarhijskom nivou – taktičkom.

B. Taktički nivo

Na nivou taktičke kontrole, kako sama reč kaže, definiše se taktika ostvarivanja skupa podciljeva dobijenih sa strateškog nivoa upravljanja. Na ovom nivou planira se postizanje skupa podciljeva kao što su planiranje putanje robotskih ruku (pozicija, orijentacija i brzina krajnjih efektora robota), sinhronizacija rada dve robotske ruke kako bi se izbegao sudar, definisanje referentne sile i momenta na hvataču robota, zatim, orijentisanje kamera u radnom prostoru zadatka, itd. Izlazni podaci sa nivoa taktičke kontrole predstavljaju referentne (tj. željene) vrednosti promenljivih koje predstavljaju ulaze za izvršni nivo upravljanja (na servo nivou).

C. Izvršni nivo



Na izvršnom nivou upravljanja komanduje se radom servo pogona koji obezbeđuju izvršavanje određenih aktivnosti. Korišćenjem povratnih petlji po poziciji/orijentaciji, brzini, sili/momentu, na izvršnom nivou postiže se željeno kretanje sistema u skladu sa taktikom i strategijom izvršavanja procesa koji su određeni na višim nivoima sistemske kontrole. Na izvršnom nivou, senzorne informacije i podaci senzora prikupljaju se sa robota i/ili iz njegovog fizičkog okruženja. Takođe se obavlja akvizicija slike i/ili video tokova iz sistema vizije robota za njihovo slanje na viši, taktički nivo upravljanja gde se vrši obrada tih signala. Dobijene povratne informacije su od velikog značaja na taktičkom nivou za vršenje neophodnih korekcija tehnike izvođenja procesa redefinisanjem referentnih vrednosti. Na ovaj način se obezbeđuje tok informacija odozgo nadole, kao i inverzni tok informacija odozdo prema gore od najvišeg nivoa upravljanja ka najnižem i obrnuto.

. *Upravljanje robotom na fizičkom nivou "Cloud" sistema*

Na Sl. 3 prikazan je blok dijagram upravljanja dvoručnim kolaborativnim robotom. Upravljanje izvršnim nivoom se realizuje korišćenjem dva nezavisna industrijska kontrolera robotskih ruku UR5 koji se isporučuju sa svojim fabričkim kontrolerima zatvorenog tipa sa već realizovanim algoritamskim rešenjima za regulator položaja/brzine i regulator sile/momenta.

Torzo robota, robotske ruke i sistem vizije se nezavisno kontrolišu, dok se centralna mikrokontrolerska jedinica (MCU) koristi za sinhronizaciju celog upravljačkog sistema,

 ISBN 978-86-7466-930-3

Sl. 3. Blok šema upravljačkog sistema razvijena na fizičkom nivou industrijskog servisnog robota upravljanog "iz oblaka".

delegiranje zadataka, komunikaciju sa udaljenim operaterima, itd. Torzo robota (Sl. 2) ima četiri zgloba aktuirana DC motorima bez četkica koji se pokreću preko drajvera. Svaki od drajvera kontroliše nezavisni Arduino mikrokontroler. Na svaki motor montiran je rotacioni enkoder koji pruža informacije o trenutnoj ugaonoj brzini i položaju motora, koje Arduino koristi za kontrolu položaja motora. Arduino mikrokontroleri komuniciraju sa glavnim MCU putem CAN bus komunikacije velike brzine. Na torzo i kolica robota postavljeni su različiti senzori uključujući i senzore kontakta/pritiska, žiroskope i akcelerometre, ultrazvučne senzore, itd. Senzori pritiska su posebno važni jer se koriste za izračunavanje tačke nultog momenta (ZMP) mobilnog industrijskog humanoida kao indikatora stabilnosti. Ove informacije se koriste da bi se utvrdilo da li je bezbedno da torzo i ruke robota stignu u datu poziciju bez pada ili prevrtanja. Sirove informacije sa senzora se obrađuju na posebnoj mikroprocesorskoj jedinici, a potom se obrađeni podaci, po potrebi, CAN komunikacijom šalju glavnom MCU, koji ih koristi za kontrolne zadatke, mere bezbednosti, itd. Ruke robota UR5 su fizički montirane na prirubnicama koje se nalaze na vrhu torza. Prirubnice su zakrivljene pod uglom od oko 15 stepeni u odnosu na torzo robota jer se time povećava opseg korisnog radnog prostora ispred torzoa.

UR5 roboti su konvencionalne industrijske ruke sa 6 stepeni slobode. Svaka od robotskih ruku ima senzor sile/momenta i hvatač sa dva prsta koji je montiran na svom vrhu. Jedna od ruku takođe ima montiranu kameru na zglobu i ovo će biti glavna ruka u dvoručnim zadacima. Servo kontrola niskog nivoa zglobova ruku robota se vrši preko originalnih UR5 kontrolera koji se isporučuju zajedno sa robotskim rukama. UR5 kontroleri komuniciraju sa MCU preko fizičkih veza (I/O signali sa MODBUS vezom), preko žičane (Ethernet) ili bežične (Wi-Fi pristup) mreže i preko ROS-a (Robot Operating Sistem).

Sistem robotske vizije je važan kontrolni podsistem koji celokupnom sistemu obezbeđuje vizuelnu povratnu informaciju. Senzor vida (Intel RealSense D435i dubinska kamera) je montiran na vrhu torzoa. Njegova uloga je da obezbedi robotu mogućnost 3D vizije sa senzorom dubine. Takav sistem se koristi za opažanje robotskog okruženja, praćenje zadataka, izbegavanje fizičkih stacionarnih ili mobilnih prepreka itd. Kamera će biti povezana sa posebnom mikrokontrolerskom jedinicom koja će se koristiti za obradu slika primljenih sa kamere. Softver koji će se koristiti za procesiranje vizuelnih podataka sastoji se kako iz klasičnih algoritama kompjuterske vizije tako i iz algoritama dubokog učenja i neuralnih mreža za obradu i prepoznavanje slika. Ovaj mikrokontroler će takođe biti povezan na glavni MCU.

Glavna jedinica mikrokontrolera (Raspberry Pi 4 sa 8GB RAM-a) je sastavni deo kontrolnog sistema. Ovaj MCU komunicira sa mrežnim nivoom (slika 2), odakle prima informacije o referentnim zadacima robotskog sistema koje treba da izvrši. Takođe prima povratne informacije od svakog kontrolnog podsistema. MCU obrađuje sve ove informacije i sinhronizuje ceo sistem (torzo+2 ruke+2 hvatača+kamera), delegira zadatke svakom podsistemu i zaustavlja aktuatore u slučaju opasnosti ili kvara. Komplementarni računar se može dodati glavnom MCU kao lokalni nadzorni sistem. Koristi se uglavnom kao pomoćno sredstvo za razvoj sistema

 ISBN 978-86-7466-930-3

upravljanja, testiranje i verifikaciju rezultata rada zadataka.

IV. ZAKLJUČAK

U radu je predložena višestepena upravljačka arhitektura servisnog industrijskog kolaborativnog robota. Hijerarhijska distribuiranost ovog sistema dozvoljava najbolje iskorišćenje pojedinačnih kontrolnih podsistema kao i već postojećih kontrolera i stavlja fokus na delegiranje zadataka na manje procesorske jedinice i sinhronizaciju pojedinačnih delova sistema. Korak dalje u dizajniranju ovakvih sistema predstavlja implementacija "Cloud" arhitekture koja omogućava daljinsko upravljanje i nadzor nad sistemom, kao i čuvanje raznih ulaznih i izlaznih sistemskih podataka na serveru.

Dalji rad autora nastaviće se u ovom pravcu. Po finalnoj montaži celokupnog sistema radiće se eksperimentalna verifikacija različitih upravljačkih zadataka. Potom će gotov sistem biti pogodan za različita istraživanja u oblasti dvoručne manipulacije, kolaboracije čoveka i robota, inteligentnog hvatanja, robotske vizije i dr.

ZAHVALNICA

Razvoj prototipa kolaborativnog robota rezultat je bilateralnog R&D projekta pod nazivom „Razvoj i eksperimentalna verifikacija performansi mobilnog robota sa dve ruke za saradnju sa čovekom" iz „Programa razvoja nauke i tehnologije – finansiranje zajedničkih istraživačko-razvojnih projekata". ABSTRACT

This paper presents a multi-level cloud-enabled control architecture of a bi-manual collaborative humanoid service robot. This architecture is designed to perform robotic tasks that require the implementation of advanced manipulative and cognitive skills within the industrial manufacturing process. The control structure of the robot is designed to meet the needs of the so-called smart production within Industry 4.0, enough to enable and facilitate the cooperation of man and robot as a complementary intelligent system, necessary in industrial tasks that humans cannot perform independently. This paper presents a hierarchically distributed management system organized into three operational levels: a) strategic, b) tactical and c) executive, enabled by the use of cloud architecture. The hardware of the control system is established on three levels: physical, communication and application. Thanks to the distributed architecture, the cloud system enables distributed execution of individual control tasks, which results in a balanced load on the multiprocessor system and reduced stimulus response time from the physical environment of the robot.

On Pulse Shaping for Generalized Faster than Nyquist Signaling with and without Equalization

Jovan Milojković, Srđan Brkić, *Member, IEEE*, Jelena Ćertić, *Member, IEEE*

***Abstract*—This paper focuses on analyses of generalized Faster than Nyquist (FTN) signaling in the presence of additive white Gaussian noise. A new method for designing pulse shaping filters, that maximize information rate and simultaneously obey constraints related to energy distribution of the pulse autocorrelation function, is proposed. The obtained pulses are coupled with the minimum mean square error (MMSE) equalizer used at the receiving side. In addition, potential for their use without any equalization scheme is also analyzed. Significance of the proposed approach is verified by comparing designed pulses with state-of-the-art FTN schemes, that employ raised cosine pulses, in terms of bit error rate and achievable information rate. We identify cases when the proposed scheme provides the same achievable information rate as the standard FTN system with more than 1.5 dB lower signal-to-noise power (SNR) ratio, without the equalization, and 0.4 dB lower SNR ratio, if MMSE equalization is employed.**

***Index Terms*—Faster than Nyquist signaling, MMSE equalization, pulse shaping**

I. Introduction

In a classical communication system information is transmitted by using orthogonal pulses (with flat frequency spectrum) and ideally no inter-symbol interference is introduced by the transmitter, which is refereed to as the Nyquist signaling approach. Intense research over the past years in the area of channel coding and modulation lead to development of Nyquist transmission systems that operate close to the ultimate Shannon spectral efficiency bounds, and obviously, additional improvement must be followed by the change of Nyquist's transmission paradigm. With the invention of new services, mostly associated with the fifth generation standard for broadband cellular networks (5GNR), the problem of designing spectral efficient transmission system comes again under the spotlight. A technique that is capable to provide a quantum leap in design of spectrally efficient systems is faster then Nyquist (FTN) signalling.

In FTN signaling systems use of orthogonal pulses is abandoned and inter-symbol inference is intentionally introduced. It follows that as the adjacent received symbols are correlated, conventionally used symbol-by-symbol detection becomes inappropriate, and information needs to be extracted by some equalization technique. The foundations of FTN were laid down by Mazo in 1975 [1], who noticed that communicating with symbol rates higher than the Nyquist rate, can provide spectrally efficient transmission, without degradation in Euclidean distances between transmitted symbols. Although the aforementioned insight was revolutionary, it was not fully explored for more than 30 years. Namely, in 2007 Rusek and Anderson [2] created the information-theoretic framework for the analysis of FTN systems and proved that capacity of conventionally used Nyquist systems (for example with raised cosine (RC) pules) can be surpassed with FTN signaling. Furthermore, the same authors showed in [3] that, by increasing the symbol transmission rate, constrained capacity saturates to a fixed value – in other words arbitrary spectral efficiency can be achieved. Their work was refined recently by Ishihara and Sugiura in [4], where it was shown that conventionally used RC pulses employed in precoded FTN systems approach Shannon capacity of the ideal rectangle pulse. For excellent overview on FTN concepts and technologies we direct readers to [5].

In order to keep the advantages of FTN over Nyquist signaling in practical systems, the equalization and channel coding need to be adjusted. The optimal FTN receiver is organized in a form of turbo equalization loop [6], where equalization is performed by employing maximum a posteriori probability (MAP) detector. Complexity of MAP detection grows exponentially with increase of symbol rate, making it infeasible for practical use. On the opposite side, using low complex equalization, for example MMSE (Minimum Mean Square Error), may be insufficient to perform significantly beyond conventional Nyquist systems. This lead to *generalized FTN signaling* approach [7], in which conventional pulses, like RC, are replaced with pulses that are adjusted to a given equalization scheme. Another benefit of custom pulse design is ability to adopt to a given practical requirements, for example peak-to-average power ratio (PAPR) or adjacent channel leakage power (ACLP), which can vary from one communication standard to another.

Over the years, different pulse designs were proposed that can be incorporated into generalized FTN concept. The most prominent approaches include pulses designed: i) to minimize Euclidean distance between different realizations of two random transmitted sequences [8] and bit error rate of uncoded transmission [9], ii) to maximize information rate [2], [10], [11], or iii) to obey predefined frequency domain constraints (and simultaneously limit PAPR) [12]. For example, Rusek and Anderson in [2] proposed an optimization procedure in which pulses with predefined number of taps maximize an upper information rate bound. The procedure was further expanded by Brkic *et al.* in [11] to enable arbitrary

 ISBN 978-86-7466-930-3

pulse energy distribution in time domain, which can be used to build generalized FTN systems with limited trellis-based equalizer complexity.

In this paper we further extend the optimization procedure presented in [2], [11] in order to make it applicable to FTN systems with MMSE equalizers, or even to FTN transmission systems which do not employ any equalization scheme. Namely, we define additional time domain constraints related to energy of the pulse autocorrelation function. We verify that designed pulses outperform state-of-the-art FTN systems (with RC pulses), for the same symbol rate and ACLP, in terms of bit error rate as well as achievable information rate in additive white Gaussian noise (AWGN) channel.

The rest of the paper is organized as follows. In Section II we briefly describe system model and MMSE equalization scheme. Section III is dedicated to the optimization procedure, while numerical results are given in Section IV. Finally, concluding remarks can be found in Section V.

II. System Model

Consider an output of the baseband equivalent of the transmitter

$$s(t) = \sum_{k=-\infty}^{\infty} a_k h(t - kT), \tag{1}$$

where $a_k \in \{\pm 1\}$ corresponds to the k-th transmitted symbol, T denotes symbol duration and $h(t)$ is the pulse shaping filter. We assume that $h(t)$ is not orthogonal with respect to the transmitting sample rate, i.e, it intentionally introduces ISI and that $h(t)$ can be represented as weighted sum of wider band pulses

$$h(t) = \sum_{l=0}^{L-1} b_l \psi(t - lT), \tag{2}$$

where $\psi(t)$ is a pulse orthogonal to the sampling rate $1/T$, while $\mathbf{b} = (b_0 \ldots, b_{L-1})$ corresponds to a vector of the sampled coefficients, i.e, $b_l = h(lT)$. Note that we restrict the effect of ISI to L consecutive symbols and that energy of the impulse response is considered to be unitary.

The waveform $s(t)$ is transmitted through additive white Gaussian (AWGN) channel, described with energy per symbol to noise power spectral density (E_s/N_0) metric.

At the receiver side in this paper we consider two observation models: i) orthogonal basis model (OBM) [13] and ii) Ungerboeck model [14] without the equalization. According to the OBM, receiving filter is matched to $\psi(t)$ (not $h(t)$), which means that noise at the receiver input is white. In our model we assume that $\psi(t)$ is square root raised cosine pulse with roll-off 0.1. To verify the performance of $h(t)$ on the OBM, we employ MMSE equalizer. Motivated by the recent findings, reported in [15], that FTN signaling can perform satisfactory even without an equalizer implemented in the receiver side, we here consider such detection scheme, for the case of the Ungerboeck observation model. In the Ungerboeck model receiving filter is matched to $h(t)$, which maximizes E_s/N_0 metric; however, received noise sequence becomes correlated.

We next briefly explain MMSE equalization used in the OBM (for more details one could see [16]). Let $\mathbf{r}_n = (r_{n-N_2}, r_{n-N_2+1}, \ldots, r_{n+N_1})^T$ denote a sequence at input of the MMSE equalizer used to estimate transmitted symbol a_n, where T is transposition sign. The parameters N_1 and N_2 specify the length of the noncausal and the causal part of the MMSE filter. Then, finite impulse response (FIR) MMSE filter coefficients $\mathbf{c}_n$ can be obtained as follows

$$\mathbf{c}_n = \mathrm{Cov}(\mathbf{r}_n, \mathbf{r}_n)^{-1} \times \mathrm{Cov}(\mathbf{r}, a_n), \tag{3}$$

where the covariance operator is given by $\mathrm{Cov}(\mathbf{x}, \mathbf{y}) = E(\mathbf{x}\mathbf{y}^H) - E(\mathbf{x})E(\mathbf{y}^H)$, where $E(\cdot)$ denotes mathematical expectation, and H is Hermitian operator. The symbol estimate $\hat{a}_n$ is obtained by $\hat{a}_n = \mathbf{c}_n^H \mathbf{r}_n$. It should be noted that values N_1 and N_2 are dependent on $h(t)$.

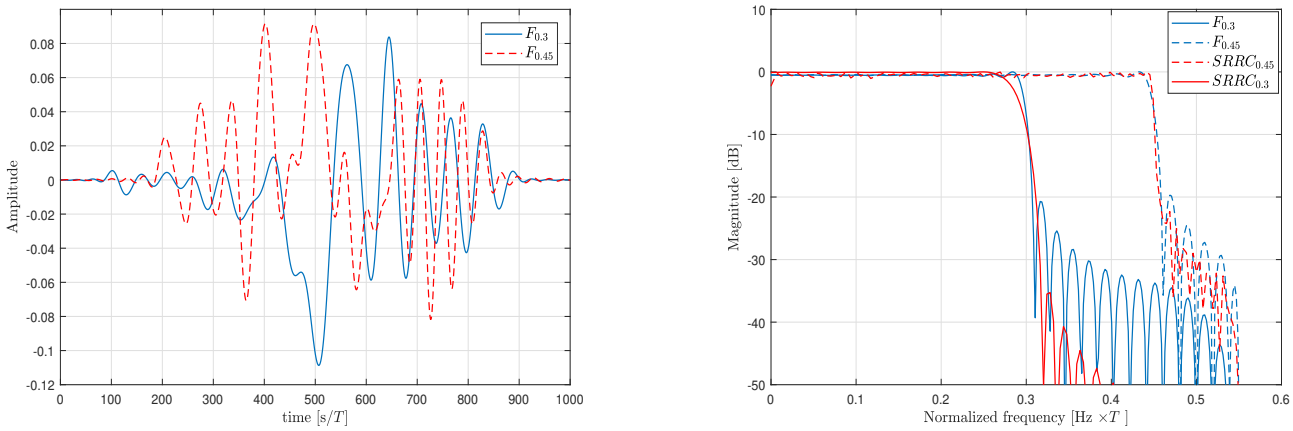
III. Optimization of pulse shaping filter

In this section we state the optimization problem for finding pulse shaping filter coefficients $\mathbf{b}$ that maximize the achievable information rate (AIR) and are also adjusted to the equalizing scheme. Fundamentals of the AIR-based optimization can be found in [17], and we first briefly explain key concept of the optimization, and then highlight modifications introduced in order to adjust the optimization procedure to the system model, given in Section II.

The procedure from [17] allows pulse design for arbitrary ACLP value and the filter length L. Let $H(f)$ denotes Fourier transform of $h(t)$. Then we can define, a complement of ACLP, the concentration of pulse energy in W Hz as follows

$$\beta = \frac{\int_{-W}^{W} |H(f)|^2 df}{\int_{-\infty}^{\infty} |H(f)|^2 df}. \tag{4}$$

Without loss of generality, we can consider normalized bandwidth defined as $w = W \times T$, and notice that $w = 0.5$ corresponds to Nyquist signaling while when $w < 0.5$ we are communicating in FTN signaling fashion. The amount of ISI introduced at transmitter side is inversely proportional to w. Alternatively, the energy concentration β can expressed in a more suitable form, as a function of pulse discrete autocorrelation function $\mathbf{g} = (g_{-L+1}, \ldots, g_{L-1})$, as follows [11]



$$\beta(\mathbf{g}, w) = \sum_{l=-L}^{L} 2 g_l w \times \mathrm{sinc}(2\pi w), \tag{5}$$

where $\mathrm{sinc}(x) = \sin(x)/x$, and

$$g_l = \int_{-\infty}^{\infty} h(t) h^{\star}(t - lT) dt. \tag{6}$$

Direct maximization of AIR, for a given discrete modulation set is infeasible as, to the best of our knowledge, a closed form expression does not exist. Instead, it is common to optimize

 ISBN 978-86-7466-930-3

(a) (b)

Fig. 1: Impulse (a) and (b) frequency responses of designed filters for $w = 0.3$ and $w = 0.45$ ($L = 50$, $\beta = 0.999$).

an information rate upper bound $C(\mathbf{b})$, derived assuming Gaussian sample distribution [17]

$$C(\mathbf{b}) = \int_0^{1/2} \log_2 \left[1 + \frac{2E_s|B(f)|^2}{N_0 T} \right] df, \tag{7}$$

where $B(f) = \sum_{k=0}^{L-1} b_k e^{i2\pi kf}$ represents Fourier transform of the vector $\mathbf{b}$.

It was reported in [11] that in large number of cases $C(\mathbf{b})$ monotonically increases with actual AIR obtained through computationally hungry Monte Carlo simulation, which means that optimizing $C(\mathbf{b})$ is meaningful.

By studying typical behavior of pulses optimized by (7), for a fixed β and w constraints we noticed the following: i) relatively small number of filter taps is sufficient to obey strict b constraint (for example $\beta = 0.999$) and ii) significant portions of energy of the pulse autocorrelation are spread across a large number of taps, i.e., the account of introduced ISI is large. Obviously, such pulses cannot be used in systems that do not use equalizers, and are inadequate when equalization is performed with the MMSE equalizer, given its modest ability to suppress ISI.

To resolve the aforementioned issue, we proposed that additional constraint is added into optimization setup that will force the optimization procedure to cluster the majority of the autocorrelation energy to main tap g_0 and potentially $2M$ adjacent taps ($g_{-M},, g_{-1}, g_1, \dots g_M$). Namely, we define a set of thresholds f $0 < f_i < 1$, $0 \leq i \leq M$, forcing the relative energy of central autocorrelation taps to be above the thresholds. However, given frequency-time duality principle, clustering autocorelation energy makes it harder to satisfy frequency domain constraint β. To overcome the problem, the filter lengths L must be increased.

For predefined normalized bandwidth w, with energy concentration β_0 we formally express the optimization problem as follows

$$\begin{aligned} \mathbf{b}_{opt} &= \underset{\mathbf{b}}{\operatorname{argmax}}\ C(\mathbf{b}) \\ s.t.\ \ &\beta(\mathbf{g}, w) = \beta_0, \\ &\frac{g_i^2}{\sum_{\ell=-L+1}^{L-1} g_\ell^2} \geq f,\ 0 \leq i \leq M. \end{aligned} \tag{8}$$

The above optimization problem can be solved similarly as the related problems described in [17] and [11], by sequential quadratic programming (SQP) method.

It should be noted that in OBM system described in Section II, we do not match the receiving filter to transmitting $h(t)$, which means that amount of ISI collected by the receiver is not directly expressed by autoccorelation of $h(t)$. However, we observed strong dependency between ability of MMSE equalizer to suppress ISI and the energy concentration of the pulse autocorrelation function.

To illustrate our optimization procedure, we designed two pulses with $\beta = 0.999$, $L = 50$ and $w = 0.3$ and $w = 0.45$, respectively, denoted by $F_{0.3}$ and $F_{0.45}$, design to obey $f_0 = 0.58$ and $f_0 = 0.85$, respectively. Their impulse and frequency responses are depicted in Fig. 1. For compression we also give frequency responses of square root raised cosine (SRRC) pulses with roll-offs equal to 0.1, designed to meet the same requirements as optimized pulses in terms of length and energy concentrations in frequency domain (denoted by $SRRC_{0.3}$ and $SRRC_{0.45}$).

IV. Numerical results

In this section we provide the performance of designed pulses $F_{0.3}$ and $F_{0.45}$, in terms of bit error rate and achievable information rates, obtained by Monte Carlo simulation (Figs. 2 and 3). We examine pulses behaviour on OBM and Ungerboeck system models, introduced in Section II. Obtained results are compared to SRRC pulses ($SRRC_{0.3}$ and $SRRC_{0.45}$). Given the fact that we only consider binary

 ISBN 978-86-7466-930-3

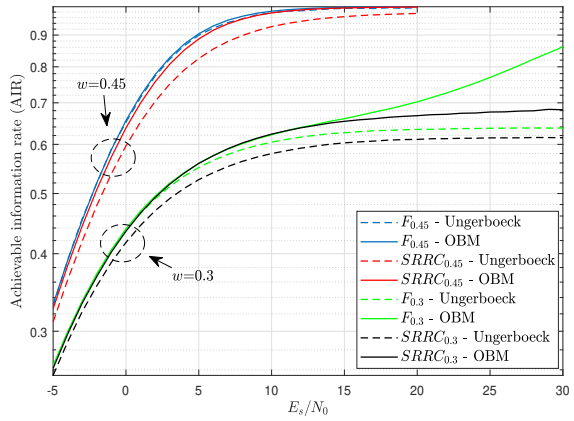


Fig. 2: Achievable information rates of designed pulses.

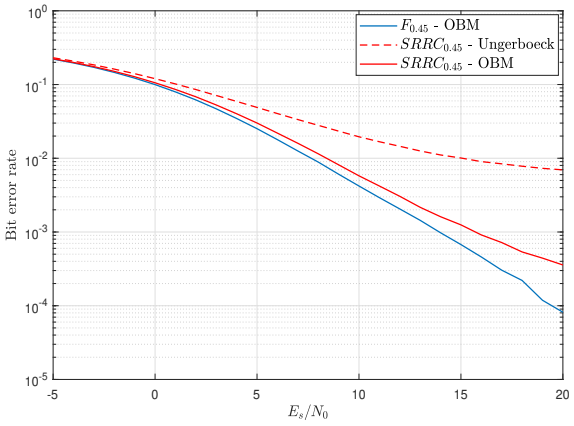

Fig. 3: Bit error rate achievable by $F_{0.45}$ filter.

transmission ($a_k \in \{\pm 1\}$), achievable information rates are calculated numerically as follows

$$AIR = \frac{1}{2} \sum_{a_k=-1,1} \int_{-\infty}^{+\infty} p(z|a_k) \times \log_2 \frac{2p(z|a_k)}{p(z|1) + p(z|-1)} dz, \tag{9}$$

where the conditional probability density function of the log likelihood ratio z of the symbols that corresponds to transmitted a_k, $p(z|a_k)$, is approximated by a histogram.

In Fig. 2 we show that designed pulses outperform SRRC counterparts in terms of AIR on the both system models. For example, $F_{0.45}$ achieves AIR, equal to 0.8 bits/symbols, with 0.4 dB less E_s/N_0 value compared to $SRRC_{0.45}$ on the OBM, while the differences on the Ungerboeck model is approximately 1.8 dB. One can also notice that $SRRC_{0.3}$ cannot achieve information rates above 0.68 bits/symbol in the OBM, while if $F_{0.3}$ is used, higher spectral efficiencies are possible. If we consider uncoded transmission we can, notice that $F_{0.45}$ achieves bit error rate of 10^{-3} with 1.7 dB less E_s/N_0 compared to $SRRC_{0.45}$ on the OBM (Fig. 3).

V. Conclusion

This paper provides novel pulse shaping filters applicable to generalized FTN signaling systems with MMSE equalization and also to systems with no equalizer employed. We show that proposed pulses outperform SRRC pulses of the same structural properties. Our future work will be oriented into examining finite length coded transmission systems that employ proposed pulses.

Performance simulation for LCR of MIMO Multi-branch SC Diversity System in α-μ fading and α-μ interference channel

Dejan Milić, Suad Suljović, Dejan Rančić, Nenad Petrović, Nenad Milošević

***Abstract* - In order to improve the overall performance of the networ in 5G telecommunication networ s, ultiple Input and ulti utput Technology (I) is applied. In this paper, the mean number of evel Crossing ate (C) of I systems with -branch selection combining (C) receiver is analyzed. During signal transmission, its distortion occurs due to low α-μ fading and α-μ co-channel interference (CCI) effects. Additionally, we applied an accelerated graphics processing unit (GP) simulation to plan a o -efficient 5G mobile networ in a smart city. This approach in combination with linear optimization and deep learning significantly optimizes the C calculation speed for the observed communication system type, while providing efficient planning - reducing costs, but ma imizing performance.**

***Index Terms*— C combining, α- fading, α- interference, C , o , GP , linear optimization.**

I. INTRODUCTION

Due to the unpredictable and dynamic nature of the wireless channel environment, the channel becomes one disruptive element in the transmission chain as it changes the broadcast signal. Therefore, the channel manages the performance of wireless communication systems [1].

Multiple Input Multiple Output (MIMO) is an efficient antenna technology for wireless communication systems where multiple antennas are used on the transmitter and receiver [2]. Antennas at each end of the system are combined to minimize errors during signal transmission, increase data rates and improve channel capacity. This technique allows signals to be transmitted on many different paths at the same time. This mode of signal transmission provides the ability for signals to reach the receiver without fading and co-channel interference. This technique increases the signal-to-noise ratio (SNR) and transmission quality, which creates more stable connections [3].

Fading is a variation of attenuation, ie. signal amplitude fluctuations. During transmission, the signal faces various obstacles such as buildings, trees, etc. present in the signal-causing environment is subject to reflection, diffraction, scattering and shading. This presence of multiple reflectors in the environment of the channel between the transmitting and receiving ends creates more paths for signal passage [4].

The most commonly used signal processing techniques in diversity systems are maximum ratio combination (MRC), equal gain combination (EGC), and selection combination (SC). MRC provides the best improvement in system performance, followed by an equal combination of reinforcements, but it is also the most complicated technique. In order to reduce the complexity of the receiver, this paper considers a simpler combination scheme related to combination selection (SC). The output of the SC receiver is the branch with the highest signal-to-noise ratio. SC has been extended to the case where signals on more than one receiving antenna are combined with the highest current SNR, this scheme is called hybrid maximum ratio selection/combination (HS/MRC). Selection Combination (SC) techniques have been applied in the design of MIMO systems to reduce system complexity and costs. Fifth generation (5G) telecommunications offers a 10-fold increase in spectral efficiency and a 1000-fold increase in system capacity compared to 4G technology [5]. In MIMO systems, there are tens to hundreds of antennas in the receiver and transmitter. Massive MIMO techniques use familiar channel features to deliver superior performance in wireless communications. Channels are modeled to include channel variations in frequency and time.

Describing and modeling channels with fading is of particular importance in mobile communications both for the design of the transceiver system and for performance analysis. During the long period of development of wireless communications, a large number of different models of channels with fading were constructed to describe the statistics of the envelope and the phase of the channel where the signal propagates in several paths, [6]. Examples of such models are Rayleigh's, Rice's, Nakagami-q, Nakagami's, Weibull's, Beckmann's, α − μ etc. The aim of this paper is to study the statistical properties of first and second order

envelopes and phases in these models, with with special reference to the α − μ model.

In mobile communications, the received signal varies in a wide range of values. Therefore, for the design of digital and analog systems, it is necessary to know the statistical characteristics of the signal. There are first and second order statistical characteristics. It is especially necessary to know the statistical characteristics of the second order, such as the average number of axial sections of the LCR and the average duration of AFD fading. These quantities provide additional information that, when combined with other statistics, allows designers to create rational system solutions [7].

Level Crossing Rate (LCR) and Average Duration of Fades (ADF) are important second-order statistical characteristics for describing fading channels. These quantities are useful in the design of mobile radio communication systems and for the analysis of their performance. In digital telecommunications, a sharp drop in the envelope value of the received signal directly leads to a sharp increase in the probability of error [8]. Second-order statistics calculation techniques are particularly applicable to diversity systems that have been shown to be very useful in reducing the impact of fading.

In this paper, we consider a 5G communication system that works over k-ading fading channels and k-μ co-channel interference. One of the most basic statistics of a wireless communication system operating in a fading environment is the mean number of axial cross-sections (LCR). The quality of service (CoS) in wireless communications depends significantly on the LCR as it allows the estimation of the minimum distance between two base stations. We first compute the cumulative distribution function (CDF) for the signal in the described environment, and then we derive a closed-form expression for the LCR. The results of this analysis can be used to design an optimal receiver for a 5G mobile network in smart cities in conditions of small α-μ fading and α -m interference.

II. LCR OF SIGNAL TO INTERFERENCE RATIO AT THE OUTPUT OF THE L-BRANCH SC RECEIVER

In this section, the statistics of the second order 5G wireless communication system with SC receiver with L branches are considered. The received desired signal experiences α-μ fading, while the interference on the co-channel is subjected to α-μ fading. The model of the receiver is shown in Fig. 1.

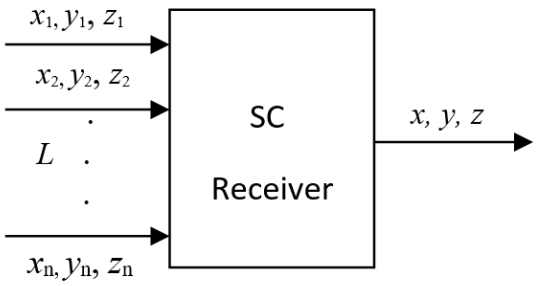

Fig. 1. The model of the SC receiver with branches

Signals $_{1}$, $_{2}$, …, $_{n}$ come to the inputs of the SC combiner. The SC receiver with L input branches *2, 3, ... n* selects the signal from the antenna with the highest SNR. Also, interference envelopes in the co-channel interference appear as $y_1, y_2, \ldots, y_n$ at each of the L inputs of the SC receiver, while the corresponding output signal is y. The PDF signal envelope on input at SC receiver have the α-μ distribution [9]:

$$p_{\ i}(\ _i) = \frac{\alpha\mu^{\mu}\ _i^{\alpha\mu-1}}{\Omega_i^{\ \mu}\Gamma(\mu)} e^{-\mu\frac{\ _i^{\alpha}}{\Omega_i}} \tag{1}$$

where α is a positive parameter, Ω_i is the mean value of the signal power, μ is the number of clusters and Γ(·) is a Gamma function. In a described channel, the co-channel interference signal follows α-μ distribution:

$$p_{y_i}(y_i) = \frac{\alpha\mu^{\mu} y_i^{\alpha\mu-1}}{s_i^{\mu}\Gamma(\mu)} e^{-\mu\frac{y_i^{\alpha}}{s_i}} \tag{2}$$

where *s* is average power of *y*, $y_i \geq 0$. The ratio of the desired signal envelope and interference on the *i*-th input branch of the SC receiver with the L branch can be written as:

$$_i = \frac{_i}{y_i}, \quad _i = \ _i y_i \tag{3}$$

SNR for *i* *2.3,... n* at the output of the SC receiver is:

$$= \max(\ _1, \ _2 \cdots \ _i) \tag{4}$$

The probability density function (PDF) of the signal $_i$ is given by [10]:

$$p_{\ i}(\ _i) = \int_0^{\infty} \mathrm{d}y_i y_i p_{\ i}(\ _i y_i) p_{y_i}(y_i) = \frac{\alpha\ _i^{\alpha\mu-1}(\Omega_i s_i)^{\mu}\Gamma(2\mu)}{\Gamma^2(\mu)\left(\Omega_i + s_i\ _i^{\alpha}\right)^{2\mu}} \tag{5}$$

Cumulative distribution function (CDF) of $_i$ is [10]:

$$F_{\ i}(\ _i) = \int_0^{\ i} \mathrm{d}t p_{\ i}(t) = \frac{\Gamma(2\mu)}{\Gamma^2(\mu)} B_{\frac{s_i\ _i^{\alpha}}{\Omega_i + s_i\ _i^{\alpha}}}(\mu,\mu) \tag{6}$$

where $B_z(a, b)$ is the incomplete Beta function, [11; 8.39]. SNR for *i* = 2.3, … *n* will be at the output of SC combination:

$$= \max(\ _1, \ _2 \cdots \ _i) \tag{7}$$

First derivative of $_{ij}$ can be written:

$$\dot{}_{ij} = \frac{1}{y_{ij}}\ \dot{}_{ij} - \frac{\ _{ij}}{y_{ij}^2}\dot{y}_{ij} \tag{8}$$

 ISBN 978-86-7466-930-3

The derivative of the random process α-k-μ is a Gaussian random process, and a linear combination of Gaussian processes is also a Gaussian random process. Therefore, the conditional Gaussian distribution ˙ with zero mean and variance applies:

$$\sigma^2_{\cdot ij} = \frac{1}{y_{ij}^2}\sigma^2_{\cdot ij} + \frac{\overset{2}{ij}}{y_{ij}^4}\sigma^2_{\dot{y}ij} \tag{9}$$

where respective variances relating to signal and interference are [12]:

$$\sigma^2_{\cdot ij} = \left(\frac{2\pi f_m}{\alpha}\right)^2 \frac{\Omega_{i\ ij}^{2-\alpha}}{\mu}, \sigma^2_{\dot{y}ij} = \left(\frac{2\pi f_m}{\alpha}\right)^2 \frac{s_i y_{ij}^{2-\alpha}}{\mu} \tag{10}$$

where f_m denotes the Doppler frequency. After replacing expression (12) with (11), the variance ˙$_{ij}$ becomes:

$$\sigma^2_{\cdot i} = \frac{1}{y_i^2}\sigma^2_{\cdot i} + \frac{\overset{2}{i}}{y_i^4}\sigma^2_{\dot{y}_i} = \frac{1}{\mu y_i^{\alpha}\ {}_i^{\alpha-2}}\left(\frac{2\pi f_m}{\alpha}\right)^2 \left(\Omega_i + {}_i^{\alpha} s_i\right) \tag{11}$$

In equation (13), fm denotes the Doppler frequency. Conditional probability density functions (CPDF) of ˙$_i$ and $_i$ are [13]:

$$p_{\cdot i}\left(\dot{}_i \middle|\ {}_i y\right) = \frac{1}{\sqrt{2\pi}\sigma_{\cdot i}} \mathrm{e}^{-\frac{\dot{}_i^2}{2\sigma^2_{\cdot i}}},$$

$$p_{\ i}\left(\ {}_i \middle| y_i\right) = \left|\frac{\mathrm{d}\ {}_i}{\mathrm{d}\ {}_i}\right| p_{\ i}\left(\ {}_i y_i\right) = y_i p_{\ i}\left(\ {}_i y_i\right) \tag{12}$$

Conditional joint probability density function (CJPDF) of $_i$, ˙$_i$ and y_i is [13]:

$$p_{\cdot\ {}_i y_i}\left(\dot{}_i\ {}_i y_i\right) = p_{\cdot i}\left(\dot{}_i \middle|\ {}_i y_i\right) p_{\ i}\left(\ {}_i \middle| y_i\right) p_{y_i}\left(y_i\right) =$$

$$= p_{\cdot i}\left(\dot{}_i \middle|\ {}_i y_i\right) p_{y_i}\left(y_i\right) y_i p_{\ i}\left(\ {}_i y_i\right) \tag{13}$$

At the output of the SC receiver, the LCR signal is calculated as the mean value of the first derivation of the signal at the output of the SC receiver. The joint probability density function (JPDF) of $_i$ and $\dot{z}_i$ [13]:

$$p_{\cdot\ {}_i}\left(\dot{}_i\ {}_i\right) = \int_0^{\infty} \mathrm{d}y_i\, p_{\cdot\ {}_i y_i}\left(\dot{}_i\ {}_i y_i\right) \tag{14}$$

By integrating the first derivative, averaging is obtained. The rate of transition of the LCR level of the random process zi is [10]:

$$N_{\ i}\left(\ {}_i\right) = \int_0^{\infty} \mathrm{d}\dot{}_i\ \dot{}_i p_{\cdot\ {}_i}\left(\dot{}_i\ {}_i\right) =$$

$$= \int_0^{\infty} \mathrm{d}\dot{}_i\ \dot{}_i \int_0^{\infty} \mathrm{d}y_i p_{\cdot\ {}_i}\left(\dot{}_i \middle|\ {}_i y_i\right) p_{y_i}\left(y_i\right) y_i p_{\ i}\left(\ {}_i y_i\right) =$$

$$= \frac{\sqrt{2\pi}\, f_{m\ i}^{(2\alpha\mu-\alpha)/2} \left(s_i\Omega_i\right)^{(2\mu-1)/2} \Gamma\left(\left(4\mu-1\right)/2\right)}{\Gamma^2\left(\mu\right)\left(s_{i\ i}^{\ \alpha} + \Omega_i\right)^{2\mu-1}} \tag{15}$$

The LCR envelope of the signal-to-interference ratio at the output of the mD SC with *n* inputs is [14]:

$$N_{\ i|\Omega_i s_i}\left(\ {}_i\right) = \left(F_{\ ij}\left(\ {}_{ij}\right)\right)^{-1} N_{\ ij}\left(\ {}_{ij}\right) = \frac{\sqrt{2\pi}\, f_{m\ i}^{\frac{2\alpha\mu-\alpha}{2}}}{\Gamma^2\ (\mu)}$$

$$\frac{\left(s_i\Omega_i\right)^{\frac{2\mu-1}{2}} \Gamma^{-1}(2\mu)\Gamma\left(\frac{4\mu-1}{2}\right)}{\left(\Omega_i + s_{i\ i}^{\ \alpha}\right)^{2\mu-1}} \left(B_{\frac{s_{i\ i}^{\ \alpha}}{\Omega_i + s_{i\ i}^{\ \alpha}}}(\mu,\mu)\right)^{-1} \tag{16}$$

Fig. 2 shows a graphical analysis of the LCR at the SC receiver outputs given, where, $\Omega_1=\Omega_2=\ldots\Omega_n$, and $s_1=s_2=\ldots s_n$; It is assumed that the correlation between the input branches in the SC receiver is minimal.

III. NUMERICAL AND GRAPHICAL RESULTS

Based on expression (16) in Fig. 2 the LCR signal-to-noise ratio is shown in relation to the transition threshold at the SC receiver output from the L branches.

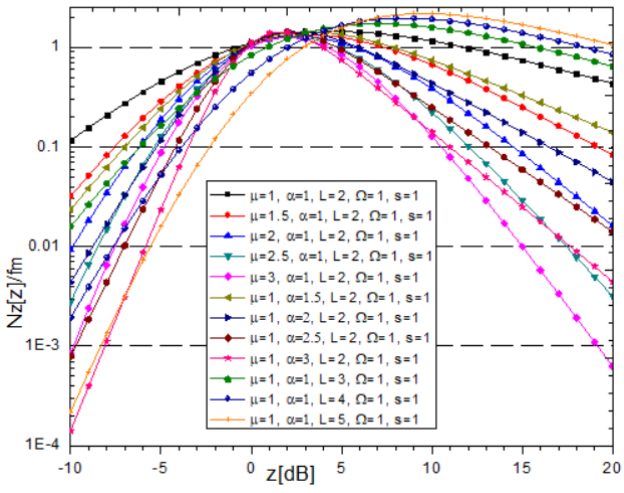

Fig. 2. LCR of system, for different values of parameters , α and L.

Fig. 2 shows that for higher values of the signal-to-noise ratio, the increase in the value of the parameter LCR decreases. When the parameter α increases then comes to narrowing the LRC function. As the number of L branches at the combinator input increases, the LCR increases by positive values of z [dB], and the system has better performance.

 ISBN 978-86-7466-930-3

IV. PLANNING AND SIMULATION ENVIRONMENT

In this section, we present how the previously derived LCR expression can be leveraged within model-driven network planning environment making use of GPU hardware and multi-objective optimization built upon our previous works [15, 16, 17]. Workflow of the underlying software environment exploiting the synergy of deep leaning and multi-objective optimization is depicted in Fig. 3.

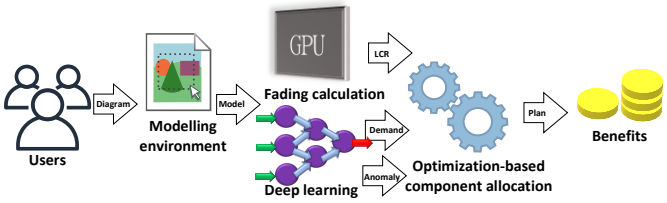

Fig. 3. LCR of system, for different values of parameters , α and L.

Within the first step, users construct network diagram inside Eclipse-based environment, according to the structure of underlying network planning metamodel [15, 16]. It considers the following aspects relevant to planning of mobile network inside smart city: operator's base stations, terrain configuration with obstacles, properties of communication channel, adaptive behavior in case of base station anomalies, consumers of telco services (including people equipped with smartphones, autonomous vehicles and smart city infrastructure).

Once modelling is done, the created model is parsed and processed using Ecore [18]. Furthermore, the corresponding parameters are used as input of network-related data processing steps: GPU-enabled LCR determination and deep learning-based predictions. For purpose of fast LCR calculation, we wrote NVIDIA CUDA [19] kernels in C programming language, as described in [17]. In our experiments, it was up to 65.5 times faster than CPU-only program in Mathematica.

On the other side, deep learning module was implemented relying on PyTorch [20] in Python programming language and deployed as Flask service. It covers predictions related to the following factors: number of service users and base station anomalies. For service user count prediction number day, daily temperature and special occasion flag (such as holiday) are considered. On the other side, for base station anomalies ratio prediction the following factors are involved: total downloaded and uploaded data, Quality of Service value, energy consumption and number of users (previously predicted). The layouts of datasets together with achieved prediction performance (Mean Relative Error) are shown in Table I. The problems are treated as regression (real-valued outcome determination), For this purpose, we designed multi-layer perceptron (MLP) with 3 hidden layers, 30 nodes each, making use of Adam optimizer with learning rate 0.01 for training.

TABLE I
OVERVIEW OF PREDICTION MODELS

Model	Input	Approach	Relative error
User number	Day Special Temperature	Regression 3 hidden 30 nodes Adam α=0.01	16%
Anomaly Ratio	Users Download Upload QoS Energy		13%

Finally, in the last step, we make use of our optimization-based model-driven framework for component allocation relying on Pymoo [21], with respect to the model which will be described. The goal of optimization procedure is finding network plan that consists of optimal base station ($bs \in B$) placement for desired smart city locations ($p \in P$), maintaining best possible QoS while keeping lowest costs at the same time. The objective function has following form:

$$minimi\ e \sum_{bs\in BS, l\in} plan[l,bs](\ C\ [l,bs]+cost[l,bs]+anomaly[l,bs]) \quad (17)$$

As it can be seen, the sum of LCR (positive impact on performance for lower values), deployment costs and base station anomaly rato is minimized. Here, *plan l, bs* denotes decision variable which is 1 in case if base station bs is going to be placed on location l, otherwise 0.

Additionally, we apply a constrint for each location *l* that capacity of base station *bs* (refered to as *ma u l,bs*) should be enough to service the predicted number of users (*demandp l*) for given location *l*.

$$\sum_{bs\in BS} plan[l,bs]ma\ u[l,bs] \geq demandp[l], l \in \quad (18)$$

V. CONCLUSION

In this paper, we have analyzed the MIMO system with a multi-branch SC receiver with L branches when coming to system inputs α - μ fading and CCI with the same distribution. We performed LCR for this model of receiver in the presence of the above-mentioned fading and interference. System performance is more favorable in case when system has lower μ and α parameter, for lower SIR. Analyzing the system, we noticed that the performers are better when the system has a larger number of input branches, because the combiner has the ability to select the branch with the best SIR, leads to better system performance. Finally, for the above fading and CCI system performance is more favorable for lower values of average LCR.

Use of the obtained expression for LCR at the output of a multifaceted SC combinator, we have suggested software environment for simulation. There are several benefits: 1)

 ISBN 978-86-7466-930-3

GPU reduces time for LCR calculation 2) costs are minimized 3) performance is maximized.

Location Privacy Improvements in Telecommunication Data Management Systems

Milan Simakovic, Zoran Cica, and Dejan Drajic, *Senior Member, IEEE*

***Abstract*—In the era of digital transformation, data are among the most valuable resources. With the development of big data technologies, it is possible to store and process huge amounts of data. Data are possible to collect on every step with high granulation. Such a trend may seriously harm peoples' privacy. Corresponding laws and regulations are declared to protect data privacy. However, even when all the regulations are obeyed, privacy leakage may still happen if the implementation has some flaws. In this paper, we focus on telecommunication data sets and show how user's location information leakage may happen in already privacy-protected data. Moreover, we give a proposition on how this leakage can be prevented while preserving the same data entropy.**

***Index Terms*— data privacy, location tracking, big data.**

I. Introduction

According to [1], more than 66% of the world's population uses the internet at the end of 2021. Dynamic environment, rapid growth, and high competition on the market push companies to further enhance their products and reduce costs. Generated data may contain a huge volume of useful information that will drive such an initiative. And just like that, data becomes one of the main fuels in the industry. This phenomenon is further enhanced with the development of big data technologies [2].

To gather as much information as possible from the data, different ways of data processing are invented. Data correlated from different sources can give new insights that do not exist in separate data sets. Such great potential raises the issue of user privacy. To protect the users' privacy and limit the usage of data, GDPR (General Data Protection Regulation) [3] is defined in the European Union, CCPA (California Consumer Privacy Act) [4] in the USA (United States of America), and PIPL (Personal Information Protection Law) [5] in China. There are also laws that specify data privacy in a particular field, like HIPAA (Health Insurance Portability and Accountability Act) for healthcare in the USA [6]. These laws define data processing by protecting users' privacy and giving individuals the right to control the data collected from them. Although companies comply with all regulations, there are situations that can indirectly harm peoples' privacy. To emphasize this phenomenon, one example of such a scenario is presented in this paper. Namely, we show how the privacy of individuals may be harmed on the already privacy-protected telecommunication data set. Also, a recommendation on how this data set can be further masked to protect users from privacy breach while keeping the same information entropy is presented in the paper.

The remaining of the paper is organized as follows. Related work is discussed in section II. A brief overview of data privacy together with appropriate regulation laws is presented in section III. Section IV presents the main contribution of the paper. It discusses telecommunication data sets, shows the vulnerability of privacy-protected data sets on a sample, and proposes privacy improvement while keeping the same information entropy. Section V concludes the paper.

II. Related work

Privacy in data technology, especially in big data is a hot topic over the last few years. This section gives a general overview of data privacy challenges, proposed solutions, and frameworks in the literature.

An overview of the privacy-preserving problems in big data stream mining is presented in [7]. Location privacy challenges for mobile applications are discussed in [8]. Location concerns are raised not only to the application provider but to the third parties that are able indirectly to calculate person location from gathered data. In addition, there is a raised concern for services that sell the location data to other parties. Following the people's position and their trajectory is recognized as a serious data privacy concern. To protect trajectory privacy from the data that contain GPS (Global Positioning System) location, a method for data masking that adds noise to the original data based on irregular polygons is proposed in [9]. Due to the rapid development of technology, IoT (Internet of Things) networks are becoming increasingly popular and, thus, becoming significant data generators. Such data may contain privacy-sensitive data. A privacy protection mechanism in industrial IoT based on information tree model is proposed in [10]. Location data is recognized as a huge potential for marketing and advertisement. Considering the number of users, generated amount of data is huge. A method based on big data technologies for location data mining while keeping the data privacy is proposed in [11]. This method uses a clustering algorithm and location entropy to emphasize the most active places.

Companies recognized data privacy as a serious problem and use different methods to solve these challenges. Data

 ISBN 978-86-7466-930-3

privacy models are introduced both for regular [12] and big data systems [13]. Big data models include all the data layers, i.e. collection, storage, and consumption. Data models state for schemas optimized for privacy issues is presented in [13]. In dynamic environments, data is shared both among other teams inside the company and externally. In such a huge data fluctuation, there is a high risk for data privacy issues. Considering that data privacy is protected by law, companies often decide to refrain from using the data which can significantly affect their business efficiency. Model for keeping the big data with a possibility to freely share and explore, and at the same time preserving the data privacy is presented in [14]. Data privacy mechanisms from the k-anonymity, l-diversity, and t-closeness perspectives are discussed in [15]. The advantages and challenges of these mechanisms are analyzed, and a new mechanism based on a combination of these three is proposed. Big data multilayer architecture and utilization of the "differential privacy" approach for sustainable data privacy are discussed in [16].

III. DATA PRIVACY

Data privacy, or information privacy, stands for the ability of the user to control what type of data is collected from him and how these collected data are used. Personal information, depending on the type of application, can be email, location, online search history, preferences, etc. Considering the complexity of modern applications and systems, it is necessary to gather some personal information (e.g. location) to provide the best possible experience to a client. However, applications can often gather more information than they really need and this might bring harm to people's privacy. Collected users' personal data can be used either inside the company to improve internal processes and services or to sell to other companies as a data set. Due to the lack of data security inside the company, data breaches may happen, and personal data can be stolen and used against the clients [17]. Data privacy is often mixed up with data security. While data security is protection from the 3rd party persons to access the data, data privacy is related to data collection methods and regulations that ensure that the user information is not exposed.

To bring closer control of data to the end-user, and restrict the companies in terms of data collection, usage, and surveillance capabilities, many governments around the world have created laws that regulate how data can be used, stored, and protected. Some of the most important regulations are GDPR [3], CCPA [4] and PIPL [5]. GDPR is the data privacy regulation law in European Union. GDPR gives clear instructions on how the data should be collected, transferred, stored, and protected. In addition, it gives users the right to control their personal data, i.e., the "right to be forgotten". This law regulative forces all the companies that collect users' data to have a mechanism to easily wipe all the data for clients without undue delay [3]. CCPA is the data privacy regulation law in the USA. This law stipulates that the user should be aware of what data are collected from him as well as give the company the right to sell his personal data. In addition, CCPA gives a guide to the company on how the law can be implemented [4]. PIPL is the data privacy law in PRC (People's Republic of China). Next to the regulations that prescript GDPR and CCPA, PIPL gives attention to data localization, i.e., that certain categories of personal data must be stored in PRC [5]. Next to the mentioned regulations, there are also many others that are implemented either in other countries or the ones that are industry-focused. For example, HIPAA is the regulation in the USA that governs how personal healthcare data should be handled [6].

To provide data privacy, companies use different techniques for data transformation. Among the most popular techniques are data anonymization and pseudonymization. Anonymization and pseudonymization present the process of transformation of UID (User Identifier) into data sets. Anonymized data stands for one-way encryption meaning that, once the UID is encrypted, there is no theoretical way to re-identify the user from it, neither directly nor indirectly. On the other side, pseudonymization stands for data masking techniques that can be reversed. It means that there is a way to decrypt the data. Pseudonymization is weaker in terms of data protection and should be used carefully. This technique is often used for data that are not related to the UID, but to some attributes. Some of the most popular methods for data pseudonymization are [18]:

- encryption – hiding data by encrypting it,
- shuffling – mixing data inside one column to disassociate attributes from the original user,
- suppression – removing sensitive columns from the dataset,
- redaction – completely removing parts with sensitive data.

Next to these two techniques, there are some other techniques for data privacy protection. Data generalization presents a way to change a value of some column with its range. For example, the value of column age 34 is modified to the range 30-40. Data synthetization presents a method to generate a completely new dataset from the original one using machine learning techniques. A newly generated dataset mimics the properties of original data. Although, these methods are useful in terms of data privacy, they distort information and reduce the data entropy. This is especially evident during the data aggregation.

IV. TELECOMMUNICATION DATA

Telecommunication networks represent a very important factor in the development of humanity. Due to their importance and high competition on the market, telecommunication operators gather data to further optimize services, reduce costs, and improve quality of their networks and services. Data are gathered on all network architecture levels, from physical and core network devices to the application layer. Modern telecommunication network providers typically implement centralized platform based on big data technologies to gather such amount of data.

Since telecommunications are always on the top of IT standards, all these systems already implement mechanisms for data privacy that are prescribed in their countries. Although, the implemented mechanisms mask the UIDs, due to the complexity and variety of data, some data privacy breaches may happen. In this section, we show one example of how the data privacy breach in terms of user tracking may happen and propose a masking mechanism that solves the problem for such a scenario while keeping the data entropy at the same level.

Mobile network operators gather data (for example, CDRs (Call Detail Record) and XDRs (Extended Detection and Response)) from base stations. This data contain information about the mobile phone device id, used frequency channel, signal strength, service type, call duration, etc. Such data helps the operators to tune the base stations, maximize the capacity of the cell, and quality of service. An example of simplified data set is shown in Table 1. In the example data set, UID is hashed due to the data privacy regulations. Assuming the anonymization is taken as the hashing mechanism, there is no way to get the UID original value.

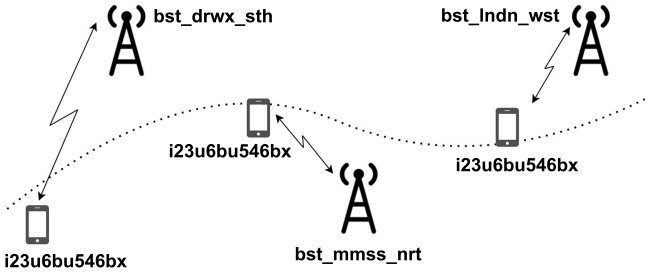

Fig. 1. User location tracking using data from base stations.

Since the same mechanism for data hashing is implemented on the data from every base station, it generates the same hashed UID for a user on every base station. This means that even though the user's UID is not known, it is possible to track user's movement as shown in Fig. 1. From the dataset shown in Table 1, it can be seen how the UID "i23u6bu546bx" is located on different base stations during the day which implies the possibility to track the location of this person. By matching the hashed UID with associated data (like base station ID, call records, etc.) it might be even possible to determine the identity of the user.

Although collected data are used for network improvement, people's privacy can be indirectly harmed in terms of location tracking. Since this information is not relevant to mobile network operators, we propose a new mechanism for data masking. The previous mechanism takes the device identifier (e.g. phone number or MAC address) and creates the hashed id by using some hashing function like shown in (1).

$$hashed_UID = hash_function(UID) \quad (1)$$

This mechanism creates the same hashed UID on all base stations. To improve this, we propose to create the hash UID from a combination of base station identifier and UID, as shown in (2). In this way, hashed value of UID will be different at each base station. Thus, information about user movement is removed, but all the necessary information relevant for quality-of-service monitoring are kept.

$$hashed_UID = hash_function(base_station_ID + UID) \quad (2)$$

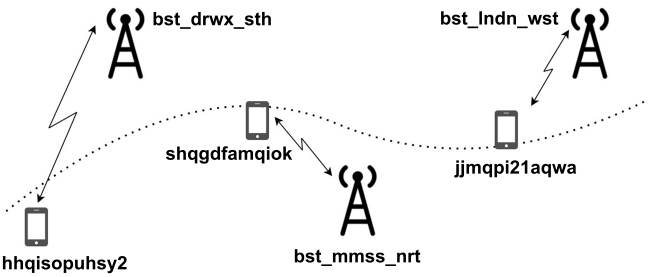

Fig. 2. Avoiding user location tracking.

The data set generated with the proposed hashed function is shown in Table 2. User that corresponds to hashed UID "i23u6bu546bx" in Table 1, has now a different UID on each base station which makes it impossible to correlate the data and track its location. Note that corresponding fields are colored in Tables 1 and 2. Fig. 2 shows the same example as Fig. 1 with a difference that now the UID is hashed with our proposed method. It can be seen in Fig. 2 that hashed UID values for the same user are different at different base stations. Thus, tracking of user movements is not possible anymore. However, if a user is connected to same base station for a

period of time, hashed UID value will be the same, thus, the information about the signal quality for the session and user is preserved.

The same data privacy leak can happen not only in mobile but in other networks as well. For example, HFC (Hybrid Fiber Coaxial) network operators gather data from their cable modems. Considering that nowadays most of the clients are connected to the internet using WiFi (Wireless Fidelity), poor quality of service can be caused either by the poor signal quality on a cable modem or poor WiFi signal. The quality of the WiFi signal depends on many aspects such are the position of the cable modem, the schema of the building, types of walls, etc. Even though HFC operators are not in charge of the quality of WiFi networks, they tend to help clients to improve quality of network either by reconfiguring the WiFi (switching WiFi channel, changing channel width), relocating cable modem to some other place where it will better cover the whole apartment or by adding WiFi extenders.

Information about the cause of the poor signal quality operators find in the data gathered from the cable modems. Modern cable modems have embedded WiFi transmitters. Next to the basic information regarding the quality of the signal, data about the WiFi can be collected as well. Example of data that are gathered is the MAC (Media Access Control) address and WiFi username of the connected device (e.g., from a laptop, tablet, or mobile phone). If the device is connected to several locations that are covered by the same provider (e.g., at home, at café, store, work) the data privacy in terms of movement tracing can be breached. To solve such problem, the same hashing mechanism, (2), we propose for mobile networks can be used. Creating a different hash for UID on different cable modems, would completely remove the possibility to track the user movements.

V. Conclusion

Data privacy concerns are raised a few years ago and present one of the most important aspects during the development of data management systems. Depending on country, data management systems implement the appropriate privacy laws. Although the laws are obeyed, data privacy leakage may still happen if implementation is not carefully done. This paper shows an example of location data privacy violations in telecommunication data systems. In addition, we show methodology for how such violations can be solved with domain-specific knowledge. Finally, a proposal for data privacy improvement while keeping the same data entropy is given.

Introducing IoT to Big Data Platform for Network Performance Monitoring

Milan Simakovic, Zoran Cica, and Dejan Drajic, *Senior Member, IEEE*

***Abstract*—Telecommunication operators are collecting large amounts of data for various purposes such as network performance monitoring, network planning, better customer support, etc. Nowadays, big data technologies are commonly used to couple with enormous amounts of data. Thus, telecommunication operators use big data platforms to process and store data collected from their networks. Data are collected from the network and user devices. Since network operators cover most of the residential users, it is possible to use this access to introduce IoT (Internet of Things) and smart city support. By extending the already existing big data platforms to support IoT devices placed at network users' premises, smooth integration of various IoT devices with the smart city concept can be achieved. Such integration would have significant benefits for network operators, users and local communities. In this paper, we propose an extension that introduces IoT support to the existing big data platform used for HFC (Hybrid Fiber-Coaxial) network monitoring. An overview of the most attractive IoT use cases that can benefit from the proposed extension is also presented in the paper.**

***Index Terms*—Big data, IoT, Smart city, Smart home, HFC network.**

I. Introduction

Telecommunication operators typically serve large number of users. In order to successfully perform such task, operators use very complex and heterogeneous telecommunication networks which need to be constantly monitored. For monitoring purposes, operators collect and store data from numerous network devices [1,2]. By processing the collected data, it is possible to achieve optimal network performance and provide high QoS (Quality of Service) to users. Since the amount of collected data is enormous, big data technologies need to be used to efficiently store and process such amount of data [3].

Smart home and smart city are IoT concepts that are becoming very popular nowadays [4,5]. Given the large number of residents and the fact that each user will typically have multiple IoT devices and sensors at home, it is obvious that amount of data collected can be very large. Thus, big data technologies would provide excellent solution for storing and processing such amounts of data [6]. Most of the residential users are covered by some telecommunication operator (HFC, passive optical network (PON), etc.) and the operators use big data platforms to store and process data collected from their networks. Given that fact, these big data platforms can be extended to collect and store data from IoT devices and sensors placed at user premises. In this way, same infrastructure could be reused for IoT purposes. By integrating existing telecom operators big data platform in smart city environment, highly economic and efficient smart city solution can be achieved.

In [7], big data platform for HFC network monitoring is extended with support for efficient failure detection and localization. In this paper, we propose extension of this big data platform to support IoT devices at users' premises. It will be shown, that such extension does not require architecture modifications in the already existing big data platform. Only, adjustments in data collection layer need to be done. Once data are collected and stored, it is up to data consumers (smart city solutions and applications, users, operators) to determine which types of processing of the collected data need to be supported. For example, application for users that graphically shows measured values from their sensors, or notification in case of threshold violation (e.g. smoke detectors detect fire). In this paper, we also present the most attractive use cases that would benefit from such IoT extension of big data platform.

Remainder of the paper is organized as follows. In section II, we give related work overview. Section III presents the existing big data platform for HFC network monitoring, and the introduced extensions to support data collection and storage from IoT devices. Section IV contains a survey of use cases that would benefit from the IoT extension of the big data platform introduced in section III. Finally, section V concludes the paper.

II. Related Work

IoT based smart home solutions represent one of the most important IoT markets since they offer a huge variety of different applications for enhancements of resident's quality of life. It is possible to install different devices for monitoring of various activities. The monitoring can be focused on the resident's activities and on the different parameters in the home. In the elderly healthcare solution, different medical sensors are provided in form of smart bracelets and other wearable devices [8], that allow efficient monitoring of movements and condition of a patient. Different sensors for environmental monitoring could be installed like sensors for temperature, relative humidity, light intensity measurements,

Milan Simakovic, Zoran Cica and Dejan Drajic are with the School of Electrical Engineering, University of Belgrade, Bulevar kralja Aleksandra 73, 11120 Belgrade, Serbia (e-mails: milanrus@hotmail.com, zoran.cica@etf.bg.ac.rs, ddrajic@etf.bg.ac.rs).

 ISBN 978-86-7466-930-3

fire/smoke detectors, etc. Based on these measurements, temperature and lighting control can be automatized and appropriate alarms can be raised. Monitoring of energy and water consumption, and water leakage detection can be achieved with appropriate sensors. Also, different appliances in home can be remotely monitored, such as sensors for audio and video surveillance, motion detection that are typically installed to increase home safety [9].

Within the smart cities many urban related problems are aimed to be solved such as air pollution, urban noise monitoring, traffic jams, smart parking, energy consumption, waste management, smart infrastructure, street lighting, assistance to senior citizens, etc [10]. This includes different types of technologies (big data, IoT, WSN (Wireless Sensors Networks) and cloud. Particularly interesting elements for planning Wi-Fi networks in large cities are presented in the paper [11]. Wi-Fi as a transmission technology is preferable in many smart city applications since it provides connectivity to smart phones, computers and many wearable gadgets. Different challenges of Smart City IoT system deployment are addressed in [4], where Security and Privacy, Smart Sensors, Networking and Big Data Analytics are recognized as the most important ones.

IoT concept is one of the most important trends in telecommunications. IoT is integral part of many "smart" solutions like smart city, smart buildings, smart agriculture, smart transport, smart healthcare... [12]. Given the significant amount of data that IoT systems generate, big data is recognized as a "key enabling technology for IoT" [12]. For this reason there are numerous papers that deal with IoT and Big Data combination. Surveys on big data in IoT can be found in [12,13]. A large number of papers on the topic of smart city shows that this concept is one of the most popular ones from the IoT area. Survey on big data in smart city solutions is given in [14]. Industry also embraced IoT concept because digitalization of industrial processes increases efficiency [15]. In [15], Industrial Big Data as a result of IoT adoption in manufacturing is discussed. Big data and IoT in smart farming are discussed in [16]. Although, many IoT solutions are already operating along with big data technologies support, there are still some open challenges. Survey on these open challenges is given in [17].

III. BIG DATA PLATFORM ARCHITECTURE

In this section, first we give a brief description of the existing big data platform architecture for HFC network performance monitoring. Then, we describe extensions necessary to introduce IoT in the existing big data platform.

Fig. 1 shows the big data platform architecture for performance monitoring of HFC network. Big data platform comprises two major parts - big data cluster and data collection layer. Big data cluster uses several big data tools to store and process collected data. The used big data tools include OpenTSDB (Open Time Series Database), Apache HBase, HDFS (Hadoop Distributed File System), Apache Spark, Hadoop YARN (Yet Another Resource Negotiator), and Zookeeper. OpenTSDB is used to verify and process incoming messages from data collection layer, and to store these messages in HBase tables. HBase writes table files to HDFS while HDFS is responsible for storing data on physical storage units. Apache Spark is necessary for data aggregations. Hadoop YARN is used to allocate resources to jobs. YARN also enables different processing frameworks to use common hardware. Zookeeper synchronizes distributed services.

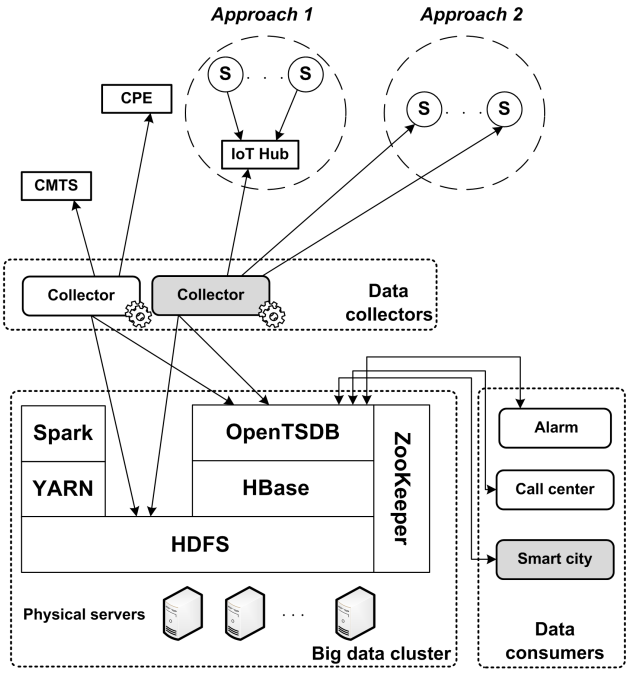

Fig. 1. Big data platform with added support for IoT devices

Data collection layer is responsible for collecting data from CMTS (Cable Modem Termination System) and CPE (Customer Premises Equipment) devices in HFC networks as they represent network devices with a possibility to collect data from them. CPE devices include cable modems and set-top boxes. SNMP (Simple Network Management Protocol) is used for data collection. There are numerous data collectors working in parallel in the data collection layer due to large number of devices in the HFC network from which data need to be collected. Various data (metrics) are collected from CMTS and CPE devices, while the data collection period depends on the data type and importance. Collection period is set in range from 1 minute to 1 hour depending on the importance of collected metrics. Collected data are sent to OpenTSDB via web socket and in parallel data are also written to HDFS.

Fig. 1 also shows the extensions necessary to accommodate IoT support. The updated or added modules are marked with grey coloring. Main update needs to be made in data collection layer. Namely, data collectors need to be aware of new devices and data types that need to be collected. The advantage of the previously described big data platform is its flexibility. Due to large number of different network devices (different vendors, versions, models, etc.), big data platform was developed to efficiently couple with variety challenge

 ISBN 978-86-7466-930-3

that is typical for big data usage [18]. This means that the data collectors are designed to be flexible and adjustable to new devices added to monitored HFC network. Obviously, IoT devices also represent new devices from the data collector point of view. Thus, adding a support for new devices is not a complex task.

The other extension is connection to new data consumers. In the case of IoT introduction that would be IoT data consumers, e.g. smart city environment as shown in Fig. 1. These IoT data consumers can be internal or external depending on the type of integration of the big data platform. For example, the big data platform besides the network monitoring system can serve also as IoT service hub operated by the network operator (internal data consumer). But, the big data platform can provide access to data to external data consumers such as local government smart city platform or external companies like distributors of electricity, water or gas.

At user premises, there are two possible approaches that affect the data collector extension for IoT devices support. One approach is to collect data directly from each IoT device. Second approach is to have a hub for all IoT devices at user premises. In this second case, data collector connects only to a hub which reduces the number of connections necessary to collect all IoT related data from user premises. The other advantage of the hub approach is simplified addition of support for IoT data in data collection layer. Namely, in this case focus is only on the types of IoT metrics not the types of IoT devices. Secondly, this gives more freedom for connecting IoT devices to central hub at home (for example, ZigBee or Bluetooth). Thirdly, if WiFi is used to connect IoT devices to central hub, a central hub might be integrated to cable modem as nowadays these modems typically have WiFi capabilities. Both approaches are illustrated in Fig. 1.

IV. USE CASES

The proposed IoT support extension of the big data platform for HFC network performance monitoring can be applied in many smart monitoring IoT based use cases. IoT and sensor networks represent sources of time series data that can be collected, stored and processed by the proposed extension of big data platform. As discussed in the previous section there are two approaches that can be used to collect data from IoT devices - direct and indirect over IoT hub. Note that these two approaches can coexist if necessary.

Some of the most important and common IoT based smart metering in homes are: indoor air quality monitoring, energy consumption and water consumption monitoring. These metering devices produce periodic and relatively small packet traffic. The most common indoor air quality monitoring parameters are CO, CO_2, PM (Particle matters), VoC (Volatile compounds), temperature and relative humidity. Additionally, some devices support O_2, CH_4, H_2S, NH_3 as well. There are a lot of already available low-cost devices for this purpose [19]. These devices can be used for air quality monitoring and fire detection. Normally, reporting period is set to 5 minutes, but for the alarm purposes it could be set to 1 minute. Expected payload is 0.5 kB per sampling interval. In the case of 1 minute monitoring period, expected data volume per one device would be 720 kB per day, i.e. 21.6 MB per month. If data collectors enrich the collected data with additional information (user id, device model/type,...), the expected data volume can be a bit larger. The required storage space for data collected over one month would be around 5.7 TB under following assumptions: each home has 2 IoT devices in average; data collected from each IoT device requires 30MB per month in average; there are 100000 homes covered by HFC network.

Telecom operators can allow access to the raw data via API (Application Programming Interface). But more attractive for their clients would be aggregation, processing and visualization of their data available via web portal where clients can easily follow the measurements and set alarms and/or notifications, calculate air quality index, etc. In case of different models and versions of IoT devices, operators can perform data aggregations per manufacturer or model to gain insight in the performance of the devices and determine which devices are more preferable and offer them to their clients in future deals. In case of air quality measurement devices, outside units can be mounted as well, for example, on balconies. Data collected from such devices can be aggregated and processed to gain deeper insight in air quality in different parts of the city, or on different height levels in case of multi-storey buildings. This information can be very important for local communities to detect critical zones.

While air quality monitoring requires quite frequent reporting, energy [20] and water [21] consumption can be reported once per day (about 0.4 kB per measurement in both cases, which means 12 kB per month). Energy module collects data about power consumption and other electric parameters, while the water consumption sensor monitors amount of water usage in the home. Measurements can be collected by the platform, where data are stored and processed. The measurements can be presented in form of graphs, and when data reach the specified level of power or water consumption, alerts can be generated and sent to the user. Also, smart city concept assumes interconnection of citizens, local governments and utility companies. Utility companies need to read measurement devices to check the consumption by their clients. If the readings of these devices are integrated with the big data platform, then that data can be passed to utility companies. In this way, multiple benefits can be achieved. Automatized and remote measurement readings, detection of anomalies which can trigger alarm to both utility companies and users. In case of multi-storey buildings, utility measurement devices are typically not part of the homes. In such cases, if the building is covered by HFC network, additional cable modem can be installed that would cover only the utility measurement devices as a part of agreement between the users, operator and utility companies. This actually perfectly represents the idea and aim of smart city concept.

As already explained, presented use cases are not very demanding in terms of storage capacity, so big data platform should be able to easily handle a lot of users. Insight into collected measurements provides to users powerful

 ISBN 978-86-7466-930-3

information how to optimize water and power consumption and how to improve the air quality. Proposed concept facilitates smart home integration and could be expanded for the smart city measurements integration with goal to create pollution and noise maps (devices can be also mounted outside for outdoor air quality monitoring), remote reading of electricity and water consumption, thus, optimizing the work of communal services. On the other hand, the proposed expansion provides an excellent opportunity for the operators to expand their service portfolio and offer new smart services to their users, which would bring a new revenue and increase users' confidence and satisfaction.

The described IoT devices are low-cost and easy for installation and handling. Of course there are a lot of other sensors and devices that could be installed for monitoring of different kinds of parameters, and in this section we presented a few useful examples for the proof of concept purposes.

V. Conclusions

In this paper we propose extension for IoT support of existing HFC network performance platform based on big data technologies. The proposed extension is incremental and not complex, and most importantly does not affect the original purpose (performance monitoring) of the big data platform. The presented use cases that would be enabled by the proposed extension show that significant benefit would be gained by all the parties involved: users, operators, utility companies, local communities. This is exactly in line with the smart city ideas and goals. As a part of our future work, we will focus on tight integration of the proposed extension to smart city solutions with special emphasis on air and noise pollution tracking and creating corresponding noise and pollution maps.

Reliability of Earth-Space Links under Deep Fades with Interleaved Reed-Solomon Codes

Srđan Brkić, *Member, IEEE*, Zoran Čiča, Andreja Radošević, Đorđe Sarač, Predrag Ivaniš, *Senior Member, IEEE*

***Abstract*—This paper contains a reliability analysis of Earth-space links subjected to deep fades, modeled as burst erasure channels. We numerically calculate lower bounds on transmission propagation latency caused by employment of packet erasure codes, when fade duration is represented by random variable with Weibull distribution. Furthermore, we propose coding scheme that involves interleaved short Reed-Solomon (RS) codes to mitigate information loss, caused by long fading events. In order to quickly and accurately evaluate residual packet loss rates of interleaved RS codes, we construct a novel simulator, called segment-based simulator, which is able to predict code performance several orders of magnitude faster than plain Monte Carlo simulation. Finally, we show that for variety of channel parameters and code rates, very short RS codes (even with length 15) can provide near optimal propagation latencies.**

***Keywords*—Fading channels, Packet erasure codes, Reed-Solomon codes, Earth-space Links, Singleton bound**

I. Introduction

SATELLITE communications are experiencing a renaissance over the past years, as their potential in providing broadband transmission is fully recognized and explored. Possibility to transfer information between arbitrary points on the Earth surface via satellites makes this type of communications attractive for emerging services, which require high accessibility, like connected vehicles. Furthermore, inclusion of satellite links into 5G ecosystem is studied in newly published 3GPP standards [1], in an attempt to create powerful hybrid satellite-terrestrial (HST) communication systems [2]. In order to build HST systems different technological challenges need to be resolved, which are partially consequences of reduced accessibility and reliability of Earth-space channels.

Despite widely assumed line-of-site visibility between ground terminals and satellites, Earth-space communications link could be blocked for a variety of reasons. In mobile satellite communications used in urban areas, line-of-site assumption may not hold, while different ground obstacles could, from time to time, disable the communication link, leading to loss of transmitted information. Furthermore, LEO (Low Earth Orbit) satellites are moving along their orbits and each LEO satellite is only shortly visible from a stationary point at Earth surface. To enable uninterrupted transmission, ground terminal periodically executes handover operations and establishes connection with different LEO satellite. Handover operation can not be instantaneously performed, which means that potentially communication channel is for a period of time blocked. Lastly, meteorological conditions, for example heavy rain, could attenuate signal such that its power cannot reach a receiving threshold.

All the above phenomenons can be described via hard-blockage model [3], where on-state (reliable transmission) and off-state (blocked channel with no transmission) are alternatively changed, while state durations are represented as uncorrelated random events. Probability density functions of state durations are chosen to fit empirical data collected over the years, mostly for Ka frequency band [4], [5].

Reliability of Earth-space links could only be improved by forward error correction, as propagation delay prohibits use of retransmission techniques. Given the fact that hard-blockage model corresponds to block erasure channel, using sufficiently long maximum distance separable (MDS) codes, for example Reed-Solomon codes, will be optimal. However, for high throughput communications, during off-states the large amount of symbols are erased, and consequently length of a required MDS code must be high (usually measured in tens of Mb or higher). Decoding complexity of MDS codes increases quadratically with code length, which makes them impractical in Earth-space channels. Instead, suboptimal solutions are of interest, like interleaved RS codes [6] and Raptor codes [7]–[9], whose decoding complexity increases only linearly with code length, or LT (Luby Transform) codes [10], with the worst case $O(n \log n)$ complexity.

Possibility of increasing reliability of Earth-space links with LT codes was analyzed in [11], [12]. The authors in [12] showed that UDP transport protocol equipped with LT codes outperform TCP transfer, when applied in DVB-S systems. Recently, a novel LT-based codes are proposed in [11], specially designed for Earth-space channel. In [3] it was shown that Raptor codes could also be beneficial in blockage mitigation of Earth-space links.

The most powerful Raptor code, called RaptorQ fails to reconstruct K information symbols if it successively receives any $K + O$ codeword symbols with probability close to the failure probability of a random fountain code constructed over Galois field GF(256), which is upper bounded by $1/255 \times 256^{-O}$ [8]. Thus, if a receiver collects only a few additional symbols (for example $O = 4$), the achievable decoding failure becomes negligible compared to any practically required residual target codeword loss rate. It follows that for $K \gg O$ RaptorQ code performs closely to the MDS code, which can recover a transmitted codeword (with zero failure probability) if it collects only K codeword symbols. RaptorQ decoders are based on the inactivation decoding algorithm, which has a serial

 ISBN 978-86-7466-930-3

structure by nature, and does not represent a very effective solution for hardware implementation. In addition, memory sizes of the largest commercially available programmable chips are not sufficient to store a single Gb long codeword of a RaptorQ code, which may be required in some high data rate Earth-space links. Splitting and decoding a codeword across multiple hardware chips can be identified as the second major drawback to consider long RaptorQ codes for practical implementation.

To resolve drawbacks of long RaptorQ codes, we propose employment of interleaved Reed-Solomon (RS) codes. Multiple independent codecs run in parallel and connected to a single (or distributed across multiple chips) interleaver/deinterleaver, resulting in a design that is free of RaptorQ's drawbacks. However, such erasure protection scheme is applicable if size of the interleaver is close to the length of the optimal MDS code with the same code rate and residual loss rate. It should be noted that the interleaved RS codes are not necessarily MDS codes for arbitrary distributed erasure channel, and therefore, their applicability needs validation. In addition, performance evaluation of inverleaved RS codes by using Monte Carlo simulation is not practical, given the large interleaver sizes.

In this paper, we analyze Earth-space channels subjected to deep fades, which cause blockage of the channel. We assume that probability density of on/off states duration is modeled by Weibull distribution. First, we numerically obtain lower bounds on the propagation latency cased by employment of MDS protection code in considered fading channel, that achieves desired residual loss rate. In addition, we propose a simulation method that enables quick and accurate performance evaluation of interleaved RS codes. With aid of designed simulator we identify interleaved RS codes that perform closely to MDS codes on Earth-space channel. Surprisingly, for majority of code rates and channel parameters extremely short RS codes (of code lengths equal to 15) will provide satisfactory latency.

The rest of the paper is organized as follows. In Section II Earth-space channel model is given. In Section III a methodology for link reliability analysis is presented, while Section IV is dedicated to numerical results. Concluding remarks are given in Section V.

II. Earth-space channel modeling

The fade phenomenon in Earth-space links usually manifests though *fade episodes*, which are defined as time intervals in which signal attenuation due to fading exceeds a *fade threshold*. Similarly, as seen in Fig. 1, *inver-fade intervals* are complementary events, in which signal attenuation is below the fade threshold [13]. It is usually considered that fade episodes have catastrophical effect on transmission through Earth-space channel, i.e., information sent during fade episodes will be erased and will not appear at the receiver side. The information passes the communication channel only in inver-fade intervals. Possible information distortion during inver-fade intervals, due to signal strength variation and additive noise, is overcome by channel coding. If a channel code recovers all information in inver-fade intervals, recovering lost information during fade episodes is done by employing an additional packet erasure

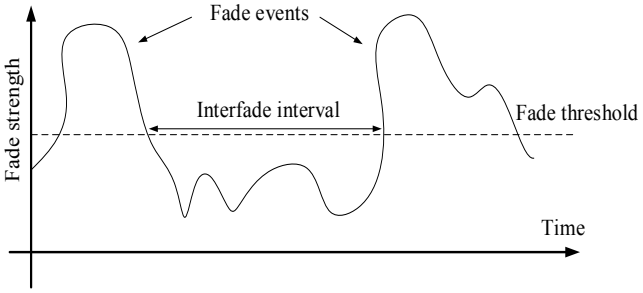

Fig. 1: Illustration of the fading model.

code. Through the paper, we will assume ideal information reconstruction during inver-fade intervals, meaning that probability of residual error after the channel coding is sufficiently low and the information reconstruction in fade episodes is not jeopardized by channel errors.

Under the aforementioned idealization, it is sufficient to describe the fading phenomenon through statistics of duration of fade episodes and inver-fade interval. Modeling such statistics, especially in Ka-band, was heavily investigated during the past years. Long-term measurements have revealed that fade episodes can be classified into two types, short-term episodes (usually less that 1 second) and long-term episodes (usually last significantly longer than 1 second), while each type has different probability density. The cause of long-term episodes is mostly rain, and average duration of long-term episodes is such that the link reliability will not benefit from deployment of packet erasure codes. Thus, will will focus only on short-term episodes, neglecting the effect of long-term fading to link reliability. We simply assume that the long-term fading is treated by some other way, for example through transmission power adaptation.

Specificity of Earth-space channel is its dependency on local climate, meaning that different points on the Earth surface will exhibit different short-term event statistics. Thus, it was proposed that in South Asia, North America and France fade episode duration is modeled with hyperexponential probability density function (PDF), while measurement in Brazil and Vancouver showed that Weibull distribution is a better fit [4]. On the contrary, measurements in Spain revealed that log-normal PDF is the most adequate to model short-term fading episodes [5]. Finally, ITU-R P.1623-1 recommends usage of the power-law distribution [13]. For the purpose of the numerical results, presented in Section IV, we will model fade episode duration as random variable following Weibull distribution. However, simulation mythology presented in Section III is invariant of the used statistical fading model.

Namely, we define the probability that a random fade duration d_f is longer than some D, given that the attenuation A exceeds a threshold a

$$P(d_f > D|a > A) = \exp(-(D/\lambda_f)^{k_f}),$$

where λ_f and k_f, represent shape and scale parameters, respectively. Similarly, we assume that interfade duration d_{if} follows the same probability low, i.e.,

$$P(d_{if} > D|a \leq A) = \exp(-(D/\lambda_{if})^{k_{if}}),$$

 ISBN 978-86-7466-930-3

where λ_{if} and k_{if}, represent shape and scale parameters of the inver-fade distribution, respectively. The channel erasure probability is defined as

$$p = \frac{E[d_f]}{E[d_f] + E[d_{if}]} = \frac{T_f}{T_f + T_{nf}} = \frac{\lambda_f \Gamma(1 + 1/k_f)}{\lambda_f \Gamma(1 + 1/k_f) + \lambda_{if} \Gamma(1 + 1/k_{if})},$$

where $\Gamma(\cdot)$ represents gamma function and $E[\cdot]$ denotes expectation operator.

We further assume that d_f and d_{if} are mutually uncorrelated and that after each fade episode receiver performs acquisition, prolonging the start of an interfade interval by a fixed time period T_{acq}. The acquisition time is included in the reliability analysis presented in the following sections.

III. Link Reliability Analysis

Given the fact that Earth-space links exhibit large propagation delay, reliability of transmission can be increased only by employing codes that can be used to recover erased information. The optimal way to recover information is to use MDS codes, which can produce the lowest residual loss rate, compared to all other codes with the same length and code rate. Alternatively, among all other codes with length N an MDS code achieves desired level of residual loss rate, with the highest possible code rate $r = K/N$, where K denotes information length. Namely, based on the Singleton bound, MSD code can reconstruct a codeword if no more than $N - K$ code symbols are missing. Given the fact that transmission latency is proportional to code length, MDS codes provide bounding latency vs. code rate dependency, for the given fading channel statistics. We only consider the propagation latency which is equal to $L = N/R_s$, where R_s is the transmission bit rate.

Obtaining close form expression for minimal latency, assuming arbitrary fading distribution, is not feasible. Instead, we rely on simulation to provide bounding latencies for desired code rate, which are depicted in Section IV. Given the fact that average fade episode duration T_f is measured in milliseconds, minimal latencies must be higher than T_f. In addition, as it is considered that modern Earth-space links must provide rate measured in Gbps, MDS codes must be at least tens of megabits long. Clearly, only suboptimal solutions are of practical interest, given the fact that decoding complexity of MDS codes grows quadratically with code length. A potential solution must include codes which decoding complexity is significantly lower. Here we investigate possibility of using interleaved MDS codes to provide satisfactory latency vs. code rate trade-offs. The main advantage of using interleaved MDS codes is that decoding complexity grows only linearly with the size of the interleaver (interleaver size represents code length). However, the unanswered question is how close inverleaved codes approach Singleton bound.

Consider transmission of packets with fixed size equal to D_P. Each packet is coded with an Reed-Solomon MDS code (N_c, K_c), with length N_c and code rate $r = K_c/N_c$. It is considered that binary length of the RS code $N_c \times \log_2(N_c) \ll D_P$, meaning that packets are divided and peace-by-peace coded. Before transmission codewords are passed through convolutional interleaver [14], which shuffles I codewords, distancing symbols from a same codeword by at least $I/(R_s * \log_2 N_c)$ seconds, where I represents the interleaver depth. At receiver side the deinterleaver restores the original bit order, while the decoder recovers the missing symbols. The propagation latency is defined as time required to fill the interleaver at the transmitter side and to empty deinterleaver at the receiver side, which based on the principe of convolution interleaving is equivalent to time needed to fill a symbol matrix of size $N_c \times I$, i.e., latency is equal to $L = \log_2(N_c) N_c I/R_s$. Given the fact that fade episodes usually corrupt multiple adjacent codewords, the packet loss rate (PLR) is approximately the same as codeword loss rate.

From the functional point of view the convolutional interleaver is the same as the block interleaver, which stores codewords in columns of $N_c \times I$ symbol matrix. By employing symbol-exact Monte Carlo simulations, it is straightforward to calculate the codeword loss probability of the decoder, i.e., the probability that the number of erased symbols in a any codeword is greater than $N_c - K_c$, for fixed K_c, N_c and I. Symbol-exact simulator alternately generates a large number of fade and non-fade blocks, according to assigned distributions, and memorize positions that correspond to start and end of each fading block. Unrepairable codewords are identified by searching and counting fade overlaps in each block interleaver column. Reliable symbol-exact simulators are computationally hungry since, for the fixed interleaver depth I and code length N_c, they process 10^8 interleaving blocks or higher with sizes measured in Gb (simulation of 10^8 interleaver blocks is needed to reliably estimate the target loss rate of 10^{-6}). Instead, we propose Segment-Based Simulator (SBS), which divides each interleaver row into S long segments, and estimates decoder failure probability assuming that codewords inside a segment are either all correctly reconstructed or all erased. This means that SBS gives an upper bound for the codeword loss rate (CWLR), for an arbitrary chosen RS codes. Inputs to the algorithm are interleaver depth measured in segments $I_{seg} = I/S$ and the number of segments that need to be simulated ($NumSegments$). We formally express SBS using algorithmic notation, as depicted in Algorithm 1.

If segment length is equal $S = 1$ symbol the SBS becomes the symbol-exact simulator. In a limiting case, for sufficiently large interleaver depth, the channel is transformed into symbol erasure channel with loss rate of

$$CWLR = \sum_{i=N_c-K_c+1} \binom{N_c}{i} P^i P^{N_c - i},$$

where P represents the erasure rate of channel that includes acquisition time, i.e,

$$P = \frac{T_f + T_{acq}}{T_f + T_{nf}}.$$

As an illustration, in Fig. 2, we depict dependency of CWLR on the introduced latency, by using (15,11) RS code. With slice modification SBS can be used to determine

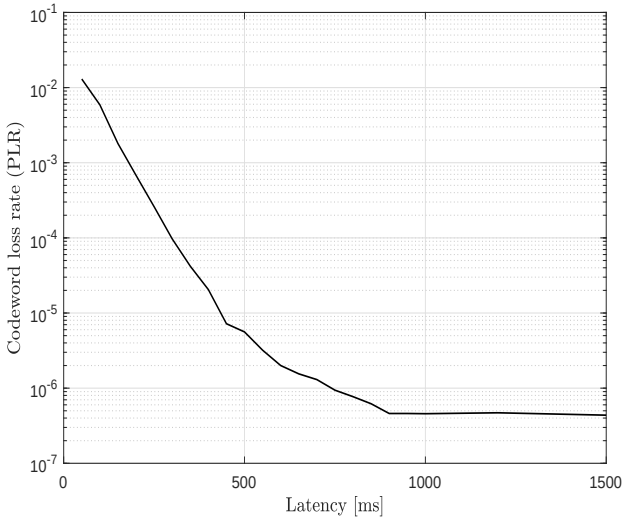

Fig. 2: PLR as a function of latency for (15,11) code ($T_f = 10$ ms, $p = 0.01$ and $k_f = k_{nf} = 1$, $S = 100$ KSymbol).

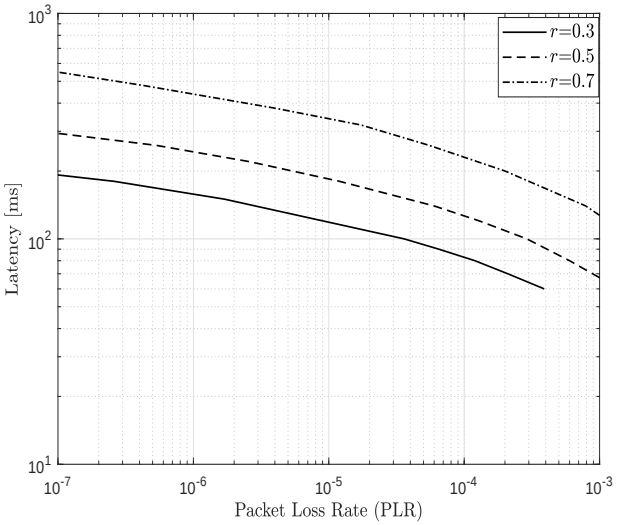

Fig. 3: Latency lower bounds for different PLR values and code rates ($T_f = 10$ ms, $p = 0.01$ and $k_f = k_{nf} = 1$).

a bounding latency for MDS codes also, when code length of a code is equal to size of the interleaver.

Clearly, speed up of SBS simulator, compared to the symbol-exact Monte Carlo simulator is proportional to segment length S. In the following section we use $S = 100$ Ksymbol long segments, for $R_s = 10$ Gbps links to show that in SBS can adequately evaluate code performance. This means that SBS is roughly five orders of magnitude faster than symbol-exact simulator.

IV. Numerical Results

We first, based on the methodology presented in Sections II and III, provide lower propagation latencies required to achieve desired PLR. In all presented results in this section we assume $D_P = 1$ Kb and $R_s = 10$ Gbps. In Fig. 3 required latency dependence of PLR is depicted, for various code rates, assuming $T_f = 10$ ms, $p = 0.01$ and $k_f = k_{nf} = 1$. For example, if $PLR = 10^{-6}$, it follows that it is not possible to construct protection code that introduces latency lower than $L = 250$ ms with code rate $r = 0.5$. If communication service requires lower

 ISBN 978-86-7466-930-3

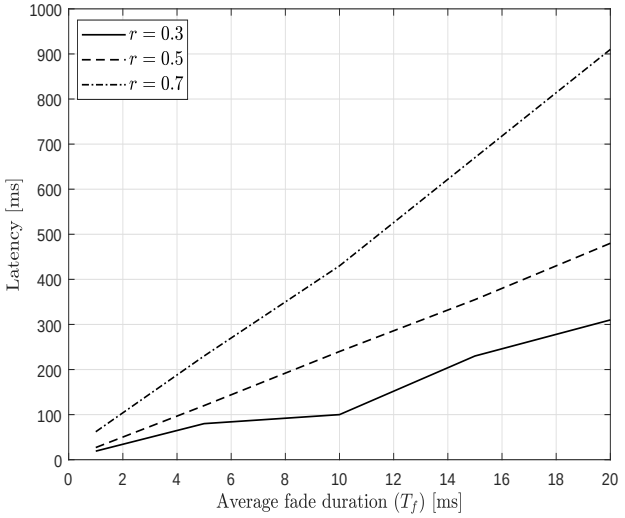

Fig. 4: Latency lower bounds as function of T_f ($PLR = 10^{-6}$, $p = 0.01$ and $k_f = k_{nf} = 1$).

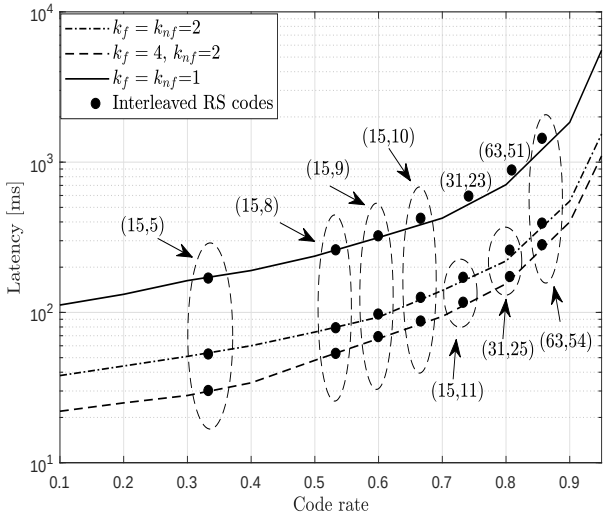

Fig. 5: Latency lower bounds as function of T_f ($PLR = 10^{-6}$, $p = 0.01$ and $k_f = k_{nf} = 1$, $S = 100$ Ksymbol).

latency spatial diversity can be used. For example, voice communications cannot successfully operate with latencies above 50 ms, which means that to operate with code rate $r = 0.5$ and $PLR = 10^{-6}$, five spatially distant links need to be established. It should also be emphasized fundamental trade-off between latency and achievable code rate, i.e., it is not possible to simultaneously increase code rate and reduce bounding latency. In Fig. 4 we depict bounding latencies for different average fade episode durations. We can observe clear linear latency growth, while slope is dependent of a considered code rate.

Finally, in Fig. 5 we investigate latencies achievable with interleaved RS codes, for the fixed $PLR = 10^{-6}$. From implementation perspective RS codes should be as short as possible. We see that it is possible to perform at lower latency bound with code length $N_c = 15$ for low and medium code rates, while code lengths of $N_c = 31$ and $N_c = 63$ are sufficient to operate at low latency bound for higher code rate. As channel condition deteriorate, which is expressed through change of parameters k_f and k_{nf} higher code length are required. For example, for $k_f = k_{nf} = 2$ it is sufficient to use (15,11) RS code to operate at latency bound, while for $k_f = k_{nf} = 1$ at least (31,23) is needed.

V. Conclusion

In this paper we provided a new look to the problem of reliable transmission through Earth-space channels, under deep fade phenomenon. We have shown that short RS coupled with convolutional interleaver ensure near optimal performance in terms of propagation latency, which cannot be avoided if we aim to ensure desired level of residual error loss rate. Interestingly, for large number of code rates it is sufficient to employ short RS codes, of length 15, which represents a low complexity solution.

During further research will use results in presented in this paper, to propose HST system, with increased information capacity, in which handover operations have extremely low blockage probability, which is currently an open research problem.

Effect of Phase Noise on Error Probability of MPSK Receiver over TWDP Channel - Simulation Study

Goran T. Djordjevic, *Member, IEEE*, Jarosław Makal, Bata Vasic and Bane Vasic, *Fellow, IEEE*

***Abstract*— The estimation of multilevel phase-shift eying (P) signal phase is adversely affected by the number of factors appearing in transmission channel and related to the receiver. The imperfect reference signal phase estimation causes error probability degradations. The higher the value of frequency, the stronger is the effect of imperfect reference signal phase recovery. The aim of this wor is to study the effect of imperfect phase estimation on error probability when signal propagates through a channel where there are two dominant components and a diffuse component, which could be the model for mmWave range. The Two-Wave Diffuse-Power (TWDP) model can accurately characterize this propagation environment. We develop a simulation model to estimate the error floor value and to identify the range of signal power when floor appears. ur simulation results give direct dependence of error rate value on channel parameters, signal power and standard deviation of phase noise. The aim of the paper is not to present the concrete estimator architecture, but to ma e a further step in studying the effect of a certain phase noise on bit error rate performance.**

***Index Terms*— rror probability, fading channel, phase noise, onte Carlo simulations.**

I. Introduction

DURING the signal propagation through a wireless telecommunication channel, random changes of the signal parameters occur at the detection point. The signal level is no longer constant, but changes randomly, and the signal phase is a random process. These changes in signal level and phase have a significant impact on the quality of information transmission through that channel. Depending on the weather conditions and the type of the propagation environment including the receiver surrounding, different models have been developed to describe variations in signal intensity [1].

To describe multipath fading, different models of this fading have been proposed, such as Rayleigh, Rice, Nakagami-*m*, Nakagami- , etc. [1]. In the case when two direct waves reach the receiver, but there is also the diffuse component of the emitted EM wave, the so-called Two-Way Diffuse-Power (TWDP) model of fading was proposed in [2]. In that paper in which the TWDP model was initially suggested, an approximation was proposed for the probability density function (PDF) of the signal envelope variations. This model of fading has been constantly the subject of study by many researchers [3]-[9]. In [3], Kim *at all* emphasized some shortcomings of approximation from [2], and they presented exact and approximate formulae for bit error rate in detecting binary phase-shift keying (BPSK) signal transmitted over a TWDP channel for large values of average signal-to-noise ratios (SNR). In [4] and [5], the authors derived some novel expressions for system performance metrics and derived interesting result showing that TWDP fading model has closed form moment generation function (MGF) of received signal envelope. The authors of [6] presented a novel way of parametrization of TWDP channel model. Generally, characterization of TWDP model is in tight relation with propagation environment where there are useful signal, co-channel interference and additive white Gaussian noise [10].

Recently it has been shown experimentally that this model of fading is just appropriate for describing signal propagation in the 60 GHz range [7]-[9].

In all those papers, it is implicitly assumed that the estimation of the phase of the received signal is ideal. However, it is well known that there is a difference between the phase of the incoming signal and the signal phase at the phase estimator output. This difference is a random process that affects signal detection. Due to the existence of this difference, the performance of the system deteriorates. The influence of this phase noise on the error probability when multipath fading is modeled by Nakagami-*m* distribution was considered in [11], while the effect of imperfect reference signal extraction on the error probability over a shadowed multipath fading was analyzed in [12]. In both papers, it was illustrated that error performance of a system can be strongly influenced by imperfect reference signal recovery. With the transition to higher frequency ranges, the influence of the phase noise becomes more pronounced. To the best of our knowledge, the impact of the phase noise on coherent detection in TWDP channel has not been considered so far. However, there is a significant difference between propagation environment considered in [11], [12], where one dominant direct component exist, compared with a TWDP channel model where two dominant waves exist. Our aim in this paper is not to deal with a concrete architecture of phase estimator, but to make a further step in studying the performance of TWDP coherent systems. We suppose the

 ISBN 978-86-7466-930-3

phase error in the receiver has widely accepted Tikhonov distribution and determine the influence of the phase noise on the bit error rate (BER) performance of the receiver of multilevel phase-shift keying (MPSK) signals transmitted over a TWDP channel. We develop appropriate simulation model and present some Monte Carlo simulations results illustrating the effect of phase noise on the BER performance in detection of MPSK signals. These results obtained under assumption of the presence of phase noise can be compared with the results previously reported in [2]-[6], where the perfect reference signal estimation was considered. The design of phase estimator over a TWDP channel will stay an open problem, but relation between BER, channel parameters and standard deviation of phase noise will be a useful standpoint in design of an estimator.

II. System model

In this Section, we describe briefly the model of the system considered here. We give basic information about modulation/demodulation process, as well as channel characteristics.

At the transmitter, signal is modulated by performing multilevel phase-shift keying. During the duration of one symbol, the modulator output signal has the form $s = Ae^{j\phi_n}$, where

$$\phi_n \in \left[0,\, 2\pi/M\,,\ldots,2(M-1)\pi/M\right], \tag{1}$$

where M is the number of phase levels.

This signal is transmitted over a wireless channel. During signal transmission, many copies of the transmitted EM wave excite the receiver antenna. The resulting signal envelope consists of specular and diffuse parts. Specular part contains two direct components having constant amplitudes and uniformly distributed phases in the interval from 0 to 2π. The amplitudes of the direct components are denoted by $_1$ and $_2$, while the phases of these components are denoted by ψ_1 and ψ_2. The scattering component has Rayleigh distribution, i.e., it consist of the in-phase and quadrature components having Gaussian distribution with zero mean value and standard deviation denoted by σ_F. These in-phase and quadrature components are denoted by $_F$ and y_F, respectively. The resulting received signal envelope is presented as [2]

$$r = {}_1e^{j\psi_1} + {}_2e^{j\psi_2} + {}_F + jy_F\,. \tag{2}$$

This model of fading can be described in terms of two parameters denoted by and Δ. The parameter denotes the power of the specular components-to-power of the diffuse component. The parameter Δ is related to the ratio of the peak specular components power-to-average specular components power. These two parameters are defined as [2]

$$= \left({}_1^2 + {}_2^2\right)\Big/\left(2\sigma_F{}^2\right), \tag{3}$$

$$\Delta = \frac{\text{Peak Specular Power}}{\text{Average Specular Power}} - 1 = \frac{2\ {}_1\ {}_2}{{}_1^2 + {}_2^2}\,. \tag{4}$$

The largest the value of the parameter , the power of the specular components is larger compared with the power of the diffuse component. In other words, fading is shallower. The typical values of parameter for the terrestrial mobile links are in the range from 0 dB to 15 dB. The values of parameter Δ lie in the range from 0 to 1. When Δ is equal to 1, specular components have the equal amplitudes, while when Δ is equal to zero either specular components amplitude is equal to zero.

It is interesting to note that the current envelope values of the signal propagating through the channel cannot be described using PDF in closed form. One approximation of the PDF was proposed in [2], while a PDF in infinite series form was recently proposed [6]. On the other hand, although there is no exact closed-form solution for PDF, there is a closed-form MGF format for this channel [4], [5]. However, for Monte Carlo simulations, the most important is eq. (2) defining the composite fading signal envelope.

After signal transmission over a TWDP channel, the receiver input signal can be presented as

$$y = re^{j(\phi_n+\psi)} + n\,, \tag{5}$$

where ψ denotes signal phase due to multipath propagation, and n denotes the thermal noise. This thermal noise can be described by Gaussian PDF with zero mean value and standard deviation σ.

In the case of BPSK, the signal in the receiver has the form

$$= \pm r\cos(\varphi) + \quad , \tag{6}$$

depending upon "1" or "0" is transmitted. In the case of MPSK, the signal in the upper and down branch of the receiver [13, p. 361] is given, respectively, by

$${}_u = r\cos(\phi_n+\varphi) + \quad , \quad {}_d = r\sin(\phi_n+\varphi) + y\,. \tag{7}$$

In the previous equations, r denotes the signal envelope defined by (2), ϕ_n denotes the modulated signal phase, φ denotes the phase noise, while and y are the in-phase and quadrature thermal noise components over a channel. The signal detection is performed based on the value of the angle γ_d that is defined by $\tan\gamma_d = {}_d\big/{}_g$.

On the contrast to previous papers considering signal transmission over TWDP channel, in our paper the emphasis is on the imperfect reference signal recovery. Actually, the estimation of the received signal phase is not just perfect and there is a difference between received signal phase and estimated signal phase performed by an estimator. This difference is a random process. The values of this process are denoted by φ. In [14], it was shown that in the case when there is a signal and additive noise at the receiver input, then the phase difference has a Tikhonov distribution. Also, it has been shown that when a useful signal is influenced by fading in such a way that there is one regular component, the Tikhonov distribution is a satisfactory model for the phase error. However, in the case where there is a modulated signal with two regular components (TWDP channel), the phase estimation process is more complicated. The design of the phase estimator itself is beyond the scope of this paper. In the first, rough step, we will consider that the phase estimation is not ideal and that the phase difference has a rough approximation of the Tikhonov distribution. We will establish a connection between the standard deviation of phase noise, channel parameters and signal power. However, the question

 ISBN 978-86-7466-930-3

remains as to how the standard deviation of the phase error is related to the receiver and fading parameters.

The random variable having uniform distribution can be generated according to the algorithm presented in [15, p. 340], and random variable having Gaussian distribution can be generated using Box-Muller method [16, p. 383]. The random values of the signal envelope are generated taking into account eq. (1). The random variables having Tikhonov distribution can be generated by applying the Modified acceptance/rejection method [16, p. 382].

III. Numerical Results

In this Section, we present simulation results and give appropriate comments. The simulation results are obtained by Monte Carlo simulations performed in C++. The maximum number of generated samples for estimating a value of BER is 2×10^9. The methods utilized for generation of samples are described in the previous Section.

Fig. 1 illustrates the dependence of the BER on the average signal-to-noise power ratio (SNR), γ_b. The BER decreases with increasing SNR. However, this decrease in the BER is not uniform in the whole range of SNRs, but is expressed for low and moderate values of SNRs. In the range of high values of the SNR, the BER value does not decrease with increasing SNR. In other words, the BER tends to a constant value called the error floor. The appearance of this floor is a direct consequence of the presence of phase noise, i.e., non-ideal extraction of the reference carrier. The value of the floor depends on the standard deviation of the phase noise. The higher the standard deviation of the phase noise, the lower the value of the floor. This value of the floor cannot be reduced by increasing the signal power, but it can only be influenced by the correct design of the part of the system in which the phase of the received signal is estimated.

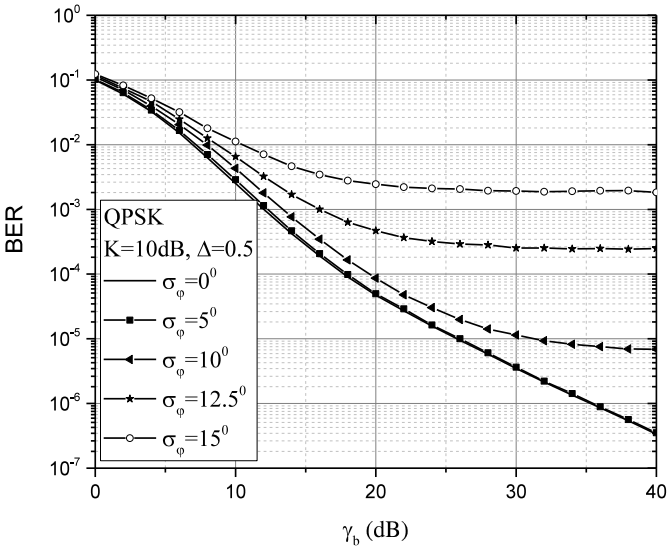

Fig. 1. BER performance for different values of standard deviation of phase noise.

Fig. 2 shows the influence of the standard deviation of the phase noise on the BER values in the detection of BPSK and QPSK signals. Firstly, it is obvious that BER values increase with increasing standard deviation values. Secondly, with the QPSK format, the BER value remains unchanged in the range of standard deviation values up to 8 degrees, while the BPSK format is insensitive to changing the standard deviation up to 16 degrees. In other words, the BPSK format is more resistant to the influence of the phase noise. This result is also logical because the areas of decision-making in the BPSK format are wider, so that the phase noise has less possibility to move the point from one area of decision-making to another.

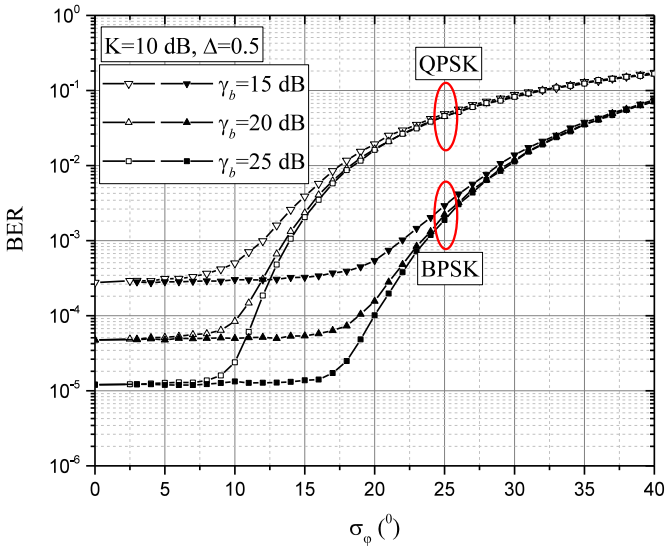

Fig. 2. BER performance for BPSK and QPSK modulation formats.

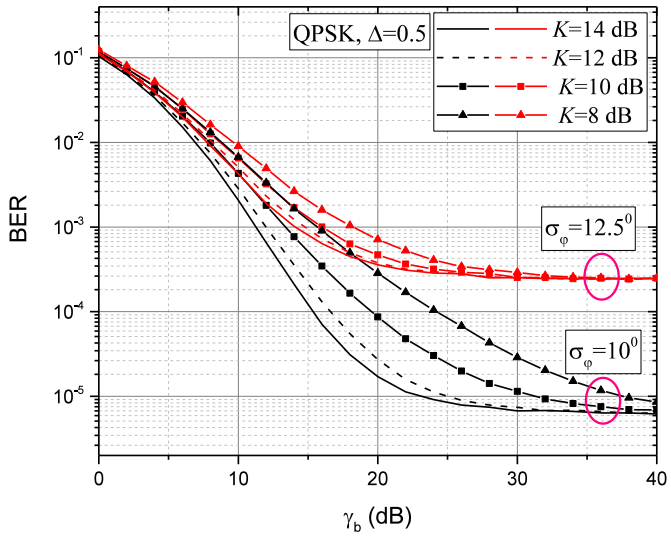

Fig. 3. BER performance for different values of fading parameter .

The influence of the ratio of the average powers of the direct and scattered part of the resulting signal (parameter) is shown in Fig. 3. The influence of the parameter on the BER value is pronounced in the range of moderate values of the SNR and in the case when the standard deviation of the phase noise is smaller. In the region of large values of the SNR, BER tends to a constant value regardless of the value of the parameter . This parameter has no effect on the value of the BER floor. In addition, when the value of the standard deviation is higher, then the influence of the phase noise is

 ISBN 978-86-7466-930-3

more pronounced, so the influence of the parameter is non-dominant.

Similar conclusions as in the previous case can be drawn regarding the influence of the parameter Δ on the BER value. Namely, the parameter Δ also has a significant effect on the BER values in the middle range of the SNR, while there is no effect on the BER values when the signal power is high, i.e., when the BER floor is reached. Also, when the standard deviation of the phase noise is larger, i.e., when the influence of non-ideal extraction is dominant, BER values are less sensitive to changes in parameter Δ compared to the case when the extraction of the reference signal phase is more precise.

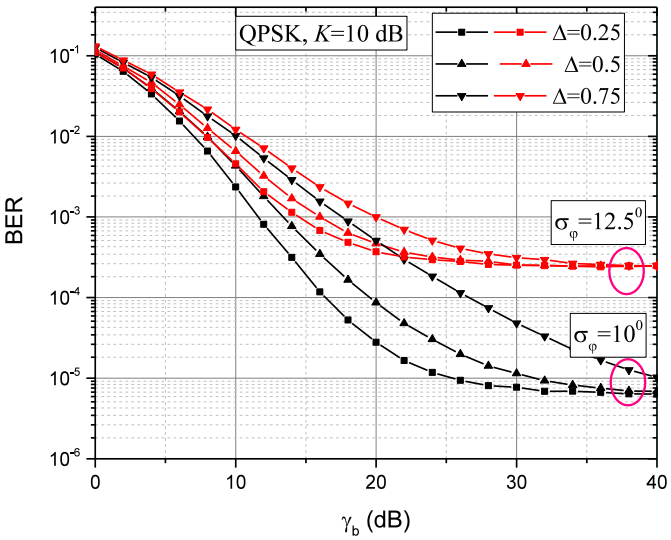

Fig. 4. BER performance for different values of fading parameterΔ.

IV. Conclusion

We have analyzed the influence of non-ideal extraction of the reference carrier on the BER performance of the receiver of MPSK signals propagating through a channel in which variations in signal levels are characterized using the TWDP model. It can be concluded that imperfect estimation of the phase of the incoming signal causes the appearance of BER floor. The value of this BER floor can be reduced by decreasing the value of the standard deviation of the phase noise, i.e., by improving the received signal phase estimation. The influence of the parameters and Δ is pronounced in the range of moderate SNR values. In addition, the results have shown that for typical values of the channel parameters, BPSK modulation format is resistant to phase noise up to the standard deviation value of 16 degrees, while in the same environment QPSK format is resistant to this phenomenon only up to the standard deviation value up to 8 degrees. The design of the phase estimator should be performed so that the predetermined value of the standard deviation of the phase noise is not exceeded.

The results obtained here should be considered as the most optimistic when there is a phase error. The problems of loop locking and phase skipping in the channel with TWDP fading remain open, as well as the connection between the standard deviation of the phase noise and the estimator parameters. Incorporation of some innovative phase noise mitigation techniques, like Viterbi-Viterbi noise estimator under given channel scenario also remains an open problem.

Initial Development of a Program for Drone Micro-Doppler Signature Modelling

Jovan Radivojević, Predrag Petrović, Aleksandar Lebl, Mladen Mileusnić

***Abstract*—Micro-Doppler signature spectrograms obtained by FMCW radars are powerful method for malicious drones detection, identification, localization and classification. Our aim in this investigation has been to replace the base of spectrograms recorded on polygons using high number of available drone types by the spectrograms obtained by the application of originally developed program. Initial program development and verification are described in the paper. It is presented how the calculated spectrograms may be used to determine the important parameters of drones' flight and construction: number of blades in a rotor, rotors' angular rotation rate and blades' length which is the first step in a decision about an applied drone type. The presented results are the starting report on our important development devoted to the improvement of overall public safety.**

***Index Terms*—Malicious drone identification; micro-Doppler signature spectrograms; drone hovering; program for drone spectrograms modelling.**

I. Introduction

DRONES or unmanned aerial vehicles (UAVs) implementation brings great benefits in everyday life by replacing human activities in many areas. Drones may perform some important actions more precisely, more promptly than humans and without people risk exposure. But, on contrary, drones may often be the cause of sudden and unexpected danger for human lives and/or the whole world economy [1], [2].

There are solutions based on several sensor types which may be applied to malicious drones' detection, identification, localization and classification (DILC). The most often applied sensors are radars, cameras (optical and infra-red), audio and radio-frequency (RF) sensors. The benefits and drawbacks of each sensor type application are emphasized in [3], [4]. The applied solutions are usually based on several (even three or four) different sensor types [5], [6]. Among the sensors, radar is especially important due to its relative independence or very low dependence on weather and lighting conditions as fog, rain, smoke or darkness [7]. The present solutions are based on two radar types implementation: Frequency Modulated Constant Wave (FMCW radar whose principles of operation are explained in [8]) and Forward Scatter Radar (FSR whose principles of operation are explained in [9]). Drone spectrograms which are obtained by FMCW and FSR radars are especially important for applied drones identification and classification. They are analyzed in a significant number of existing solutions and [10], [11] are just two examples. In the case of FMCW radar, the obtained spectrograms follow from the Doppler effect of drone parts micro motion to the transmitted radar signal. We speak about drones micro-Doppler signatures, i.e. the obtained graphs are specific for each type of drones [12]. In practical situations the special problem is to distinguish drones from other flying objects with similar dimensions (e.g. birds) whose spectrograms may be similar to drone spectrograms [13].

Drones DILC using spectrograms supposes collecting a great number of practical records on the significant number of different drone types. The records have to be made when drones are at different heights, at different distance from radar (meaning at different elevation angles), when they are hovering or when they are flying, when there are more drones present in the same time (drone swarms) and so on. Besides, the spectrograms appearance depends on some specific drones characteristics as the number of drone's rotors, number of blades on each rotor, the length of blades and the rotors' rotation rate (in rounds per minute – RPM or in rounds per second – RPS). So, it is necessary to have different drone types and to make many spectrograms for each type under different conditions. Due to these problems it is important to develop the program which allows spectrograms calculation and presentation (without practical scenarios recording), especially in the initial phases when DILC criteria have to be defined [7], [11], [14].

IRITEL has a great experience in the development, modernization and implementation of radar systems, development of software for radar systems receivers and simulators of radar operation. The contribution [15] has two-fold relation to the solution presented in this paper: as a realized simulator and as it considers radars with Doppler Effect. Micro-Doppler signatures are formed on the base of the received radar signal and IRITEL has developed both simulators of radar signal receivers [16], [17] and practical solutions of these receivers [18], [19]. The control of radar receivers is the subject of contributions [20], [21]. A good-quality generated signal is also important for FMCW radar operation and IRITEL's solutions in this area have an international verification [22], [23]. IRITEL's complete radar systems in the area of AESA radars [24], [25] and in the area of existing radars modernization [26] - [28] are additional guarantee for future successful practical implementation of solution from this paper.

The main theoretical aspects of FMCW radar operation are explained in the Section II. This explanation includes the method how spectrograms are calculated. The block-scheme of the developed program for spectrograms calculation is

 ISBN 978-86-7466-930-3

presented in the Section III. Several calculated spectrograms are presented in the Section IV. The suggested method to determine characteristic parameters of drone flight and drone construction is described in the Section V. At the end, the conclusions are in the Section VI.

II. SPECTROGRAM SIGNAL CALCULATION

The signal generated in FMCW radar is sinusoidal and its frequency is linearly variable as a function of time. The drone spectrograms are obtained on the base of the returned echo signal from the moving rotor blades. The echo signal from all blades forming one rotor may be expressed by [29]:

$$S_{\Sigma}(t)=\sum_{k=0}^{N_b-1}s_{lk}(t)= \\ =L\cdot\exp\left(-j\frac{4\cdot\pi}{\lambda}\cdot\left(R_0+z_0\cdot\sin\beta\right)\right)\cdot \\ \cdot\sum_{k=0}^{N_b-1}\sin c\left(\Phi_k(t)\right)\cdot\exp\left(-j\cdot\Phi_k(t)\right) \quad (1)$$

where it is $\mathrm{sinc}(\Phi_k(t)) = \sin(\Phi_k(t))/(\Phi_k(t))$ and

$$\Phi_k(t)=\frac{4\cdot\pi}{\lambda}\cdot\frac{L}{2}\cdot\cos\beta\cdot \\ \cdot\cos\left(\Omega\cdot t+\varphi_0+\frac{2\cdot\pi\cdot k}{N_b}\right)\quad (k=0,1,2,...N_b\text{-}1). \quad (2)$$

The sign may be + or – before $\Omega\cdot t$, depending on the direction of the rotor rotation for each unique rotor.

The meaning of variables in these two equations may be expressed with the reference to the Fig. 1:

- L – the length of each blade;
- N_b – number of blades in each rotor (two possibilities are presented separately: rotors with two or three blades);
- R_0 - distance between the radar and the drone rotor (approximately the same as between radar and drone);
- z_0 – drone height;
- β – drone elevation angle;
- Ω – rotor angular rotation rate;
- λ – radar signal wavelength;
- φ_0 – rotor starting rotation angle.

The returned signal from all drone rotors is:

$$S_{\Sigma}(t)=\sum_{i=1}^{N_r}\sum_{k=0}^{N_b-1}s_{lk}(t)= \\ =\sum_{i=1}^{N_r}L\cdot\exp\left(-j\frac{4\cdot\pi}{\lambda}\cdot\left(R_{0i}+z_{0i}\cdot\sin\beta_i\right)\right)\cdot \\ \cdot\sum_{k=0}^{N_b-1}\sin c\left(\Phi_{ik}(t)\right)\cdot\exp\left(-j\cdot\Phi_{ik}(t)\right) \quad (3)$$

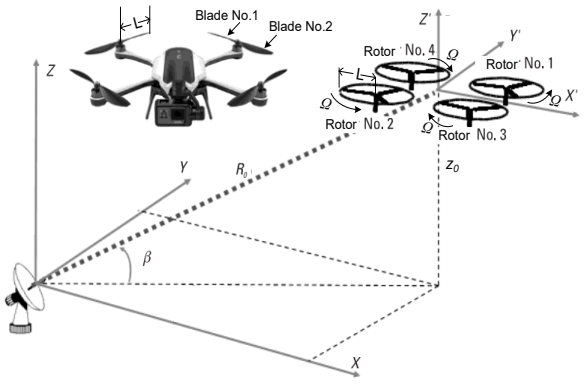

Fig. 1. Parameters included in drone spectrograms calculation

where it is:

$$\Phi_{ik}(t)=\frac{4\cdot\pi}{\lambda}\cdot\frac{L}{2}\cdot\cos\beta_i\cdot \\ \cdot\cos\left(\Omega_i\cdot t+\varphi_{0i}+\frac{2\cdot\pi\cdot k}{N_b}\right)\quad (k=0,1,2,...N_b\text{-}1) \quad (4)$$

and

- N_r - the number of rotors on the drone.

In general case, all rotors have their own specific angular rotation rate Ω_i. The difference in rates may be even more than 2:1 when drone is flying left or right [30]. In our analysis in this paper we consider that drone is hovering. Thus we suppose that all rotors have the same Ω_i. The range of Ω_i values may be estimated on the base of graphs from [31] which present drone performances when rotors angular rotation rate changes in the range 1400-8600 RPM, or, approximately, 20-150 RPS. The direction of rotors rotation is standardized to allow stable flight. In the case of drone with four rotors (quadcopter) two opposite rotors rotate in the clockwise direction and to other opposite rotors rotate in counter clockwise direction [32]. The length of blades when quadcopters or hexacopters are applied varies in the range between 11.9cm and 38.1cm according to some available literature [11], [13], [33]-[36]. The heights z_{0i} for all rotors are also the same as we may assume that drone is always positioned parallel to the ground. The assumption of all R_{0i} values equality is not quite valid. It would be necessary to precisely involve distances between rotor centres to determine exact values of R_{0i}. Nevertheless, we shall also suppose that there is no difference between R_{0i}s without important loss of generality. The elevation angles β_{0i} for all rotors are also practically the same and they are calculated as the ratio of z_{0i} and R_{0i}. Our investigation has been performed for FMCW radar operating at 24GHz, i.e. λ=12.5mm. The most often applied drones have not more than four rotors (quadcopters), but still exist drones with six (hexacopter) or eight (octocopter) rotors [37].

The standard procedure to calculate spectrogram includes calculation of Short Time Fourier Transform (*STFT*) of the considered signal according to the equation [38]:

$$STFT\left(S_n(m,\omega)\right)=\sum_{n=-\infty}^{\infty}S_n\cdot w_{n-m}\cdot\exp\left(-j\cdot\omega\cdot t_n\right) \quad (5)$$

where w_n is the Hanning window defined by [39]:

$$w_n=\frac{1}{2}\cdot\left(1-\cos\frac{2\cdot\pi\cdot n}{N}\right)\quad (n=0,1,2...N) \quad (6)$$

III. PROGRAM STRUCTURE SHORT PRESENTATION

The block-diagram of the program for spectrogram calculation is presented in the Fig. 2.

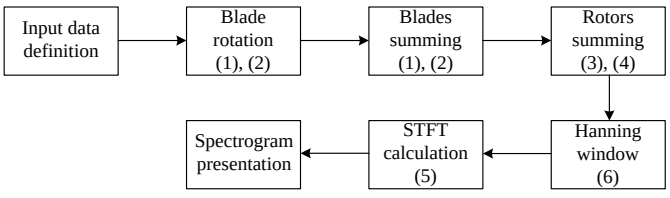

Fig. 2. Block-diagram of the program for spectrogram calculation

The first step in the program flow is to define input data: parameters of drone position towards radar, drone construction and operation, radar signal characteristics and the characteristics of desired spectrogram presentation. The parameters of drone position are its elevation angle (β), its

 ISBN 978-86-7466-930-3

height over ground (z_0) and distance between radar and drone (R_0). The drone construction parameters are the number of drone rotors (N_r), number of blades in each rotor (N_b) and the length of blades (L). Drone operation parameter is its rotors' angular rate (Ω) and direction of rotors rotation (clockwise or counter clockwise). Radar operational frequency (f_r) is the characteristic of radar signal. The characteristic parameters for spectrogram calculation and presentation are time step for spectrogram calculation (t_{step}) and time step for spectrogram display (t_{disp}).

The first step in calculation realization is related to each blade rotation. The calculation procedure follows the equations (1) and (2) in this step. The following step is to sum the echo signals from all single blades forming one rotor. This summing is also the part of equations (1) and (2). The third step in calculation process is to sum all echo signals from drone rotors, according to equation (3) and (4). The final step is related to spectrogram calculation using *STFT* according to the equation (5). Before *STFT* calculation, echo signal is modelled applying Hanning window signal according to the equation (6).

The output result of our calculation is the spectrogram presentation. A new spectrogram is obtained for each selected combination of input data parameters according to their defined values from ranges specified in the previous Section II. This is our initial investigation and this program version is realized in Excel. Some of input parameters could not be selected in the whole specified range according to the data from the Section II. There are three such parameters: the number of rotors is limited to 4 (thus covering the great majority of applied drones), the blade length is limited to 25.4cm (the most drones do not have longer blades according to the presented examples from literature) and the rotor angular rate is limited to about 40 RPS (its usual value is in the range 30-40 RPS [11], [40]).

IV. The Results of Calculation

Figures 3-12 present micro-Doppler signature graphs obtained by the implementation of our program. In all these cases it is considered that a drone has four rotors (N_r=4) and that it is positioned at a distance R_0=100m. The parameters which are varied are: 1) the number of blades constituting each rotor (N_b=3 in the figures 4, 5, 6, 7 and 9, N_b=2 in the remaining figures); 2) the length of blades (L=0.12m in the Fig. 5, L=0.18m in the Fig. 6, L=0.24m in remaining figures); 3) rotor angular rotation rate (Ω=20RPS in the figures 9 and 10, Ω=40RPS in the figures 7 and 8, Ω=30RPS in the remaining figures) and 4) the elevation angle i.e. the drone height over the ground (z_0=77m in the Fig. 11, z_0=94.8m in the Fig. 12, z_0=30m in the remaining figures). The frequency division 0-200Hz on the vertical axis of spectrograms is not the absolute value of Doppler shift for the applied 24GHz radar. It is a consequence of frequency bandwidth compression when STFT is calculated and it approximately corresponds to the compression factor 20.

The legends on the right side of figures 3-12 present the signal level (in dB) at the corresponding figure. The frequency components with the higher level in the range between -20dB and +10dB (which are presented in the brown, red and orange colour) are important for the spectrogram analysis. The other components are of lower or significantly lower level and are not important for consideration. The transition between the part of the graph with the higher frequencies level and the part of the frequencies with the low signal level (lower than -40dB which is presented by turquoise, blue and pink colour) is on all graphs rather sharp. The bandwidth of the area in brown, red and orange colour depends on the value of some parameters for which the graphs are calculated.

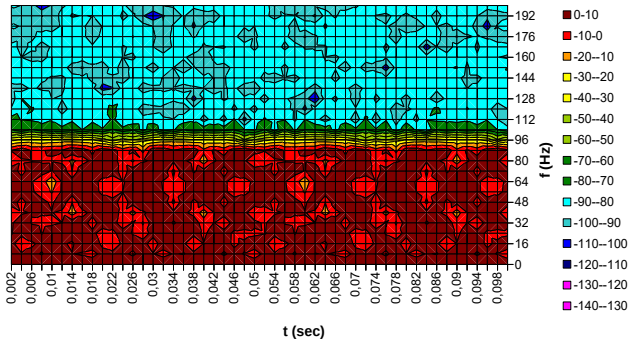

Fig. 9. Micro-Doppler signature of a drone with N_r=4, N_b=3, L=0.24m, R_0=100m, z_0=30m, Ω=20RPS

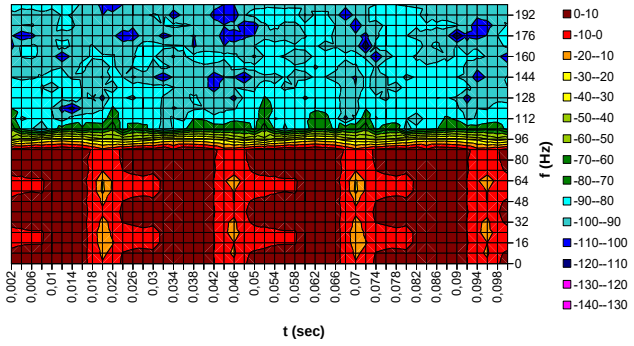

Fig. 10. Micro-Doppler signature of a drone with N_r=4, N_b=2, L=0.24m, R_0=100m, z_0=30m, Ω=20RPS

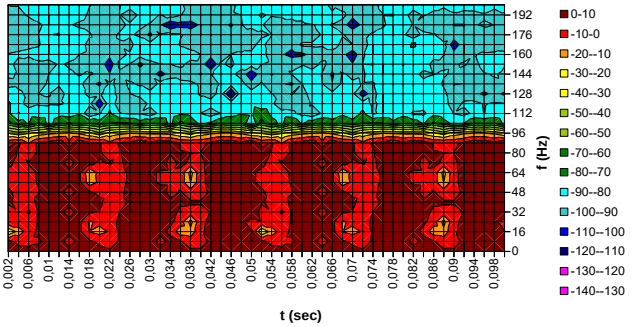

Fig. 11. Micro-Doppler signature of a drone with N_r=4, N_b=2, L=0.24m, R_0=100m, z_0=77m, Ω=30RPS

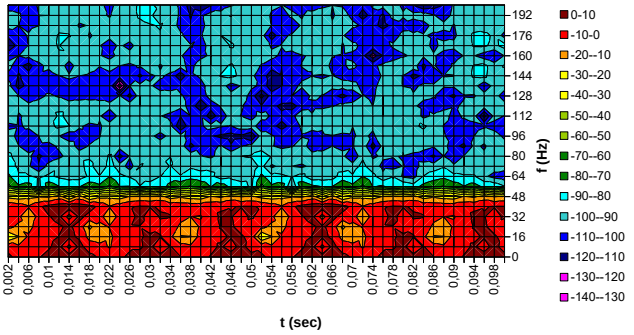

Fig. 12. Micro-Doppler signature of a drone with N_r=4, N_b=2, L=0.24m, R_0=100m, z_0=94.8m, Ω=30RPS

The number of blades in each rotor does not have any influence on the frequency bandwidth of the area with higher signal level. This is approved mutually comparing Fig. 3 (N_b=2, Ω=30RPS) and Fig. 4 (N_b=3, Ω=30RPS), then Fig. 7 (N_b=3, Ω=40RPS) and Fig. 8 (N_b=2, Ω=40RPS) and, finaly, Fig. 9 (N_b=3, Ω=20RPS) and Fig. 10 (N_b=2, Ω=20RPS). When comparing these cases two by two, we see that the number of blades only causes different configuration of brown, red and orange surfaces within the area of higher signal level.

The blades' length has the influence on the frequency bandwidth of the area with higher signal level. Dependence may be considered as linear according to the mutual comparison of the figures 4, 5 and 6. The width is approximately Δ=70Hz when it is L=0.12m (Fig. 5), Δ=104Hz when it is L=0.18m (Fig. 6) and Δ=140Hz when it is L=0.24m (Fig. 4).

The rotor angular rotation rate also has the influence on the frequency bandwidth of the area with higher signal level. Dependence is also linear, as in a case of blades' length. This statement is approved considering the graphs in the figures 9 and 10 (the width is Δ=94Hz at Ω=20RPS), then figures 3 and 4 (the width is Δ=140Hz at Ω=30RPS) and figures 7 and 8 (the width is Δ=186Hz at Ω=40RPS).

The frequency bandwidth of the area with higher signal level is proportional to the cosine value of the elevation angle. This is obvious comparing the graphs in the figures 3, 11 and 12. The drone heights (z_0=30m, z_0=77m and z_0=94.8m) are selected in such way that the ratios $\cos(z_0/R_0)$ in these three cases are 0.954, 0.638 and 0.318 or proportional to 3:2:1. The corresponding widths of the area with higher signal level in the figures 3, 11 and 12 are Δ=140Hz, Δ=96Hz and Δ=48Hz respectively, which is very near to 3:2:1.

 ISBN 978-86-7466-930-3

It is possible to distinguish graphs for the drones which have rotors with two blades (figures 3, 8, 10, 11 and 12) from those which have three blades (the remaining five figures). The characteristics when there are 2 blades usually have clearly separated, periodic parts with the highest signal level between 0dB and +10dB (brown segments). The shape of these parts depends on the rotation starting angle. There are six such parts in the figures 3, 11 and 12, eight in the Fig. 8 and four in the Fig. 10. It means that the number of repeatable parts (N_p) when there are 2 blades may be expressed as

$$N_p = N_r \cdot \Omega \cdot T_p \tag{7}$$

where T_p is the time interval of spectrogram investigation.

When there are 3 blades such clear periodic parts may not be easily islolated.

V. Reading the Parameters of Drone Flight and Construction from Spectrograms

In the Section IV it is investigated how the parameters of drone flight and of the drone construction affect its micro-Doppler signature appearance. Frequency bandwidth of the area with higher signal level depends on 3 parameters: blades' length, rotors' angular rotation rate and drone elevation angle. The spectrogram itself gives two values for the calculation. The first one is the frequency bandwidth of the area with higher signal level and the second one is the number of periodic areas with the highest signal level. So, it is necessary to determine one of the three parameters in some other way, not from spectrogram. The most logical is that this parameter is elevation angle β because it may be also determined by some algorithm implementation on FMCW radar [41], [42] (the concrete algorithm for this function is not studied in this paper).

In order to determine L and Ω from some measured spectrogram let us start from the spectrogram from the Fig. 13, which is calculated for the same parameters as in the Fig. 3 with only the exception that it is z_0=0m, i.e. cos(β)=1. It follows from the graph in the Fig. 13 that it is now Δ=148Hz. In this paper we have concluded that this value of Δ is proportinal to Ω and L. This statement may be expressed mathematically as

$$K_m \cdot L \cdot \Omega = 148 \tag{8}$$

Our goal is to determine the value of multiplication coefficient K_m.

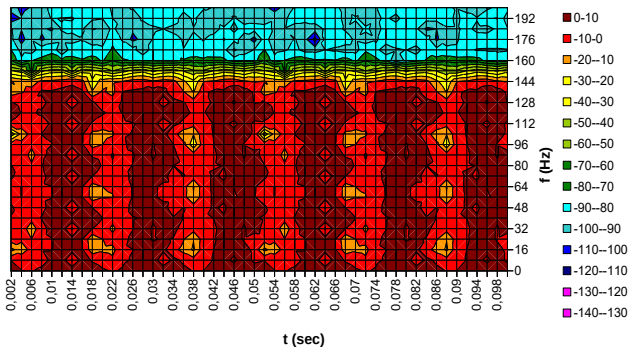

Fig. 13. Micro-Doppler signature of a drone with N_r=4, N_b=2, L=0.24m, R_0=100m, z_0=0m, Ω=30RPS

The graph in the Fig. 13 is obtained as a result of calculation for the condition that it is L=0.24m and Ω=30RPS. If we put now these values in the equation (8), we obtain that K_m=20.55.

Starting from this value of K_m, the value of elevation angle β_m (which is determined by some other algorithm of drone DILC process on FMCW radar) and the value of Δ_m from the analyzed spectrogram, it is possible to calculate the value of the product

$$L_m \cdot \Omega_m = \frac{\Delta_m}{K_m \cdot \cos(\beta_m)} \tag{9}$$

Further, if Ω_m is determined from the appearance of the spectrogram part with higher frequency components, it is possible to calculate the length of blades as

$$L_m = \frac{\Delta_m}{K_m \cdot \Omega_m \cdot \cos(\beta_m)} \tag{10}$$

VI. Conclusions

In this paper we have presented the initial development of a program for calculation and presentation of drones' micro-Doppler spectrograms as well as some results of its implementation. The benefits of such program application are that it is not necessary to have a high number of different drones and to perform significant volume of recording during drones operation in order to form the base of their spectrograms. This program follows the analytical model from [29]. The initial modelling is limited to hovering drones whose rotors have equal angular rotation rate. A number of spectrograms with differently defined input parameters is presented in the paper. The method for determination of drone's flight and construction characteristics is defined on the base of presented spectrograms. The number of blades in each rotor, rotors' angular rotation rate and blades' length, which contribute to specificities of spectrograms, may be concluded on the base of spectrograms appearance.

These initial calculations and presentations are performed in Excel as other, more suitable possibilities, were not available to us. Excel allows to perform good quality presentations of calculation results, as is also demonstrated in our contribution [43]. We plan to perform future investigations in some more powerful surrounding where it would be possible to model drone flying (besides hovering). It is also necessary to model drones with higher number of rotors (hexacopters, octocopters) as well as drone swarms to further improve drones DILC by FMCW radars.

FMCW radars are not the only way to obtain spectrograms as the ones presented in this paper. The similar results may be also obtained by using pulsed radar where the returned pulse delay is the measure of Doppler shift [13]. IRITEL already has experience in the development and improvements of such radars [21], [26]-[28]. In the case of single carrier radar the measure of Doppler shift would be the change of returned signal phase which is more complicate for realization.

Execution Time Improvement using CPU Parallelization and Non-Uniform High-Resolution Range-Doppler Map Estimation in HFSWR

Dragan Golubović, Nenad Vukmirović, Zoran Lončarević, Marko Marković and Miljko Erić

***Abstract*— igh-resolution range-Doppler (D-) map estimation, used for primary signal processing in a igh requency urface Wave adar (W), is the most computationally demanding step of the vessel detection algorithm. In order to reach real-time processing, which is of great importance in practical implementations of such systems, a very high-speed computation is required. In this paper, we propose non-uniform signal frame selection, to reduce the load with almost no loss in performance, and parallel processing on a CP to get high-resolution range-Doppler maps in a multi-antenna scenario. The paper contains the description of the proposed algorithm and the performance analysis. The e perimental results show a - to 1 -fold improvement in the e ecution time of the program for vessel detection.**

***Index Terms*— W ; range-Doppler map; high-resolution methods; multi-core; parallelized algorithms; speedup.**

I. INTRODUCTION

The focus of numerous scientific papers is maritime surveillance of vessels at long distances. The reason for that are many illegal crime activities over the horizon, drug trafficking, attacks on petrol platforms and strategic objects, etc. High Frequency Surface Wave Radars (HFSWRs) are widely used for this purpose [1]-[3].

To make these systems have better ship detection accuracy, as well as the ability to detect some ships, which are not visible at all using the currently used primary signal processing algorithms, high-resolution algorithms are used [4].

The downside is that the computational burden of HFSWRs is huge in that case, and high-speed computation is required in order to have real-time processing. It is of great importance in practical implementations.

In recent years, the demand for high performance numerical computing in many radar systems was increased. The focus of many papers is the formulation of parallel algorithms for the MIMO radar based on the Central Processing Unit (CPU)/ Graphical Processor Unit (GPU) architecture [5]-[9]. The architecture must be capable of multitasking, which allows multi-threaded execution of the program for vessel detection. GPUs have an essential role in designing the real-time programs because they are highly parallel, multithreaded processors. Graphic cards are equipped with multi-core GPUs enabling the development of high computationally demanding programs. But the performance improvement of multithreaded programs depends on the algorithms used and their implementations, which is often not a trivial task. This improvement is limited by the fraction of the program source code that can be run on multiple cores simultaneously. It is important to say that high execution efficiency is possible, only if hardware characteristics are appropriate.

The focus of this paper will be a real-time implementation of target detection in HFSWRs by improving the existing implementation of the high-resolution range-Doppler (RD-HR) map estimation, which is the most computationally demanding task of the entire algorithm. The algorithm runs in real-time if its execution time is shorter than the acquisition time of the frames used for the estimation (32.768 s in this particular case).

The existing implementation did not run in real-time, so we solved this problem in two ways. Firstly, we significantly reduced the computational load of the RD-HR map estimation with very little performance loss by using non-uniform sampling across the frames. Secondly, the parallel signal processing on CPU was performed. An advantage of the proposed implementation is that it requires only a general-purpose computer and no expensive dedicated hardware, like graphic cards, or Digital Signal Processing (DSP) cards.

The paper is organized as follows. In Section II, we presented a detailed algorithm description to estimate high-resolution range-Doppler map. In Section III, we explained the numerically efficient method to achieve real-time processing requirement. We discussed some experimental results and made some comparisons in Section IV and

outlined some conclusions and further research activities in Section V.

II. High-Resolution Range-Doppler Map Estimation

HFSWR to be analyzed in this paper operates in HF spectrum 3-30 MHz and it uses Frequency Modulated Continuous Waves (FMCW). The radar consists of a transmitter (Tx) antenna array, receiver (Rx) antenna array and transceiver hardware. The numerical results in this paper are based on the signals from an N-element linear Rx antenna array. Other geometries are also possible. At the receiving channels, acquired complex time samples of IQ branch signals are available for further signal processing. In Fig. 1 the complete high-resolution target detection algorithm in HFSWR was proposed.

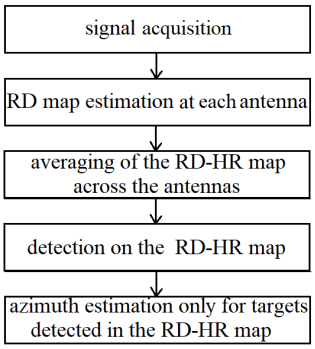

Fig. 1. The overview of the proposed high-resolution algorithm for vessel detection in HFSWR

The proposed algorithm has five steps, but the most computationally demanding task is step two – RD-HR map estimation at each antenna. Because of that, in order to improve program performance in terms of execution time, it is necessary to describe the creation of RD-HR map in detail and find a way to reduce its numerical complexity. So, other steps are not the focus of this section and only RD-HR creation will be explained.

In practical situations, P (the number of signal samples in one frame) and N are predefined values and M can be varied and it represents the number of frames used for the creation of one segment. Based on this segment, RD-HR map is formed. The developed algorithms were tested for the length of the segment of M=256, where the successive segments overlap in 128 frames. This ensures that the results are refreshed every 128 frames. The first step in the RD-HR creation process, is the implementation of FFT algorithm in P points for all frames m=1, 2, ... , M and all antennas n=1, 2, ... , N. By adding zeros to the vectors with signal samples, better grid resolution can be achieved when applying FFT. For further processing and a better estimate of the covariance matrix later, we need to extend the segment by L-1 additional frames. Fig. 2 shows the forming of the first two segments, with a 128-frame overlap. The same procedure is used for all other segments during signal processing.

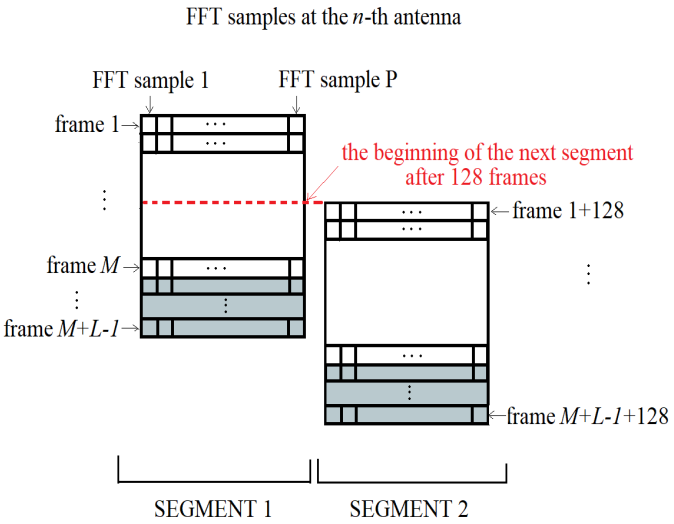

Fig. 2. Segment creation in the proposed algorithm

For each range cell, with index p, and each antenna, n, we form a matrix $_{p,n} \in C^{M\times}$ as in Fig. 4 from the p-th FFT sample from each frame in Fig. 3. Columns of matrix $_{p,n}$ are vectors $\mathbf{q}_{l,p,n}$, for $1 \le l \le$, $1 \le p \le P$ and $1 \le n \le N$.

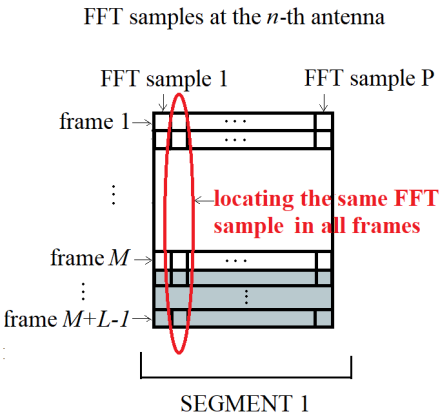

Fig. 3. Locating the same FFT sample in all frames

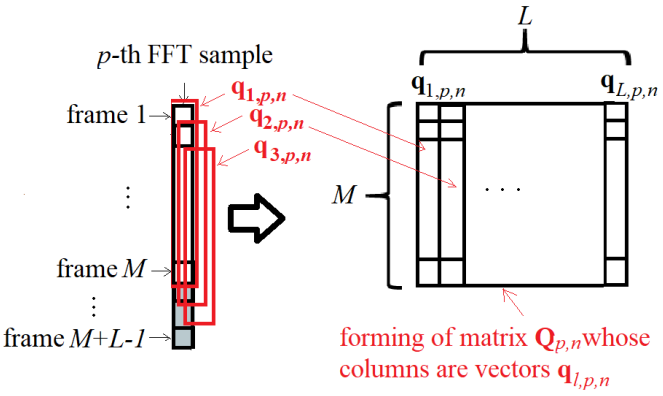

Fig. 4. The creation of the $_{p,n}$ matrix

 ISBN 978-86-7466-930-3

Then the covariance matrices $\mathbf{C}_{p,n} \in \mathrm{C}^{M\times M}$ are formed for n=1, 2, ... , N and p=$P-$ +1, $P-$ +2, ... , P, where represents the maximum projected radar range, as follows:

$$\mathbf{C}_{p,n} = \frac{1}{L}\mathbf{Q}_{p,n}\mathbf{Q}_{p,n}^{\mathrm{H}} \in \mathrm{C}^{M\times M} . \quad (1)$$

The formation of the covariance matrix $\mathbf{C}_{p,n}$ is a key step in the RD-HR map creation. Based on the covariance matrix, the criterion function of high-resolution MUSIC-based algorithm is formulated, as follows:

$$P_{\mathrm{MUS}}^{RD}(\mu,p,n) = \frac{1}{\left\|\mathbf{a}_{\mu}(\mu)^{\mathrm{H}}\,\mathbf{E}_{p,n}\right\|}, \quad (2)$$

where the columns of $_{p,n} \in \mathrm{C}^{M\times(M-}$ are the $M-$ eigenvectors from the noise subspace of $\mathbf{C}_{p,n}$, corresponding to the $M-$ smallest eigenvalues of the covariance matrix $\mathbf{C}_{p,n}$, is a parameter of the MUSIC-based algorithm, and $\mathbf{a}_{\mu}(\mu) \in \mathrm{C}^{M\times 1}$ is a steering vector formulated in the normalized Doppler domain as

$$\mathbf{a}_{\mu}(\mu) = \left[1, e^{-j\mu}, \dots , e^{-j\mu(M-1)}\right]^{\mathrm{T}} , \quad (3)$$

where the parameter μ denotes the normalized Doppler frequency in radians per frame. The criterion functions are calculated for a set of discrete values of normalized Doppler frequencies and with a grid resolution that is many times better than the Doppler FFT resolution, thus obtaining an RD-HR map.

III. NUMERICALLY EFFICIENT METHOD FOR RD-HR MAP ESTIMATION

As presented in the previous section, the RD-HR map estimation is numerically complex (long execution time). Program for vessel detection of the proposed algorithm must be improved to achieve real-time requirement. Because of that, we propose here a numerically efficient method realized in two steps.

In the first step, we want to make some kind of pattern according to which we select a small subset of the frames from each segment. The reason for that is to reduce numerical complexity. In that case, the dimensionality of the covariance matrix will be smaller (×) where < M. The problem of non-uniform sampling method is analogous to the problem formulated in the field of antenna arrays - how to replace a linear uniform antenna array with a non-uniform antenna array with the same aperture and a smaller number of antennas without significant degradation of the antenna array factor. This problem in antenna array theory is known as the problem of minimally redundant linear antenna arrays. Fig. 5 shows the forming of the matrix $^{(l}_{p,n}$ by selecting a subset of rows of the matrix and according to a chosen mapping ℓ : {1, 2, ... , } → {1, 2, ... , M}, < M.

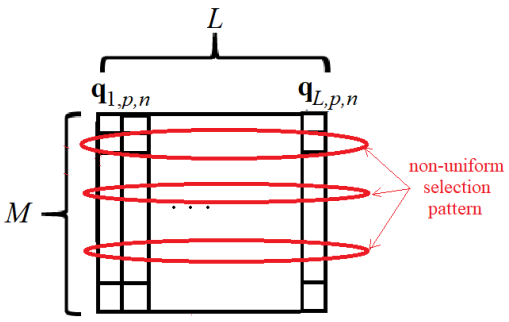

Fig. 5. The creation of the $^{(l}_{p,n}$ matrix using some non-uniform pattern

The same mapping ℓ is used to form the steering vector $\mathbf{a}_{\mu}{}^{l}(\mu)$ by non-uniform selection of the elements of the vector $\mathbf{a}_{\mu}(\mu)$.

The criterion function of the high-resolution MUSIC-type algorithm for creating RD-HR map with non-uniform sampling has the same form as the criterion function for the variant with uniform sampling, as follows:

$$P_{\mathrm{MUS}}^{RD\,(l)}(\mu,p,n) = \frac{1}{\left\|\mathbf{a}_{\mu}^{(l)}(\mu)^{\mathrm{H}}\,\mathbf{E}_{p,n}^{(l)}\right\|} . \quad (4)$$

The numerical complexity is significantly reduced, because the eigenvalue decomposition of the covariance matrix is numerically simpler in this case.

Despite the significant reduction in execution time, real-time processing is still not achieved. Therefore, we perform another step in the algorithm optimization.

As can be seen, a similar signal processing is performed on each of the antennas. This leads us to the idea not to form RD-HR maps at all antennas sequentially, one after the other, but simultaneously. Therefore, it is necessary to create a multi-threaded process.

Fig. 6 shows the proposed method for multithreaded RD-HR estimation in order to reduce execution time. A thread is the smallest unit of a processing that can be scheduled by an operating system. The multithreading was realized on CPU cores.

Therefore, the most demanding job, which is the formation of RD maps, was realized through parallel execution on multiple cores, while the rest of the program, which is not computationally demanding, remained to be executed sequentially. The algorithm is also applicable to a system with more antennas, but the performance depends directly on the number of processor cores.

IV. NUMERICAL RESULTS

The results presented in this section are based on the measured radar data. P=1536 and L=64 are predefined values and the developed algorithm was tested for the length of the segment M=256, where the successive segments overlap with 128 frames. Number of antennas directly affect the execution time of the program for vessel detection, and we made some tests with N=16 antennas in the Rx antenna array.

 ISBN 978-86-7466-930-3

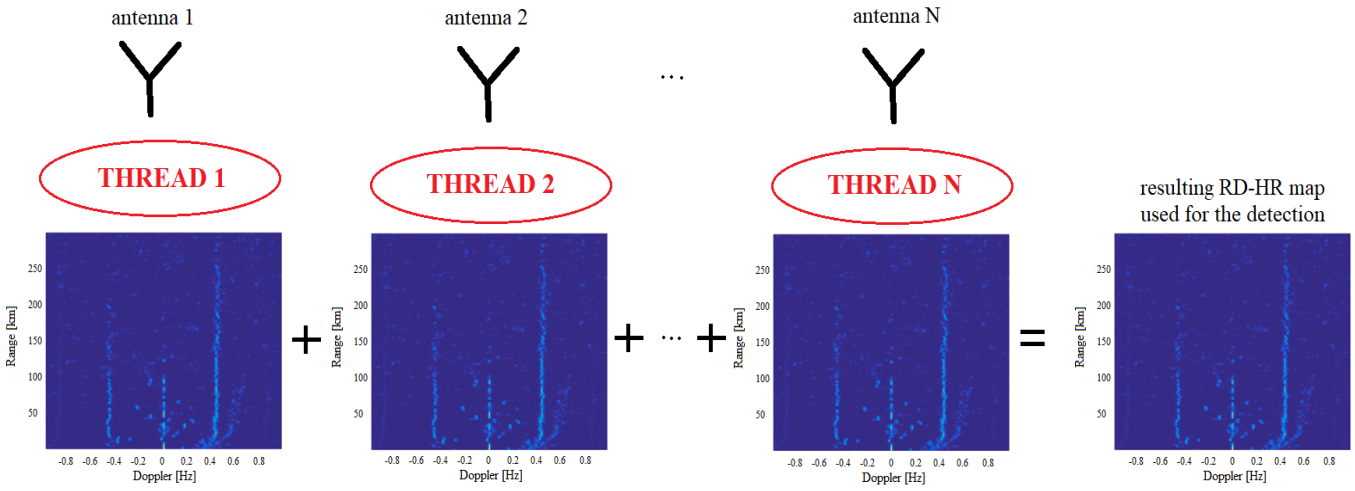

Fig. 6. Multithreaded RD-HR maps creation simultaneously at all antennas

The selected frame duration is 0.256 seconds, and since we want to output the results after every 128 frames, the real-time requirement is 32.768 seconds. Thus, the processing time of one segment must be shorter than 33.28 seconds. We choose also 3 predefined values for the parameter of the MUSIC-based algorithm: 10 for ranges up to 120 km, 20 for ranges from 120 to 200 km, and 30 for ranges up to 300 km. The number of grid points along the Doppler frequency dimension is 513. These are actually the basic system parameters.

For testing purposes, a program was developed using the programming language C and multithreading is realized too. We first formulate a testing methodology, seen in Fig. 7.

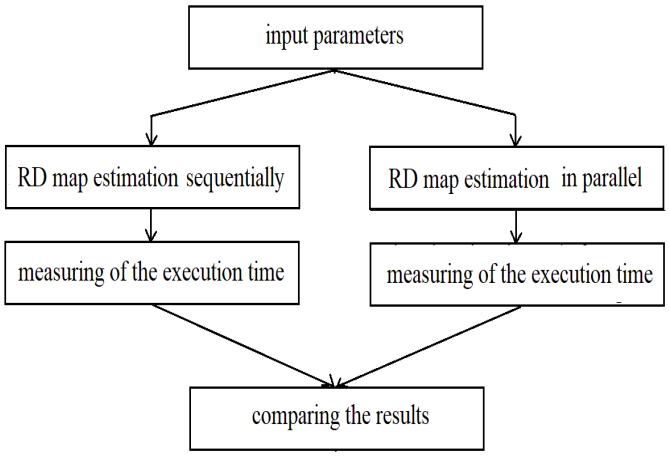

Fig. 7. The overview of the proposed testing methodology

We run the program on a PC with 6-cores CPU (i7), and on a PC with better 8-cores CPU (AMD Ryzen), and for 2 predefined patterns in order to get non-uniform RD-HR maps. The comparison with uniform RD-HR map is also presented. The first pattern is based on prime numbers between 1 and 256 (the last frame number in the segment) and the length of this pattern is =56, as follows: pattern56={1, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, 131, 137, 139, 149, 151, 157, 163, 167, 173, 179, 181, 191, 193, 197, 199, 211, 223, 227, 229, 233, 239, 241, 251, 256}.

The length of the second pattern is 88 and it is also based on prime numbers, with some more numbers inserted, in order to reduce the distance between the numbers in the pattern. This leads us to create an RD-HD map that visually resembles a uniform RD HR map, while being numerically simpler: pattern88 ={1, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 35, 37, 41, 45, 48, 50, 53, 55, 59, 61, 63, 67, 71, 73, 76, 77, 83, 85, 89, 92, 97, 101, 103, 105, 107, 109, 111, 113, 115, 118, 121, 125, 127, 129, 131, 134, 136, 137, 139, 142, 145, 147, 149, 151, 155, 157, 160, 163, 167, 171, 173, 179, 181, 184, 187, 191, 193, 197, 199, 202, 205, 209, 211, 215, 219, 223, 227, 229, 233, 236, 239, 241, 245, 247, 251, 254, 256}.

Fig. 8-10 show RD-HR maps for different patterns.

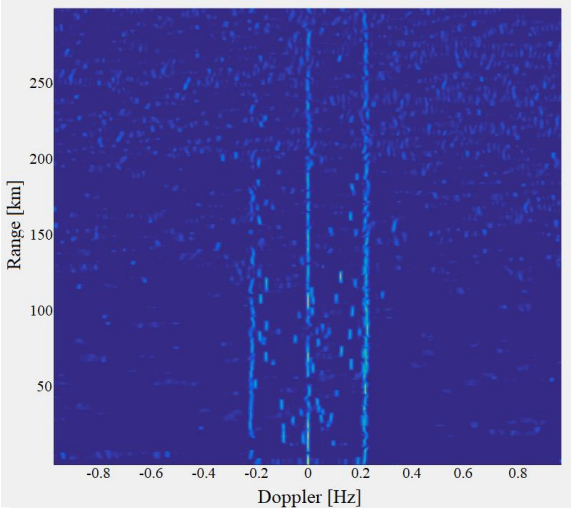

Fig. 8. Uniform obtained RD-HR map of the first segment

 ISBN 978-86-7466-930-3

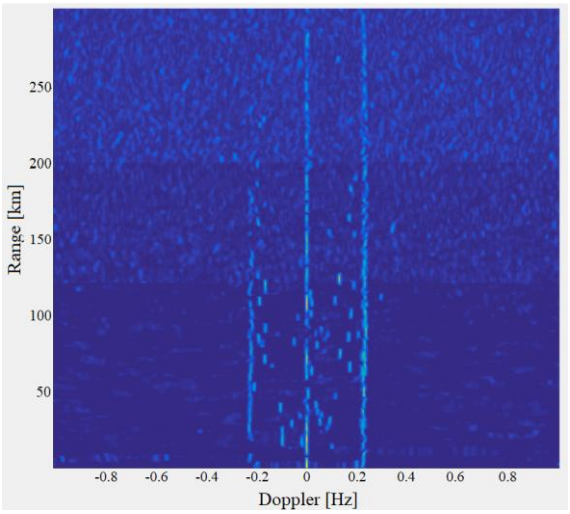

Fig. 9. Non-uniform obtained RD-HR map of the first segment (pattern88)

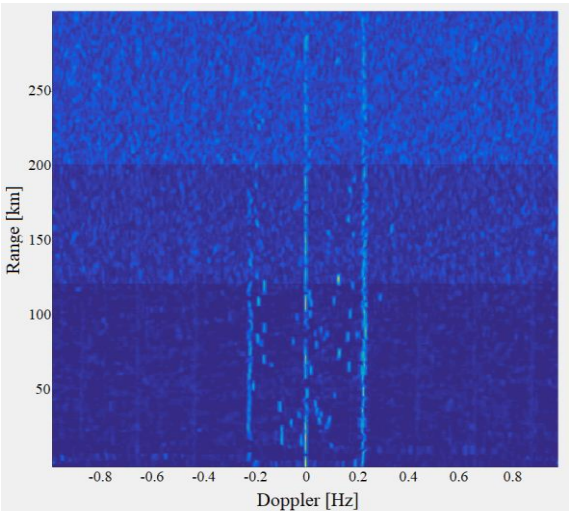

Fig. 10. Non-uniform obtained RD-HR map of the first segment (pattern56)

As can be seen from the figures, non-uniform sampling of frames increases the number of peaks in the RD-HR map compared to the case with uniform sampling, but vessels on the map are clearly visible in all 3 cases.

The dominant tasks in terms of the number of complex multiplications and additions are the eigenvalue decomposition and the calculation of MUSIC criterion function [10]. The approximate number of operations is

$$N_{\text{op}} \sim \frac{13}{3} J^3 RN + N_{\text{d}} J(J+1)RN . \quad (7)$$

In uniform variant $=M$. Thus, we decrease this number by a factor 44.6 and 15.3 for pattern56 and pattern88, respectively. N_{d} is the length of RD-HR map by Doppler dimension. In this particular case N_{d}=513. Since the numerical complexity is much lower, a non-uniform variant can be used for real-time processing.

Table I shows the execution time of the program (with no-parallelized code) for vessel detection on different computers. Also, the measured execution time to form the RD map is compared to the measured execution time of the rest of the program.

TABLE I
EXECUTION TIME OF THE PROGRAM (NO-PARALLELIZED CODE)

CP type	ecution time of D-estimation (seconds)	ecution time of the rest of the program (seconds)
Intel CORE i7 1075H	880	3.12
AMD Ryzen 9 5900HX	606	2.64

The results clearly show that the estimation of the RD-HR map is numerically most complex, and the execution time improvement is required in order to reach real-time processing.

Now, we can define the speedup S and the efficiency E by comparing the execution time on one core, T_1, and on n cores, T_n:

$$S = \frac{T_1}{T_n} \quad (5)$$

$$E = \frac{T_1}{nT_n} . \quad (6)$$

Table II shows the comparison between the execution time of the program with and without parallelized code. The obtained results show that the real-time processing is achieved.

TABLE II
EXECUTION TIME OF THE PROGRAM (PARALLELIZED CODE)

CP type and selected pattern	ecution time of the program without parallelization (seconds)	ecution time of the program with parallelization (seconds)
Intel CORE i7 1075H (uniform)	883.12	132
Intel CORE i7 1075H (pattern88)	91.2	14.21
Intel CORE i7 1075H (pattern56)	32.12	7.54
AMD Ryzen 9 5900HX (uniform)	608.64	90.75
AMD Ryzen 9 5900HX (pattern88)	60.32	9.63
AMD Ryzen 9 5900HX (pattern56)	24.56	4.4

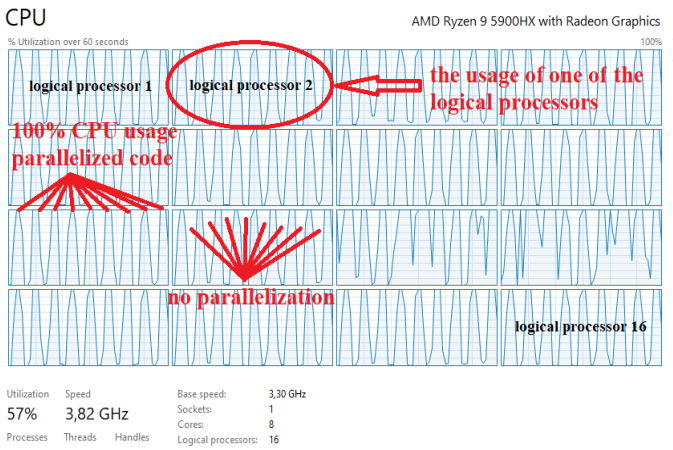

Fig. 13. Logical processors usage in multithread software

V. Conclusion

In this paper, we propose a numerically efficient algorithm that can help many researchers to reach real-time requirement in their programs for vessel detection. The obtained results show that the parallelization of the code is needed, so the parallel signal processing on CPU was performed. Additionally, the proposed method, does not need any specialized hardware, only a general-purpose computer.

Layer 2 Forwarding Using T4P4S: P4 Language and Data Plane Development Kit

Dimitrije Jovanović and Aleksandra Smiljanić, *Member, IEEE*

***Abstract*—P4 is an open-source programming language designed to program protocol-independent pac et processors. T4P4 is a P4 compiler that can enable P4 programs to run on networ devices using the Data Plane Development it (DPD) framewor . This paper covers the test environment for layer 2 forwarding using DPD . We compare the layer 2 forwarding switch compiled using T4P4 and the appropriate P4 program versus the layer 2 forwarding switch provided with DPD pac age.**

***Index Terms*—Programmable data plane, P4 language, DPD , T4P4 .**

I. Introduction

P4 language (Programming Protocol-Independent Packet Processors) [1] is an open source, domain specific programming language used to specify packet processing of data plane devices. It provides high-level instructions for describing transformations of network data, and enables the end-user to define data plane functionalities, regardless of the network protocol.

Before the introduction of programmable data planes [2], the specialized hardware and low-level programming languages were used to implement data plane logic, as the only way to achieve satisfactory packet processing rates. P4 programmable hardware devices (targets) have so far achieved great performances, but they are still very expensive. Originally, the main goal of P4 is protocol-independence. However, it was not designed to be target-independent.

T4P4S (Translator for P4 Switches) is a P4 compiler able to support a variety of hardware devices [3]. To solve direct target-dependence, the Networking Hardware Abstraction Layer (NetHAL) has been introduced. The compiler translates the P4 program into C language code of a hardware independent core switch, using NetHAL as an interface between hardware and the switch code. The result is a hardware dependent DPDK software switch compatible with a given device. The simplified process of generating a switch program is illustrated in Fig. 1

Introduced software abstraction makes the P4 program target-independent. However, the overall performance is potentially lower. To this end, we conduct a simple layer 2 forwarding experiment (l2fwd), where we first forward packets using DPDK (Data Plane Development Kit) [4]. Then, we implement a P4 program with the same forwarding function by using T4P4S with DPDK. The goal is to verify integration of P4 and DPDK, by showing that the tests T4P4S l2fwd and DPDK l2fwd produce similar results.

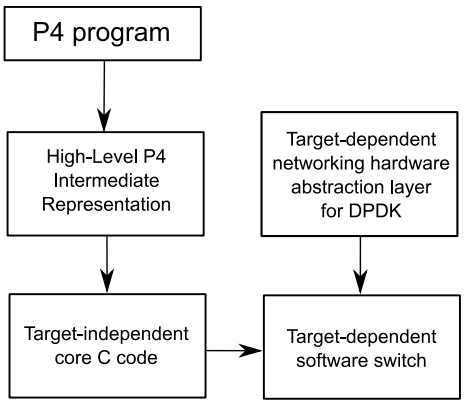

Fig. 1. Generation of the DPDK software switch using T4P4S.

This paper is structured as follows. Sections II, III and IV introduce the P4 language and its components. In section V, we cover an example of P4 program used for layer 2 forwarding. The testing environment is presented in Section VI. Finally, the testing results are shown in Section VII. We conclude the work in Section VIII.

II. Packet Forwarding in P4

While the data plane performs transformations and forwarding of packets, the control plane configures the data plane and supplies it with network data. P4 defines functionalities of the data plane that was traditionally defined by the manufacturer. Inside a P4 switch, the data plane and its set of tables are not fixed in advance but rather defined by a P4 program. Thus, the data plane has no in-built knowledge of the existing network protocols [5].

P4 language adopts an abstract model for the packet processing pipeline which consists of three main stages [6]:

- Parser extracts user-defined packet headers from the received packet. Parsers are written in the form of finite state machines with three predefined states: start, accept and reject.
- Controls perform transformations on extracted headers. They define the control flow, an imperative program which operates on tables called match-action units. These tables consist of keys, matching types and actions that are executed upon matching.
- Deparser assembles the packet from processed headers. It performs the serialization of user-defined packet headers into the packet, and emission of these headers on the proper egress port.

Aleksandra Smiljanić is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: aleksandra@etf.bg.ac.rs).

 ISBN 978-86-7466-930-3

III. P4 Architecture

The P4 architecture of each target consists of its P4 programmable elements and their data plane interfaces [5]. Regardless of the target's architecture type, the core of packet processing is the programmable match-action pipeline, which consists of metadata bus and a sequence of connected match-action units.

Metadata bus allows the communication between different phases of the match-action pipeline. It is considerably wider than common CPU buses, thus, these kinds of architectures can achieve high data processing speeds.

The most general architectural model consists of the ingress and egress match-action pipeline on its ends, and the traffic manager in between. The traffic manager performs packet queueing, replication and scheduling. The pipelines, parser and deparser are P4 programmable, while the traffic manager is fixed function.

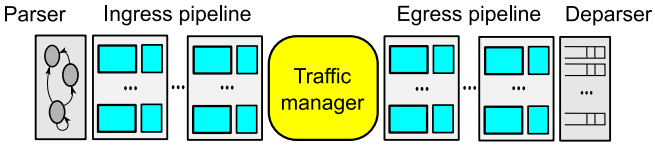

Fig. 2. V1Model P4 architecture.

One of the most common P4 architectures is the V1Model [7], which is illustrated in Fig. 2. Here, the ingress pipeline is placed after the parser and performs checksum verification. Symmetrically, the egress pipeline is placed before the deparser and performs checksum update. For example, T4P4S can use the V1Model architecture, which will also be implemented in this paper for testing.

IV. P4 Programming Components

The core of the P4 language consists of data types, expressions, declarations and statements. The rest of the language is directly used for expressing parsers, match-action units and architectures [5].

P4 is a statically typed language. It provides several built-in base types (void, error, strings, match kind, Boolean, integers) and derived data types (enumeration, header, struct, tuple, extern, parsers, control blocks, packages, etc.).

Certain sorts of expressions in P4 can be executed only on a limited set of data types. The complete grammar production rule for general expressions can be found in the language specification.

Declarations are used for introducing functions, constants, and variables, which are executed at run time. Specially, data types with constructors (extern, control blocks, parsers, packages) use instantiations, which are executed at compilation time.

Statements can appear within parser states, a control block or an action. Some kinds of statements cannot appear in certain blocks. Control blocks support all of the following statements: assignment, empty, block, exit, return, switch.

Control blocks are used to manipulate and transform parsed headers. Data is transformed by match-action units, which are described by tables. One action consists of the code, which is in the P4 program, and the data, which is in table entries populated by the control plane. This is shown in Fig. 3.

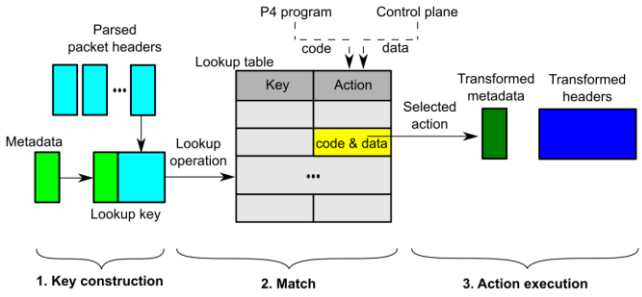

Fig. 3. Match-action unit.

Match-action units perform the following operations:

- Key construction, using packet headers or metadata.
- Match, by searching the key in the lookup table.
- Action execution, by which the input data is transformed.

Control blocks are also used to define deparsing (packet reconstruction), which is an inverse operation of parsing.

V. P4 Layer 2 Forwarding Example Program

A simple configuration of layer 2 forwarding between two servers is illustrated in Fig. 4. A DPDK-compatible traffic generator is used to produce and transmit packets from server 1 (source server) to server 2 (target server). In the first case, server 2 uses a basic DPDK l2fwd example [8] to receive and forward packets. In the second case, we use a P4 program compiled by T4P4S. The same packet processing function is implemented in both cases.

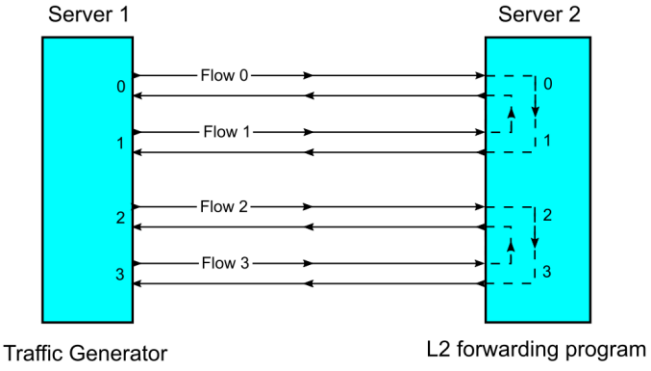

Fig. 4. Test configuration [8].

The P4 program given in Fig. 5 is used to generate our l2fwd switch example. Lines 1-8 define header types to be parsed from the packet. Lines 10-13 define the parser, which in this case extracts the Ethernet header from the ingress packet. Lines 15-58 define the control flow, which consists of tables (smac, dmac), actions (_drop, _nop, mac_learn, forward, broadcast) and controls (ingress, egress).

In this example, exact matching is used for table lookup. If the source MAC address is not found in the smac table, a digest is sent to the control plane to add the source address and the ingress port to both tables (action mac_learn).

If the source MAC address already exists in the table, nothing needs to be done (action _nop). In the dmac table,

 ISBN 978-86-7466-930-3

the exact matching lookup determines the egress port based on the destination MAC adress. If there is a match, the packet is forwarded to that egress port (action forward). Otherwise, if the destination MAC address is not found in the table, the packet is sent to all ports except the ingress port (action bcast).

VI. Test Environment

One of the testing goals is the comparison of running DPDK l2fwd from the CentOS host and the Ubuntu container, to verify the Docker solution and to detect the performance degradations if any. Also, DPDK l2fwd can be compared with T4P4S l2fwd, both on Ubuntu, in terms of different metrics, such as bit rate and packet size. The tests are performed on the target server using 2x2 ports (port 0 forwards to port 1 and port 2 forwards to port 3 and vice versa), as shown in Fig. 4.

The source test server used to generate traffic is Supermicro with 125 GB RAM, 24 cores and four Intel X710 NICs, each with 4 x 10 Gbit/s Ethernet ports. The traffic is generated using the Pktgen traffic generator.

The target test server is Supermicro with 250 GB RAM, 32 cores and five Intel X710 NICs, each with 4 x 10 Gbit/s Ethernet ports. The existing CentOS 7 host operating system contains the working DPDK version 18.11, which is not suitable for T4P4S installation due to incompatibility. To resolve that, we installed the latest version of T4P4S with underlying DPDK 21.11 on the Ubuntu 20.04 Docker container.

The configuration of the CentOS host includes the installation of DPDK required kernel modules uio, uio_pci_generic, vfio_pci and igb_uio (the last one compiled from dpdk-kmods Github repository), as well as the reservation of hugepages that will be used by DPDK. The Ubuntu 20.04 Docker container needs to be started with the option that mounts the host file system /dev/hugepages under /mnt/huge mounting point. Also, the container needs to run in the privileged mode with the host networking option, to allow the full access to the host drivers and the network cards.

In the Ubuntu container, it is required to install several missing packages, because the basic Ubuntu 20.04 Docker image assumes the very minimal configuration without development libraries, tools and compilers.

The detailed instructions on how to build T4P4S are given in the GitHub P4ELTE/t4p4s project [9]. Before testing, it is required to bind network cards to DPDK igb_uio driver, using the dpdk-devbind.py command. The packet generator (GitHub Pktgen-DPDK project) is located on another similar server, where four X710 NICs are directly connected to the selected four X710 NICs on the testing server, as shown in Fig. 4. The test configuration measures internal packet transfer between ports 0-1 and between ports 2-3, and also measures performances of parallel processing of two independent forwarding mechanisms.

 ISBN 978-86-7466-930-3

DPDK l2fwd is configured using command line options, which consist of Environment Abstraction Layer (EAL) options and application options. T4P4S l2fwd is configured by user-defined command line options, that we need to define in advance in the T4P4S configuration file opts_dpdk.cfg. EAL options are the same, but the application options differ for DPDK l2fwd and T4P4S l2fwd. For T4P4S l2fwd, we also need to specify the P4 architectural model, for example the V1Model.

The command line options presented in Table I will be used in all of the following tests. The number of processor cores is set to 4 (option -c and bit mask 0xf), the number of enabled ports is also 4 (option -p, bit mask 0xf). In the case of DPDK l2fwd, ports 0 and 1 forward packets to each other and ports 2 and 3 forward packets to each other by default. For T4P4S l2fwd, we need to explicitly map each RX port to the specific port, queue and processor core (port, queue, core). Ports that form the same traffic flow must be on the same socket, which is socket 0 in this case. The last option of the T4P4S l2fwd command in Table I is used to provide the proper RSS value, at compilation time. Configuration of the T4P4S l2fwd switch can be verified by looking at the command output presented in Fig. 6. One port handles ingress packets in nb_rxq queues, and egress packets in nb_txq queues. This output is practically the same for both DPDK l2fwd and T4P4S l2fwd.

VII. Test Results

The relation between the maximal packet rate and bit rate on an Ethernet link is given in (1). Ethernet frame of size is preceeded by preamble (7 B) and SFD field (1 B), and it is followed by an inter-frame gap (at least 12 B). Therefore, the total size of transmitted data is at least + 20 B.

$$_{packet,\max} = \frac{bit}{+20B} \quad (1)$$

There is a hardware upper limit for packet rate when the traffic is generated on all four ports simultaneously. This value depends on the model of used NIC. The maximal TX packet rate on one port for the shortest frames (64 B) is given in the last row of Table II, which equals 10.066 Mp/s. If we had used only two ports in our experiment, the maximal TX packet rate on one port would be 14.88 Mp/s, according to (1).

The results of several tests for layer 2 forwarding, for different frame sizes and TX packet rates, are given in Table II. We initiated the Ethernet traffic with the given parameters on all four ports simultaneously, and measured RX packet rate on each port. Table II gives the achieved RX packet rate for one port. We considered four values for Ethernet frame size, ranging from 1518 B to 64 B (column 1). TX packet rate (column 2) is given as the percentage of the maximal packet rate (column 3), because the rate is set that way in the Pktgen command line. For each frame size, we considered TX packet rate values of 10% and 100% of the maximal packet rate.

The tests produced practically identical results for RX rate comparing DPDK l2fwd on CentOS host and on Ubuntu Docker container. That excludes any performance degradation possibly caused by the Docker container.

TABLE II
Comparing DPDK l2fwd on CentOS host and Ubuntu Docker container: RX packet rate

Frame size [B]	% max packet rate	TX packet rate [Mp/s]	RX packet rate CentOS Host [Mp/s]	RX Packet rate Ubuntu container [Mp/s]

64	100	10.0798	9.40504	9.39915

Pktgen [10] is a software traffic generator that is a part of the DPDK framework. It can configure and display metrics for traffic flows at real time. Pktgen command line options (Fig. 7) are split into Environment Abstraction Layer (EAL) options and application options. The mask of used processor cores and the number of memory channels are the required EAL arguments. We can also specify the PCI devices and

 ISBN 978-86-7466-930-3

the memory allocated from hugepages on specific sockets. In the application options, we can map ports to logical cores. Run time commands are entered in Pktgen prompt while it is running. For each port, we can specify the number of packets to transmit and their size, packet rate (in percentage of the maximal rate), as well as the source and the destination MAC address (or their range).

In our tests, the source MAC address of port 0 is the destination MAC address of port 1 and vice versa. Ports 2 and 3 are paired in the same way. Pktgen displays traffic results for each port at real time, such as the achieved rate and number of transmitted and received packets. The example of Pktgen output for ports 0 and 1 is presented in Fig. 7.

Fig. 7. Pktgen output for T4P4S l2fwd (showing ports 0 and 1 only).

By turning on T4P4S l2fwd debugging, in Fig. 8 one can see how the process of MAC learning and forwarding goes on. We can follow the specified packet by looking at lines that begin with its assigned string. For the packet on the ingress port 3 (lines 0@0), the parser enters the start state and extracts the Ethernet header. The source MAC address ac:1f:6b:2d:1a:cb is not found in the smac table, and therefore that address-port pair is added both to the smac table and the dmac table. The next incoming packet on the ingress port 2 (lines 1@0) has the destination MAC address ac:1f:6b:2d:1a:cb. Since now there is a match in the dmac table, the packet is forwarded to the port 3.

Since we concluded that l2fwd tests behave the same on the CentOS host and the Ubuntu Docker container, we can compare DPDK l2fwd and T4P4S l2fwd, both on the Docker container. We executed the tests with analogous parameters with the parameters for comparing DPDK l2fwd on CentOS host and Ubuntu Docker container. The results are shown in Table III and Table IV.

 ISBN 978-86-7466-930-3

In Table III and Table IV, one can observe that the RX rate of T4P4S l2fwd is similar to RX rate of DPDK l2fwd for lower rates and longer packets. But in the case of higher rates and shorter packets, there is a considerable amount of lost packets in the case of T4P4S l2fwd. The values for RX rate for T4P4S l2fwd denoted with (*) in Table III and Table IV represent that case. The encountered issues are caused by a suboptimal software integration of DPDK and P4, which includes a trade-off between flexibility and performance. Target-independence of the T4P4S compiler introduces generalizations related to memory allocation, which are common sources of performance issues. The improvement in that area will be the subject of future work.

VIII. Conclusion

We have demonstrated that P4 features can be readily tested using standard equipment, consisting of two Linux servers with sufficient memory and processor cores, and standard network cards. We have considered two cases: when packet forwarding is done just using DPDK, and when P4 program is executed on the receiver side, by using T4P4S over DPDK. We have shown that, in most cases, there are no considerable differences between RX bit rate measured for DPDK layer 2 forwarding and T4P4S layer 2 forwarding that implements the P4 language program. We have observed a drop in performance of the implemented P4 software for the shortest packets. On the other hand, the P4 language greatly improves the flexibility of packet processing, while T4P4S makes P4 programs portable across multiple targets. In the future, we will work on improving the performance of the integrated DPDK and P4 software.

Mogućnost primene beacon tehnologiji za razvoj Covid-19 sistema za praćenje kontakta u visokoškolskim institucijama

Ivana Stefanović, Milutin Nešić i Marko Milivojčević

***Apstrakt*—U ovom radu razmatrana je mogućnost primene *beacon* tehnologije za razvoj rešenja koje omogućava praćenje rizičnih kontakta kao i automatizaciju sprovođenja propisanih mera u realnom vremenu, u cilju sprečavanja zaražavanja i širenja infekcije izazvane virusom Covid-19 u visokoškolskim institucijama. Za realizaciju sistema dovoljno je da studenti i zaposleni kod sebe imaju pametni telefon na kome je instalirana odgovarajuća aplikacija. Sistem se bazira na tome da će student i zaposleni kod kojih je utvrđeno prisustvo virusa Covid-19, putem aplikacije, dobrovoljno obavestiti visokoškolsku ustanovu o pozitivnom testu. Sprovedena je anonimna anketa kako bi se utvrdilo da li su student i zaposleni zainteresovani za implementaciju Covid-19 sistema za praćenje kontakta. Izvršena su i praktična merenja, a dobijeni rezultati potvrđuju da je *beacon* tehnologija odličan izbor za implementaciju sistema.**

***Ključne reči*—Beacon; BLE; Covid-19; pozicioniranje.**

I. Uvod

Globalna pandemija izazvana virusom Covid-19 utiče na sve aspekte ljudskog života, uključujući i obrazovanje. Zavisno od trenutne epidemiološke situacije i u skladu sa preporukama Ministrastva prosvete, nauke i tehnološkog razvoja nastava u visokoškolskim ustanovama odvija se uživo, na daljinu ili kombinovano. Za razliku od samog početka pandemije, kada se celokupna nastava odvijala na daljinu, danas je u većini visokoškolskih ustanova usvojen kombinovani model koji podrazumeva da se deo nastave održava uživo u školama. Većina mera za zaštitu zdravlja studenata i zaposlenih odnosi se na održavanje fizičke distance, nošenje maski, redovno pranje ruku, čišćenje i dezinfekciju školskih prostorija. Uprkos svim merama koje škole sprovede, dolazi do zaražavanja studenata i zaposlenih, što dovodi u rizik druge studente i zaposlene koji su bili u neposrednom kontaktu sa zaraženim.

U okviru ovog rada predstavljen je centralizovani sistem čija je osnovna funkcija identifikacija i obaveštavanje studenata i zaposlenih o neposrednom kontaktu u školi sa osobom kod koje je potvrđeno prisustvo virusa Covid-19. Sistem je baziran na upotrebi *beacon* tehnologije koja pored praćenja kontakta omogućava i automatizaciju sprovođenja skoro svih propisanih mera u realnom vremenu u cilju sprečavanja zaražavanja i širenja infekcije. Pomoću *beacon* tehnologije moguće je u realnom vremenu pratiti kretanje studenata i zaposlenih i obavestiti ih kada je potrebno povećati rastojanje sa sagovornikom. Na ovaj način može se unapred smanjiti broj rizičnih kontakta, a samim tim i broj zaraženih. Takođe, u slučaju velike koncentracije studenata koji se dugo zadržavaju na istom mestu, što se često dešava tokom pauza između nastave, moguće je obavestiti i covid redara. Pomoću *Covid-19* sistema za praćenje kontakta može se vršiti prebrojavanje ljudi u prostorijama i na osnovu toga odrediti kada je potrebno izvršiti provetravanje i čišćenje prostorija. Na osnovu kretanja, broja bliskih kontakata, vremena provedenog u određenim prostorijama moguće je podsetiti studente i zaposlene o pranju ruku.

Beacon tehnologija se bazira na upotrebi BLE (Bluetooth Low Energy) protokola, čime se postiže visoka energetska efikasnost. Srž tehnologije su *beacon* uređaji koji na osnovu snage primljenog signala određuju rastojanje između sebe i drugih uređaja poput pametnih telefona. Glavna prednost *beacon*-a je mogućnost slanja poruka korisnicima u blizini putem aplikacije na pametnom telefonu. Zbog niske cene, jednostavne implementacije, male potrošnje energije i visoke preciznosti, *beacon* tehnologija je postala veoma popularna kod sistema koji uključuju lociranje, navigaciju i praćenje u zatvorenom prostoru. Kompanija Apple je predstavila *beacon* tehnologiju 2013. godine. Već 2016. godine *beacon* tržište procenjeno je na 519.6 miliona dolara, a predviđa se da će do 2026. godine vrednost porasti na 56.6 biliona dolara [1].

Međunarodni aerodrom u Hong Kongu ima preko 17000 *beacon*-a koji se koriste za navigaciju putnika po aerodromu [2]. Macy's robne kuće su 2014. godine instalirale oko 4000 *beacon*-a u preko 850 prodavnica kako bi se povećala prodaja i broj kupaca [3]. Mnogi muzeji širom sveta, poput muzeja umetnosi San Diego, koriste *beacon*-e kako bi poboljšali iskustvo posetioca [4]. Neki univerziteti koriste *beacon* tehnologiju kako bi automatizovali proces evidencije prisustva studenata na predavanjima [5].

Naredne sekcije rada organizovane su na sledeći način. U sekciji II. razmatrane su različite tehnologije koje se koriste za implementaciju lokacijskih servisa u zatvorenom prostoru. Detaljno je objašnjen princip funkcionisanja sistema. Najznačajniji rezultati istraživanja i njihova analiza predstavljeni su u sekciji III. Na kraju rada, prikazane su različite mogućnosti za modifikaciju sistema, čime bi se obezbedila održivost sistema i nakon završetka pandemije.

II. Metod

Implementacija Covid-19 sistema za praćenje kontakta podrazumeva korišćenje proaktivnih lokacijskih servisa u zatvorenom prostoru koji omogućavaju stalno praćenje

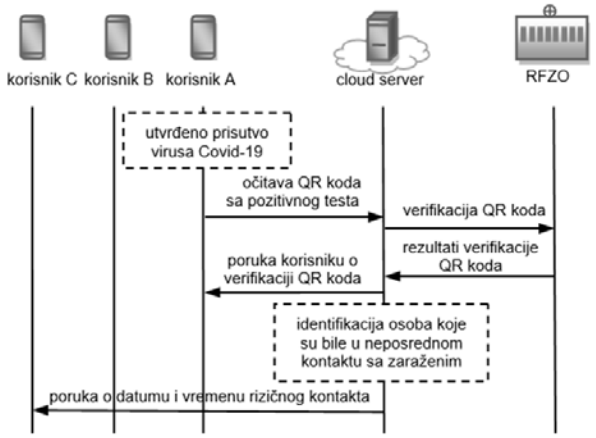
Ivana Stefanović – Akademija tehničko-umetničkih stukovnih studija Beograd, Odsek Visoka škola elektrotehnike i računarstva, Starine Novaka 24, 11000 Beograd, Srbija (e-mail: ivanas@ viser.edu.rs).

Milutin Nešić – Akademija tehničko-umetničkih stukovnih studija Beograd, Odsek Visoka škola elektrotehnike i računarstva, Starine Novaka 24, 11000 Beograd, Srbija (e-mail: nesic@ viser.edu.rs).

Marko Milivojčević – Akademija tehničko-umetničkih stukovnih studija Beograd, Odsek Visoka škola elektrotehnike i računarstva, Starine Novaka 24, 11000 Beograd, Srbija (e-mail: markom@ viser.edu.rs).

 ISBN 978-86-7466-930-3

korisnika i iniciraju se automatski. Različiti lokacijski servisi koriste različite tehnike pozicioniranja koje se međusobno razlikuju po pitanju tačnosti, preciznosti, efikasnosti, kašnjenju, ceni i kompleksnosti implementacije.



GNSS nude niz pogodnosti kada je u pitanju pozicioniranje na otvorenom, ali u zatvorenom prostoru ne mogu obezbediti zahtevanu tačnost koja je neophodna za implementaciju Covid-19 sistema za praćenje kontakta. Za implementaciju sistema razmatarane su različite tehnike pozicioniranja poput RFID (radio-frequency identification), NFC (Near Field Communication), UWB (Ultra-wideband) tehnologija, kao i pozicioniranje u okviru WLAN mreža koje je bazirano na upotrebi Wi-Fi-a i Bluetooth-a. RFID, NFC i UWB tehnologije podrazumevaju korišćenje različitih tagova i čitača ili senzora za prijem signala sa tagova. Korišćenje bilo koje od navedenih tehnika podrazumevalo bi da svi studenti i zaposleni kod sebe moraju imati tag, dok bi čitači ili senzori bili raspoređeni po školi. Zbog ograničenog dometa, broja tagova koji se istovremeno mogu skenirati, broja čitača i senzora povećava se kompleksnost i cena implementacije sistema. *Beacon* tehnologija je specifična zbog jednostavne integracije i kompatibilnosti između *beacona* i pametnih telefona. Upotrebom *beacon* tehnologije dovoljno je da studenti i zaposleni kod sebe imaju pametni telefon na kome je instalirana odgovarajuća aplikacija. Prema Republičkom zavodu za statistiku, 2020. godine, u Republici Srbiji 94.1% stanovništva koristi mobilni telefon. Za starosnu grupu od 16 do 24 godine, kojoj pripada većina studenata, ovaj procenat iznosi 100%, za mušku populaciju, i 99.6% za žensku populaciju [6].

Wi-Fi i Bluetooth tehnologije su pogodne za implementaciju Covid-19 sistema za praćenje kontakta, jer je kao i u slučaju *beacon* tehnologije dovoljno da studenti i zaposleni kod sebe imaju pametni telefon na kome je aktiviran Wi-Fi, odnosno Bluetooth. Pozicioniranje korisnika primenom Wi-Fi vrši se na osnovu snage primljenog signala sa pristupnih tačaka, a može se koristiti i cirkularna lateracija, gde je pozicija korisnika određena presekom kružnica. Da bi se obezbedila neophodna tačnost prilikom pozicioniranja studenata i zaposlenih u školi potrebno je povećati trenutni broj pristupnih tačaka, dodavanjem novih. Ugradnja novih pristupnih tačaka i povezivanje na postojeću infrastrukturu je znatno komplikovanije i skuplje u poređenju sa ugradnjom *beacon*-a. Takođe, *beacon*-i se lako mogu postaviti na bilo kojoj lokaciji u školi, jer ne zahtevaju mrežno napajanje niti dodatne infrastrukturne radove, za razliku od pristupnih tačaka.

Pozicioniranje pomoću Bluetooth-a nudi niz prednosti u odnosu na Wi-Fi. Jedna od njih je energetska efikasnost koja je postignuta BLE protokolom. Takođe još jedna značajna prednost Bluetooth-a je mogućnost povezivanja pametnog telefona sa drugim pametnim telefonima, a da pri tome nisu neophodne pristupne tačke [7]. Razvijen je veliki broj aplikacija za praćenje Covid-19 kontakta koje koriste Bluetooth tehnologiju, poput COVIDSafe aplikacije koja se koristi u Australiji, eRouska u Češkoj, STOP COVID – Protego u Poljskoj [7]. Sve navedene aplikacije dostupne su na Google PlayStore-u i imaju preko million preuzimanja. Potrebno je naglasiti da se u ovom slučaju zapravo ne vrši pozicioniranje korisnika, nego isključivo dolazi do razmene podataka između korisnika koji su bili u neposrednom kontaktu. Na ovaj način moguće je implementirati Covid-19 sistem za praćenje kontakta, ali se ne mogu implemetirati dodatne funkcionalnosti za automatizaciju sprovođenja propisanih mera u cilju sprečavanja zaražavanja i širenja infekcije.

Na osnovu razmatranih tehnologija koje bi mogle biti implementirane u osmišljeni sistem, *beacon* tehnologija se ističe dobrim odnosom *price/performanse* i jednostavnošću implementacije.

Osnovni funkcija Covid-19 sistema za praćenje kontakta je identifikacija i obaveštavanje osoba koje su bile u neposrednom kontaktu, u školi, sa osobom kod koje je potvđeno prisustvo korona virusa Covid-19. Student ili zaposleni, kod kojeg je utvrđeno prisustvo Covid-19 virusa, putem aplikacije instalirane na svom telefonu, obaveštava školu o pozitivnom SARS-CoV-2 testu, očitavanjem QR koda sa testa. Verifikacija QR koda vrši se na sajtu republičkog fonda za zdravstveno osiguranje. Nakon uspešne verifikacije vrši se identifikacija osoba sa kojima je zaraženi bio u neposrednom kontaktu. Evropski centar za prevenciju i kontrolu bolesti (ECDC) definisao je dva kriterijama na osnovu kojih se vrši identifikacija osoba koje su bile u neposrednom kontaktu sa zaraženom osobom. Prvi kriterijum odnosi se na rastojanje između osoba, a drugi na dužinu trajanja kontakta. Prema ECDC izveštaju [8] i klasifikaciji kontakta, visok rizik od zaražavanja postoji ukoliko je osoba boravila u zatvorenom prostoru sa zaraženom osobom najmanje 15 minuta na udaljenosti manjoj od 2m. Takođe, prema ECDC izveštaju [9], koji se odnosi na školske ustanove, postoji visok rizik od zaražavanja za sve osobe koje su bile u istoj učionici za zaraženom osobom duže od 15 minuta. Sledeći korak je obaveštavanje osoba, za koje je utvrđeno da su bile u neposrednom kontaktu sa zaraženim, putem aplikacije o datumu i vremenu kontakta. Neophodno je naglasiti da prilikom obaveštavanja osoba koje su bile u neposrednom kontaktu sa zaraženom osobom neći biti otkriven identitet zaražene osobe. Osoba koja je bila u kontaktu samo se obaveštava o datumu i vremenu kontakta, zbog eventualne izolacije i praćenja simptoma. Na Slici 1. prikazani su koraci postupka identifikacije i obaveštavanja osoba o neposrednom kontaktu sa zaraženim.

Sl. 1. Koraci postupka identifikacije i obaveštavanja osoba o neposrednom kontaktu sa osobom kod koje je utvrđeno prisustvo Covid-19 virusa.

Nedostatak ovakvog sistema je taj što se bazirana na tome da će osoba kod koje je utvrđeno prisustvo SARS-CoV-2 virusa dobrovoljno obavestiti ustanovu o pozitivnom testu. Kako bi se utvrdilo da li su student i zaposleni

 ISBN 978-86-7466-930-3

zainteresovani za ovakav sistem izvršeno je anonimno anketiranje na Akademiji tehničko-umetničkih strukovnih studija Beograd, odsek Visoka škola elektrotehnike i računarstva. Anketa sadrži 6 pitanja, sa ponuđenim odgovorima "da" i "ne":

1. Da li biste želeli da se u Školi implementira sistem pomoću kojeg se vrši identifikacija studenata i zaposlenih koji su bili u neposrednom kontaktu sa osobom kod koje je potvrđeno prisutvo Covid-19 virusa?
2. Da li biste na svom telefonu instalirali besplatnu aplikaciju za ove potrebe?
3. Da li biste u okviru aplikacije uneli Vaš broj telefona i JMBG?
4. U slučaju da ste bili u neposrednom kontaktu sa zaraženom osobom da li biste želeli da budete obavešteni putem aplikacije o datumu i vremenu kontakta?
5. U slučaju da se Vi zarazite Covid-19 virusom da li biste obavestili Školu o tome, putem aplikacije?
6. U slučaju da se Vi zarazite Covid-19 virusom da li biste želeli da se osobe koje su bile u bliskom kontaktu sa Vama tokom boravka u Školi obaveste putem aplikacije o datumu i vremenu kontakta? Osobe sa kojima ste bili u bliskom kontaktu dobile bi isključivo podatke o datumu i vremenu kontakta, ali ne o osobi sa kojom su bile u kontaktu.

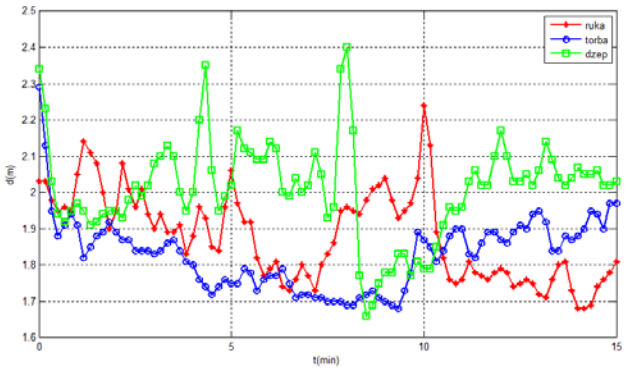
Anketirano je 73 studenata i 17 zaposlenih. Rezultati ankete prikazani su u sekciji III.

III. Glavni rezultati

A. Rezultati ankete

U Tabeli I. prikazani su rezultati ankete za svako pitanje pojedinačno. Iz Tabele I. se vidi da više od 75% anketiranih želi da se u školi implementira sistem za identifikaciju studenata i zaposlenih koji su bili u neposrednom kontaktu sa osobom kod koje je potvrđeno prisustvo virusa Covid-19, i da bi za tu potrebu instalirali besplatnu aplikaciju na svom telefonu. Čak 87.78% anketiranih je spremno da putem aplikacije obavesti školu o pozitivnom SARS-CoV-2 testu. Većina anketiranih, preko 80% želi da bude obavešteno o neposrednom kontaktu, kao i da drugi budu obavešteni. Sa druge strane, 34.44% anketiranih ne želi da unese broj telefona i JMBG u okviru aplikacije. Ovi podaci su neophodni radi verifikacije testa i obaveštavanja korisnika o neposrednom kontaktu.

TABELA I
REZULTATI ANKETE



Pitanje	Odgovor DA	Odgovor NE
1.	75.56 %	24.44 %
2.	75.56 %	24.44 %
3.	65.56 %	34.44 %
4.	81.11 %	18.89 %
5.	87.78 %	12.22 %
6.	84.44 %	15.56 %

Prilikom analize odgovora anketiranih izdvojile su se tri grupe odgovora. 52.22% anketiranih je na sva pitanja odgovorilo sa da, dok je svega 12.22% na sva pitanja odgovorilo sa ne. Takođe uočena je i grupa anketiranih, 15.56%, koja je na sva pitanja sem trećeg dala odgovor da.

B. Rezultati merenja

Na osnovu 128-bitnog UUID (*Universally Unique Identifier*) broja *beacon*-a lako se može izvršiti identifikacija osoba koje su boravile u istoj učionici sa zaraženom osobom duže od 15 minuta. Sa druge strane, identifikacija studenata i zaposlenih koji su proveli više od 15 minuta sa zaraženim na rastojanju manjem od 2 m, u nekom drugom prostoru poput hodnika ili kabineta, zahteva veću preciznost.

Za merenje rastojanja i prijemne snage korišćena je Radius Networks aplikacija *Locate*. Telefon marke Huawei p20 pro korišćen je kao *ibeacon*, pri čemu je predajna snaga podešena na -56dBm. Kao prijemnik korišćen je telefon marke Huawei p30 pro. Telefoni su postavljeni na rastojanju od 2 metra, a merenje je vršeno tokom 15 minuta, za tri slučaja. U prvom slučaju telefon koji je korišćen kao prijemnik nalazi se u ruci, u drugom slučaju u torbi, a u trećem u džepu od pantalona. Na Slici 2. dat je grafički prikaz procenjene udaljenosti tokom vremenskog intervala od 15 minuta, pri čemu je na horizontalnoj osi prikazano vreme u minutima, a na vertikalnoj osi procenjeno rastojanje u metrima, za sva tri slučaja, pri čemu su rezultati beleženi svakih 10 sekundi.

Sl. 2. Procena udaljenosti korisnika od *beacon*-a tokom vremenskog intervala od 15 minuta

Najveće izmereno odstupanje procenjenog rastojanja od realnog iznosi 0.4m. Ovo odstupanje dobijeno je u trećem slučaju, kada se telefon nalazio u džepu. Sa Slike 2. se može uočiti da je za slučaj kada se telefon nalazi u torbi procenjeno rastojanje skoro uvek manje od stvarnog rastojanja. Takođe, u slučaju kada se telefon nalazi u ruci, tokom 81% vremena merenja, rastojanje je procenjeno na manje od stvarnog. Sa druge strane, u slučaju kada se telefon nalazi u džepu, procenjeno rastojanje je veće od stvarnog rastojanja tokom 54% vremena merenja. Ovo je najverovatnije posledica statičnosti telefona i njegovog položaja kada je torbi, dok se u ruci i džepu telefon pomera pa samim tim i dijagram zračenja menja svoj pravac. Srednja greška procenjenog rastojanja za sva tri slučaja, dobijena na osnovu 273 merenja iznosi ±0.14m. Na ovaj način postignuta je preciznost od 74.73%. Pri tome najviša preciznost postiže se u slučaju kada se telefon nalazi u torbi, čak 97.8%, dok se najniža preciznost postiže u slučaju kada se telefon nalazi u džepu, samo 39.56%. Preciznost je definisana kao odnos broja merenja kada je detektovano da se korisnik nalazi na rastojanju manjem ili jednakom od 2 m i rastojanju koje je veće od 2 m.

 ISBN 978-86-7466-930-3

Kako je utvrđeno da srednja greška procenjenog rastojanja iznosi ±0.14 m na dobijene rezultate merenja primenjen je novi kriterijum pri čemu se kao kritično rastojanje uzima 2.14 m. Povećanjem rastojanja sa 2 m na 2.14 m postiže se preciznost od 95.97%. U Tabeli II. dat je pregled preciznosti za sva tri slučaja, pojedinačno, kada se kao kritično rastojanje koristi 2 m i 2.14 m. Kao što se vidi iz Tabele II. promena rastojanja sa 2 m na 2.14 m dovodi do povećanja preciznosti u sva tri slučaja, pri čemu se u trećem slučaju beleži najveći porast preciznosti od čak 50.55%.

TABELA II
PRECIZNOST

	kriterijum 2 m	kriterijum 2.14 m
ruka	82.42 %	98.90 %
torba	97.80 %	98.90 %
džep	39.56%	90.11 %

Na Slici 3. dat je grafički prikaz izmerenog RSSI (*Received Signal Strength Indicator*), za sva tri slučaju, tokom vremenskog intervala od 15 minuta. Srednja vrednost RSSI dobijena sumiranjem svih prikupljenih podataka iznosi -66.07 dBm. Potrebno je naglasiti da postoje mala odstupanja srednje vrednosti RSSI za sva tri slučaja pojedinačno. Minimalna izmerena vrednost RSSI je -71 dBm, a maksimalna -61 dBm.

Sl. 3. Izmerene vrednosti RSSI tokom vremenskog interval od 15 minuta

Pomoću jednačine (1) može se odrediti eksponent slabljenja, *n*. $RSSI_{do}$ predstavlja srednju vrednost izmerenog RSSI na rastojanju od 1m, dok $RSSI_d$ predstavlja srednju vrednost izmerenog RSSI na rastojanju *d* [10].

$$n = \frac{RSSI_{d0} - RSSI_d}{10 \cdot \log d} \quad (1)$$

Na osnovu 20 merenja srednja vrednost RSSI na rastojanju od 1m iznosi -58.20 dBm. Zamenom dobijenih vrednosti u jednačinu (1) dobija se eksponent slabljenja *n*=2.61. Dobijeni eksponent slabljenja odgovara eksponentu slabljenja u poslovnim zgradama, isti sprat, pri frekvenciji od 2.4 GHz, čija se vrednost kreće u opsegu od 1.6 do 3.5 [11].

Izvršena su merenja RSSI i na rastojanjima 0.5 m, 1.5 m, 2.5 m i 3 m. Dobijene vrednosti eksponenta slabljenja prikazane su u Tabeli III. Na osnovu dobijenih rezultata srednja vrednost eksponenta slabljenja iznosi 2.32. Pri eksponentu slabljenja od 2.32 i srednjoj vrednosti RSSI od -66.07 dBm procenjuje se da je korisnik udaljen od *beacon*-a 2.18m, odnosno srednja greška procenjenog rastojanja iznosi ±0.18 m. Dakle, dobijeno je odstupanje od svega ±0.04 m u odnosu na rezultate dobijene merenjem i novo uvedeni kriterijum od 2.14m.

TABELA III
EKSPONENT SLABLJENJA NA RAZLIČITIM RASTOJANJIMA

d	0.5 m	1.5 m	2 m	2.5 m	3 m
n	2.01	2.14	2.61	2.15	2.67

IV. ZAKLJUČAK

U ovom radu je pokazano da je *beacon* tehnologija odličan izbor za implementaciju Covid-19 sistema za praćenje kontakta u zatvorenom prostoru jer nudi niz pogodnosti poput visoke preciznosti, niske cene, jednostavne implementacije, održavanja i nadogradnje.

Sistem koji je prikazan u ovom radu namenjen je za visokoškolske institucije ali se može implementirati i u drugim zatvorenim prostorima poput tržnih centara, bankama, bolnicama, domovima zdravlja, firmi i kompanija sa velikim brojem zaposlenih i sl. U slučaju implementacije sistema npr. u tržnim centrima mogu se iskoristiti već postojeće aplikacije, poput aplikacija Tvoj Centar, Ada Loyalty Club i dr.

Nedostatak opisanog sistema je ograničeno trajanje koje zavisi od završetka pandemije, međutim u visokoškolskim institucijama nakon završetka pandemije sistem se lako može prilagoditi i koristiti za druge potrebe, poput navođenja kandidata po školi prilikom predaje dokumenata, polaganja prijemnog ispita i upisa, evidenciju studenata na nastavi i ispitima, obaveštavanje studenata i zaposlenih o rasporedu nastave, lociranje zaposlenih i sl. Takođe, i u drugim institucijama van obrazovanja po završetku pandemije moguće je prilagoditi sistem konkretnim potrebama u cilju unapređenja radnih procesa, povećanja efikasnosti i zadovoljstva klijenata.

ABSTRACT

This paper discusses the possibility of applying beacon technology to develop solutions that allow monitoring of close contacts and automate the implementation of prescribed measures in real time, in order to prevent spread of infection caused by Covid-19 virus in higher education institutions. For the realization of the system, it is enough that students and employees have a smartphone on which the appropriate application is installed. The system is based on the fact that the student and employees who have been diagnosed with the Covid-19 virus will voluntarily inform the higher education institution about the positive test, through the application. An anonymous survey was conducted to determine whether students and employees are interested in implementing the Covid-19 contact tracking system. Practical measurements were also performed, and the obtained results confirm that beacon technology is an excellent choice for system implementation.

Possibility of applying beacon technologies for the development of Covid-19 contact tracking systems in higher education institutions

Zaštita prenosa paketskog telefonskog saobraćaja upotrebom tehnologije virtuelnih privatnih mreža

Mićo Živanović, Jovan Bajčetić, Ivan Tot

***Apstrakt*—Istraživanje predstavljeno u ovom radu prikazuje jednu realizaciju zaštite paketskog telefonskog saobraćaja primenom tehnologije virtuelnih privatnih mreža kroz konfiguraciju servera za prenos paketskog telefonskog saobraćaja i zaštićeni prenos uz primenu tehnologije virtuelnih privatnih mreža u tunel modu, primenom odgovarajućeg protokola za zaštitu tajnosti, autentifikaciju, zaštitu integriteta i razmenu kriptografskih ključeva. Izvršeno je snimanje i analiza saobraćaja primenom softvera Wireshark u zaštićenom i nezaštićenom prenosu. Prikazani rezultati omogućavaju lakše razumevanje kompleksnog procesa uspostave tunela upotrebom simulacionog softvera u edukaciji.**

***Ključne reči*—paketski telefonski saobraćaj; virtuelne privatne mreže; zaštićena komunikacija; kriptografski ključ.**

I. Uvod

Stalan razvoj Interneta ima za posledicu da je Internet postao univerzalno sredstvo za komunikaciju. U toku razvoja, postavio se zahtev za bezbednošću prenošenih informacija koji se ogledao u obezbeđenju bezbednosnih servisa: autentifikacije, poverljivosti, neporecivosti i integriteta podataka [1]. Razvijeni su sistemi zaštite u tri ravni: upravljačkoj, kontrolnoj i ravni podataka. Za potrebe ovog rada biće razmotreni mehanizmi zaštite u ravni podataka koji se odnose na informacioni saobraćaj. Ravan podataka se štiti pomoću implementiranja pravila (bezbednosnih polisa) po kojima se informacioni sadržaj prenosi upotrebom mrežnih uređaja.

Jedna od tehnologija koja omogućava zaštitu prenosa podataka u ravni podataka je tehnologija virtuelnih privatnih mreža (VPN – Virtual Private Networks). Navedena tehnologija pruža sledeće mogućnosti umrežavanja:
– Intranet, umrežavanje geografski dislociranih objekata;
– Udaljeni pristup mobilnih korisnika (rad od kuće);
– Ekstranet, ograničeni pristup nekoj mreži iz drugih mreža (pristup poslovnih partnera korporativnom WAN-u) [2].

Za realizaciju virtuelne privatne mreže mogu se koristiti periferni korisnički uređaji (host, ruter ili svič), na lokaciji korisnika (CE – Customer Edge) i periferni mrežni uređaji provajdera (PE – Provider Edge).

Virtuelnu privatnu mrežu čini više udaljenih mreža koje su povezane preko Interneta. Zbog korišćenja zajedničkih resursa na Internetu, komunikacija među korisnicima virtuelne privatne mreže se mora zaštititi. Zaštita virtuelne privatne mreže se ostvaruje pomoću barijera koje implementiraju IPSec protokol u tunel modu [3].

VPN tunel je veza između dva PE rutera ili dva CE uređaja koji predstavljaju krajnje tačke tunela [2].

Prema IETF, IP VPN se mogu klasifikovati u zavisnosti od odgovornosti u pogledu upravljanja na:
– VPN kojima upravlja korisnik (Customer Provisioned VPN, CP VPN);
– VPN kojima upravlja provajder servisa (Provider Provisioned VPN, PP VPN) [2].

Prema lokaciji VPN opreme, PP VNP se mogu podeliti na:
– CE – bazirane, kod kojih su krajnje tačke VPN locirane kod korisnika;
– PE – bazirane, kod kojih su krajnje tačke VPN tunela locirane kod provajdera, na PE ruteru.

U zavisnosti od ponuđenog servisa, PE – bazirane VPN se dele na:
– PE – bazirane L2 VPN (koje pružaju servise OSI sloja 2);
– PE – bazirane L3 VPN (koje pružaju servise OSI sloja 3);
– CE – bazirane IP VPN pružaju samo servise OSI sloja 3.

Istovremeno sa razvojem bezbednosnih servisa razvijaju se arhitekture za pružanje različitih komunikacionih servisa koji koriste Internet protokol (telefonija, video, podaci, multimedijalni servisi). Prenos telefonije preko Interneta razvijao se postupno, pre svega zbog prethodno razvijenih sistema klasičnih javnih telefonskih mreža (PSTN) i digitalnih mreža sa integrisanim servisima (ISDN).

U cilju razvoja telefonije zasnovane na komutaciji paketa (VoIP telefonija), razvijene su grupe protokola za prenos VoIP telefonije i povezivanje VoIP telefonije sa telefonijom koja se prenosi u drugim sistemima prenosa (H.323 i SIP protokol) [4].

Prikaz istraživanja u ovom radu će se sastojati iz opisa načina realizacije zaštite informacije korišćenjem VPN tehnologije, a potom u jednoj realizaciji zaštite prenosa paketskog telefonskog saobraćaja upotrebom tehnologije

virtuelnih privatnih mreža, upotrebom IPSec protokola u tunel modu ka udaljenom korisniku, uz prikaz analize mrežnog saobraćaja korišćenjem programskog alata Wireshark.

II. ZAŠTITA PODATAKA PRIMENOM TEHNOLOGIJE VIRTUELNIH PRIVATNIH MREŽA

Za prenos informacionog sadržaja preko Interneta neophodno je obezbediti zaštitu u prenosu. Čest je slučaj da kompanije koriste Internet kao okosnicu za povezivanje svojih filijala ili klijenata kako bi ostvarili prenos podataka za svoje potrebe. Iz navedenog razloga nameće se potreba za zaštitu prenošenog saobraćaja. U tu svrhu koriste se različite tehnologije, od kojih je jedna - tehnologija virtuelnih privatnih mreža. Za realizaciju virtuelnih privatnih mreža na raspolaganju je više tehnologija, zavisno od toga da li se VPN realizuje kao "oblast – oblast" (site–to–site) ili kao "udaljeni pristup" (remote access). U oba navedena slučaja najčešće se koristi IPSec (IP security) protokol.

IPSec protokol štiti pakete između dva uređaja u mreži [3].

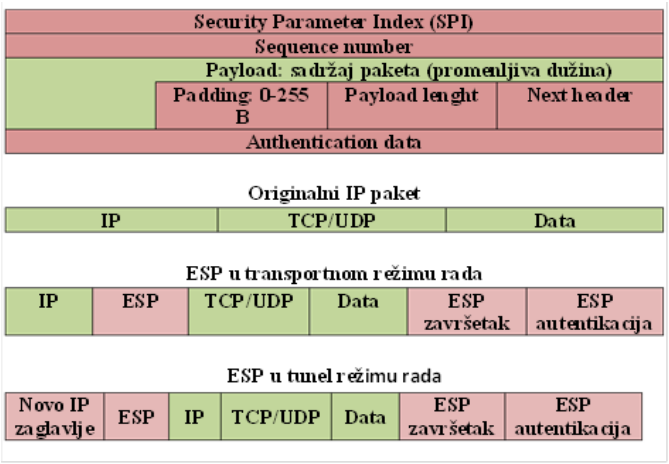
Uređaji kojima se realizuje IPSec su: server, ruteri, korisnički računari ili specijalizovani hardver. IPsec pruža dve vrste zaštite: autentifikaciju i poverljivost.

Mehanizam autentifikacije osigurava da je primljeni paket zaista poslao onaj ko je u zaglavlju paketa naveden kao izvor i da se paket nije promenio tokom prenosa, dok mehanizam poverljivosti omogućava entitetima u komunikaciji da šifruju poruke kako bi sprečili nepozvana lica da dođu do sadržaja poruka [1]. Za šifrovanje podataka se koriste simetrični algoritmi (DES, 3DES, AES), što zahteva pouzdanu razmenu ključeva strana u komunikaciji i za tu svrhu se koriste protokoli za autentifikaciju (neki od protokola iz IETF (IKE - Internet Key Exchange) standarda) [3].

Razvoj bezbednosti u arhitekturi Interneta se odvijao postepeno u čemu je značajno mesto imala Radna grupa za inženjering Interneta (IETF – Internet Engineering Task Force). Sâmo uvođenje standarda je išlo postepeno. Prvi u nizu standard IETF koji se odnosio na bezbednost u arhitekturi Interneta bio je standard RFC 1636 (Request for Comments). Standard se odnosio na osnove bezbednosti Interneta (upotreba firewall – a, servis autentifikacije, privatnost i dr.) [5].

Da bi se adekvatno razumeo način formiranja VPN sesije in a pravi način predstavio prilikom edukacije, biće razmotreno nekoliko najvažnijih dokumenata IETF kojima su definisani režimi rada VPN, mehanizam autentifikacije, razmena kriptografskih ključeva i zaštita poverljivosti.

IPSec koristi dva protokola za bezbednost: AH (Authentication Header) i ESP (Encapsulating Security Payload). Zaglavlje autentifikacije (AH) je definisano specifikacijom RFC 4302 (IP Authentication Header), dok je ESP enkapsulirajuće bezbedno pakovanje (Encapsulating Security Payload) definisan specifikacijom RFC 4303. AH i ESP podržavaju dva režima rada: transportni režim i tunelovanje.



U transportnom režimu AH autentifikuje IP koristan sadržaj i odabrane delove IP zaglavlja, dok ESP šifruje i opciono autentifikuje IP koristan sadržaj. Tunelovanje vrši zaštitu celog IP paketa. Navedeno se postiže nakon dodavanja AH i ESP polja i tretiranja celog paketa kao korisnog sadržaja novog spoljnog IP paketa sa novim IP zaglavljem.

U režimu tunelovanja ESP šifruje i opciono autentifikuje ceo unutrašnji IP paket, uključujući unutrašnje IP zaglavlje, dok AH u režimu tunelovanja autentifikuje ceo unutrašnji IP paket i odabrane delove spoljnog IP zaglavlja [1].

Redosled postupaka sa paketima za rad ESP u transportnom i tunel režimu, je sledeći:

– U transport režimu blok podataka koji se sastoji od segmenta transportnog sloja sa dodatim ESP završnim blokom se šifruje, sa dodatim zaglavljem za autentifikaciju (opciono);

– U režimu tunelovanja, ESP se koristi za šifrovanje celog IP paketa, ESP zaglavlje ide ispred paketa i šifruje se paket zajedno sa ESP završnim blokom.

Sl. 1 Opseg ESP šifrovanja u transportnom i tunel modu [6]

Sl. 1 prikazuje format jednog ESP paketa. Indeks bezbednosnih parametara (SPI) definiše jednu bezbednosnu asocijaciju kojom se određuje algoritam šifrovanja i autentifikacije, ključevi, inicijalizacione vrednosti, životni vek ključeva i vezani parametri koji se koriste uz ESP. Broj sekvence je vrednost brojača paketa kojom se sprečava ponavljanje paketa. Sadržaj paketa je promenljive dužine i predstavlja segment transportnog sloja (transport režim) ili IP paket (tunel režim). U tunel modu, celom paketu se dodaje novo IP zaglavlje koje ima dovoljno informacija za rutiranje, ali ne i za analizu saobraćaja [6].

Važan deo IPSec koji se odnosi na upravljanje ključevima obuhvata određivanje i distribuciju ključeva. Dokumentom RFC 4301 definisane su dve vrste upravljanja ključevima:

– Ručno (administrator definiše sistem sopstvenim ključevima i ključevima drugih sistema sa kojima komunicira);

– Automatizovano (omogućava generisanje ključeva za bezbednosnu asocijaciju na zahtev koji je pogodan za velike sisteme sa rastućom konfiguracijom) [7].

Protokol koji se koristi za automatizovano upravljanje ključevima za IPSec je ISAKMP (Internet Security

 ISBN 978-86-7466-930-3

Association and key Management Protocol) i definisan je dokumentom IETF RFC 2408. ISAKMP definiše procedure za kreiranje i upravljanje bezbednosnim asocijacijama, tehnike generisanja ključeva, ublažavanje pretnji (npr. od DDoS napada) [8].

ISAKMP ne nalaže konkretan algoritam za razmenu ključeva, već se sastoji od jednog skupa tipova poruka koje omogućavaju upotrebu raznovrsnih algoritama za razmenu ključeva.

Karakteristike IKE određivanja ključeva su:
– Osujećenje DDoS napada;
– Omogućava razmenu ključeva za pregovaranje oko grupe ključeva;
– Obezbeđuje od napada ponavljanjem korišćenjem jednokratnih brojeva;
– Omogućava razmenu javnih ključeva;
– Onemogućava napad tipa "čovek u sredini".

IKE potprotokol obezbeđuje dogovaranje protokola, algoritama i ključeva između učesnika u komunikaciji, proverava autentičnost učesnika koji učestvuju u postupku dogovaranja, omogućava razmenu podataka na osnovu kojih će se generisati ključevi i upravljati razmenom ključeva. IKE potprotokol obavlja se u dve faze [9].

U prvoj fazi dva učesnika uspostavljaju bezbedni komunikacioni kanal kojim će se obaviti dogovaranje bezbednosnih parametara i razmena ključeva. Dogovaranje parametara i razmena ključeva, odnosno uspostava bezbednosne asocijacije obavlja se u drugoj fazi. Za sprovođenje postupka koriste se tri načina razmene informacija, dva za prvu fazu i jedan za drugu fazu IKE potprotokola:
– Osnovni način;
– Agresivni način;
– Brzi način.

Osnovni način razmene informacija (engl. Main mode) koristi se u prvoj fazi IKE potprotokola i služi da bi se uspostavio bezbednosni komunikacioni kanal kojim će se obaviti razmena podataka potrebnih za kasniju komunikaciju AH ili ESP potprotokolima.

Agresivni način razmene, slično kao i osnovni, koristi se u prvoj fazi IKE potprotokola i služi za uspostavljanje sigurnog komunikacionog kanala za dogovor učesnika i ne obavlja se kroz bezbedni kanal. Agresivni način koristi samo tri poruke u razmeni i nešto je jednostavniji i brži od osnovnog načina, ali se dokazivanje identiteta ne vrši kroz bezbedan kanal.

Nakon uspostave bezbednog kanala primenom osnovnog ili agresivnog načina razmene, započinje druga faza IKE potprotokola. Druga faza koristi se brzim načinom razmene ključeva koja služi za dogovaranje bezbednosnih parametara komunikacije AH ili ESP potprotokolom i za razmenu tajnih simetričnih ključeva.

III. JEDNA REALIZACIJA ZAŠTITE PAKETSKOG TELEFONSKOG SAOBRAĆAJA UPOTREBOM TEHNOLOGIJE VIRTUELNIH PRIVATNIH MREŽA

U uvodu rada predstavljena je podela VPN prema tome ko je odgovoran za uspostavu zaštićene komunikacije (provajder ili korisnik), kao i koja vrsta servisa se ostvaruje (sloj 2 ili 3 OSI referentnog modela). Predloženi model koje će u nastavku biti prikazan omogućava realizaciju jedne VPN koja bi predstavljala primer uspostave zaštite VoIP putem VPN za koju je „odgovoran" provajder, na OSI sloju 3 i da se primenom programskog alata „Wireshark" snimi i analizira ostvareni saobraćaj. Za navedene potrebe je uspostavljena mrežna topologija prikazana na Sl. 2.

Ruteri predstavljaju periferne rutere provajdera na kojima se vrši konfigurisanje VPN konekcije, po modelu "oblast – oblast". Na ruteru 1 su konfigurisani i uspostavljeni VPN, VoIP i DHCP server.

VPN server je konfigurisan sledećim parametrima:
– ISAKMP razmena kripto ključeva (policy 10);
– Kripto algoritam 3DES;
– Algoritam za autentifikaciju MD5 [10];
– Rad u tunel modu.

VoIP server je određen sledećim parametrima:
– Konekcija SIP protokolom;
– Kodek g711 ulaw.

Za razumevanje rada VoIP, ukratko će biti objašnjen prenos signalizacije i kontrola saobraćaja u VoIP prenosnim sistemima, u kojima se najčešće koriste H.323 i SIP protokoli.

H.323 preporuka je deo familije ITU-T preporuka sa zajedničkom oznakom H.32x koje se odnose na multimedijalne komunikacije preko različitih mreža. H.323 definiše protokole zadužene za usluge multimedijalnih komunikacija preko mreža zasnovanih na komutaciji paketa. H.323 se najčešće koristi kao signalizacioni i kontrolni protokol u VoIP i za video konferencije, a bio je prvi standard koji je koristio RTP protokol (Real-time Transfer Protocol) za konkretni prenos audio i video signala preko mreže.

H.323 je standard koji omogućava multimedijalnu komunikaciju preko različitih mreža (usko pojasne ISDN, širokopojasne B-ISDN, lokalne računarske mreže, mreže na bazi komutacije kola). Cilj je postizanje interoperabilnosti sa različitim mrežama za prenos multimedijalnih informacija, kroz upotrebu zajedničkih preporuka, procedura i poruka, kao i uvođenjem komponente mrežnog prolaza. H.323 standard predstavlja skup protokola namenjenih za obavljanje različitih funkcija u okviru H.323 sistema i to: audio kodere i dekodere, video kodere i dekodere, signaliziranje poziva, kontrola poziva, protokol prenosa u realnom vremenu (RTP), protokol kontrole prenosa u realnom vremenu (RTCP), registraciju, pristup i status i ostale protokole za prenos podataka u realnom vremenu [4].

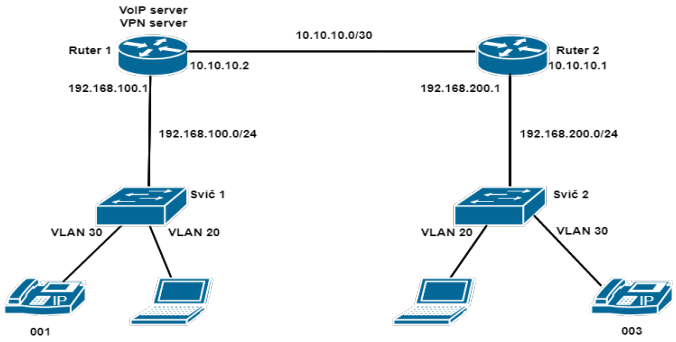
 ISBN 978-86-7466-930-3

SIP je protokol za uspostavljanje, modifikaciju i raskidanje multimedijalnih sesija u paketskim mrežama. SIP u kombinaciji sa drugim protokolima se koristi za opis karakteristika sesije potencijalnim učesnicima [11]. SIP je delo IETF (Internet Engineering Task Force) i razvijen je kao mehanizam za uspostavljanje raznovrsnih sesija, a može se koristiti za unicast i multicast komunikaciju. SIP je peer-to-peer protokol, što znači da nije centralizovan, već je servisna inteligencija izmeštena prema krajevima mreže ka krajnjim korisnicima, kao kod računarskih mreža. U okviru SIP poruka se najčešće prenosi SDP (Session Description Protocol), mada standard ostavlja otvorenim i druge mogućnosti [12].

H.323 i SIP su dva konkurentska protokola za multimedijalne komunikacije na paketskim mrežama.

SIP se odlikuje sledećim prednostima:

– Fleksibilnost (omogućava korišćenje sa različitim transportnim i drugim protokolima);
– Arhitektura i osobine mu se prirodno uklapaju Internet okruženje, dok H.323 ima neke osobine protokola fiksne telefonije;
– Poseduje mnoga proširenja potrebna za različite sisteme ličnih komunikacija (prisutnost, instant poruke, posredno upravljanje pozivom) [13].



DHCP server je uspostavljen za opseg adresa koji obezbeđuje formiranje logički odvojenih mreža sa opsegom adresa 20.20.20.0 i 30.30.30.0 u različitim virtuelnim lokalnim mrežama. Prema mrežnoj topologiji formirane su dve LAN mreže u okviru kojih je izvršeno razdvajanje saobraćaja (telefonskog i podaci), uspostavom dve VLAN na OSI sloju L2, konfigurisanjem svičeva 1 i 2 (VLAN 20 i 30), dok je po jedan interfejs na svičevima konfigurisan kao trank interfejs [14]. Nakon provere konektivnosti, uspostavljen je paketski telefonski saobraćaj bez zaštite pomoću virtuelne privatne mreže i realizovano snimanje saobraćaja, upotrebom programskog alata "Wireshark". Rezultat i procesi analize nezaštićenog saobraćaja prikazani su u Tabeli 1. Uspostavljena je VPN sesija između dva rutera i realizovano snimanje saobraćaja u zaštićenom modu. Procesi u toku uspostave zaštićenog paketskog telefonskog saobraćaja prikazani su u Tabeli 2.

Za realizaciju mrežne topologije na slici 2 korišćena je sledeća mrežna oprema:

– CISCO 2900 ruter…….2 kom;
– CATALIST 3650 svič ……..2 kom;
– Računar sa ETH mrežnim interfejsom…. 2 kom;
– IP telefoni……..2 kom.

Procesi prikazani u Tabeli 1, a koji se odnose na uspostavu i održavanje nezaštićenog telefonskog saobraćaja prikazuju proces uspostavljanja prisutnosti uređaja u mreži i utvrđivanja mrežnih usluga (SSDP), uspostavu logičke topologije mreže i saobraćaja protokola za sprečavanje petlji (STP). Pozivanjem jednog korisnika od strane drugog korisnika ustanovljava se IP adresa pozvanog korisnika kroz broadcast upit od strane pozivajućeg korisnika (ARP proces). Kroz DNS proces se povezuju IP adresa i ime domena pozvanog korisnika. Istovremeno se šalje poruka radi utvrđivanja dostupnosti korisnika (ICMP poruka). U toku uspostave VoIP komunikacije šalje se "hello poruka" u OSPF procesu, radi konstruisanja putanje između dva rutera. Kroz SIP signalizaciju vrši se pozivanje jednog od strane drugog korisnika, nakon čega se ostvaruje TCP sesija kroz proces "trostrukog rukovanja". U sklopu SIP procesa razlikuju se faze (traying, ringing i OK), u kojima se mogu uočiti status procesa pozivanja, koji se na kraju završava uspešnom uspostavom komunikacije. Ceo proces je praćen slanjem kontrolnih TCP poruka (ACK), kojima se određuje broj bajtova koji se može poslati pre dobijanja sledeće dozvole za slanje, kao i slanjem poruka kojima se vrši sinhronizacija uspostave TCP sesije (SYN). Poseban segment kontrole komunikacije predstavlja kontrola konektivnosti na L2 nivou (LOOP). Dalji proces komuniciranja je praćen razmenom paketa u realnom vremenu (RTP) koji nose govorni informacioni sadržaj.

Procesi prikazani u Tabeli 2, a koji se odnose na uspostavu i održavanje zaštićenog telefonskog saobraćaja, pored na početku navedenih procesa u nezaštićenom prenosu, sadrži proces razmene kripto ključeva u procesu uspostave IPSec tunela (ISAKMP). Specifično za proces prenosa u zaštićenom modu je uspostavljen trank između dva sviča na kojima su konfigurisane dve VLAN (DTP).

Sl. 2 Mrežna topologija za potrebe jedne realizacije zaštite paketskog telefonskog saobraćaja upotrebom tehnologije virtuelnih privatnih mreža

Prikazana realizacija mrežne topologije, snimanje i analiza mrežnog saobraćaja omogućava detaljno razumevanje uspostave VPN tunela, uz upotrebu simulacionog softvera, kao i praćenje procesa razmene informacionog sadržaja u realnom vremenu. Tokom procesa prenosa informacionog sadržaja u realnom vremenu, periodično se uočavaju procesi uspostavljanja prisutnosti uređaja u mreži (SSDP), obaveštavanja o nedostupnosti uređaja u slučaju prekida konektivnosti (ICMP poruke) i razmena "hello" poruka u OSPF procesu. Navedena realizacija stoga omogućava potpun uvid u sve procese u toku prenosa paketskog telefonskog saobraćaja, što može poslužiti u edukaciji i o procesima prenosa multimedijalnih informacionih sadržaja.

IV. ZAKLJUČAK

Rezultat jedne realizacije zaštite paketskog telefonskog saobraćaja, predstavljen u ovom radu prikazuje da uspostava i održavanje VPN tunela kao načina zaštite paketskog telefonskog saobraćaja podrazumeva primenu niza protokola, specifično dizajniranih za prenos informacionih sadržaja u realnom vremenu (SIP, SSDP, RTP) kao i protokola za obezbeđenje zaštite u toku prenosa (ISAKMP, IPSec). Specifično za predstavljenu realizaciju predstavlja upotreba linka za prenos različitih servisa i time korišćenje protokola kojima se omogućava konvergencija servisa u prenosu (DTP, SSDP).

ABSTRACT

The research presented in this paper addresses an example of how to execute packet telephone traffic protection using virtual private network technology through configuring servers for packet telephone traffic and also demonstrates the secure transfer with the use of virtual private network technology in tunnel mode by applying the appropriate protocols for privacy protection, authentication, integrity protection and crypto key exchange. Traffic recording and analysis has been performed using the Wireshark software in both secure and non-secure transfer. The results obtained can help better understand the complex process of setting up a tunnel through the use of simulation software in education.

Packet Telephone Traffic Transfer Protection Using Technology of Virtual Private Networks

LDPC dekoderi sa reinicijalizacijama koji objedinjuju tvrde odluke i razmenu mekih poruka

Predrag Ivaniš, *Senior Member, IEEE*, Srđan Brkić, *Member, IEEE* i Bane Vasić, *Fellow, IEEE*

***Apstrakt* — U ovom radu predloženi su postupci koji kombinuju dve klase iterativnih algoritama koje se uobičajeno koriste za dekodovanje zaštitnih kodova sa proverama parnosti male gustine (eng. Low Density Parity Check, LDPC). Prva strategija zasnovana je na bit-fliping algoritmu male kompleksnosti, a predložena modifikacija omogućava značajno poboljšanje performansi dekodera uz zadržavanje male prosečne računske kompleksnosti. Druga strategija zasnovana je na algoritmu sa propagacijom verodostojnosti i za cilj ima dodatno poboljšanje korekcionih sposobnosti dekodera, naročito kada se koriste kodovi sa malom dužinom kodne reči.**

***Ključne reči* — Bit-fliping algoritam, belief-propagation algoritam, iterativno dekodovanje, kodovi sa proverama parnosti male gustine.**

I. UVOD

KODOVI sa proverama parnosti male gustine (eng. Low Density Parity Check, LDPC) predloženi su od strane Roberta Galagera 1960. godine [1], a posebno veliku popularnost su doživeli u poslednjoj deceniji XX veka [2], [3]. Njihova sposobnost da dostignu kapacitet kanala uz relativno nisku kompleksnost dekodovanja [4] učinila ih je poželjnim rešenjem za obezbeđivanje pouzdanog prenosa podataka u bežičnim telekomunikacionim sistema novije generacije. Ovi kodovi se danas koriste u digitalnoj televiziji (eng. Digital Video Broadcasting, DVB) [5], bežičnim lokalnim mrežama (eng. Wireless Local Area Networks, WLAN) [6], a od skora su uvršteni i u standard za petu generaciju širokopojasnih mobilnih mreža (5G) [7].

Poboljšanje performansi sistema usled primene LDPC kodova pre svega je diktirano algoritmom koji se koristi za njihovo dekodovanje. Ovi algoritmi su po pravilu iterativni i implementiraju se nad Tanerovim grafom [8], koji je u potpunosti određen matricom provere parnosti koja definiše kod. U najvećem broju slučajeva, optimalne performanse se postižu ako se pri dekodovanju koristi tzv. algoritam propagacije verodostojnosti (eng. belief-propagation, BP), kod koga čvorovi u grafu razmenjuju poruke na osnovu kojih se procena kodne reči po pravilu poboljšava u svakoj narednoj iteraciji. Verzija BP algoritama pogodna za primenu u dekoderima LDPC kodova poznata je i pod nazivom algoritam sumiranja i množenja (eng. Sum Product Algorithm, SPA), a više detalja vezanih za njegovu efikasnu implementaciju može se naći u radu [9].

Predrag Ivaniš – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: predrag.ivanis@ etf.bg.ac.rs).

Srđan Brkić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: srdjan.brkic@ etf.bg.ac.rs).

Bane Vasić – Department of Electrical and Computer Engineering, University of Arizona, Tucson, AZ 85721 USA (e-mail: vasic@ece.arizona.edu).

Mana BP algoritma je velika složenost implementacije. Računske operacije koje se izvode u čvorovima Tanerovog grafa mogu biti veoma kompleksne, a pritom se podrazumeva da su poruke koje se razmenjuju realni brojevi. Pri hardverskoj implementaciji poželjno je da se operacije u čvorovima pojednostave i da se poruke predstave sa konačnom preciznošću (implementacija sa fiksnim zarezom). Stoga se u većini postojećih sistema koriste podoptimalne verzije BP algoritma, kao što su razne vrste min-sum algoritma [10]. Drugi značajan nedostatak BP algoritma je vezan za činjenicu da je on optimalan samo ako Tanerov graf ima oblik stabla. Ako se u grafu pojavljuju ciklusi male dužine, performanse BP algoritma su daleko od performansi koje bi bilo moguće dobiti primenom algoritma koji postiže maksimalnu verodostojnost pri odlučivanju (eng. Maximum Likelihood, ML). Ovo je posebno izraženo za kratke kodove. U literaturi se mogu naći rešenja koja obezbeđuju bolje performanse od BP algoritma za isti broj iteracija [11], a koja sa povećanjem broja iteracija obezbeđuju performanse bliske ML granici [12].

Sa druge strane, algoritam koji u svakoj iteraciji invertuje određene bitove kodne reči (eng. bit-flipping, BF) predstavlja postupak izuzetno niske kompleksnosti. Iako originalni BF algoritam ima prilično loše performanse po pitanju ispravljanja grešaka, isto se ne može reći i za nedavno predloženu modifikaciju BF algoritma nazvanu bit fliping algoritam sa gradijentnim spustom (eng. Gradient Descent Bit Flipping, GDBF) [13]. U našem prethodnom radu [14] predložen je probabilistički GDBF algoritam (PGDBF), kod koga primena slučajne sekvence pri dekodovanju omogućava ispravljanje kombinacije grešaka koje klasičan GDBF algoritam ne može korigovati. Dalje unapređenje ove ideje je razmotreno u radu [15]. Kombinovanje PGDBF algoritma i slučajnih reinicijalizacija može u velikoj meri poboljšati performanse dekodera (odgovarajući algoritam MUDRI je izložen u radu [16]). Analiza data u radovima [17]-[20] pokazuje da dekoderi bazirani na tvrdom odlučivanju uz slučajne reinicijalizacije obezbeđuju performanse bliske ML granici, ukoliko se može dozvoliti veliki broj iteracija pri dekodovanju.

Nedavno je pokazano da se performanse GDBF algoritma mogu približiti performansama BP algoritma, ako se destimuliše invertovanje istog bita u nekoliko uzastopnih iteracija [21]. Kombinacija tog pristupa sa determinističkim reinicijalizacijama ima potencijal da omogući čak i bolje performanse od BP algoritma, uz znatno manju računsku kompleksnost [22].

U nastavku će biti razmotreno nekoliko strategija za kombinovanje BP i GDBF algoritma, sa ciljem da se postigne veća pouzdanost odlučivanja ili manja kompleksnost implementacije, koristeći prednosti jednog i drugog pristupa.

 ISBN 978-86-7466-930-3

II. MODEL SISTEMA I PREGLED TIPIČNIH ALGORITAMA ZA DEKODOVANJE LDPC KODOVA

U ovom radu posmatramo binarne LDPC kodove kod kojih je informaciona reč $\boldsymbol{i}$ dužine k, dok je odgovarajuća kodna reč $\boldsymbol{x}$ dužine n. Ovi kodovi se označavaju sa (n,k), a njihov kodni količnik iznosi $R=k/n$.

LDPC kod se opisuje matricom provere parnosti $\boldsymbol{H}$, dimenzija $n\times m$, koja je po pravilu retka (broj jedinica u ovoj matrici je znatno manji od broja nula). U ovom radu će biti razmotreni kodovi kod kojih u svakoj koloni matrice $\boldsymbol{H}$ ima tačno γ jedinica, dok svaka vrsta matrice $\boldsymbol{H}$ sadrži tačno ρ jedinica (regularni kodovi). Parametri γ i ρ nazivaju se težina kolona i težina vrsta, respektivno. Odgovarajući bipartitni graf $\mathcal{G}$ sastoji se od skupa varijabilnih čvorova $\boldsymbol{V} = \{v_1, v_2, ..., v_n\}$ i skupa čvorova provere parnosti $\boldsymbol{C} = \{c_1, c_2, ..., c_m\}$. Čvorovi v_i i c_j su susedi ako su povezani na grafu, tj. ako je ispunjeno $\boldsymbol{H}_{ij}=1$. Skup suseda čvora v_i je označen sa N_{v_i}, dok je skup suseda čvora c_j označen sa N_{c_j}.

Nakon što LDPC koder od informacione reči $\boldsymbol{i}$ formira kodnu reč $\boldsymbol{x}$, ona se prenosi kroz binarni simetrični kanal (BSC). Ovaj kanal unosi nasumične, tj. vremenski nekorelisane, greške sa verovatnoćom p. Odgovarajuća sekvenca greške $\boldsymbol{e}$ može se dobiti uz pomoć generatora slučajne promenljive sa Bernulijevom raspodelom $B(1, p)$. U ovom slučaju, primljena reč $\boldsymbol{y}$ na izlazu kanala formira se tako što se poslata kodna reč $\boldsymbol{x}$ sabere bit-po-bit sa sekvencom greške $\boldsymbol{e}$, tj. $\boldsymbol{y}=\boldsymbol{x}\oplus\boldsymbol{e}$.

Primljena reč se dovodi na ulaz dekodera koji ima zadatak da verno rekonstruiše poslatu kodnu reč, odnosno poslatu informacionu sekvencu (koju treba dostaviti odredištu). Pošto je izdvajanje informacione sekvence prilično jednostavno ako se ispravno rekonstruiše poslata kodna reč, pri analizi dekodera se teži da procena kodne reči bude što je moguće pouzdanija. Drugim rečima, treba minimizovati verovatnoću da se procena poslate kodne reči, označena sa $\hat{\boldsymbol{x}}$, razlikuje od poslate reči $\boldsymbol{x}$. Ova verovatnoća se obično naziva verovatnoća greške po kodnoj reči (eng. Word Error Rate, WER). Iterativni dekoder procenu poslate kodne reči po pravilu poboljšava iz iteracije u iteraciju, čime se omogućava da i za prilično duge kodne reči kompleksnost dekodera ostane relativno mala [10].

Dekoder u svakoj iteraciji proverava da li su sve provere parnosti zadovoljene. Kada je ovaj uslov ispunjen, proces dekodovanja se prekida (tada procena odgovara kodnoj reči). Obično se zadaje maksimalan broj iteracija koje se mogu iskoristiti za dekodovanje, označen sa L.

Neka je procena kodne reči u l-toj iteraciji označena sa $\hat{\boldsymbol{x}}^{(l)}$, $l=1,2,...,L$. Odgovarajući sindrom $\boldsymbol{S}^{(l)}=\hat{\boldsymbol{x}}^{(l)}\boldsymbol{H}^T$ ima sve komponente ravne nuli samo u slučaju da su sve provere parnosti zadovoljene. Ako dekoder tokom L uzastopnih iteracija ne formira procenu za koju je $\mathbf{S}^{(l)}=\mathbf{0}$, dekodovanje se proglašava neuspešnim. Ukoliko se dekodovanje prekine za $l_0\leq L$ i ako je $\hat{\boldsymbol{x}}^{(l_0)}=\boldsymbol{x}$, smatra se da je ta kodna reč uspešno dekodovana nakon l_0 iteracija.

U današnjim telekomunikacionim sistemima i sistemima za zapis podataka obično se za dekodovanje LDPC kodova koriste dve klase algoritama. Jedna je zasnovana na BP algoritmu, koga odlikuju visoka pouzdanost pri dekodovanju i velika složenost implementacije. Druga klasa algoritama je zasnovana na BF postupku, koji je daleko jednostavniji ali uz nešto veću verovatnoću greške pri odlučivanju. Osnovne karakteristike dve pomenute klase algoritama, kao i njihovih varijanti, navedene su u nastavku.

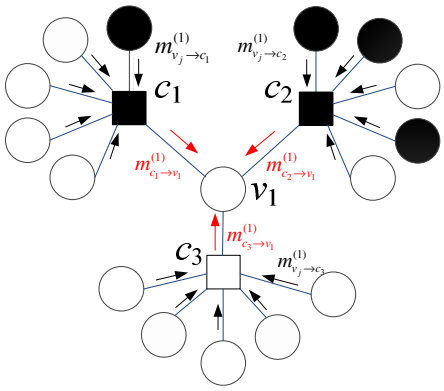
A. *Algoritmi sa propagacijom verodostojnosti*

Poznato je da se LDPC kodovi mogu uspešno dekodovati korišćenjem algoritama kod kojih se poruke iterativno razmenjuju između povezanih čvorova u grafu (eng. message-passing). Poruke koje se razmenjuju mogu biti veoma jednostavne, kao kod Galager-A/B algoritma (binarne poruke), ali se znatno bolji rezultati dobijaju ako ove poruke imaju oblik realnih brojeva.

Osnovna ideja BP algoritma će biti ilustrovana na grafu prikazanom na slici 1, gde su ispravno primljeni biti kodne reči označeni belim varijabilnim čvorovima, dok pogrešno primljenim bitima odgovaraju crni čvorovi. Zadovoljene provere parnosti označene su belim, a nezadovoljene crnim kvadratima. U BP algoritmu poruke koje varijabilni čvorovi inicijalno šalju ka povezanim proverama parnosti zavise samo od verovatnoće greške u binarnom kanalu

$$m^{(1)}_{v_i\to c_j}(v_i=0\,|\,y_i)=P(v_i=0\,|\,y_i)=\begin{cases}p, & y_i=1,\\ 1-p, & y_i=0,\end{cases} \qquad (1)$$

a pošto su u pitanju verovatnoće, jasno je da se može pisati $m^{(1)}_{v_i\to c_j}(v_i=1\,|\,y_i)=1-m^{(1)}_{v_i\to c_j}(v_i=0\,|\,y_i)$. Intenzitet ovih poruka srazmeran je uverenosti čvora v_i da bi mogao da ima vrednost $v_i=a$, kada mu je poznata primljena vrednost y_i.



Imajući u vidu da vrednosti varijabilnih čvorova treba da odgovaraju bitima validne kodne reči (za koju su sve provere parnosti ravne nuli), u narednim iteracijama su poruke koje se razmenjuju između čvorova na Tanerovom grafu određene izrazima [10]

$$m^{(l)}_{c_j\to v_i}(v_i=0)=\frac{1}{2}\left(1-\prod_{v_k\in N_j\setminus v_i}\left(2m^{(l)}_{v_k\to c_j}(v_k=1)-1\right)\right), \qquad (2)$$

$$m^{(l+1)}_{v_i\to c_j}(v_i=0)=P(v_i=0\,|\,y_i)\prod_{c_z\in N_i\setminus c_j}m^{(l)}_{c_z\to v_i}(v_i=0), \qquad (3)$$

a jasno je da i dalje važi $m^{(l)}_{c_j\to v_i}(v_i=1)=1-m^{(l)}_{c_j\to v_i}(v_i=0)$, $m^{(l+1)}_{v_i\to c_j}(v_i=1\,|\,y_i)=1-m^{(l+1)}_{v_i\to c_j}(v_i=0\,|\,y_i)$. Verovatnoća da je v_i=0 se sada ažurira na osnovu uverenja povezanih čvorova

$$P^{(l)}(v_i=0)=P(v_i=0\,|\,y_i)\prod_{c_z\in N_i}m^{(l)}_{c_z\to v_i}(v_i=0). \qquad (4)$$

Sl 1. Ilustracija BP algoritma na grafu koji odgovara regularnom kodu sa parametrima γ=3, ρ=5.

 ISBN 978-86-7466-930-3

Na ovaj način se uverenost čvora o vrednostima koje na njega povezani čvorovi treba da imaju, pod datim uslovima, po pravilu poboljšava iz iteracije u iteraciju, što obično rezultuje sve pouzdanijim odlukama. Da bi se ublažili numerički problemi, BP algoritam se obično implementira u logaritamskom domenu, tako što se u svakoj iteraciji određuje logaritamski količnik verodostojnosti [8]

$$LLR_i^{(l)} = \log\left(P^{(l)}(v_i=1)/P^{(l)}(v_i=0)\right). \quad (5)$$

Ipak, uvek treba imati na umu da je BP algoritam optimalan samo u slučaju da je graf oblika stabla. Ovo nije ispunjeno kada u grafu postoje ciklusi male dužine, a posebno je kritično kada je dužina kodne reči mala.

B. *Bit-fliping algoritmi*

Bit-fliping algoritam je jednostavan postupak iterativnog dekodovanja LDPC kodova, koji je predložio Galager [1]. Algoritam je zasnovan na određivanju broja nezadovoljenih provera parnosti koje su povezane na svaki varijabilni čvor. Ovo izračunavanje se izvodi nad trenutno dostupnom procenom kodne reči, pa tako čvoru v_i u l-toj iteraciji odgovara energetska funkcija oblika

$$\Lambda_{BF}^{(l)}(v_i) = \sum_{c_j \in N_{v_i}} \bigoplus_{v_k \in N_{c_j}} \hat{x}_k^{(l)}. \quad (4)$$

Ukoliko je ova veličina za i-ti bit (i=1,2,…,n) veća od unapred definisanog praga T, vrši se invertovanje tog bita, čime se formira njegova procena u narednoj iteraciji

$$\hat{x}_i^{(l+1)} = \begin{cases} \hat{x}_i^{(l)} \oplus 1, & \Lambda^{(l)}(v_i) \geq T, \\ \hat{x}_i^{(l)}, & \Lambda^{(l)}(v_i) < T. \end{cases} \quad (5)$$

Polazeći od primljenog vektora ($\hat{\boldsymbol{x}}^{(0)} = \boldsymbol{y}$), na ovaj način se u svakoj iteraciji po pravilu formiraju sve pouzdanije procene poslate kodne reči. Ovaj algoritam često greši, pa bi za tipičnu vrednost $T = \gamma/2$ u primeru sa slike 1 bila doneta pogrešna odluka da čvor v_1 treba invertovati.

GDBF algoritam uvodi dve modifikacije – u energetsku funkciju se dodaje korelacioni član koji zavisi od odgovarajućeg bita primljene reči i invertuju se samo vrednosti onih varijabilnih čvorova koje u toj iteraciji imaju maksimalnu vrednost energetske funkcije [13, 14]:

$$\Lambda_{GDBF}^{(l)}(v_i) = y_i \oplus \hat{x}_i^{(l)} + \sum_{c_j \in N_{v_i}} \bigoplus_{v_k \in N_{c_j}} \hat{x}_k^{(l)}, \quad (6)$$

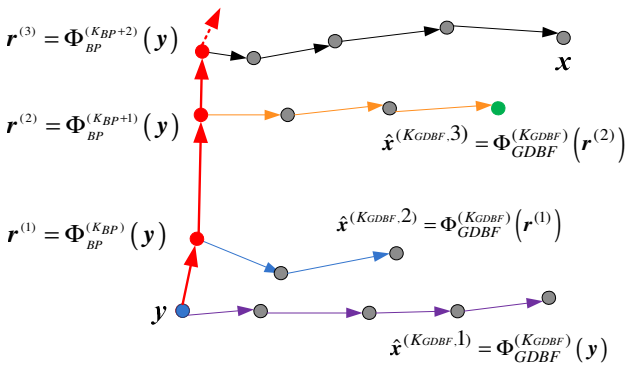
$$\hat{x}_i^{(l+1)} = \begin{cases} \hat{x}_i^{(l)} \oplus 1, & \Lambda^{(l)}(v_i) = \max_i \Lambda^{(l)}(v_i), \\ \hat{x}_i^{(l)}, & \Lambda^{(l)}(v_i) < \max_i \Lambda^{(l)}(v_i). \end{cases} \quad (7)$$

Kod GDBF algoritma sa momentumom (GDBF-w/m) energetska funkcija ima oblik [21]

$$\Lambda^{(l)}(v_i) = \alpha\left(y_i \oplus \hat{x}_i^{(l)}\right) + \beta \sum_{c_j \in N_{v_i}} \bigoplus_{v_k \in N_{c_j}} \hat{x}_k^{(l)} + \mu_i^{(l)}, \quad (8)$$

gde se korelacionom članu i broju nezadovoljenih provera parnosti pridružuju težinski koeficijenti (označeni sa α i β, respektivno), a na čitavu funkciju se dodaje novi član $\mu_i^{(l)}$ (momentum). Vrednost momentuma zavisi od broja iteracija koje su protekle od prethodnog invertovanja tog bita (koji je označen sa w_i) i može uzeti vrednosti definisane momentum vektorom $\mu = [\mu(1), \mu(1), ..., \mu(w_{\max})]$, pri čemu je $\mu(w_i) = 0$ ako je $w_i > w_{\max}$. Pokazano je da ovaj algoritam za neke kodove ima performanse uporedive sa BP algoritmom, naročito za male vrednosti parametra p [21].

III. STRATEGIJE ZA KOMBINOVANJE BF I GDBF ALGORITMA



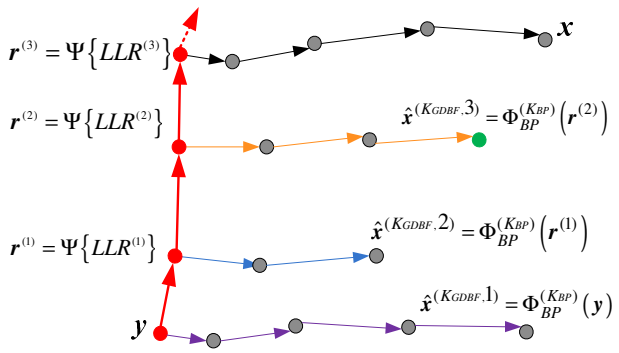
Jasno je da dve prethodno opisane klase algoritama rade na osnovu različitih principa, pa se nameće pitanje da li bi se mogle kombinovati tako da se objedini "najbolje iz dva sveta". Prvi korak u tom smeru učinjen je u radu koji smo nedavno objavili [22], pri čemu se GDBF-w/m algoritam modifikuje samo u nekim iteracijama.

Za razliku od prethodnih istaraživanja, u ovom radu je predlažemo kombinovanje BP algoritma i GDBF algoritma, pri čemu se jedan od njih koristi kao osnovno rešenje, dok se elementi drugog algoritma koriste za reinicijalizaciju ulaza dekodera. Dve takve strategije opisane su u nastavku.

A. *GDBF-w/m kao osnovni algoritam*

U ovoj varijanti se primljena reč dovodi na ulaz GDBF-w/m dekodera i za datu vrednost parametra p posmatra se kako se menja WER u zavisnosti od L. Formalno se može zapisati da GDBF-w/m dekoder nakon l iteracija preslikava $\boldsymbol{y}$ u procenjenu vrednost $\hat{\boldsymbol{x}}^{(l)} = \Phi_{GDBF}^{(l)}(\boldsymbol{y})$. Kada postane jasno da GDBF-w/m u dodatnim iteracijama neće značajno smanjiti WER, dekodovanje se prekida. Broj iteracija nakon koga se dekodovanje prekida je K_{GDBF} i određuje se empirijski. Primljena reč se zatim dovodi na ulaz BP dekodera, koji nakon K_{BP} iteracija na svom izlazu formira procenu $\boldsymbol{r}^{(1)}$, tj. $r^{(1)} = \Phi_{BP}^{(l)}(\boldsymbol{y})$, koja se koristi kao ulaz GDBF-w/m dekodera u novoj rundi. Po potrebi, postupak se ponavlja na način ilustrovan slikom 2, tako što se referenca $\boldsymbol{r}^{(q)}$ dobija kao izlaz BP dekodera nakon K_{BP}+q-1 iteracija, a energetska funkcija se računa na osnovu izraza

$$\Lambda^{(l)}(v_i) = \alpha\left(r_i^{(q)} \oplus \hat{x}_i^{(l)}\right) + \beta \sum_{c_j \in N_{v_i}} \bigoplus_{v_k \in N_{c_j}} \hat{x}_k^{(l)} + \mu_i^{(l)}.$$



Sl 2. Ilustracija prve strategije, osnova je GDBF w/m algoritam, dok procena nakon odgovarajuće iteracije BP algoritma određuje referencu.

B. *BP kao osnovni algoritam*

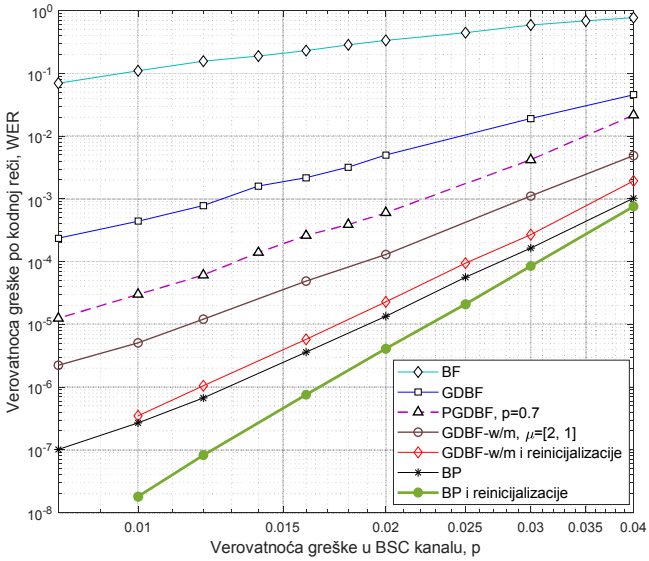
U ovom scenariju se primljena reč dovodi na ulaz BP dekodera. Nakon svake iteracije pronađu se čvorovi v_i kod kojih je $LLR_i^{(l)}$ najveći po apsolutnoj vrednosti, uz uslov da bi taj bit bio invertovan kada bi se odluka donela u toj iteraciji, tj. $LLR_i^{(l)} \times LLR_i^{(0)} < 0$. Ove pozicije se redom zapisuju u odgovarajuću memoriju i čine skup kritičnih čvorova. Ako BP algoritam tokom K_{BP} iteracija ne obavi dekodovanje, postupak se ponavlja za novi ulaz dekodera. Odgovarajuća referenca r_q se formira tako što se u reči $\boldsymbol{y}$ invertuje samo jedan od kritičnih čvorova, pa se može formalno pisati $\boldsymbol{r}^{(q)} = \Psi\{LLR^{(q)}\}$ (videti sliku 3).

 ISBN 978-86-7466-930-3

Sl 3. Ilustracija prve strategije, osnova je GDBF w/m algoritam, dok procena nakon odgovarajuće iteracije BP algoritma određuje referencu.

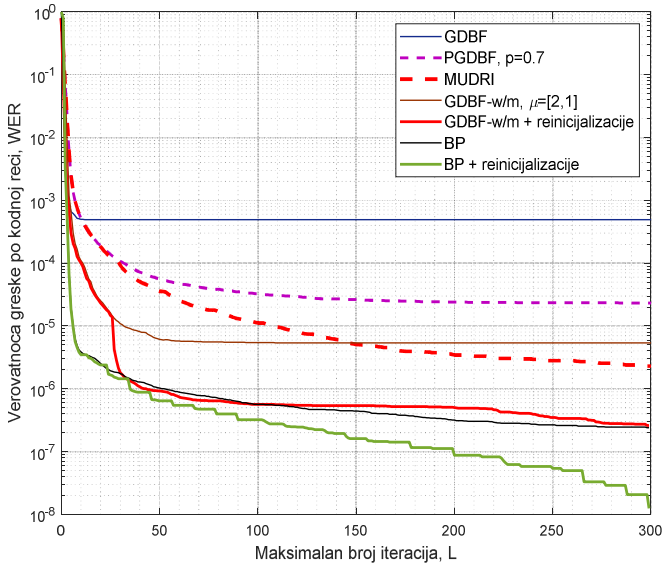
IV. NUMERIČKI REZULTATI

Efekat dve predložene strategije će biti ilustrovan za dva regularna koda, koji su konstruisani koristeći različite postupke, pri čemu oba imaju težinu kolona γ=3 i dužinu najkraćeg ciklusa jednaku g=8. Kodovi imaju male dužine kodnih reči, a poznato je da tada BP algoritam predstavlja podoptimalno rešenje.



Verovatnoća greške po kodnoj reči određena je Monte Karlo simulacijom, pri čemu se generišu kodne reči dužine n i na svaku od njih se superponira slučajno generisan vektor greške iste dužine, generisan u skladu sa zadatom verovatnoćom greške u BSC. Kako bi bili sigurni da je simetrija dekodera zadovoljena, ne šalje se uvek kodna reč "sve nule", već se na izlaz kodera emituju različite kodne reči. U slučaju kada se dekodovanje završi za najviše L iteracija, porede se poslata i procenjena kodna reč, da bi bili sigurni da procena ne odgovara kodnoj reči koja je različita od poslate kodne reči. U slučaju kada se tokom L uzastopnih iteracija ne formira procena kodne reči kod koje su sve provere parnosti jednake nuli, dekodovanje se proglašava neuspešnim. Simulacija za jedan skup parametara se zaustavlja kada se detektuje 200 pogrešno primljenih kodnih reči, što određuje jednu tačku na grafiku.

Performanse dekodera će prvo biti prikazane za regularni Tanerov kod (155,64), koji ima težinu kolona γ=3 i težinu vrsta ρ=5. U pitanju je kvazi-ciklični LDPC kod, a odgovarajući metod konstrukcije predložen je u radu [23]. Ovaj kod se često koristi za testiranje algoritama dekodovanja [11, 24, 25].

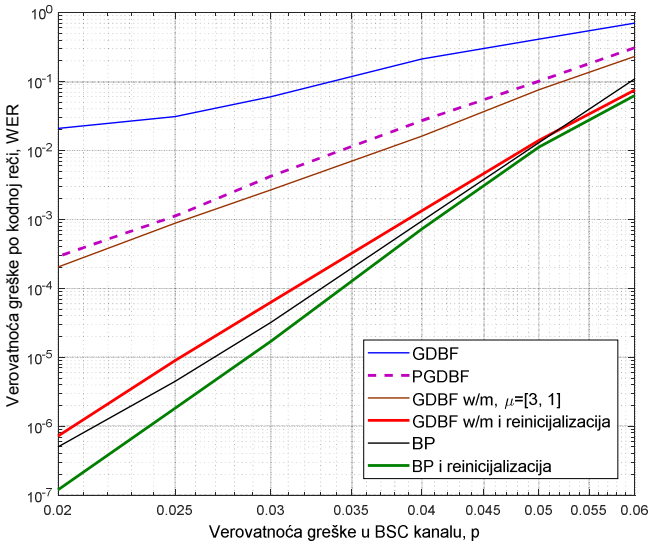


Zavisnost verovatnoće greške po kodnoj reči od verovatnoće greške u BSC prikazana je na slici 4. U slučaju kada BP algoritam određuje samo reinicijalizovane reference od kojih GDBF-w/m počinje dekodovanje u svakoj rundi, kriva je prikazana crvenom punom linijom. Svaka runda traje po K_{GDBF}=25 iteracija i ako se za to vreme ne detektuje da su sve provere parnosti jednake nuli, referenca se reinicijalizuje (sa K_{BP}=5) i ponovo se pokreće GDBF-w/m algoritam za nešto izmenjenu ulaznu sekvencu. Zelena kriva odgovara slučaju kada se koristi samo BP algoritam, ali se u svakoj rundi od K_{BP}=10 iteracija kao ulaz dekodera koristi reinicijalizovana referenca. Za male vrednosti parametra p, prva strategija obezbeđuje performanse uporedive sa BP algoritmom dok drugoj strategiji odgovaraju superiorne performanse.

Verovatnoća greške po kodnoj reči u zavisnosti od maksimalnog dozvoljenog broja iteracija pri dekodovanju ilustrovana je na slici 5. Vidi se da već nakon prve reinicijalizacije (L>30) performanse modifikovanog GDBF-w/m dekodera postaju uporedive sa performansama BP dekodera. Sa druge strane, modifikovani BP dekoder za bilo koju vrednost parametra L ima bolje performanse od ostalih razmatranih rešenja.

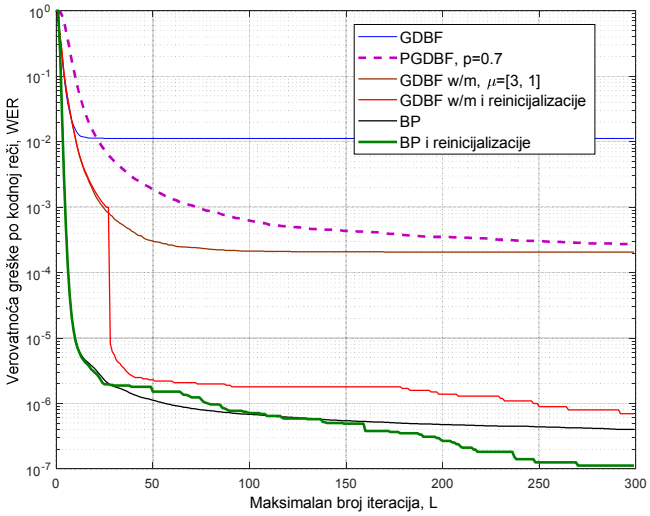
Dok strategija br 1. obezbeđuje verovatnoću greške po kodnoj reči koja je praktično ista kao u slučaju primene znatno složenijeg BP algoritma, jasno je da strategija br. 2 obezbeđuje dodatno poboljšanje performansi u odnosu na BP algoritam. Ovo je rezultat reinicijalizacija kod kojih se invertuju vrednosti najkritičnijih varijabilnih čvorova, što je princip sličan onom koji se primenjuje u GDBF algoritmu.

Sl. 4. Zavisnost verovatnoće greške po kodnoj reči od verovatnoće greške u BSC, za Tanerov kod (115,64) i L=300. Prikazane su performanse za GDBF-w/m i BP, kao i dve strategije njihovog kombinovanja.



Sl. 5. Zavisnost verovatnoće greške po kodnoj reči od broja iteracija, za Tanerov kod (115,64) i p=0.01. Prikazane su performanse za GDBF-w/m i BP, kao i dve strategije njihovog kombinovanja.

 ISBN 978-86-7466-930-3



Numerički rezultati za regularni PEG kod (504,252), koji ima težinu kolona γ=3 i težinu vrsta ρ=6. U pitanju je kod formiran pomoću tehnike sa progresivnim formiranjem ivica grafa (eng. Progressive Edge Growth, PEG), koja je prvobitno predložena u radu [26].

Zavisnost verovatnoće greške po kodnoj reči od verovatnoće greške u BSC prikazana je na slici 6. Crvena linija odgovara slučaju kada se BP algoritam koristi samo za formiranje reinicijalizovane reference (sa K_{BP}=10), dok osnovu dekodera predstavlja GDBF-w/m algoritam (opisano u odeljku III-A). Kao i u prethodnom slučaju, svaka runda traje po K_{GDBF}=25 iteracija. Zelena puna linija odgovara slučaju kada se u svakoj rundi koristi samo BP algoritam, a kao ulaz dekodera koristi se reinicijalizovana referenca (na način opisan u odeljku III-B). U ovom slučaju, prva runda se završava nakon K_{BP}=25 iteracija, dok se nakon prve reinicijalizacije ova vrednost smanjuje na K_{BP}=10. U oba slučaja postižu se performanse uporedive sa BP algoritmom, dok druga strategija rezultuje osetnijim poboljšanjem performansi u tzv. *error floor* regionu.

Uticaj parametra L na performanse dekodera za PEG kod (504,252), kada je p=0.02, prikazan je na slici 7. Performanse dekodera u kome je primenjena strategija opisana u odeljku III-B su za malu vrednost parametra L uporedive sa performansama BP dekodera. Neznatna degradacija performansi u intervalu $25<L<75$ može da posluži kao indikacija da bi se još bolji rezultati mogli dobiti ako se u prvoj rundi dekodovanja parametar K_{BP} dodatno poveća. Sa druge strane, može se uočiti da se sa povećanjem maksimalnog broja iteracija performanse značajno poboljšavaju u odnosu na BP algoritam. Ovo je posledica reinicijalizacija u svakoj rundi dekodovanja. Taj efekat smo prethodno uočili u radu [16], za slučaj kada se koriste slučajne reinicijalizacije. U radu [17] pokazano je da se sa dovoljnim povećanjem parametra L performanse PGDBF dekodera asimptotski približavaju ML granici. U radovima [19] i [20] pokazano je da se sličan efekat postiže ako se slučajne reinicijalizacije kombinuju sa najjednostavnijim algoritmom koji koristi massage-passing princip za dekodovanje LDPC kodova (Gallager-B algoritam).

Sl. 6. Zavisnost verovatnoće greške po kodnoj reči od verovatnoće greške u BSC, za Tanerov kod (115,64) i L=300. Prikazane su performanse za GDBF-w/m i BP, kao i dve strategije njihovog kombinovanja.

Sl. 7. Zavisnost verovatnoće greške po kodnoj reči od broja iteracija, za PEG kod (504,252) i p=0.02. Prikazane su performanse za GDBF-w/m i BP, kao i dve strategije njihovog kombinovanja.

Rezultati prikazani na slikama 4-7 pokazuju da se značajno poboljšanje performansi može postići i kada su reinicijalizacije deterministčke. Za razliku od pristupa izloženog u radu [22], gde se opisan prilično složen postupak deterministčke reinicijalizacije, ovde je predložen koncept zasnovan na kombinaciji dva algoritma:

- U prvoj strategiji, reč od koje GDBF-w/m dekoder započinje dekodovanje u svakoj rundi dobija se na osnovu procena u pojedinim iteracijama BP algoritma.
- U drugoj strategiji se metoda bliska GDBF algoritmu (flipovanje najkritičnijeg bita) koristi za reinicijalizaciju, dok se BP koristi za dekodovanje u svakoj rundi. U prethodnim primerima pretpostavljeno je da se u procesu reinicijalizacije invertuju samo oni čvorovi v_i za koje je zadovoljeno $LLR_i^{(l)} = \max_i \left\{ LLR_i^{(l)} \right\}$. Ipak, preliminarni rezultati pokazuju da se za kodove sa dužim kodnim rečima bolje performanse postižu ako se ovaj skup proširi čvorovima za koje je ispunjena relacija $LLR_i^{(l)} \geq 0.9 \times \max_i \left\{ LLR_i^{(l)} \right\}$.

Treba zapaziti da se u prvoj strategiji dekodovanje najčešće završi primenom GDBF algoritma. Ukoliko je $p=10^{-2}$, prosečan broj iteracija potrebnih za dekodovanje reči Tanerovog koda (155,64) pomoću GDBF-w/m algoritma sa reinicijalizacijama iznosi $\bar{l} = 1.85$, dok je za $p=3\times10^{-2}$, prosečan broj iteracija $\bar{l} = 3.59$. Ako je $p=10^{-2}$, verovatnoća da GDBF-w/m tokom prvih K_{GDBF}=25 iteracija ne završi dekodovanje iznosi $\mathrm{WER}(25) \approx 1.2\times10^{-5}$ (videti sliku 5), iz čega se može zaključiti da se BP algoritam veoma retko pokreće, naročito u error-floor regionu, gde performanse predloženih rešenja posebno dolaze do izražaja.

Direktna posledica je da postupak predložen u prvoj strategiji obezbeđuje znatno manju prosečnu računsku kompleksnost u odnosu na slučaj kada se koristi BP dekoder. Ovaj postupak je baziran na GDBF-w/m algoritmu, a u radu [27] i doktorskoj disertaciji [28] navedeno je da u slučaju koda dužine n=1296 implementacija GDBF algoritma obezbeđuje šest puta veći prosečan protok i približno devet puta manju površinu na čipu u odnosu na najefikasniju poznatu implementaciju min-sum algoritma (koji predstavlja podoptimalnu varijantu BP algoritma, pogodnu za implementaciju zasnovanu na fiksnom zarezu).

 ISBN 978-86-7466-930-3

V. ZAKLJUČAK

Dve predložene strategije kombinovanja BP i GDBF-w/m algoritama pogodne su u slučaju kada su u prijemniku dostupna oba tipa dekodera. Dobijeni rezultati pokazuju da se kombinovanjem dva uobičajena pristupa mogu dobiti značajno poboljšane performanse ili performanse uporedive onima koje ima BP dekoder, ali uz smanjenu kompleksnost.

U ovom radu su parametri dekodera određeni empirijski. Sigurni smo da se dodatno poboljšanje performansi može dobiti ako se izvrši optimizacija pojedinih parametara, kao što su momentum vektor ili pragovi za odlučivanje kod GDBF-w/m algoritma, kao i broj iteracija koji odgovara pojedinim rundama dekodovanja. Ovo će biti tema naših budućih istraživanja.

ZAHVALNICA

Rezultati objavljeni u ovom radu delom su dobijeni u okviru saradnje ostvarene kroz i program Saradnje srpske nauke sa dijasporom Fonda za nauku Republike Srbije (br. ugovora 6462951), kao i kroz ERASMUS+ KA2 program saradnje Univerziteta u Beogradu i Univerziteta u Arizoni. Angažovanje Predraga Ivaniša i Srđana Brkića podržano je od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije. Angažovanje Baneta Vasića podržano je od strane NSF u okviru projekata CIF-1855879, CCF-2106189, CCSS-2027844 i CCSS-2052751 i NASA-SURP.

ABSTRACT

In this paper we propose the approaches that combine two types of iterative decoding algorithms that are usually used for decoding of low density parity check codes (LDPC). One strategy is based on a low-complexity bit-flipping algorithm, and the proposed modification enable significant performance improvement, with no significant increase of the average computing complexity. The other strategy is based on belief propagation decoder, and the resulting decoder has improved error correction capabilities for the codes with short codeword length.

LDPC decoders with re-initializations based on synergy of hard decision and message passing principles

Analiza performansi kooperativnog diverziti sistema u kompozitnom fedingu modelovanom odnosom α-μ i gama raspodela

Edis Mekić, Irfan Fetahović, i Edin Dolićanin

***A stra t*— U ovom radu je izvedeno novo opšte, jednostavno rešenje u zatvorenom obliku za funkciju gustine verovatnoće odnosa proizvoda slučajnih promenljivih predstavljenih α-μ i Gama raspodelama i slučajne promenjive predstavljene Gama raspodelom. Ova rešenja se primenjuju u analizi performansi omuni acionih sistema sa ooperativnim diverziti sistemom oji se oristi za poboljšanje prijema signala na čije anvelope utiče brzi i spori feding, do na anvelopu o analne interference utiče samo brzi feding.**

***Ključne reči*— α-μ raspodela; Gama raspodela; feding; ooperativni diverziti**

I. UVOD

Proizvodi i odnosi slučajnih promenljivih, kao i rešenja funkcija gustina verovatnoća (PDF) i kumulativnih funkcija (CDF) u zatvorenoj formi su u žiži interesovanja telekomunikacionih istraživanja.

Rešenja u zatvorenom obliku za PDF i CDF se mogu koristiti u analizi verovatnoće otkaza multihop kognitivnih mreža [1]. Kao posebno značajni u analizi otkaza i ergodičnog kapaciteta mreža i u prisustvu fedinga su se pokazali odnosi i proizvodi anvelopa signala koje su modelovane α-μ raspodelom [2]. Analiza odnosa signal interference (SIR) datog kao odnos proizvoda dve k- μ slučajne promenljive i Nakagami-m slučajne promenljive, kao i odnos proizvoda dve Rayleigh-ove slučajne promenljive i Rayleigh-ove slučajne promenljive je evaluirana u radovima [3,4] i korišćena za analizu bežičnih relejnih komunikacionih sistema koji se sastoje od dve sekcije, u prisustvu fedinga i kokanalne interferencije. Jednostavno matematičko rešenje u slučaju kada se koriste samo α-μ slučajne promenljive je dato u [5]. Dobijeno rešenje se koristi za modelovanje fedinga u multihop sistemima, u prisustvu kokanalne interference

Slučajna promenljiva može se koristiti za modelovanje anvelope signala u prisustvu fedinga. Feding je pojava da kvalitet prenosa signala opada zbog refleksije i refrakcije signala o objekte koji se nalaze na putanji istog (brzi feding) ili zbog velikih prepreka na putanji signala (spori feding). Osim ovoga, na anvelopu signala utiče i kokanalna interferenca koja se javlja zbog višestrukog korišćenja frekvencija. Anvelopa signala u prisustvu fedinga se može modelovati proizvodom dve slučajne promenljive [6], dok se kokanalna interferenca modeluje odnosom slučajnih promenljivih [7].

Proizvod α-μ i lognormalne slučajne promenljive daju odlične rezultate u modelovanju realnih efekata sporog fediga, međutim primena lognormalne raspodele ne daje rešenja u zatvorenom obliku za PDF anvelope signala na prijemu [8]. Kao alternativa lognormalnoj rapodeli može se koristiti Gama raspodela [9].

Da bi ublažili efekte fedinga na anvelopu signala mogu se koristiti diverziti tehnike koje se sastoje od većeg broja antena [10].

U ovom radu ćemo analizirati bežičnu mrežu sa kooperativnim diverziti protokolom za ublažavanje efekta fedinga [11].

Brzi feding i njegovo delovanje na signal između predajnika i prijemnika u slučaju idealnog koherentnog prenosa u poludupleks modu modelovaćemo kao odnos α-μ promenljivih, dok ćemo efekat sporog fedinga modelovati kao proizvod ovog odnosa sa Gama slučajnom promenljivom. Dobijena rešenja za PDF biće primenjena u modelu kooperativne diverziti mreže, pošto su multihop relejni sistemi specijalni slučajevi ove diverziti tehnike. Validnost rezulata ćemo pokazati na primeru jednostavnog dual hop sistema.

II. FIZIČKI MODEL BEŽIČNE MREŽE SA KOOPERATIVNIM DIVERZITI PROTOKOLIMA

Primer bežične mreže koja se sastoji iz niza releja je dat na Sl.1. Terminali TS_1, TS_2,…TS_N prenose signal do terminala TR_1, TR_2,…,TR_M , respektivno. Ovako definisan sistem može da se koristi kao osnova za modelovanje različitih bežičnih sistema. Recimo, možemo da predstavimo sistem mobilne telefonije ako pretpostavimo da su TS_1, TS_2,…,TS_N mobilni uređaji, a $TR_1= TR_2=…=TR_M$ bazne stanice. Model možemo da koristimo za reprezentaciju LAN mreže, bilo da je u pitanju ad-hoc ili mreža zasnovana na pristupnim tačkama. Ako pretpostavimo da su terminali $TR_1= TR_2=…=TR_M$, onda imamo LAN mrežu sa pristupnom tačkom, a ako pretpostavimo da je $TR_1\neq TR_2\neq…\neq TR_M$, onda imamo ad-hoc mrežu. Najzad, ako se svi terminali fokusiraju na prenos informacija od TS_1 do TR_M, dok su prelazni koraci prenosa redom od TR_1 do TS_2, od TS_2 do TR3, … TS_N do TR_M, onda imamo multihop sistem.

Poslednji navedeni model ćemo analizirati tako što ćemo

 ISBN 978-86-7466-930-3

ga ograničiti na mod poludupleksa, i to na takav način da svaki od releja pojačava primljeni signal. Radi jednostavnijeg računa pretpostavićemo da imamo idealni koherentni prenos, gde se primljeni signal u potpunosti obnavlja na transmisionom releju.

Sl.1. Bežična mreža zasnovana na sistemu releja

Kanale između releja ćemo podeliti na ortogonalne podkanale, pri čemu će svaki od terminala koristiti i/n stepena slobode u kanalu (Sl.2).

Sl.2. Alokacija kanala

Sa obzirom na to da je prenos između predajnika i prijemnika pod uticajem i brzog i sporog fedinga, simetrija kanala će nam omogućiti da stavimo fokus za početak na jedan par predajnik-terminal.

III. Statistička analiza proizvoda odnosa α-μ i Gama slučajnih promenljivih

Anvelope polaznog signala su modelovane slučajnim promeljivim a[n], gde je n=1,2,…,N/2, dok drugi terminal prenosi vrednosti n=N/2+1,…N. Terminal može da koristi samo polovinu stepena slobode. Anvelopu primljenog signala modelovaćemo kao proizvod odnosa slučajnih promenljivih.

$$\varphi[n] = \frac{a[n]\,c[n]}{b[n]} \tag{1}$$

Slučajne promenljive a[n] i b[n] su modelovane kao α-μ dok je c[n] modelovana gama slučajnom promenljivom. PDF proizvoda odnosa izračunaćemo tako što za početak računamo PDF odnosa dve α-μ slučajne promenljive.

$$\phi[n] = \frac{a[n]}{b[n]} \tag{2}$$

$$p_\phi(\phi[n]) = \int_0^\infty |J| p_\phi(\phi[n]a[n]) p_b(b[n]) db \tag{3}$$

Vrednost |J| je Jakobijan defnisan na sledeći način:

$$|J| = \left|\frac{da[n]}{d\phi[n]}\right| = b[n] \tag{4}$$

PDF združene promenljive φ[n] može se izračunati korišćenjem sledećeg izraza:

$$p_\varphi(\varphi[n]) = \int_0^\infty |J| p_\phi\left(\frac{\varphi[n]}{c[n]}\right) p_c(c[n]) dc \tag{5}$$

Odabir odgovarajuće kooperativne ili nekooperativne akcije je zasnovan na merenju odnosa signal-interferenca (SIR). Na prijemnoj strani merimo vrednosti anvelope signala. Možemo primeniti adaptiran mod prenosa, u skladu sa izmerenom vrednošću. Ako izmerena vrednost anvelope pada ispod određenog praga, ponavljamo prenos, a ako je iznad ovog praga onda prenosimo signal, ovo je korišćenje pojačaj i prosledi tehnike da bi se postigao diverziti.

Za kooperativni diverziti sistem, gde signal prolazi kroz niz releja, PDF slučajne promenljive može biti izračunat na sledeći način:

$$\varphi[n] = \min(\varphi[n]_1, \varphi[n]_2, \dots, \varphi[n]_N) \tag{6}$$

$$p_\varphi(\varphi[n]) = \sum_{m=1}^{N} |J| p_{\varphi_m}(\varphi[n]) \prod_{\substack{k=1 \\ k\neq m}}^{N} (1 - F_{\varphi_k}(\varphi[n])) \tag{7}$$

Sada ćemo modelovati efekte, brzog, sporog fedinga i interference. Za modelovanje anvelope na koju deluje brzi feding i interference koristimo α-μ raspodelu. Vrednost μ predstavlja broj klastera prenosa, dok koeficijent α predstavlja nelinearnost okoline. Radi jednostavnije analize slučajnu promenljivu između bilo kojih releja *a n* , predstavljamo kao promenljivu a.

Slučajna promenljiva α-μ raspodele je opisana sledećom jednačinom:

$$p_a(a) = \alpha \left(\frac{\mu_a}{\Omega_a}\right)^{\mu_a} \frac{\gamma^{\alpha\mu_a - 1}}{\Gamma(\mu_a)} e^{-\frac{\mu_a a^\alpha}{\Omega_a}} \tag{8}$$

U datoj jednačini snaga anvelope signala je $\Omega_a = \varepsilon\langle a^\alpha \rangle$, α predstavlja nelinearnost okoline, μ_a je inverzna vrednost normalizovane varijanse *α, ($\mu_a \geq 0.5$)*.

Spori feding modelovaćemo sledećom Gama slučajnom promenljivom:

$$p_a(a) = \frac{a^{k-1} e^{-\frac{a}{\Omega_a}}}{\Gamma(a)\Omega_a} \tag{9}$$

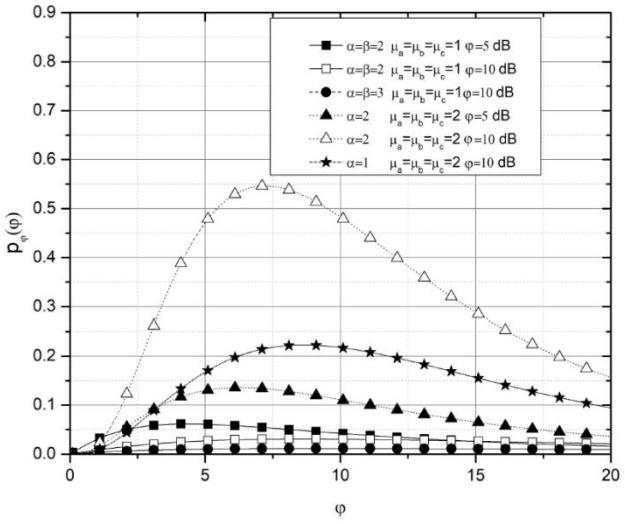
Vrednost sporog fedinga definisana je promenljivom k, pri čemu niža vrednost k znači da je veći uticaj sporog fedinga.

Da bi izračunali odgovarajući PDF slučajne promenljive φ dat jednačinom (5), prvo moramo da izračunamo PDF odnosa dve slučajne α-μ promenljive $\phi = a/b$, rešavanjem jednačine (3). Ovaj međukorak nam omogućuje da izračunamo združenu gustinu verovatnoće zaobilazeći kompleksnije Mellinove transformacije.

Primenom jednačina [12 (3.461 i 6.631), 13 (26)] združena gustina verovatnoće se može prikazati preko Meijer's G

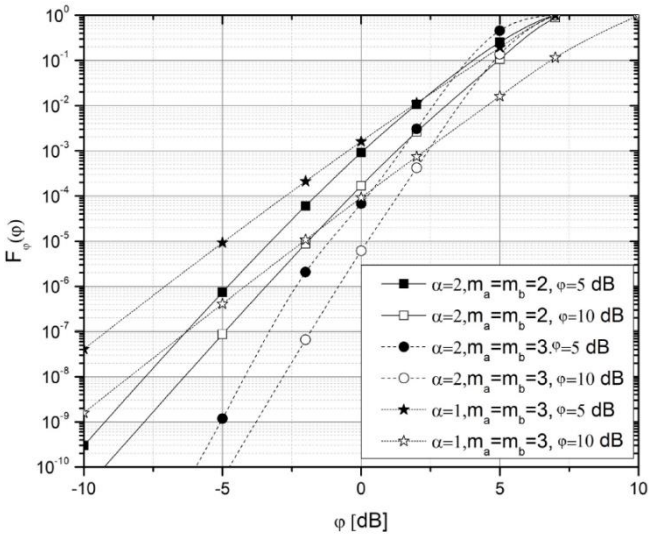
 ISBN 978-86-7466-930-3

funkcija.



$$p_\phi(\phi) = \alpha\left(\frac{\mu_a\Omega_b}{\mu_b\Omega_a}\right)^{\mu_a}\frac{\phi^{\alpha\mu_a-1}}{\Gamma(\mu_a)\Gamma(\mu_a)}G_{1,1}^{1,1}\left(\frac{1}{\varphi^\alpha}\frac{\mu_a\Omega_b}{\mu_b\Omega_a}\middle|\begin{matrix}1-\mu_a-\mu_b\\0\end{matrix}\right) \quad (10)$$

PDF promenljive φ se izvodi primenom izraza (5). Korišćenjem izraza [14, 15] dobijamo izraz za PDF u zatvorenom obliku preko Meijer's G funkcija.



$$p_\varphi(\varphi) = \left(\frac{\mu_a\Omega_b}{\mu_b\Omega_a}\right)\left(\frac{1}{\Omega_c}\right)^{\alpha\mu_a}\frac{\alpha^{k-\alpha\mu_a-1}\varphi^{\alpha\mu_a-1}}{(2\pi)^{\frac{\alpha-1}{2}}\Gamma(\mu_a)\Gamma(\mu_c)\Gamma(k)}\times \times G_{1+\alpha,\ 1}^{1,\ 1+\alpha}\left(\frac{1}{\varphi^\alpha}\frac{\mu_b\Omega_a\Omega_c}{\mu_a\Omega_b}\middle|\begin{matrix}\frac{1-k+\alpha\mu_a}{2},\dots,\frac{1-k+\alpha\mu_a}{2},1\\ \mu_a+\mu_b\end{matrix}\right) \quad (11)$$

CDF se može izračunati primenom sledećeg izraza

$$F_\varphi(\varphi) = \int_0^\varphi p_\varphi(s)ds \quad (12)$$

Sl.3. PDF za različite vrednosti parametra α-μ promenljive

Sl.4. CDF za različite vrednosti parametra α-μ promenljive

Primenom dobijenih izraza, a menjajući parametar α-μ u izvedenim izrazima, dobijen je matematički model koji pokazuje da povećanje snage anvelope signala smanjuje verovatnoću otkaza sistema. Na Sl.3. je dat PDF združene gustine verovatnoće anvelope modelovanog signala, dok je verovatnoća otkaza data kroz numeričko izračunavanje CDF anvelope koja je modelovana novom združenom gustinom verovatnoće (Sl.4), dok povećanje dubine fedinga povećava verovatnoću otkaza.

IV. Zaključak

U radu je predstavljena analiza kooperativnog diverziti sistema kao jednog od pristupa za smanjivanje uticaja brzog i sporog fedinga na prenos signala u prisustvu interference. Uticaj efekata brzog fedinga i kokanalne interference smo modelovali odnosom dve α-μ slučajne promenljive, dok je efekat sporog fedinga modelovan proizvodom navedenog odnosa i Gama slučajnom promenljivom. Izračunat je izraz za PDF u zatvorenom obliku. Međutim, za kompletnu analizu neophodno je izračunati i CDF u zatvorenom obliku. To bi omogućilo brzu i efikasnu simulaciju ne samo navedenog slučaja, već i velikog broja drugih slučajeva koji se mogu izračunati kao specijalni slučajevi predstavljenog.

ABSTRACT

In this paper, we present novel general, simple, exact and closed-form expressions for the probability density function (PDF) and of ratio of product of random α-μ distributed variable and generalized Gamma distributed variable and random α-μ distributed variable. These results have application in performance analysis of cooperative diversity communication systems in different fading transmission environments where envelope of the signal is affected by fast and slow fading and envelope of co-channel interference by fast fading.

Performance Analysis of the Cooperative Diversity Communication ystems in Composite ading cenario odelled as Ratio of α-μ Variates and Gamma Variate

Code Comment Classification Taxonomies

Marija Kostić, Aleksa Srbljanović, Vuk Batanović and Boško Nikolić, *Member, IEEE*

***Abstract*—Code comments have become an increasingly important ind of software development metadata, due to the possibilities of automated code comment analysis and generation. Different downstream tas s inherently prioritize certain inds of code comments over others, ma ing it necessary to properly define and identify different comment classes. In this paper, we analyze, compare, and systematize previously proposed code comment classification ta onomies according to their comment classes and applicability. We also present a new ta onomy designed for the tas s of semantic code search and semantic te t similarity, and we contrast it to the e isting approaches.**

***Index Terms*—code comments; code comment ta onomy; comparison of classification ta onomies.**

I. Introduction

Code comments represent an invaluable source of metadata regarding software implementation. They describe code functionalities and algorithmic specifics, provide usage instructions, point towards additional resources, denote potential or observed programming bugs and issues, etc. In short, code comments play a vital role in helping developers comprehend source code [1]. In this manner, code comments greatly increase code maintainability, particularly when dealing with large software projects and development teams.

Depending on the downstream task in focus, not all code comments are of equal importance. For instance, if one wishes to compare the functionality of two methods, comments which provide authorship information are of little consequence, whereas those describing program implementation are of much greater significance. However, distinct kinds of code comments can be difficult to distinguish, particularly when no clear keywords for each comment type exists. A further complication in identifying relevant comments is the fact that a standardized code comment taxonomy does not exist. Instead, multiple different code comment categorization solutions have been proposed so far, most often designed with a specific programming language and downstream task in mind.

In this paper, we first present a survey of the existing code comment taxonomies and their applications in downstream tasks. Afterward, we present a new comment classification schema suitable for the tasks of semantic code search and semantic textual similarity and applicable to various programming languages. We then compare our approach with previous code comment taxonomies and conclude with some pointers regarding the future use of our comment schema.

II. A Survey of Existing Taxonomies

In this section, we review existing code comment classification taxonomies and describe how those systems were applied to specific tasks. A similar, but much shorter survey of this kind was previously presented within [2].

Zhai et al. [3] wanted to leverage program analysis to systematically propagate comments, so that they can be passed on to uncommented code entities and help detect bugs. A bi-directional analysis was designed where: (1) program analysis propagates and updates code comments, and (2) comments provide additional semantic hints to enrich program analysis. For effective propagation, it was vital to understand what kind of information comments convey and to which code elements they refer to, as comments of different categories require different propagation rules. The authors introduced a code comment taxonomy in which there are two dimensions of interest: code entity and content perspective. Code entities commonly commented on are *class*, *method*, *statement*, and *ariable*. As for the content perspective, five of them were identified: 1) *what* – a definition or a summary of the code entity's functionality; 2) *why* – the reason why the code entity is provided or its design rationale; 3) *how-it-is-done* – description of the implementation details; 4) *property* – properties of the entities such as pre-condition and post-conditions; 5) *how-to-use* – description of the usage, expected set-up, or the environment of the entity. A set of 5,000 comments from four popular Java libraries were classified at the sentence level. The agreement between two coders, measured using Cohen's Kappa metric [4], was 0.826.

Chen et al. [1] investigated the use of the relationship between code blocks and the categories of the corresponding comments to improve code summarization, where the aim is to automatically generate a code comment based on the given block of source code. They showed that a composite approach, where the most suitable summarization model is selected based on the comment category, outperforms other approaches. Comments were classified into six categories – *what*, *why*, *how-to-use*, *how-it-is-done*, *property* and *others*. Five of them are the same as categories of content perspective in [3], while the sixth one, named *others*, covers unspecified or ambiguous comments. For this task, 20,000 Java methods and their corresponding comments were manually classified.

 ISBN 978-86-7466-930-3

The overall agreement of the three annotators, expressed in the terms of Fleiss' Kappa score [5], is 0.79.

Padioleau et al. [6] studied code comments to understand developers' needs regarding the creation of new tools and languages or the improvement of the existing ones. Comments were classified along four dimensions according to the question of interest: 1) *What* – content: What is in the comment? Does it contain useful information? Its categories *type*, *interface*, *code relationship* and *pastFuture* and subcategories are closely related to the specific usage of the C programming language for operating systems; 2) *Who* – people involved: Who or which tool can benefit from a comment? Who is the comment author?; 3) *Where* – code entity: Where in a file is a comment located?; 4) *When* – time: When was a comment written? How did the comment evolve over time? The authors considered 1050 comments randomly sampled from the code of three operating systems written in the C programming language: Linux, FreeBSD and OpenSolaris. The *What* and *Who* dimensions were manually annotated for each comment, while the other two dimensions were labeled automatically.

Haouari et al. [7] investigated developers' commenting habits via an empirical study. For the quantitative aspect of the study, the authors determined the distribution of the comments with respect to the program construct type that follows it. This allowed them to see what program construct types are documented more often than others. Some of the observed constructs are *package declaration*, *import declaration*, *class declaration*, *method*, *constructor*, *for*, *while*, etc. For the qualitative aspect of the study a new comment taxonomy was designed. This taxonomy has four high-level dimensions: 1) *bject of the comment* which can be a single subsequent instruction (*follow*); the following block of instructions (*block*), no code in the vicinity (*nocode*), or any other situation (*other*); 2) *Comment type* which can be the description of the code functionality (*e planation*), future task to be completed like TODO items (*working*), old code that is commented out instead of being removed (*code*), or any other comments (*other*); 3) *Style* dimension is only observed in the case of explanatory comments (*type e planation*) and can be either *e plicit* or *implicit*; 4) *uality* dimension is also specific only to explanatory comments. It involves three categories: *fair* where comments describe functionalities of related code and give other information; *fair* where code functionality is adequately described; and *poor* where some or none of the functionality is described. Analysis for the quantitative aspect was fully automated and applied to all comments within three open-source Java projects. For the qualitative aspect, the authors had 49 developers manually classify 407 comments.

Steidl et al. [8] developed a model for comment quality analysis with four criteria (*coherence*, *usefulness*, *consistency,* and *completeness*). Their comment taxonomy consists of seven high-level categories: 1) *copyright* – copyright or license; 2) *header* – overview of the class functionality; 3) *member* – functionality of a method/field; 4) *inline* – implementation decisions within a method body; 5) *section* – group of methods/fields that belong to the same functional aspect; 6) *code* – commented out code; 7) *task* – developer notes with a remaining todo, a bug, or an implementation hack. Authors created a training set by classifying 830 Java and 500 C++ comments from twelve open-source projects.

Pascarella et al. [9]–[11] focused on increasing the empirical understanding of the types of comments that developers write in source code. After an iterative process of analyzing code files, the authors defined a fine-grained hierarchical taxonomy with two layers: the outer one consisting of six top-level categories (*purpose*, *notice*, *under de elopment*, *style I E*, *metadata*, and *discarded*) and the inner one consisting of 16 subcategories. The *purpose* category contains comments that describe the functionality of the related source code. Its three subcategories *summary*, *e pand*, and *rationale* respond to the question words what, how, and why, similarly to the categories in [1], [3]. The *notice* category covers comments about warnings, alerts, messages, or functionalities that should be used with care. Its subcategories are *deprecation*, *usage*, and *e ception*. Subcategories *todo* (explicit actions to be done), *incomplete* (partial or empty comment bodies), and *commented code* belong to the *under de elopment* top-level category. The *style I E* comments are used for communication with the IDE (*directi e*) and logical separation of the code (*formatter*). The *metadata* comments define meta information about the code such as license, terms of use, authors, links to external resources (subcategories *license*, *ownership*, and *pointer*). All other comments that do not fit in the previous categories belong to the *discarded* category (subcategories *automatically generated* and *unknown*). Authors decided to classify comments at the character level. That means that annotators had to specify the starting and the ending character of each comment block and its category. After this process, it was found that in only 4% of cases one line had to be classified into more than one category. The study was conducted on more than 6,000 source code files with more than 40,000 lines of Java comments in open source and industrial software projects. To validate the proposed taxonomy, three developers were asked to manually classify 138 lines of comments in three Java source code files. They achieved a Fleiss' Kappa value of 0.9.

Unlike previously mentioned efforts, Shinyama et al. [12] worked only on comments inside functions or methods that explain code at the microscopic level i.e., on *local comments*. These comments are not visible in the documentation and often give insight into developers' minds. They are often crucial for understanding nontrivial parts of the code. As there usually is a relationship between a comment and the code it describes, the authors represented that relationship as an arc with three elements: (1) source – the comment itself; (2) destination – target code; and (3) type of relationship – comment category. They independently made a list of categories suitable for local comments: 1) *postcondition* – conditions that hold after the code is executed, typically used to explain what the code does; 2) *precondition* – conditions that hold before the code is executed, typically used for explaining why the code is needed; 3) *alue description* – a

 ISBN 978-86-7466-930-3

phrase that can be equated with a variable, constant or expression; 4) *instruction* – instructions for code maintainers (todo comments); 5) *guide* – guides and examples for code users; 6) *interface* – description of a function, type, class, or interface; 7) *meta information* – author, date, or copyright; 8) *comment out* – commented out code; 9) *directi e* – compiler directives that are not directed to human readers; 10) *isual cues* – comments inserted just for the ease of reading; 11) *uncategori ed* – all other comments. For each arc element, a statistical classifier was built and trained on 1,000 manually classified Java comments. Classifiers were applied on large corpora of Java and Python comments. Annotation agreement was measured on a separate set of 100 Java comment-code pairs and reached Fleiss' Kappa value of 0.491.

Zhang et al. [13] used supervised learning to automatically classify Python code comments. Since most of the related work is based on Java and C/C++ programming languages, the authors conducted an iterative content analysis session to devise a Python-specific classification taxonomy. Their taxonomy contains 11 categories: 1) *metadata* – license and copyright; 2) *summary* – description of the functionality of the related code; 3) *usage* – explanations on how to use the code that can contain examples; 4) *parameters* – explanations of function parameters; 5) *e pand* – detailed explanations of the purpose of a small block of code, usually inline comments; 6) *ersion* – library version information; 7) *de elopment notes* – comments for developers concerning ongoing work, temporary tips, explanations of functions etc.; 8) *todo* – explicit actions to be done in the future like bug fixing or feature improving; 9) *e ception* – indications that a function throws exceptions or suggestions how to prevent unwanted behaviors; 10) *links* – links to external resources; 11) *noise* – meaningless symbols which may be used for separation. The training set consisted of 330 annotated comments from seven popular Python open-source projects on GitHub.

III. A New Code Comment Taxonomy

We explored code comment classification taxonomies in order to differentiate between different kinds of comments for the tasks of semantic code search and cross-level sematic textual similarity. In semantic code search (SCS), the goal is to construct a system which returns the most relevant code block(s) from a software repository for a given query in a natural language. To do so, most models rely on the accompanying code comments which describe the functionality of their respective code blocks [14]. Cross-level semantic similarity (CLSS) is the task in which a computational model ought to return a numerical semantic similarity score for a given pair of texts written in a natural language, where the length of the texts can be dissimilar (e.g., one text is a paragraph, the other is a sentence) [15]–[16]. Solving CLSS is of great use for semantic code search, since SCS implies finding semantic links between texts of different lengths – queries are usually limited to a couple of words or a sentence, whereas the length of code comments can range from a phrase to a paragraph. Obviously, these tasks are not limited to a particular programming or natural language.

We found that no previous code comment taxonomy was designed with these two downstream tasks in mind, so it was necessary to consider the previous classification systems and devise a suitable set of comment categories. Furthermore, we wanted to create a classification taxonomy that would be applicable to various programming languages, including C, C++, C#, Java, JavaScript/TypeScript, PHP, Python, and SQL. Upon reviewing the papers presented in the previous section, we decided to develop our own taxonomy using the approaches of Pascarella et al. [9]–[11] and Steidl et al. [8] as a starting point. This choice was based on the emphasis these works placed on the comments that describe code functionality, since such comments are the most relevant ones for SCS. We therefore distinguish between functional and non-functional comments via two top-level categories. These two categories are then subdivided into eight subcategories. In the remainder of this section, we will present the definition and scope of each of them.

A. Functional

The *Functional* category contains comments that describe the functionality of the corresponding source code. Descriptions can be short, or they can extend over multiple lines. These comments are usually written in a natural language and are used to describe the purpose, behavior, or the reason why something is implemented in a particular way. They can respond to questions *What* , *Why* , and *ow* . We do not distinguish between these aspects of functionality because all of them are relevant for the SCS task. However, we do differentiate between three subcategories based on the type of the corresponding source code: 1) *Functional-Module* comments describe the functionality of a particular module like a class or an interface. If a programming language does not use the object-oriented paradigm, these comments pertain to entire files or scripts; 2) *Functional-Method* comments describe the functionality of a function or a method. They are usually located above or at the beginning of a function/method definition or declaration; 3) *Functional-Inline* are all the other comments that describe some functionality. They can describe the functionality of a variable or an expression and can be located inside a method body.

B. Non-Functional

The *Non-Functional* category covers all comments that do not describe code functionality. Subcategories in this top-level category are not relevant for the SCS and CLSS tasks, but we still decided to include them because we wanted to make the annotated datasets usable for other downstream tasks as well. We distinguish between the following five subcategories: 1) The *Notice* category encompasses warnings, alerts, and messages intended for other developers or users of the source code. It also covers information about deprecated artifacts and instructions about alternative methods or classes that should be used. Comments that explain something is implemented in a certain way because of a bug, or a known issue, also belong to this category. Finally, examples or explicit suggestions how

 ISBN 978-86-7466-930-3

to use a functionality are classified as *Notice* comments as well; 2) *General* comments usually define meta-information about the code such as license, copyright, authorship, module/class version, timestamps, the name or path of the file, information about the libraries used in the source code, etc. These comments are usually located at the top of the file; 3) The *Code* category is composed of comments that contain source code that is commented out by developers. This is usually done during testing or debugging. This code may represent new or hidden features, work in progress, features being tested, temporarily removed code or older variants of the code; 4) *I E* comments are used for communication with the IDE or the compiler to change their default behavior. Comment content is usually of limited value to human

readers; 5) The *Todo* category covers explicit tasks to be done and notes about bugs that need to be fixed.

IV. Comparison With Previous Code Comment Classification Taxonomies

In this section, we present a comparison between the previously described taxonomies. Table 1 shows examples of code comments and their classes according to different taxonomies. In places where we were not sure what category the authors would choose for a specific comment, we put a dash symbol. Comments in italic are new examples, while others are taken from the cited papers. We have omitted the taxonomy presented in [6] from the table since it is extremely specific regarding the type of code it is applied to (operating systems code). Additionally, its authors have not disclosed all the categories they have devised.

All the comments which describe code functionality belong to one of the following classes - *What*, *Why*, *ow*, *Property*, *Module*, *Method*, *Inline* and *ariable Field*. However, these classes can be classified based on two perspectives: (1) according to the type of the commented functionality – categories *What*, *Why*, *ow*, and *Property,* or (2) the comment's structural position within the code – categories *Module*, *Method*, *Inline*, *ariable Field*. Depending on the downstream task, some taxonomies use the functionality type classification [1], [13], others use the comment place classification [8], some use both [3], [12], or neither [7]. The new taxonomy we propose takes into account the placement of a comment within the code. It should be emphasized we do not differentiate between *Inline* and *ariable Field* functional comments like in some taxonomies [3], [8], [12], but rather group them together under the *Functional-Inline* class.

In some papers there is a separate class for comments which visually divide the code into sections [8], [11]–[12]. We classify such comments as *Functional-Inline* as well.

Some comments do not describe code functionality, but rather contain notes to developers and code users. Several different classes for these kinds of comments have been previously proposed. There are authors [1], [3], [7]–[8] who recognize only some of these comments because not all of them are relevant for their downstream task. In other papers [11]–[13] most of these comments are recognized, but every paper uses a different approach concerning their classification. Some authors [11], [13] use a higher level of granularity while others [12] perceive some or all such comments as one class. In [12] the authors also differentiate between the comments meant for developers and those meant for users. Regarding TODO comments, some taxonomies [12]–[13] clearly separate them from the other comments, while in others [8], [11] there is an overlap between TODO and other comment categories. Our taxonomy distinguishes between *Notice* and *Todo* classes. All the notes for developers/users, use cases, warnings about deprecation, exceptions and links are classified as *Notice*. Messages about missing/unfinished parts of code and bugs are classified as *T* .

Several taxonomies [7]–[8], [11]–[12], treat comments which represent parts of code as a separate class, while others do not mention them. In [11], code which is commented out is classified as a *Todo* comment, along with comments for bugs and unfinished code. In our taxonomy parts of code which are commented out are placed in a separate class – *Code*.

Most previous approaches use a separate class for meta-information comments. Some [8], [11], [13] utilize a more granular classification according to license information, authorship, version information etc. In our approach all the meta-information is classified into the *General* category.

A few authors [11]–[12] have proposed a separate class for comments which represent some instructions for the compiler or the development environment. We also include an *I E* category in our taxonomy.

Some papers [1], [7], [11]–[13] use a separate category for all other comments which are not of interest. However, our taxonomy does not employ such a category, because we do not want to allow annotators to easily dismiss ambiguous comments which are difficult to categorize.

Additional information about the presented comment taxonomies is shown in Table 2. It contains the number of comments that are/will be annotated for each taxonomy, the used comment granularity, the natural and programing languages each taxonomy is applied to, the annotation agreement (if reported), and the downstream task. Data from the table shows that annotations are typically done on small sets of code comments written in English, and that comments are taken from one or two programming languages at most. It is hard to compare annotation agreements because agreement measures differ from paper to paper and relate to different numbers of annotators and different comment set sizes.

Some of the earliest taxonomies were specific for the task they were solving [6]–[7] and observed more than two perspectives (e.g., object, style, beneficiary etc.). Because of their complexity, they are not useful for tasks other than the ones they were designed for. But, over time, two perspectives became prominent: (1) what is the entity of a comment, and (2) how a comment describes the functionality of the entity.

All papers in this survey worked with comments in English and in one of the following programming languages: C/C++, Java, or Python. As mentioned in [11] many object-oriented languages have very similar functionalities, and it is reasonable to expect that their comments will behave the same. We can see that in more recent works [1], [3], [8], [11]–[13] taxonomies designed for Java, Python, and C++ are similar. For other programming paradigms (e.g., functional), further research must be done.

Although some authors wanted only to empirically study and understand the types of code comments [11]–[13], most of the times classification was done as a first step in solving a particular downstream task. In a couple of papers, it is shown that that kind of approach is fruitful. For example, Chen et al. [1] have found that different summarization models work best for different categories of comments. By including comment

Zhai [3]	2020	5000	Sentence	English	Java	Cohen's Kappa = 0.826	Code-comment propagation.
Chen [1]	2021	20000	Comment	English	Java	Fleiss' Kappa = 0.79	Code summarization.
Our proposal	2022	~10000	Character	English	C/C++, C#, Java, JavaScript/ TypeScript, PHP, Python, SQL	To be determined	Semantic code search and cross-level semantic textual similarity.

classification, they were able to design a composite summarization model that outperforms a standard approach where one model is applied to all comments. Another example is the work of Zhai et al. [3] focused on code comment propagation. Here, comment classification was necessary because comments with different content related to different programming entities cannot be propagated in the same way.

V. CONCLUSION

In this paper, we have analyzed and compared previously proposed code comment classification taxonomies. We have systematized them according to the comment classes they use as well as according to their applicability to different programming languages and downstream tasks. We have also presented a new comment taxonomy, designed for the tasks of semantic code search and semantic textual similarity, applicable to various programming languages.

In order to validate the usefulness of our taxonomy, we are currently engaged in the creation of a code comment corpus which will encompass around 10,000 comments written in English or Serbian, and taken from a spectrum of programming languages(C/C++, C#, Java, PHP, Python, SQL, and JavaScript/TypeScript). We aim to manually annotate this corpus using the proposed taxonomy and use it to enable automated comment classification, both as a stand-alone task and as a first step within the mentioned downstream tasks.

Primena ConvLSTM modela za predikciju optičke debljine aerosola

Uzahir R. Ramadani, Dušan P. Nikezić, Dušan S. Radivojević, Nikola Mirkov i Ivan Lazović

***Apstrakt*—Napravljen je ConvLSTM model sa ConvLSTM2D slojevima za predvđanje optičke debljine aerosola. Ulazni skup podataka čine satelitski snimci optičke debljine aerosola na 8 dana od 2000. godine. Kada je model obučen dato je predviđanje optičke debljine aerosola kao i evaluacija modela. Razvijen je i primenjen nad istim podacima i CNN LSTM model i dato je poređenje oba modela. Za evaluaciju je korišćena Srednja kvadratna greška (MSE) kao i Srednja apsolutna greška (MAE). ConvLSTM model je pokazao manju grešku i rezultati su pokazali da može da se koristi za predviđanje optičke debljine aerosola.**

***Ključne reči* — Optička debljina aerosola; ConvLSTM; satelitski snimci; CNN LSTM.**

I. Uvod

MAŠINSKO učenje kao deo veštačke inteligencije omogućuje napredovanje nauke u raznim oblastima. Savremeni tehnološki razvoj preko Interneta i velikih količina podataka omogućuje jednostavan pristup i korišćenje tih velikih baza podataka. Satelitski snimci kao skup podataka preko daljinske detekcije postali su dostupni naučnicima što omogućuje njihovo istraživanje. NASA pruža preko 50 različitih globalnih skupova podataka satelitskih snimaka. Jedan od tih skupova podataka je MODAL2_E_AER_OD koji predstavlja optičku debljinu aerosola snimanu svaki 8 dan od 2000. godine.

Odranije je poznato da aerosoli igraju važnu ulogu u oblikovanju vremena i klime, a novo istraživanje pokazalo je da i najsitnije čestice imaju nesrazmerno veliko dejstvo. Aerosoli iako mali su proizvođači snažnih kiša. Računarskim simulacijama naučnici su pokazali dejstvo tih čestica na olujne oblake. Iako su te čestice male, ima ih mnogo, i mogu da formiraju male kapi, na koje se kondenzuje isparavanje vode. To rezultuje oslobađanjem veće količine toplote koja osnažuje vazdušne mase. Više toplog vazduha ulazi u oblake i time stvara više leda, snega, munja i kiše.

II. Metod

Spektroradiometar umerene rezolucije (MODIS - Moderate Resolution Imaging Spectroradiometer) je satelitski senzor koji se koristi za merenja zemlje i klime. MODIS instrumenti hvataju podatke u 36 spektralnih opsega u talasnim dužinama od 0.4 mm do 14.4 mm i u različitim prostornim rezolucijama (2 opsega na 250 m, 5 opsega na 500 m i 29 opsega na 1 km). Sa svojom visokom prostornom rezolucijom, ali niskom vremenskom rezolucijom, MODIS podaci su korisni za praćenje promena u globalnoj koncentraciji aerosola tokom vremena.

NASA skupovi podataka dostupni su kao RGB i kao PNG fajlovi i u rezoluciji 3600 x 1800 piksela. Sl. 1 prikazuje jedan snimak iz skupa podataka MODAL2_E_AER_OD koji predstavlja globalni AOT (aerosol optical thickness) na svakih 8 dana [12, 13] što predstavlja 993 slike do 14.09.2021.

Sl. 1. Snimak od 2021-07-12 globalnog AOT.

Optička debljina manja od 0.1 (bledožuta) ukazuje na kristalno čisto nebo sa maksimalnom vidljivošću, dok vrednost od 1 (crvenkasto smeđa) ukazuje na veoma maglovite uslove.

Preko MODIS-a na NASA-inim satelitima Terra i Aqua prati se AOT kao i distribucija aerosola, u većem delu sveta (okeani i vlažni delovi kontinenata) na dnevnom nivou, svakih 8 dana i mesečno. MODIS se koristi za praćenje masene koncentracije aerosola, optičkih svojstava i zračenja. MODIS-ove informacije o aerosolu se koriste za proučavanje klimatologije aerosola, za praćenje izvora i ponora specifičnih tipova aerosola (kao što su sulfati i drugi industrijski/urbani

 ISBN 978-86-7466-930-3

aerosol i aerosol sagorevanja biomase), i služe kao ulazni podaci za klimatsko modeliranje [7]. MODIS-ove informacije o aerosolu mogu se koristiti za predviđanje PM [11].

Satelitski snimci MODAL2_E_AER_OD predstavljaju ulazne podatke u modelu mašinskog učenja ConvLSTM. Tradicionalne metode predviđanja vremenskih serija fokusiraju se na univarijantne podatke sa linearnim odnosima i fiksnom i ručno dijagnostikovanom vremenskom zavisnošću. Neuronske mreže dodaju mogućnost učenja potencijalno nelinearnih odnosa sa proizvoljno definisanim, ali fiksnim brojem ulaza i izlaza koji podržavaju multivarijantno i višestepeno predviđanje.

Duboko učenje (DL – Deep Learning) je deo ML zasnovan na veštačkim neuronskim mrežama (ANN - Artificial Neural Networks). U DL konvoluciona neuronska mreža (CNN - Convolutional Neural Network) je klasa ANN, koja se najčešće primenjuje za analizu vizuelnih slika. U CNN-u ulaz je tenzor sa oblikom (broj ulaza) x (visina) x (širina) x (kanali). [17 , 18]. Jedna od primena CNN-a je izdvajanje prostornih informacija iz slika.

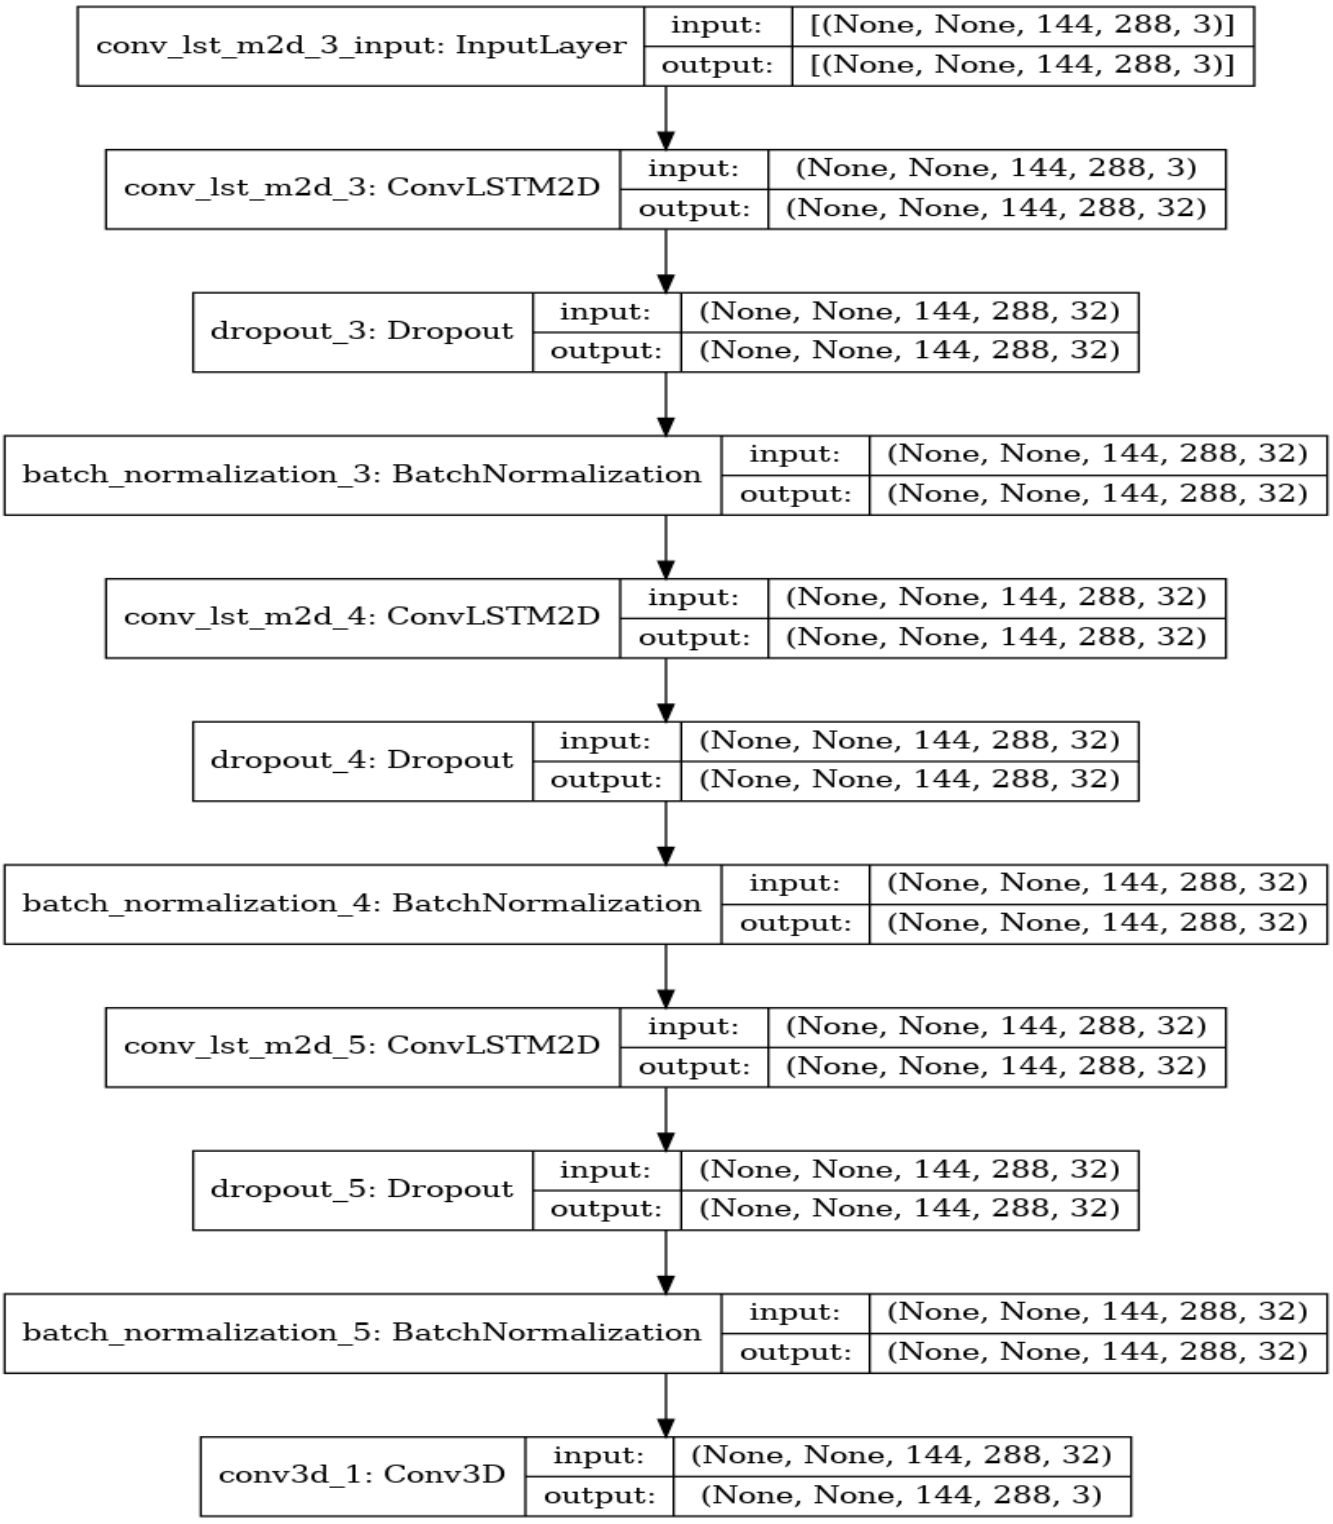
LSTM - Long Short-Term Memory je tip Rekurentne neuronske mreže (RNN - Recurrent Neural Networks) dizajniran tako da nema problem sa nestajućim gradijentom. LSTM mreže imaju povratne veze koje daju neuronima mogućnost odluke na temelju ne samo trenutne već i prethodnih vrednosti [19].

Prostorno-vremensko predviđanje može da se uradi CNN i LSTM, gde CNN (Convolution2D) služi za ekstrahovanje prostornih karakteristika, dok se LSTM koristi za otkrivanje korelacija tokom vremena [20]. Međutim, slaganjem ovih vrsta slojeva, korelacija između prostornih i vremenskih karakteristika možda neće biti pravilno ekstrahovana. Rešenje je mrežna struktura sposobna da uhvati prostorno-vremenske korelacije ConvLSTM [21]. U Kerasu je napravljena klasa (sloj) ConvLSTM2D, koja izračunava konvolucione operacije i u ulaznoj i u rekurentnoj transformaciji da bi istovremeno uhvatila prostorno-vremenske podatke. ConvLSTM2D je rekurentni sloj, baš kao i LSTM, ali interna množenja matrice se razmenjuju sa operacijama konvolucije. Kao rezultat toga, podaci koji teku kroz ConvLSTM ćelije zadržavaju ulaznu dimenziju umesto da budu samo 1D vektor [21 - 23]. Glavna razlika između ConvLSTM i LSTM je broj ulaznih dimenzija. Pošto su LSTM ulazni podaci jednodimenzionalni, nisu pogodni za podatke o prostornoj sekvenci kao što je video, satelitske slike itd. ConvLSTM je dizajniran za 3D podatke na ulazu.

III. CONVLSTM MODEL

Ulaz kod LSTM je 3D tenzor sa oblikom: broj uzoraka, vremenski korak, karakteristike (samples, time steps, features). Ulaz konvolucionog sloja je 4D tenzor sa oblikom: uzorci, redovi, kolone, kanali (samples, rows, cols, channels). Ulaz za ConvLSTM model je 5D tenzor sa oblikom: uzorci, vremenski koraci, redovi, kolone, kanali (samples, time steps, rows, cols, channels).

Izlaz ćelije LSTM zavisi od atributa return_sekuence. Kada je postavljeno na True, izlaz je sekvenca tokom vremena (jedan izlaz za svaki ulaz). U ovom slučaju, izlaz je 3D tenzor sa oblikom: uzorci, vremenski koraci, karakteristike. Kada je return_sekuences podešen na False, izlaz je poslednja vrednost niza, odnosno 2D tenzor sa oblikom (uzorci, karakteristike). Izlaz ConvLSTM sloja je kombinacija Convolution i LSTM izlaza. Baš kao i LSTM, ako je return_sekuences = True, onda vraća niz kao 5D tenzor sa oblikom: uzorci, vremenski koraci, redovi, kolone, filteri. Kada je return_sekuences = False, onda vraća samo poslednju vrednost niza kao 4D tenzor sa oblikom (uzorci, redovi, kolone, filteri).



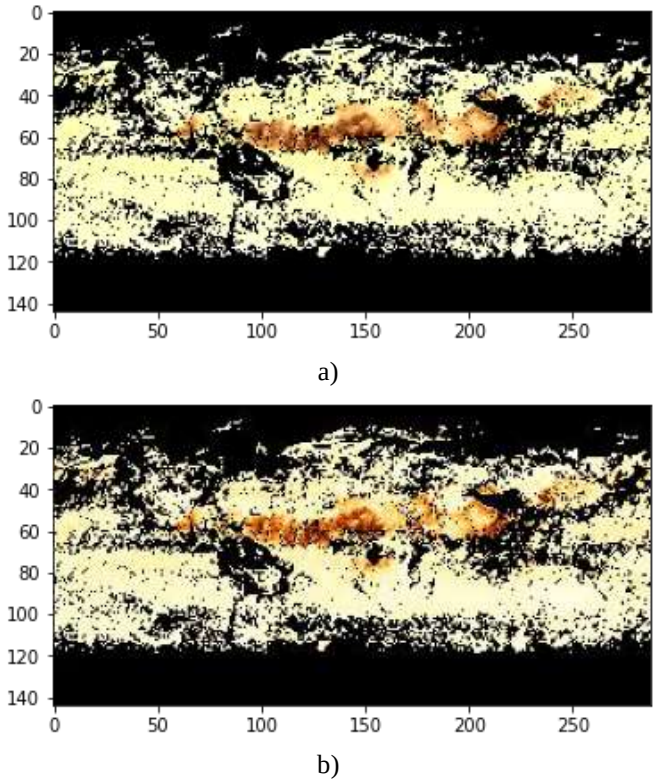
ML model koji se koristi u ovoj studiji sastoji se od 3 sloja ConvLSTM2D i krajnjeg sloja Conv3D kao izlaza. Conv3D sloj stvara konvoluciono jezgro koje je konvoluirano sa ulazom sloja da bi se proizveo tenzor izlaza, tj. visina, širina, kanal slike. ML model je napravljen u Kerasu.

CNN LSTM model ima prvi ulazni sloj koji prima niz od 10 slika rezolucije 144x288 piksela sa tri RGB kanala. Obzirom da Conv2D sloj može da funcioniše samo sa jedom slikom, njemu i u narednih 5 slojeva dodat je sloj TimeDistributed koji omogućava rad sa nizom ulaznih podataka. Drugi sloj Conv2D ima 32 filtera radi boljih performansi modela. BatchNormalization u trećem i petom sloju se koristi radi prevecije takozvane eksplozije loss funkcije i ravnomernijeg napredovanja odnosno normalizacije tokom procesa učenja, sprečavanjem prevelikog napredovanja pojedinih težina u odnosu na ostale u neuralnoj mreži odnosno svakom sloju zasebno. Četvrti sloj Conv2D sa tri filtera vraća format na tri RBG kanala. Šesti sloj Reshape vrši poravnanje 2D formata slike u 1D format zbog pripreme za sledeći sedmi LSTM memorijski sloj. Osmi Dropout sloj vrši prevenciju preteranog učenja kod koga se javlja veoma dobro procesiranje poznatih, ali loše procesiranje novih podataka. Deveti Dense sloj formira konačan broj piksela izlazne predikovane slike koji se u desetom Reshape sloju transformniše u odgovarajući format.

Skup ulaznih podataka bio je MODAL2_E_AER_OD, skup satelitskih slika od 18.02.2000. do 14.09.2021. na svakih 8 dana. Odnos train/test bio je 70/30, 80/20 i 90/10. Optimum je postignut podelom 80/20. Najbolje rezultate dala je funkcija aktivacije 'hard_sigmoid' za Conv3D sloj i optimizator 'adam' (learning_rate=0,001). Problem prediktivnog modeliranja regresije uključuje predviđanje veličine realne vrednosti, tako da je za funkciju gubitka korišćen 'mse', a za metriku RootMeanSkuaredError (RMSE). Sl. 2 prikazuje korišćeni ConvLSTM model (slika je dobijena komandom: plot_model(model, to_file='model.png', show_shapes=True, show_layer_names=True)).

https://www.kaggle.com/code/dusan75/convlstm-notebook09a46b0eb3

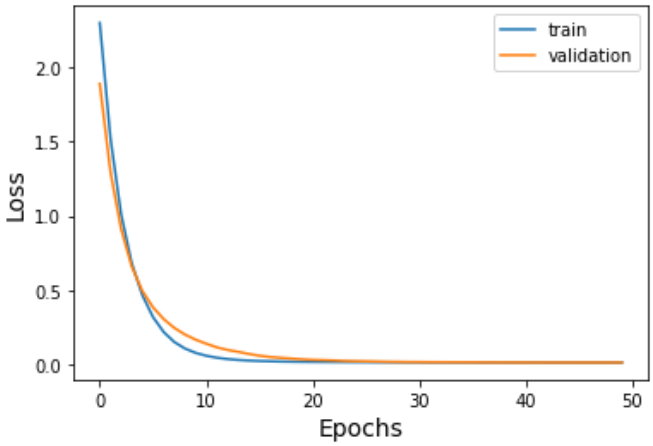
 ISBN 978-86-7466-930-3



Sl. 2. Prikaz ConvLSTM modela.

Nakon obuke ML modela, urađeno je predviđanje prve slike iz skupa test podataka i upoređeno je sa originalnom prvom slikom iz skupa podataka testa.

IV. REZULTATI I DISKUSIJA

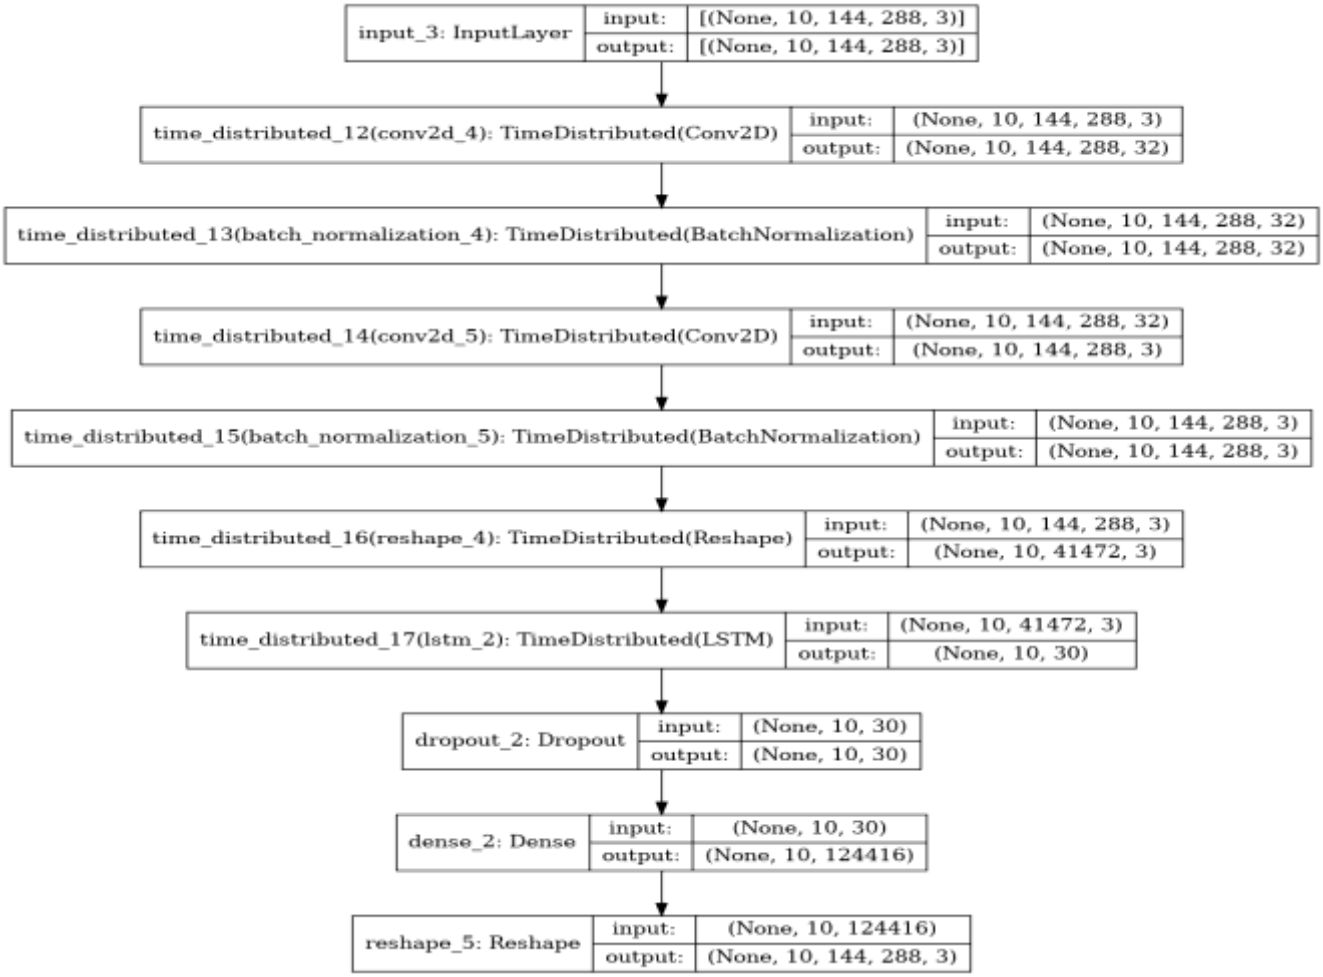


Sa ConvLSTM modelom je predikovana prva slika iz test skupa podataka, Sl. 3a. Sl. 3b prikazuje originalnu prvu sliku iz test skupa podataka.

 ISBN 978-86-7466-930-3

Sl. 3. Globalni AOT a) predikovani; b) realni.

Validacija ML modela je zasnovana na metrici evaluacije, tj. mse 0,0116 (mean squared error). Ovi rezultati dokazuju da se predloženi ML model može koristiti za AOT prognoze. Sl. 4 prikazuje grafikon gubitka tokom 50 epoha obuke.



Sl. 4. Grafikon gubitka u zavisnosti broja epoha.

Pre ConvLSTM2D za prostorno-vremensku zavisnost i predikciju se koristio CNN+LSTM model [24]. Za poređenje ConvLSTM i CNN LSTM razvijen je novi CNN LSTM model. Sl. 5 prikazuje novi model CNN LSTM.

Metrika evaluacije bila je za mse 0,1117 i u poređenju sa ConvLSTM modelom (mse 0,0116) je veća vrednost. Niže vrednosti mse ukazuju na manju grešku.

 ISBN 978-86-7466-930-3

Sl. 5. Prikaz CNN LSTM modela.

Primena Mean Absolute Percent Error metrike na konkretnom primeru nije primenljiva, obzirom na činjenicu da se među y-true vrednotima nalazi i vrednost 0 zbog koje metoda ne daje vrednosti u predviđenom opsegu od 0 do 1. Testiranje modela nalazi se na adresi:

https://www.kaggle.com/code/dusan75/test-of-convlstm-notebook09a46b0eb3?scriptVersionId=94940211

Za bolje poređenje dva modela urađena je sledeća statistika. Srednja apsolutna greška (MAE - Mean Absolute Error) koristi se za predviđanja u segmentu od 9 frejmova po slici, Tabela 1.

TABELA I
PROSEČNA GREŠKA PREDVIĐANJA U SEGMENTU OD 9 FREJMOVA PO SLICI

ConvLSTM	CNN LSTM
0.02200718	0.24474642
0.02213584	0.2462145
0.02251104	0.24545886
0.02263835	0.2449535
0.0227564	0.24526556
0.02259156	0.24504275
0.02232519	0.24720876
0.02259231	0.2456902
0.02278301	0.24560421

Iz dobijenih rezultata može se zaključiti da je ConvLSTM model zahtevao dobro strukturirane ulazne podatke, pravi izbor i optimalno podešene hiperparametre modela pre nego što bi mogao da se koristi za pouzdana AOT predviđanja.

V. ZAKLJUČAK

Aerosoli su jedan od najvećih izvora nesigurnosti u modeliranju klime. Zračenje aerosolima može objasniti razliku između posmatranih i modelovanih trendova prosečne globalne temperature. U stvari, interakcija sa sunčevim i zemaljskim zračenjem pomoću aerosola remeti radijativni budžet rasejanjem i apsorpcijom sunčeve svetlosti. Mnoge nedavne studije pokazuju važnost uključivanja aerosola u klimatske modele za posmatranje i merenje ljudskog uticaja na atmosfersku hemiju i klimatske promene.

Ova studija je istraživala mogućnost ConvLSTM modela za predviđanje globalnog AOT-a sa MODIS satelitskih snimaka. Sloj ConvLSTM2D u Kerasu spaja prostornu i vremensku komponentu i omogućava predikciju. Satelitski snimci pomažu u sagledavanju globalnog transporta zagađivača.

Modeli mašinskog učenja kreirani su od strane autora, tj. originalne i inovativne su strukture, pa se i rezultati treniranja

 ISBN 978-86-7466-930-3

i predviđanja modela, pored originalne strukture, mogu uzeti kao doprinos zajednici radi poređenja postignutih rezultata.

ZAHVALNICA

Ovaj rad je realizovan u okviru istraživačke teme 1002205 koga finansira Ministarstvo prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

ConvLSTM model was developed with ConvLSTM2D layers for predicting aerosol optical thickness. The input dataset was satellite images of aerosol optical thickness on 8-day beginning from 2000. When the model was trained, aerosol optical thickness prediction as well as model evaluation was given. The CNN LSTM model was developed and applied over the same dataset and a comparison of both models is given. Mean square error (MSE) as well as Mean absolute error (MAE) were used for evaluation. The ConvLSTM model showed less error and the results showed that it could be used to predict the aerosol optical thickness.

ConvLSTM Application for Prediction Aerosol Optical Thickness

Primena veštačke inteligencije na terminal za daljinsko upravljanje stanice za punjenje električnih vozila koja se napaja iz obnovljivih izvora električne energije

Jovan Vujasinović i Goran Savić

***Apstrakt*— U ovom radu je opisana primena veštačke inteligencije na terminal za daljinsko upravljanje stanice za punjenje električnih vozila, koja se napaja iz obnovljivih izvora električne energije. Kako terminal omogućava daljinsko upravljanje punjačima električnih vozila, pametnim baterijama, pametnim brojilima, fiskalnim kasama i eventualno daljinsko upravljanje obnovljivim izvorom električne energije i drugim uređajima u okviru objekta, neophodno je definisati i razraditi odgovarajući algoritam upravljanja radom terminala. U ovom radu je razmatrana realizacija tog upravljanja primenom veštačke inteligencije. Na ovaj način ovakve stanice za punjenje električnih vozila postaju potpuno autonomne u svom radu, i daju optimalne rezultate, što podiže njihovu dostupnost korisnicima električnih vozila. To potencijalno podstiče povećanje obima korišćenja električnih vozila za koje se energija obezbeđuje iz obnovljivih izvora, čime se smanjuje stepen zagađenja vazduha kao i negativni efekti koje ono sa sobom donosi.**

***Ključne reči*— Veštačka inteligencija; punjači električnih vozila; obnovljivi izvori energije.**

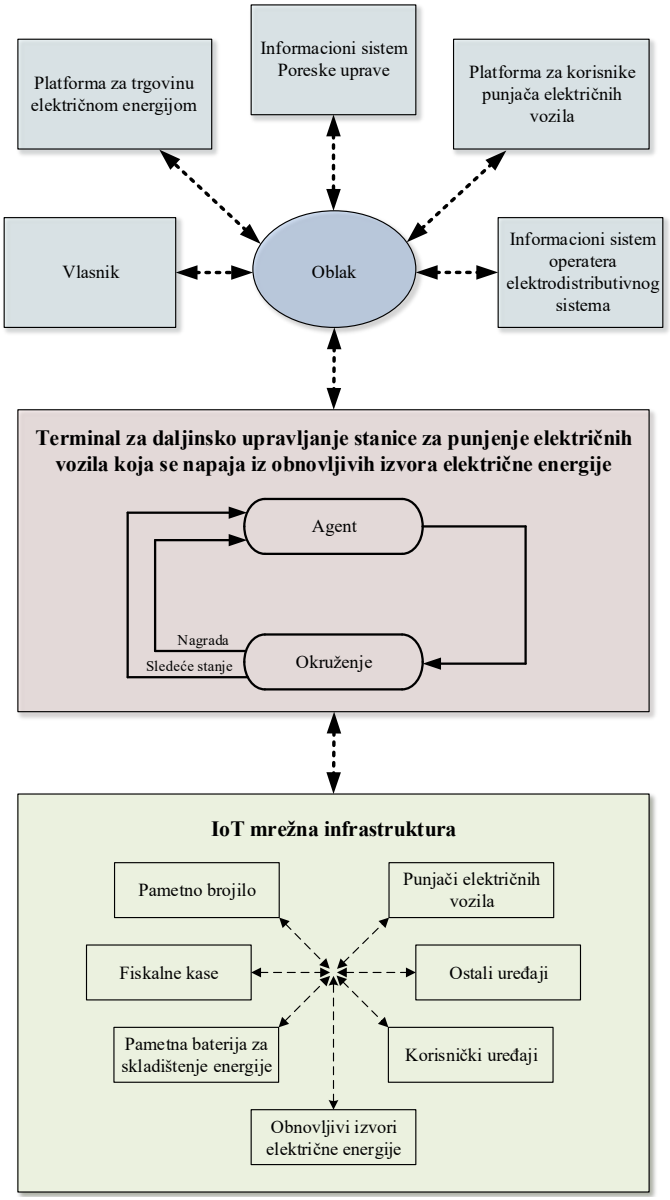
I. Uvod

Povećanje broja proizvedenih i korišćenih električnih vozila, ima za cilj smanjenje zagađenja životne sredine i štetnih efekata koje ono sa sobom nosi, a koji su posledica emisije štetnih gasova vozila na dizel i benzinski pogon. Međutim, preduslov da bi upotreba vozila na električni pogon zaista doprinela smanjenju zagađenja životne sredine, je da električna energija koja se koristi za punjenje električnih vozila bude proizvedena iz izvora koji ne zagađuju životnu sredinu, tj. iz obnovljivih izvora električne energije. To dovodi i do neminovnog razvoja infrastrukture za punjenje električnih vozila, što se ogleda i u stalnom povećanju broja stanica za punjenje električnih vozila koje se napajaju iz obnovljivih izvora električne energije [1].

Povećanje dostupnosti stanica za punjenje električnih vozila, kako korisnicima električnih vozila, tako i operaterima elektrodistribucije, snabdevača i poreske uprave, kao i vlasnicima i korisnicima same stanice, ostvaruje se integracijom u jedan veći sistem, zahvaljujući kojem se postiže ušteda vremena i novca, i efikasnija upotreba elektrodistributivne mreže. Da bi se ostvarile funkcionalnosti tog sistema, koje su od značaja svim korisnicima, realizovano je daljinsko upravljanje stanice za punjenje električnih vozila. Ključni uređaj koji omogućava pomenuto daljinsko upravljanje je terminal za daljinsko upravljanje stanice za punjenje električnih vozila koja se napaja iz obnovljivih izvora električne energije. Proces upravljanja je zasnovan na primeni naprednih algoritama veštačke inteligencije, čija je primena na terminal za daljinsko upravljanje stanice za punjenje električnih vozila prezentovana u ovom radu.

U Sekciji II ovog rada je opisana arhitektura sistema za daljinsko upravljanje stanice za punjenje električnih vozila koja se napaja iz obnovljivih izvora električne energije, u Sekciji III je data kategorizacija stanica i terminala, u Sekciji IV je predstavljena veštačka inteligencija, u Sekciji V je opisano mašinsko učenje, u Sekciji VI je razmatrana primena veštačke inteligencije na terminal, dok Sekcija VII predstavlja kratak zaključak.

II. Arhitektura sistema



Blok šema arhitekture sistema za daljinsko upravljanje stanice za punjenje električnih vozila koja se napaja iz obnovljivih izvora električne energije [2] je prikazana na Sl. 1. Terminal za daljinsko upravljanje stanice za punjenje električnih vozila, koji predstavlja osnovnu komponentu sistema, je povezan sa punjačima električnih vozila, pametnom baterijom za skladištenje energije, obnovljivim izvorima električne energije, pametnim brojilom, fiskalnim kasama, korisničkim uređajima i ostalim uređajima, pomoću IoT mrežne infrastrukture. Pored toga, terminal za daljinsko upravljanje stanice za punjenje električnih vozila je povezan i sa oblakom preko internet veze, čime je omogućeno da se podaci dobijeni od punjača električnih vozila, pametne baterije za skladištenje energije, obnovljivih izvora električne energije, pametnog brojila i fiskalnih kasa, prate, skladište i obrađuju. Pristup tim podacima je omogućen sledećim platformama: platformi za korisnike punjača električnih vozila, platformi za trgovinu električnom energijom, informacionom sistemu operatera elektrodistributivnog sistema i informacionom sistemu Poreske uprave. Platforma za korisnike punjača električnih vozila omogućava vlasnicima električnih vozila da dobiju sve potrebne informacije o punjačima električnih vozila. Platforma za trgovinu

Jovan Vujasinović – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11120 Beograd , Srbija (e-mail: jovan.vujasinovic@vfholding.rs).

Goran Savić – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar Kralja Aleksandra 73, 11120 Beograd, Srbija (e-mail: gsavic@etf.rs).

 ISBN 978-86-7466-930-3

električnom energijom omogućava obavljanje trgovine električnom energijom koja je raspoloživa u sistemu. Takođe, pristup podacima u oblaku imaju i vlasnici stanica za punjenje električnih vozila. Ti podaci se procesiraju primenom algoritama veštačke inteligencije, čime se ostvaruje efikasna upotreba distributivne mreže uz korišćenje inovativnih pametnih energetskih usluga, kao i značajne uštede u celom sistemu.

Sl. 1. Blok šema arhitekture sistema za daljinsko upravljanje stanice za punjenje električnih vozila koja se napaja iz obnovljivih izvora energije.

III. KATEGORIJE STANICA I TERMINALA

Stanice za punjenje električnih vozila koje se napajaju iz obnovljivih izvora električne energije možemo kategorisati na rezidencijalne, komercijalne i industrijske stanice [3]. Isto tako, prema tipu stanice kod koje se primenjuje, terminale možemo podeliti na light, standard i extended terminale [4].

Rezidencijalne stanice su namenjene za kućnu upotrebu, samo za potrebe domaćinstva. U okviru ove stanice očekuje se instalacija 1-2 punjača za električna vozila. Potrebe ovakvih stanica mogu se pokriti samo korišćenjem solarnih obnovljivih izvora. Kod ovih stanica koristi se light terminal koji ima najjednostavniji hardver i softver, a ceo sistem za upravljanje ovakvom stanicom je vrlo sličan sa sistemom za upravljanje energijom u domaćinstvima.

Komercijalne stanice su male i srednje stanice za punjenje električnih vozila koje imaju visoku frekvenciju punjenja vozila. Obično su to stanice namenjene prodaji električne energije vlasnicima električnih vozila, kao što su srednje stanice koje će eventualno zameniti postojeće benzinske pumpe sa 10-20 punjača, manje stanice u domaćinstvima sa 1-2 punjača za ovu namenu, kao i kao stanice na manjim parkiralištima sa do 20 punjača. Potrebe ovakvih stanica ne mogu se pokriti korišćenjem samo solarnih obnovljivih izvora. Gde geografsko područje dozvoljava, ima smisla koristiti vetrogenerator. Moguća je upotreba generatora na biomasu, ako prostorni kapaciteti to dozvoljavaju, što bi prvo mogao biti slučaj u ruralnim područjima. U urbanim sredinama, u mnogim mestima jedini način da se nadoknadi nedostatak električne energije je preuzimanje energije iz elektro distributivne mreže. Kod ovih stanica koristi se standard terminal koji ima složeniji hardver i softver, a ceo sistem za upravljanje ovakvom stanicom je složeniji od sistema za upravljanje energijom u domaćinstvima..

Industrijske stanice su velike stanice za punjenje električnih vozila namenjene za opsluživanje flote električnih vozila od nekoliko stotina komada. U ovu grupu stanica spadaju stanice kod proizvođača električnih vozila, stanice kod velikih drumskih prevoznika i stanice na masovnim parkiralištima kao što su garaže, tržni centri itd. Slično komercijalnim stanicama, potrebe ovakvih stanica ne mogu se pokriti korišćenjem samo obnovljivih izvora električne energije, a često jedini način da se nadoknadi nedostajuća električna energija je preuzimanje iste iz elektro distributivne mreže. Kod ovih stanica koristi se extended terminal, koji ima najsloženiji hardver i softver.

IV. VEŠTAČKA INTELIGENCIJA

Veštačka inteligencija se može definisati kao sposobnost digitalnog računara ili kompjuterski kontrolisanog robota da obavlja zadatke koji se obično povezuju sa inteligentnim bićima [5]. Izraz se često primenjuje na projekat razvoja sistema obdarenih intelektualnim procesima karakterističnim za ljude, kao što je sposobnost rasuđivanja, otkrivanja značenja, generalizacije ili učenja iz prethodnog iskustva. Psiholozi generalno ne karakterišu ljudsku inteligenciju samo jednom osobinom, već kombinacijom mnogih različitih sposobnosti. Istraživanja u oblasti veštačke inteligencije su se uglavnom fokusirala na sledeće komponente inteligencije: učenje, rasuđivanje, rešavanje problema, percepciju i korišćenje jezika. Pored ovih osnovnih komponenti, mogu se naći istraživanja koja se bave i razvojem mašina koje imaju sledeće sposobnosti: planiranje, predstavljanje znanja, kretanje, socijalna inteligencija i opšta inteligencija.

Rasuđivanje znači izvođenje zaključaka koji odgovaraju situaciji. Zaključci se klasifikuju kao deduktivni ili induktivni.

 ISBN 978-86-7466-930-3

Najznačajnija razlika između ovih oblika rezonovanja je u tome što u deduktivnom slučaju istinitost premisa garantuje istinitost zaključka, dok u induktivnom slučaju istinitost premise daje podršku zaključku bez da daje apsolutnu sigurnost. Postignut je značajan uspeh u programiranju računara za izvođenje zaključaka, posebno deduktivnih zaključaka. Međutim, pravo rezonovanje uključuje više od samog izvođenja zaključaka; podrazumeva izvođenje zaključaka relevantnih za rešenje konkretnog zadatka ili situacije. Ovo je jedan od najtežih problema sa kojima se veštačka inteligencija suočava.

Rešavanje problema, posebno u veštačkoj inteligenciji, može se okarakterisati kao sistematsko traženje niza mogućih radnji u cilju dostizanja nekog unapred definisanog cilja ili rešenja. Metode rešavanja problema dele se na metode posebne namene i metode opšte namene. Metoda posebne namene je skrojena za određeni problem i često koristi veoma specifične karakteristike situacije u kojoj je problem ugrađen. Nasuprot tome, metoda opšte namene je primenljiva na širok spektar problema. Mnogi različiti problemi rešeni su programima veštačke inteligencije. Neki primeri su pronalaženje pobedničkog poteza (ili niza poteza) u igri na ploči, osmišljavanje matematičkih dokaza i manipulacija „virtuelnim objektima“ u kompjuterski generisanom svetu.

Percepciju možemo opisati kao skeniranje okoline pomoću različitih čulnih organa, stvarnih ili veštačkih, i razlaganje scene na zasebne objekte u različitim prostornim odnosima. Analiza je komplikovana činjenicom da objekat može izgledati drugačije u zavisnosti od ugla iz kojeg se posmatra, pravca i intenziteta osvetljenja u sceni i koliko je objekat u kontrastu sa okolnim poljem. Mašinsku percepciju [6] možemo definisati kao sposobnost da se koriste ulazni signali sa senzora (kao što su kamere, mikrofoni, bežični signali, sonar, radar i taktilni senzori) da bi se zaključili aspekti sveta, odnosno okruženja. Aplikacije uključuju i prepoznavanje govora, prepoznavanje lica i prepoznavanje objekata. Trenutno je veštačka percepcija dovoljno napredna da omogući optičkim senzorima da identifikuju pojedince, autonomnim vozilima da voze umerenom brzinom na otvorenom putu i robotima da lutaju kroz zgrade skupljajući prazne limenke soda.

Korišćenje jezika omogućava mašinama da čitaju i razumeju ljudski jezik. Dovoljno moćan sistem za obradu ljudskog jezika bi omogućio korisničke interfejse na ljudskom jeziku i sticanje znanja direktno iz izvora pisanih od strane ljudi, kao što su tekstovi i vesti. Neke jednostavne primene korišćenja jezika uključuju pronalaženje informacija, odgovaranje na pitanja i mašinsko prevođenje [7].

Planiranje omogućava računaru da predviđa kako će ga njegove akcije promeniti i da donosi odluke koji maksimiziraju korist iz dostupnih izbora [8]. U klasičnim problemima planiranja, računar može pretpostaviti da je on jedini sistem koji deluje na svetu, dozvoljavajući sebi da bude siguran u posledice svojih akcija. Međutim, ako računar nije jedini akter, onda to zahteva da agent razmišlja u neizvesnosti, i kontinuirano ponovo procenjuje svoje okruženje i prilagođava se. Planiranje sa više računara koristi saradnju i konkurenciju mnogih računara za postizanje zadatog cilja.

Predstavljanje znanja i inženjering znanja [6] omogućavaju programima veštačke inteligencije da inteligentno odgovaraju na pitanja i donose zaključke o činjenicama iz stvarnog sveta. Reprezentacija „onog što postoji“ je ontologija: skup objekata, relacija, koncepata i svojstava formalno opisanih tako da softverski programi mogu da ih tumače. Najopštije ontologije se nazivaju gornje ontologije, koje pokušavaju da obezbede osnovu za sva druga znanja i deluju kao posrednici između ontologija domena koje pokrivaju specifično znanje o određenom domenu znanja.

Kretanje se u velikoj meri koristi u robotici [6]. Lokalizacija je način na koji robot zna svoju lokaciju i mapira svoje okruženje. Kada se dobije malo, statičko i vidljivo okruženje, ovo je lako; međutim, dinamična okruženja, kao što je (u endoskopiji) unutrašnjost tela koje diše, predstavljaju veći izazov.

Razvoj sposobnosti socijalne inteligencije je interdisciplinarna oblast koji obuhvata sisteme koji prepoznaju, tumače, obrađuju ili simuliraju ljudska osećanja, emocije i raspoloženje [9]. Na primer, neki virtuelni asistenti su programirani da pričaju razgovorno ili čak da se šale na duhovit način; to čini da izgledaju osetljiviji na emocionalnu dinamiku ljudske interakcije ili da na drugi način olakšaju interakciju između čoveka i računara.

Mašina sa opštom inteligencijom može rešiti širok spektar problema sa širinom i svestranošću sličnom ljudskoj inteligenciji. Postoji nekoliko konkurentnih ideja o tome kako razviti veštačku opštu inteligenciju.

V. MAŠINSKO UČENJE

Mašinsko učenje je disciplina veštačke inteligencije koja se bavi implementacijom kompjuterskih softvera koji su u stanju da samostalno uče [10]. Kako bi mogli da predviđaju ili donose odluke, algoritmi mašinskog učenja grade model zasnovan na uzorku podataka, poznatih kao podaci o obuci. Podskup mašinskog učenja je usko povezan sa statistikom, ali nije svako mašinsko učenje statističko učenje. Pretraga podataka, odnosno praksa analize velikih baza podataka u cilju generisanja novih informacija, je srodna oblast proučavanja, koja se fokusira na istraživačku analizu podataka.

Generalno, algoritmi mašinskog učenja se koriste za predviđanje ili klasifikaciju [11]. Na osnovu nekih ulaznih podataka, koji mogu biti označeni ili neoznačeni, algoritam će proizvesti procenu o obrascu u podacima. Zatim se vrši procena takvog predviđanja. Ako postoje poznati primeri, funkcija greške može da napravi poređenje da proceni tačnost predviđanja. Ako predviđanje može bolje da se uklopi u tačke podataka u skupu za obuku, onda se odgovarajući koeficijenti prilagođavaju da bi se smanjila neslaganja između poznatog primera i procene. Algoritam će ponoviti ovaj proces evaluacije i optimizacije, samostalno ažurirajući koeficijente dok se ne dostigne prag tačnosti.

Mašinsko učenje se može klasifikovati na: nadgledano, nenadgledano i polunadgledano učenje, kao i pojačano učenje. Učenje pod nadzorom, takođe poznato kao nadgledano mašinsko učenje, definisano je upotrebom označenih skupova podataka za obuku algoritama koji klasifikuju podatke ili tačno predviđaju ishode. Kako se ulazni podaci unose u

 ISBN 978-86-7466-930-3

model, on prilagođava svoje koeficijente dok se model ne uklopi na najbolji mogući način. Učenje bez nadzora, poznato i kao nenadgledano mašinsko učenje, koristi algoritme mašinskog učenja za analizu i grupisanje neoznačenih skupova podataka. Ovi algoritmi otkrivaju skrivene obrasce ili grupisanje podataka bez potrebe za ljudskom intervencijom. Njegova sposobnost da otkrije sličnosti i razlike u informacijama čini ga idealnim rešenjem za istraživačku analizu podataka, strategije unakrsne prodaje, segmentaciju kupaca, prepoznavanje slika i obrazaca. Polu-nadgledano učenje nudi optimalan odnos između učenja pod nadzorom i učenja bez nadzora. Tokom obuke, koristi manji skup označenih podataka da vodi klasifikaciju i izdvajanje karakteristika iz većeg, neoznačenog skupa podataka. Polu-nadgledano učenje može da reši problem nedostatka označenih podataka (ili nemogućnosti da priuštite da označite dovoljno podataka) za obuku algoritma za učenje pod nadzorom. Pojačano učenje je model mašinskog učenja ponašanja koji je sličan nadgledanom mašinskom učenju, ali algoritam nije obučen korišćenjem uzoraka podataka. Ovaj model uči koristeći pokušaje i greške. Niz uspešnih ishoda će biti pojačan kako bi se razvila najbolja preporuka ili politika za dati problem.

Neke metode koje se koriste u mašinskom učenju uključuju neuronske mreže, Bajesove mreže, linearnu regresiju, logističku regresiju, slučajnu šumu (drvo odlučivanja), mašinu vektora podrške (SVM), grupisanje k-srednjih vrednosti, metode verovatnoće klasterisanja i još mnogo toga. Metoda neuronske mreže imitira rad biološkog mozga.

VI. Primena veštačke inteligencije na terminal

U radu koji daje pregled stanja u oblasti sistema upravljanja energijom u domaćinstvu [12] može se uočiti da između ostalih postoje i grupe radova koji se bave primenom veštačke inteligencije u toj oblasti. Uvidom u to, možemo uočiti da se najviše primenjuje pojačano učenje. Ovo saznanje se takođe odnosi i na sistem za daljinsko upravljanje stanicom za punjenje električnih vozila, iz razloga što je *light* varijanta terminala namenjena za korišćenje kod rezidencijalne stanice za punjenje električnih vozila. Rezidencijalna stanica za punjenje električnih vozila predstavlja sistem upravljanja energijom u domaćinstvu. Pored rezidencijalne stanice, postoje i komercijalne i industrijske stanice, kod kojih se koriste dosta složenije *standard* i *extended* varijanta terminala. Ipak, zbog njihove sličnosti sa *light* varijantom terminala, možemo reći da se i na njih odnosi gore pomenuto saznanje. Dakle, generalno za rad terminala za daljinsko upravljanje najzgodnije je primeniti pojačano učenje. Iz svega prethodno rečenog sledi da možemo u daljem tekstu dati pregled glavnih zaključaka iz primene tehnika mašinskog učenja, odnosno tehnika pojačanog učenja na sisteme upravljanja energijom u domaćinstvu, jer su oni potpuno primenljivi i dobra polazna osnova za primenu istih tehnika na terminal za daljinsko upravljanje stanicom za punjenje električnih vozila, koja se napaja iz obnovljivih izvora električne energije.

Kod upravljanja energijom u domaćinstvu, glavni cilj je optimizacija, odnosno minimiziranje ukupne potrošnje električne energije i smanjenje računa za struju u pametnoj kući [13], kao i optimalan plasman električne energije dobijene iz obnovljivih izvora, ako su oni primenjeni. Tipičan sistem upravljanja se ne može uspešno prilagoditi raznim uređajima sa različitom složenošću rasporeda, niti je prikladan za primenu u realnom vremenu. Algoritmi pojačanog učenja (RL) su u poslednje vreme predloženi kao potencijalni kandidati za rešavanje ovih problema zbog njihove prilagodljivosti i sposobnosti da nauče prioritete i navike kupaca i optimizuju upravljanje ovakvim energetskim sistemima koji su često podložni različitim ulazima kao što su dinamičke cene električne energije, podaci meteorološke prognoze (sunce, vetar,...) i obrasci potrošnje energije (ponašanje korisnika). RL se smatra tipom algoritma sa mašinskim učenjem za donošenje odluka u stohastičkom okruženju. Ne zahteva matematički model i pogodan je za složene aplikacije u realnom vremenu. RL algoritam ima šest parametara, a to su agent, okruženje, skup stanja S, skup akcija A, nagrade R i vrednost akcije Q(s,a). Generalno, RL agent je u interakciji sa okruženjem kao što je prikazano na Sl. 1 u samom bloku terminala.

Prva upotreba pojačanog učenja za upravljanje energijom kod kuće opisana je u [14], gde se neuronska mreža koristi za kontrolu grejanja, ventilacije, klimatizacije (HVAC) i osvetljenja kako bi se smanjila nelagodnost korisnika i smanjili troškovi energije. Pored toga, postoje i radovi u kojima se koristi pojačano učenje za planiranje uključivanja/isključivanja uređaja kao odgovor na signale o cenama. To praktično znači pomeranje određenih fleksibilnih opterećenja, što omogućava minimiziranje troškova za potrošnju električne energije, tako što ne se prelazi određeni prag snage a bez izazivanja nezadovoljstva korisnika zbog odlaganja rada uređaja. Pojačano učenje primenjuje se takođe i na realizaciju različitih funkcija koje mere nezadovoljstvo korisnika kada uređaji ne uspeju da obave traženi zadatak u potrebnom vremenu. Od početka dosta je primenjivana metoda neuronske mreže [15,16], a u poslednje vreme prilično se primenjuje i metoda nazvana Q-učenje.

Algoritmi Q-učenja su RL tehnike koje su usvojene da bi se stekla optimalna politika određivanja akcija koje agent preuzima. Na osnovu primljene nagrade , agent je u stanju da optimizuje svoju politiku određivanja akcija koje treba preuzeti, i time maksimizira ukupne nagrade koje će dobiti u budućnosti. To se postiže ažuriranjem odgovarajućih koeficijenata prilikom svake iteracije, kako bi se optimizovale performanse agenta. U zavisnosti od složenosti arhitekture konkretnog sistema, moguće je i optimizaciju upravljanja energijom rešiti direktno primenom Q-učenja [13], ili primeniti Q-učenje za razbijanje glavnog problema na podzadatke koji se zatim rešavaju nezavisno korišćenjem RL [17].

Pored navedenih mogućih primena tehnika veštačke inteligencije na rešavanje glavnog problema optimizacije upravljanja energijom u ovakvim sistemima, postoje i primene u kojima se glavni problem optimizacije upravljanja energijom rešava primenom neke druge tehnike za upravljanje energije, ali se veštačka inteligencija koristi kao pomoćna metoda za predviđanje ulaznih parametara [18,19].

VII. Zaključak

U ovom radu je razmatrana primena veštačke inteligencije

 ISBN 978-86-7466-930-3

na terminal za daljinsko upravljanje stanice za punjenje električnih vozila, koja se napaja iz obnovljivih izvora energije. Prvo je prikazana arhitektura kompletnog sistema za daljinsko upravljanje stanice. Zatim je dat i pregled komponenti inteligencije koje su dosada istraživači pokušali da implementiraju u mašinama. Posebno je prikazana komponenta mašinsko učenje sa klasifikacijom i metodama koje se koriste. Potom je dat pregled primene veštačke inteligencije u oblasti sistema za upravljanje energijom u domaćinstvima. Uzevši u obzir određene sličnosti ovakvih sistema sa sistemima za daljinsko upravljanje stanicom za punjenje električnih vozila, koja se napaja iz obnovljivih izvora električne energije, zaključeno je da u ovom trenutku na terminal za daljinsko upravljanje ovakvom stanicom najviše smisla ima primeniti tehniku pojačanog učenja, i to tzv. metodu Q-učenja. Konkretna primena ove metode može biti predmet daljeg rada.

ABSTRACT

Application of artificial intelligence to the terminal for remote control of renewable energy sources powered station for electric vehicles charging has been presented in this paper. As the terminal enables remote control of electric vehicle chargers, smart storage batteries, smart electricity meters, cash registers, as well as, remote control of renewable energy sources and other devices within the station for electric vehicles charging, it is necessary to define and develop an algorithm for managing the terminal. In this paper, the realization of that management using artificial intelligence is considered. In this way, such charging stations for electric vehicles become completely autonomous in their work and give optimal results, which raises their availability to users of electric vehicles. It potentially encourages an increase in the use of electric vehicles for which energy is provided from renewable sources, which reduces the degree of air pollution as well as the negative effects it brings.

Application of Artificial Intelligence to the Terminal for Remote Control of Renewable Energy Sources Powered Station for Electric Vehicles Charging

Prepoznavanje imena na slikama lekarskih izveštaja na srpskom jeziku u cilju zaštite ličnih podataka

Aldina Avdić, Ulfeta Marovac

***A stra t*— Savremeni način života neizostavno uključuje upotrebu računara i mobilnih telefona u svim svojim segmentima, pa i ada je u pitanju zdravstvo. Pored elektronskog zdravstva koje se sve više razvija, pogotovo od kada se svet suočio sa pandemijom korona virusa, sve više ljudi traži i savete o zdravlju na društvenim mrežama. Tom prilikom dodaju slike koje sadrže njihove zdravstvene rezultate, ne mareći o tome da na taj način ostavljaju i svoje lične podatke. U ovom radu data je metoda za prepoznavanje imena na sli ama medicins ih izveštajima napisanih na srpskom jeziku u cilju njihove de-identifikacije. Ova metoda bazirana je na optičkom prepoznavanju ara tera, metodama obrade prirodnog jezi a i pravilima i ima široku upotrebu, jer je de-identifi acija elektronskih medicinskih izveštaja neophodan korak za njihovu bilo a vu dalju analizu.**

***Ključne reči*— de-identifi acija, ele trons i medicins i izveštaji, prepoznavanje imenovanih entiteta, obrada prirodnog jezi a, optičko prepoznavanje ara tera, zaštita privatnosti, srps i jezi .**

I. UVOD

Informacione i komunikacione tehnologije već duže vreme nalaze svoju primenu u zdravstvenom sistemu. E-zdravstvo (engl. *e- ealth*) je termin nastao krajem dvadesetog veka i zasniva se na efikasnijem i kvalitetnijem pružanju zdravstvenih usluga uz pomoć savremenih tehnologija, mogućnostima za obezbeđivanje mobilnosti lekara i pacijenata uz integraciju sa postojećim sistemima [1].

Savremene tehnologije u zdravstvu omogućavaju kompletno elektronsko vođenje zdravstvene dokumentacije u svim segmentima rada (elektronski karton pacijenta), telemedicinu, telekonsultacije, upravljanje znanjem o zdravlju i mobilno i sveprisutno zdravstvo. Na ovaj način omogućava se lakše i uspešnije lečenje pacijenata i smanjenje administrativnih ograničenja prilikom pružanja medicinskih usluga.

Prednosti e-zdravstva su elektronsko praćenje i beleženje zdravstvenog stanja pacijenata, bolja dijagnostika, pristup medicinskim podacima bilo gde i bilo kada, kao i brz prenos informacija korisnicima putem telemedicine i Internet servisa.

Aldina Avdić – Departman za tehničko-tehnološke nauke, Državni Univerzitet u Novom Pazaru, Vuka Karadžića 9, 36300 Novi Pazar, Srbija (e-mail: apljaskovic@np.ac.rs).

Ulfeta Marovac – Departman za tehničko-tehnološke nauke, Državni Univerzitet u Novom Pazaru, Vuka Karadžića 9, 36300 Novi Pazar, Srbija (e-mail: umarovac@ np.ac.rs).

Elektronski medicinski zapis (engl. *EM* ili *E* - *electronic medical health report*) je izveštaj pacijenta koji čuva podatke o zdravstvenom stanju, dijagnozama i terapijama. Oni se kreiraju pomoću medicinskih informacionih sistema i sadrže privatne podatke o pacijentu (ime, prezime, lični broj, datum rođenja, broj kartice, broj osiguranja, adresu itd.), beleške lekara, dijagnoze, laboratorijske izveštaje, terapije itd [2].

Motivacija za ovaj rad je pripremanje elektronskih izveštaja za dalju analizu korišćenjem metoda veštačke inteligencije, mašinskog učenja i metoda obrade prirodnog jezika. U kakvom god da su obliku elektronski medicinski izveštaji (tekst ili slika) prvi korak ka njihovoj etičkoj obradi jeste uklanjanje ličnih podataka (ovo je uređeno regulativom – engl. *General ata Protection egulation - G P*). Za potrebe rada prikupljen je skup podataka, i kreirana i primenjena metoda za prepoznavanje imena i prezimena na srpskom jeziku sa slika medicinskih izveštaja bazirana na optičkom prepoznavanju slova (engl. *ptical Caracter ecognition - C*) i metodama obrade prirodnog jezika (engl. *Natural anguage Processing - N P*) i prepoznavanja imenovanih entiteta (engl. *Named Entity ecognition – NE*). Stoga će nadalje ovi pojmovi biti detaljno objašnjeni.

Uredba Evropske unije o zaštiti podataka o ličnosti GDPR definiše propise o zaštiti podataka ličnosti u Evropskoj uniji, ali se ona odnosi i na kompanije sa sedištem u zemljama izvan Evropske unije, ukoliko one obrađuju podatke o ličnosti rezidenata Evropske unije. Po članu 3 GDPR regulative potrebno je da se uskladi zaštita osnovnih prava fizičkih lica u vezi sa aktivnostima obrade ličnih podataka. U Srbiji je na snazi Zakon o zaštiti podataka o ličnosti iz 2018. godine koji je usklađen sa GDPR [3]. Ona obezbeđuje pojedincima veću kontrolu nad ličnim podacima i obavezuje kompanije koje prikupljaju i analiziraju lične podatke da promene svoj model poslovanja u skladu s njom. Pod ličnim podacima podrazumeva se bilo koja kombinacija ličnih činjenica koja tačno određuje jednog pojedinca, to su, između ostalog, ime i prezime, JMBG, podaci o lokaciji, fizički, fiziološki, genetski, mentalni, ekonomski, socijalni, kulturni ili bilo koji drugi faktori.

Osnovni zadatak OCR softvera je da digitalne slike, na kojima se nalaze skenirani ili fotografisani tekstovi sa štampača, pisaćih mašina, knjiga, novina, časopisa ili poslovne dokumentacije, pretvori u promenljivi digitalni tekstualni oblik, tako što će sa rasterskih slika, prepoznati

 ISBN 978-86-7466-930-3

slova, reči i čitave tekstove.[4].

Procesiranje prirodnog jezika je grana veštačke inteligencije koja omogućava sistemu da razume značenje podataka na ljudskom jeziku. Njen krajnji cilj je čitanje, dešifrovanje, razumevanje i nalaženje smislenosti u prirodnom jeziku. Većina NLP tehnika oslanja se na mašinsko učenje da bi se zaključilo o značenju podataka na prirodnim jezicima. Prepoznavanje imenovanih entiteta je grana NLP-a kojom se u tekstu označavaju sintagme u nestrukturiranom tekstu u unapred definisane kategorije kao što su imena osoba, organizacije, lokacije, medicinski kodovi, vremenski izrazi itd [5] [6].

Ovaj rad je organizovan na sledeći način. U drugom poglavlju dat je pregled radova iz oblasti. U trećem poglavlju opisani su korišćeni podaci i metoda za prepoznavanje imena na slikama medicinskih izveštajima napisanih na srpskom jeziku u cilju njihove de-identifikacije. Zatim sledi opis korišćenih tehnologija, dobijeni rezultati i njihova diskusija. Na kraju je dat zaključak i pravci daljeg istraživanja.

II. Stanje u oblasti

Povezana istraživanja na ovu temu opisuju metode za normalizaciju i izdvajanje znanja iz medicinske evidencije koje nisu direktno povezane sa primenom na srpskom jeziku. Većina istraživanja odnosi se na korpuse engleskog govornog područja i leksičke resurse koji su javno dostupni. Za bugarski jezik postoje rezultati izdvajanja informacija iz velikog korpusa nestrukturiranih podataka i njihovog pribavljanja u strukturiranom obliku [7].

Normalizacija je prvi korak koji se koristi u klasifikaciji i obeležavanju medicinskih termina [8]. Obrada medicinskog izveštaja sastoji se od nekoliko koraka kao što su prečišćavanje podataka, integracija, transformacija, redukcija i na kraju zaštita podataka. Izvlačenjem kliničkih odnosa iz medicinskih izveštaja mogu se identifikovati odnosi između referenci na lekove i njihovih atributa. Pregled medicinskih informacionih sistema pokazuje da 60% komercijalnih sistema koristi metode zasnovane na pravilima, dok se u naučnim istraživanjima više koriste metode mašinskog učenja [9]. Najpopularniji sistemi za obeležavanje medicinskog teksta su CTAKES i CLAMP sistemi [9] [10]. Autori su se u radu bavili identifikacijom medicinskih pojmova u tekstovima koje su napisali pacijenti, koristeći kraudsoursing [11] .

Na jezicima bivše Jugoslavije nisu pronađeni radovi koji bi se bavili procesom slobodnog teksta u medicinskim izveštajima i javno dostupnim leksičkim izvorima u medicinskom domenu. „Wordnet za biomedicinske nauke“ za srpski jezik sadrži skupove sinonimnih reči ili tačnije različite delove govora (engl. PoS, parts of speech) sa novim konceptom za šest ontoloških kategorija (genetika, virus, bakterije, ćelije, naučna polja i mikroorganizam) [12].

Klasifikacija u medicinskim izveštajima na srpskom jeziku opisana je u radu [13]. De-identifikacija ličnih podataka u srpskom jeziku opisana je u radu [14].

Primena OCR u zdravstvu opisana je u radu [15].

III. Podaci i metodologija

Za potrebe ovog istraživanja sakupljena je 71 slika sa društvene mreže Facebook, koja sadrži medicinski izveštaje koje sadrži lične podatke. Ove izveštaje su okačili korisnici zatvorene grupe Insulinska rezistencija. Neki učesnici u grupi svesni su izlaganja privatnih podataka i pre postavljanja slike svoje ime oboje ili iseku sliku tako da lični podaci nisu dostupni, ali budući da su ovo samo slike od januara 2022. godine, to govori koliko je jednostavno naći elektronske izveštaje koji sadrže lične podatke na internetu na sličnim grupama.

Metoda za prepoznavanje imena sadrži sledeće korake:

- na sve slike je prvo primenjen OCR softver otvorenog koda *Tessaract* [17], čime se izdvaja tekst sa slike (Sl. 1),

```
from PIL import Image
import pytesseract
import numpy as np
import spacy
from spacy import displacy
import translators as ts
import os
import re

directory = 'C:/Users/aldin/Desktop/Podaci/Insulinska'
NER = spacy.load("en_core_web_sm")

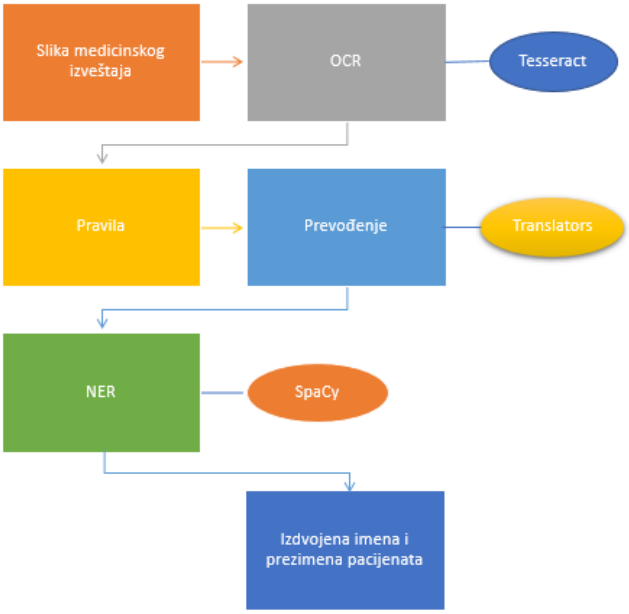
for filename in os.listdir(directory):
    f = os.path.join(directory, filename)
    if os.path.isfile(f):
        filename = f
        print(f)
        img1 = np.array(Image.open(filename))
        pytesseract.pytesseract.tesseract_cmd =
        r'C:\Users\aldin\AppData\Local\Tesseract-OCR\tesseract.exe'
        text = pytesseract.image_to_string(img1)
```

Sl. 1 Izdvajanje teksta iz slika

- zatim su primenjena pravila i regularni izrazi za obeležavanje imena i prezimena (Sl. 2). Pravila su definisana od strane autora, a odnose se na to da je u liniji koja se čita veća verovatnoća da se nađe ime i prezime, ako se u toj liniji nalaze reči „prezime“, „pacijent“, „ime i prezime“ i sl. Takođe, ako je na medicinskom izveštaju neka sintagma napisana velikim slovima, ili prvim početnim slovima sa blanko znakovima između, i to treba uzeti u obzir kao moguće ime i prezime pacijenta. Do ovih pravila došlo se analizom sadržaja prikupljenog skupa podataka.

```
        lines = text.split('\n')
        for line in lines:
            if "prezime" in line:
                print(line)
            if "pacijent" in line:
                print(line)
            rl = re.findall('^[a-zA-Z]+(?:[\s.]+[a-zA-Z]+)*$', line)
```

Sl. 2 Primeri pravila



- u koliko je prethodni korak neuspešan, sledi prevođenje teksta na engleski korišćenjem *Python* paketa *Translators* [18],
- zatim se koristi *Spacy* softver za NER na engleskom za prepoznavanje vlastitih imena [19] (Sl. 3).

 ISBN 978-86-7466-930-3

U program su uključene biblioteke *Image* za rad sa slikama, *PyTesseract* za OCR, *NumPy* za jednostavniju obradu i programiranje, zatim *SpaCy* za prepoznavanje imenskih entiteta, *Translators* za prevođenje reči, *os* za rad sa fajlovima i *re* za rad sa regularnim izrazima.

```
        if rl:
            textt = ts.google(rl[0], from_language='sr',
            to_language='en')
            textl= NER(textt)
            for word in textl.ents:
                if word.label_=="PERSON":
                    print(word.text)
```

Sl. 3 Primeri prevođenja i primene Spacy alata za prepoznavanje imenovanih entiteta

Sl. 4. Koraci u prepoznavanju ličnih imena u slikama medicinskih izveštaja na srpskom jeziku

Ova metoda ne zahteva prethodno obeležavanje niti treniranje modela metodama mašinskog učenja (Sl. 4). To su koraci koji su pravci daljeg istraživanja, uz povećanje skupa podataka kako bi se prvobitni rezultati popravili. Uklanjanje ovih podataka na izvornoj slici nije rađeno, ali jeste na tekstovima EHR-ova koji se čuvaju u bazi podataka.

IV. Rezultati i diskusija

U tabeli 1 dati su rezultati primene metode za izdvajanje ličnih imena prezimena. Rezultati uključuju samo one podatke gde je izvučeno samo ime i prezime pacijenta.

Pod preciznošću se smatra odnos broja slika sa izdvojenim ličnim podacima i ukupnog broja slika, a pod odzivom odnos broja tačno izdvojenih imena i prezimena i ukupnog broja slika.

Ono što utiče na rezultate jeste i kvalitet slika i sama preciznost OCR alata, pa je kod jednog broja izveštaja izdvajanje teksta bilo nemoguće. Zato je potrebno uključiti i dodatna predprocesiranja slike. Rezultati pokazuju da je ovo dobra osnova, ali da bi se oni popravili potrebno je razmotriti korišćenje dodatnih resursa za srpski jezik, poput rečnika imena. Takođe, rezultati se mogu popraviti i korišćenjem modela mašinskog učenja i proširenjem trening skupa kao i proširenjem skupa pravila.

TABELA I
Rezultati primene metode

Broj slika	71
Broj slika sa izdvojenim ličnim podacima	41
Broj tačno izdvojenih imena i prezimena	22
Preciznost	58%
Odziv	54%

V. Zaključak

Pacijenti često traže mišljenja o svojim zdravstvenim rezultatima na socijalnim mrežama, u specijalizovanim grupama korisnika sa istom dijagnozom. Tada često postavljaju slike koje sadrže privatne podatke. Alat za de-identifikaciju elektronskih medicinskih izveštaja imao bi široku primenu, jer pored toga što bi se korisniku skrenula pažnja da postavlja dokument sa osetljivim podacima, čak bi se mogli koristiti podaci iz medicinskih informacionih sistema za dalju obradu, analizu i dobijanje znanja. U radu je dat jedan način za izdvajanje imena i prezimena pacijenta zasnovan na OCR i NER. U daljem radu radiće se na dopunjavanju resursa, pravila i uključivanja modela mašinskog učenja, proširenja trening skupa, uz predprocesiranje slika, kako bi se postigli što bolji rezultati. Takođe, jedan od pravaca daljeg istraživanja jeste uklanjanje (zamagljivanje) pronađenih ličnih podataka na procesiranoj slici medicinskog izveštaja.

Zahvalnica

Ovaj rad je delimično finansiran od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije u okviru projekata III44007.

ABSTRACT

The modern way of life inevitably includes the use of ICT in all its segments, even in healthcare. In addition to e-health, whose development is growing, especially since the world faced the coronary virus pandemic, most people are also looking for health advice on social networks. On that occasion, they upload pictures that contain their health results, with their personal data. This paper presents a method for recognition of personal names in images of medical reports written in Serbian to de-identify them. This method is based on optical character recognition, natural language processing methods and rules and has wide application, as de-identification of electronic medical reports is a necessary step for their further analysis.

ecognition of names on images of medical reports in erbian to protect personal data

Sistem za automatizaciju testova za proveru znanja baziran na transformaciji predikatskih iskaza

Ulfeta Marovac, Department for Technical Sciences, State University of Novi Pazar, Serbia
Aldina Avdić, Department for Technical Sciences, State University of Novi Pazar, Serbia

***A stra t*— bradom prirodnog jezika omogućava se da računari uspostave komunikaciju sa čovekom, da razumeju jezik čoveka, ali i da ga transformišu i da se čoveku obrate na njemu prirodnom jezi u. Problem istinitnosne vrednosti is aza izrečenih prirodnim jezikom je teško utvrditi zbog bogatstva rečnika i dvosmislenosti značenja. Preslikavanjem iskaza prirodnog jezika u iskaze predikatske logike moguće je utvrditi odnose među različitim predikatskim iskazima kao i izvršiti transformaciju iz jednog obli a pojavljivanja u drugi. edna od primena ovakvog znanja može biti u automatizovanom kreiranju testova znanja.**

***Ključne reči*—obrada prirodnog jezi a, predi ats a logi a, automatizovani testovi znanja, srps i jezi**

I. UVOD

Testiranje je važna komponenta učenja, jer omogućava da se vidi da li je ispitanik usvojio informacije koje su mu izložene. Sve prisutnije e-učenje zahteva digitalizaciju okruženja za predavanja, ali i ispitivanje. Postoji puno dostupnih softverskih alata koji olakšavaju izradu testova. Njihove prednosti su brojne kao:

- Ušteda vremena u kreiranju testova, jer nema potrebe za tradicionalnim metodama
- Uvek su dostupni na mreži, deljivi su i lakše im pristupaju ispitanici.

Međutim ovi alati se uglavnom koriste kako bi ubrzali proces kreiranja testa i njegovu implementaciju, ali ne i u kreiranju baze znanja za test, i ne poseduju mogućnost provere ispravnosti pitanja koja su data kao slobodan tekst.

Obrada prirodnog jezika (Natural Language Processing - NLP [1]) je oblast veštačke inteligencije koja olakšava komunikaciju čoveka i računara. Naravno da je u procesu obrazovanja uloga nastavnika nezamenljiva, ali se novim tehnologijama može olakšati njihov posao. Ključni faktor u formiranju baze znanja za jedan kurs je uvek nastavnik, jer on daje činjenice koje su relevantne za problem koji se obrađuje. Utvrđivanje tačnosti iskaza koji su napisani na prirodnom jeziku nije jednostavno zbog njihove dvosmislenosti i složenosti, tako da se automatizacija testova svodi na postavljanje pitanja i adekvatnih tačnih i netačnih odgovora koje ispitanik treba da izabere. U ovom procesu određivanje tačnosti nekog pitanja vrši nastavnik. Da bi se pomoglo nastavniku u kreiranju veće količine testova od početnog tačnog ili netačnog iskaza, primenom pravila iskazne logike mogu se dobiti iskazi u drugom obliku čija je istinitnosna vrednost poznata. Sličan postupak se može vršiti i u obrnutom smeru gde bi se provera datog odgovora ispitanika u obliku slobodnog teksta pokušala izjednačiti sa nekim od poznatih odgovora.

Obrada prirodnog jezika je teška zbog specifičnosti jezika na kome se primenjuje. Uvođenjem formalnih jezika formiraju se rečenice na osnovu unapred definisanih pravila. Formalni jezici koriste logičke veznike, kvantifikatore, promenljive (termine), oznake za svojstva i odnose (predikate) i pomoćne znakove (zagrade) za izražavanje rečenica. Jedan primer formalne gramatike koja proizvodi predikatske iskaze na hrvatskom jeziku dat je u diplomskom radu autora Stanić [2].

U ovom radu biće prikazana obrada rečenica datih na srpskom jeziku. Da bi se izvršila obrada ovih rečenica moraju se koristiti pravila srpskog jezika kao i specijalni jezički resursi kojima će se umanjiti pojavljivanje sinonima.

Rad je organizovan na sledeći način: u drugom poglavlju opisani su predikatski iskazi i njihovi odnosi; u trećem poglavlju su prikazani algoritmi za transformaciju predikatskih iskaza unutar logičkog kvadrata; model za automatizaciju testova znanja prikazan je u četvrtom poglavlju i u poslednjem poglavlju dat je zaključak i ideje za proširenje modela.

II. PREDIKATSKI ISKAZI I NJIHOV ODNOS

Iskazna logika je precizan matematički alat za računanje logičkih vrednosti složenih iskaznih formula kao i za donošenje zaključaka iz njih. Iskazna logika se bavi rečenicama u celini i ne zalazi u njihovu unutrašnju strukturu. Predikatska logika razmatra smisao polaznih iskaza.

U predikatskoj logici razlikujemo:

- **Term (T)-** objekta o kome se govori
- **Predi at (P)** – osobina objekta ili veza među objektima.

Term može biti konstanta (konkretan objekat) ili promenljiva (nedovoljno određen objekat). Atomični predikatski iskaz sastoji se od terma i predikata.

Neki iskazi sadrže neodređen objekat pa ne mogu imati jedinstvenu vrednost. Upotrebom negacije, veznika i kvantifikatora formira se predikatska formula [3].

Kvantifikacija je tema koja spaja lingvistiku, logiku i filozofiju. Kvantifikatori su osnovni alati pomoću kojih, u jeziku ili logici, upućujemo na količinu stvari [4]. Upotrebom kvantifikatora izražava se koliko je neko tvrđenje tačno i

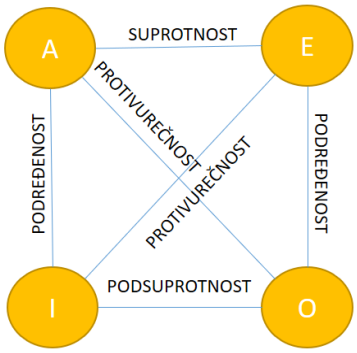
Ulfeta Marovac is with Department for Technical Sciences, State University of Novi Pazar, Vuka Karadžića bb, 36300 Novi Pazar ,Serbia (e-mail: umarovac@np.ac.rs), https://orcid.org/0000-0001-7232-3755

Aldina Avdić is with Department for Technical Sciences, State University of Novi Pazar, Vuka Karadžića bb, 36300 Novi Pazar ,Serbia (e-mail: apljaskovic@np.ac.rs) , https://orcid.org/0000-0003-4312-3839

 ISBN 978-86-7466-930-3

dobijaju se rečenice koje imaju jedinstvenu logičku vrednost. Univerzalni kvantifikator (∀) se koristi da prikaže izraze koji su tačni za sve vrednosti terma. Sa druge strane, egzistencijalni kvantifikator se koristi da prikaže da postoji term za koji je tvrđenje tačno.

Predikatske rečenice se mogu podeliti prema kvantitetu na:



- Univerzalne - opisuju osobinu koju imaju svi pripadnici nekog skupa
- Partikularne - opisuju osobinu koju ima bar jedan element nekog skupa
- Singularne - opisuju osobinu jednog člana nekog skupa.

Predikatske rečenice po kvalitetu se dele na:

- afirmativne - opisuju da subjekat ima neku osobinu,
- negativne - opisuju da subjekat nema neku osobinu,
- limitativne - opisuju da subjekat ima neku osobinu opisanu negacijom.

Izdvojimo četiri tipa predikatskih iskaza koja su prikazana u logičkim kvadratu suprotnosti (Slika 1):

- $(\forall T)P(T)$ - univerzalno-afirmativni iskaz (A)
- $(\forall T)\neg P(T)$ - univerzalno-negativni iskaz (E)
- $(\exists T)P(T)$ - - partikularno-afirmativni iskaz (I)
- $(\exists T)\neg P(T)$- partikularno-negativan iskaz (O).

Slika 1. Logički kvadrat

Predikatske rečenice prikazane u logičkom kvadratu su povezane i ukoliko se zna istinitost jednog tipa može se zaključiti o istinitosti bar još jednog od ostala tri tipa [5].

Prikazani logički kvadrat je motivacija za kreiranje modela za transformaciju jednog predikatskog iskaza za koji je poznata logička vrednost u iskaz kome se može zaključiti tačna logička vrednost.

Može se uočiti povezanost između predikatske logike i prirodnog jezika i to: termi igraju ulogu sličnu onoj koju u prirodnom jeziku igraju imenice i zamenice, a predikati ulogu sličnu glagolima. Prirodni jezik je mnogo bogatiji i nisu dovoljno precizni. Problem prirodnog jezika je i u tome što se isti iskaz može izraziti na više načina.

III. AUTOMATIZOVANO PRESLIKAVANJE PREDIKATSKIH ISKAZA NA SRPSKOM JEZIKU UNUTAR LOGIČKOG KVADRATA

Rečenice u srpskom jeziku mogu se podeliti na proste i složene [6]. Proste rečenice se mogu predstaviti pomoću dva tipa:

1. subjekta (S) i glagolskog predikata (GP)
2. subjekat (S), pomoćni glagol (PG) i imenski predikat (IP).

Prosta rečenica srpskog jezika može se povezati sa atomičnim predikatskim iskazom. Predikatska forma na prirodnom jeziku izražava se upotrebom veznika, negacije i kvantifikatora. U srpskom jeziku se negacija, veznici i kvantifikatori mogu javiti u različitim oblicima. U radu [7] prikazana je veza između predikatske logike i srpskog jezika, kao i pravila prelaza predikatskih formula izraženih na srpskom jeziku unutar logičkog kvadrata.

U ovom radu je dat algoritam za automatizaciju preslikavanja predikatskih iskaza na srpskom jeziku unutar logičkog kvadrata zasnovan na pravilima definisanim u [7]. Za ove potrebe napravljeni su rečnici sa različitim signalima negacije (**D**) kao i rečnik sa potvrdnim (P_PG) i odričnim oblicima (O_PG) pomoćnih glagola (PG) "imam", „biti" i „hteti" pomoću kojih se može graditi negacija (**D PG**).

Formiran je takođe:

- **D** **P**-rečnik različitih termina kojima se izražava univerzalni kvantifikator u potvrdnom obliku (UKP);
- **D** -rečnik različitih termina kojima se izražava univerzalni kvantifikator u odričnom obliku (UKO);
- **D** -rečnik različitih termina kojima se izražava egzistencijalni kvantifikator UEK.

Kvantifikatori u srpskom jeziku se menjaju po licima, rodu i broju pa se ove informacije nalaze u odgovarajući rečnicima (L,R,B).

U partikularnim rečenicama uz neke kvantifikatore (na primer „postoji") se pojavljuje odnosna zamenica (OZ) iza subjekta pa je napravljen i rečnik odnosnih zamenica **D** sa odgovarajućim informacijama (L,R,B). Za neke oblike egzistencijalnog kvantifikatora se ne upotrebljava odnosna zamenica (na primer „neki"), stoga uz svaki egzistencijalni kvantifikator stoji i opis („tip") da li ide uz odnosnu zamenicu.

Dalje će biti prikazan algoritmi kojim se od iskaza A dobijaju drugi iskazi logičkog kvadrata. Dobijenim iskazima se može pridružiti i njihova logička vrednost (T-tačno , N-netačno, NaN-nepoznata logička vrednost).

Sva četiri tipa predikatskih iskaza u srpskom jeziku se mogu naći u jednom od dva tipa rečenica prethodno navedenih i to:

Univerzalno-afirmativni iskaz (iskaz_A)

- TIP1 - UKP+S+GP
- TIP2 - UKP+S+PG+IP

Univerzalno-negativni iskaz (iskaz_E)

- TIP1 - UKP+S+SN+GP
- TIP2 - UKO+S+O_PG+IP

Partikularno-afirmativni iskaz (iskaz_I)

- TIP1 - EK+S [+ OZ] +GP

 ISBN 978-86-7466-930-3

- TIP2 - EK+S [+OZ]+P_PG+IP

Partikularno-negativan iskaz (iskaz_O)

- TIP1 - EK+S [+ OZ] +SN +GP
- TIP2 - EK+S [+OZ]+O_PG+IP.

Algoritam 1 (**P transformacija**) vrši transformaciju univerzalnih iskaza (A i E) u partikularne (I i O). Inverzna funkcija (**P transformacija**) može se slično predstaviti i ona vrši transformaciju partikularnih iskaza (I i O) u univerzalne iskaze (A i E).

```

Očigledno je da kombinacijom datih transformacija možemo iz svakog tipa predikatske rečenice dobiti preostala tri, i to u više oblika u zavisnosti od oblika kvantifikatora koji se izabere.

IV. MODEL ZA AUTOMATIZACIJU TESTOVA ZA PROVERU ZNANJA

Prirodni jezici nisu precizni pa predloženi model transformacije zavise od jasnoće ulaza. Većina tvrdnji može se uklopiti u jedan od tipova predikatskih rečenica i ukoliko je njena istinitost poznata može izvršiti transformaciju polazne tvrdnje u skup iskaza koji imaju istu ili suprotnu tačnost. Tabela 1 prikazuje ulazne parametre, primenjene transformacije i rezultat kada se na ulazu nađu iskazi tipa A i E. Slično se može odrediti i za iskaze tipa I i O za koje ukoliko su netačni možemo zaključiti istinitnosne vrednosti o ostala tri tipa predikatskih iskaza koje možemo dobiti odgovarajućim transformacijama ili ukoliko su tačni možemo ih transformisati u netačne iskaze tipa (E i A).

 ISBN 978-86-7466-930-3

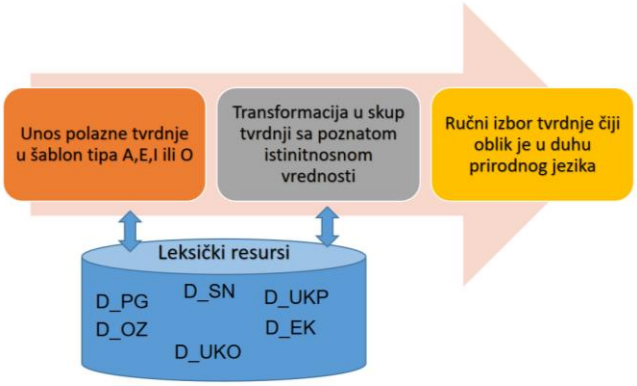

TABELA I
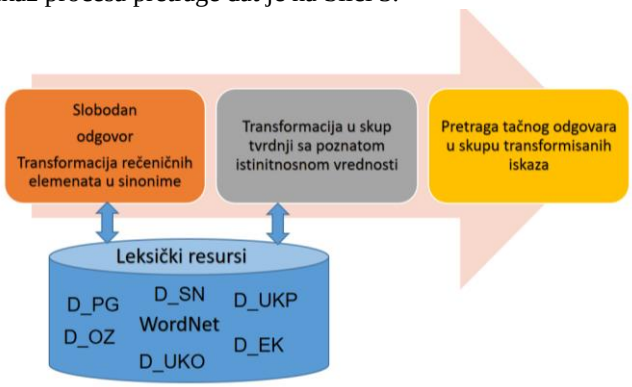
OPIS MOGUĆEG TIPA ULAZA, PRIMENJENIH TRANSFORMACIJA I IZLAZA

Tip ulaznog iskaza	Tačnost	Primenjene transformacije	Tip skupa izlaznih iskaza	
A	Tačno	AN	E	Netačno
A	Tačno	UP	I	Tačno
A	Tačno	AN+UP	O	Netačno
A	Netačno	AN+UP	O	Tačno
E	Tačno	NA	A	Netačno
E	Tačno	UP+NA	I	Netačno
E	Tačno	UP	O	Tačno
E	Netačno	UP+NA	I	Tačno

Postoje dva slučaja koja se pri obradi testova znanja mogu tretirati:



1. postavljanje pitanja
2. provera ispravnosti odgovora.

Kod postavljanja pitanja popularna su zaokruživanja više tačnih odgovora tako da se dubina razumevanja materije može upravo proveriti postavljanjem istog odgovora u nekom od njegovih transformacija unutar logičkog kvadrata. Slika 2. prikazuje proces formiranja liste tvrdnji sa poznatom istinitnosnom vrednošću koje mogu da učestvuju u ispitnim pitanjima.

Slika 2. Proces dopune baze sa tvrdnjama za ispitivanje

Provera ispravnosti odgovora se najlakše rešava zaokruživanjem što je na osnovu poznatih istinitnosnih vrednosti procesom formiranja pitanja moguće. Ukoliko se ispitaniku dozvoli unos slobodnog odgovora u šablon tipa A, E,I ili O mora se proveriti ekvivalentnost odgovora sa datim ključem (tačnim odgovorom zadatim od strane ispitivača). Zbog postojanja različitih oblika za izražavanje iste stvari ovaj proces će biti malo teži. Ovde se mogu koristiti napravljeni leksički resursi kako bi se dobili različiti oblici kvantifikatora, simbola negacije, odnosnih zamenica čijom zamenom se neće promeniti odgovor već njegova forma. Takođe za neke dalje korake može se koristi WordNet za srpski jezik [8] za pretragu sinonima i za druge rečenične delove. Ispravan odgovor može biti dat i u nekoj od drugih predikatskih formi pa zato ukoliko se transformacijama može dobiti odgovor koji se poklapa sa ključem i pritom je tačan pa se može prihvatiti. Prikaz procesa pretrage dat je na Slici 3.

Slika 3. Proces provere da li dati odgovor ekvivalentan rešenju

Primenu predloženih algoritama demonstriraćemo na primeru transformacije tačnog iskaza “Svaki prirodan broj je pozitivan.”, koji se može ubaciti u šablon tipa A. Tabela 2 prikazuje rezultate primene različitih transformacija na ovaj polazni iskaz. Kao rezultat dobijaju se tačni iskazi tipa I kao što su na primer:

- Neki prirodan broj je pozitivan.
- Bar jedan prirodan broj je pozitivan.
- Postoji prirodan broj takav da je pozitivan.
- Postoji prirodan broj koji je pozitivan.

Primenom transformacije AN(+UP) dobijamo netačne iskaze tipa E i O kao što su:

- Svaki prirodan broj nije pozitivan.
- Neki prirodan broj nije pozitivan.
- Postoji prirodan broj takav da nije pozitivan.

TABELA II
PRIMER PRIMENE PRIKAZANOG ALGORITMA NA ISKAZ TIPA A

REČENIČNI ČLAN	ULAZ	IZLAZ			
		TRANSFORMACIJA			
		AN	UP (BEZ OZ)	UP (SA OZ)	AN+UP

 ISBN 978-86-7466-930-3

IV. ZAKLJUČAK

U ovom radu je predstavljen sistem za automatizaciju testova za proveru znanja na srpskom jeziku baziran na transformaciji predikatskih iskaza. Predikatski iskazi iz logičkog kvadrata se predloženim transformacijama mogu preslikati jedni u druge. Ova osobina je primenjena na tvrdnje u testovima znanja koje se transformacijama mogu pretvoriti u druge oblike sa poznatom istinitnosnom vrednosti i kao takvi mogu se uključiti u testove. Doprinos ovog rada su i kreirani rečnici kvantifikatora u različitim oblicima pojavljivanja kao i metode za transformaciju. Sinonimi su jedan od velikih problema pri obradi prirodnog jezika. Primena obrade sinonima prilikom validacije slobodnih odgovora jeste jedan od sledećih puteva razvoja sistema. Primena De Morganovih pravila i drugih tautologija takođe može proširiti skup ekvivalentnih iskaza.

ZAHVALNICA

Ovaj rad je delemično podržan od strane Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije po projektu III44007.

ABSTRACT

By processing natural language, we enable computers to establish communication with humans, to understand human language, but also to transform it and to address human in natural language. The problem of the truth value of statements uttered in natural language is difficult to determine due to the richness of vocabulary and ambiguity of meaning. By mapping the statements of natural language into the statements of predicate logic, it is possible to determine the relationships between different predicate statements as well as to perform the transformation from one form of appearance to another. One of the applications of this knowledge can be in the automated creation of knowledge tests.

ystem for automation of nowledge verification tests based on transformation of predicate statements

Konferencije ETRAN/IcETRAN kroz statistiku

Vladimir A. Katić, *Senior Member, IEEE,* Marko Jarnević, Dragomir Nikolić, Mirjana Jovanić

***Apstrakt*— Konferencija ETRAN je jedan od najstariji naučnih skupova u Srbiji, koji se neprekidno organizuje već 66 godina. Njeno međunarodno izdanje IcETRAN se sada približava prvoj deceniji postojanja. Obe konferencije uspešno organizuje Društvo za ETRAN, čiji kolektivni članovi su sve najznačajnije naučne i obrazovne institucije u Srbiji i Republici Srpskoj (BIH). U radu je prvo predstavljena struktura, kao i ključne teme, koje se na konferencijama razmatraju. Zatim su zajedno posmatrani odgovarajući, karakteristični statistički podaci o broju radova i autora. Oni su obrađivani u tri vremenska intervala, nešto širem (poslednjih 26 god., 1996.-2021. god.), srednjoročnom (poslednjih 9 god., 2014.-2022. god.), i nešto kraćem (poslednjih 4-5 god., 2018. – 2021(2). god.). Brojevi radova su analizirani agregatno, po pojedinačnim konferencijama, ali i detaljnije po tematskim sekcijama, dok su podaci o autorima vezivani za državu i instituciju zaposlenja, kao i za pol istraživača. Zaključeno je da ovi skupovi najčešće predstavljaju mesto prikazivanja naučnih rezultata istraživača iz akademske zajednice (fakulteta i instituta), a da je prisustvo privrede, vojnog i zdravstvenog sektora manje zapaženo. Takođe, najveći broj učesnika je iz Srbije i to sa tri najveća domaća fakulteta. Međutim, značajna je i međunarodna komponenta, kroz autore iz 31 zemlje. Učešće žena je popravljeno, ali još uvek nije adekvatno i iznosi 30%.**

***Ključne reči*— Konferencije ETRAN/IcETRAN, Naučno-stručni radovi, Statistika.**

I. Uvod

Prve inicijative da se organizuje okupljanje inženjera, koji se bave elektronikom pojavile su se još daleke 1953. god. pod rukovodstvom dr Rajka Tomovića. Odbor za elektroniku uradio je sve pripremne aktivnosti i prva konferencija održana je od 7-11. juna 1955. god. [1, 2, 3]. U prvih par godina, konferencija je obuhvatala radove iz elektronike i srodnih disciplina, ali je već 1957. god. osnivanjem Saveznog centra za elektroniku, telekomunikacije i automatiku (ETA) oblast delovanja i zvanično proširena na telekomunikacije i automatiku. Naredne 1958. god. osnovan je Jugoslovenski komitet za ETAN, kada je uz pomenute tri oblasti dodata i nuklearna tehnika (ETAN).

Jugoslovenski komitet, kasnije Jugoslovenski savez za ETAN (od 1976. god.), pa republička Društva za ETAN (od 1980. god.) vodili su konferencije ETAN-a do 1992. god.

Vladimir A. Katić – Predsednik Društva za ETRAN, Univerzitet u Novom Sadu, Fakultet tehničkih nauka, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija(e-mail: katav@uns.ac.rs)

Marko Jarnević – Firaso, Kneza Miloša 9/IV sprat, 11000 Beograd, Srbija (e-mail: marko@firaso.rs)

Dragomir Nikolić – Univerzitet u Novom Sadu, Fakultet tehničkih nauka, Trg Dositeja Obradovića 6, 21000 Novi Sad, Srbija (e-mail: nikolicd@uns.ac.rs)

Mirjana Jovanić – Društvo za ETRAN, Kneza Miloša 9/IV sprat, 11000 Beograd, Srbija (e-mail: etran.konferencija@gmail.com)

Društvo za elektroniku, telekomunikacije, računarstvo, automatiku i nuklearnu tehniku (Društvo za ETRAN), osnovano je 1993. god., kada je u tematske sadržaje konferencije uključeno i računarstvo, kao posebna sekcija [1]. To je rezultiralo promenom naziva iz ETAN u ETRAN. Društvo je nastavilo sa širenjem delatnosti i već 1994. god. je osnovana sekcija za elektroenergetiku (EE), a 1997 sekcija za metrologiju (ML).

Potreba za širom vidljivošću rezultata istraživanja u Srbiji dovela je do pokretanja međunarodne konferencije, IcETRAN (*International Conference on Electrical, Electronic and Computing Engineering*) 2014. god. sa istim tematskim okvirom, a na kojoj se predstavljaju radovi na engleskom jeziku u IEEE formatu. Od tada se konferencije ETRAN i IcETRAN odvijaju zajedno (paralelno) u istim terminima i na istoj lokaciji.

Trenutno ETRAN ima šesnaest sekcija, kojima su pokrivene sve moderne oblasti elektrotehnike. Karakteriše ga veliki broj individualnih, ali i kolektivnih članova (28 institucija i organizacija iz Srbije, Bosne i Hercegovine i Crne Gore). Ove 2022. god. održava se LXVI konferencija ETRAN-a, odnosno IX konferencija IcETRAN-a.

U literaturi se retko pojavljuju radovi u kojima je urađena statistička obrada naučne produkcije konferencija ETA, ETAN, ETRAN i IcETRAN. U publikaciji [1], dat je prikaz perioda od 2006. – 2015. god., s tim da su pojedine sekcije dale i celokupan pregled kretanja broja radova od svog osnivanja do 2015. god., dok je u [2] dat prikaz ranijih konferencija (1955-2014. god.), s tim da statistika nedostaje za period 1985-1996. god. U [4] je dat reprint svih radova u periodu 1955. – 2006. god., ali nema agregiranog statističkog prikaza, kao ni dela radova iz zbornika 1992. i 1993. god. i nekih ostalih godišta.

Neki podaci mogu se dobiti i iz uvodnih referata podnesenih na konferencijama ETRAN-a. Tako je na XL konferenciji u Budvi u junu 1996. god. prof. Milić Stojić, tadašnji predsednik ETRAN-a napisao: „Na proteklih 39 konferencija bilo je podneto ukupno 10.021 rad, koji su zatim publikovani na oko 70.000 stranica u 187 tomova zbornika radova. Na jubilarnoj XL Konferenciji očekuje se da će biti podneto 624 rada 1156 autora u okviru 15 stručnih komisija i 67 radnih sednica.“ [5].

Na sajtu ETRAN/IcETRAN konferencija dati su reprinti kompletnih zbornika sa poslednjih pet konferencija (2017.-2021. god.), a unos ranijih godišta je u toku [6]. Zbog kratkoće vremena i teškoće nabavke, autori ovog rada nisu bili u prilici da konsultuju ostalu literaturu vezanu za aktivnosti društva za ETAN/ETRAN, što ostaje kao zadatak za naredni period.

Cilj ovog rada je da predstavi sumirani pregled tematike i

 ISBN 978-86-7466-930-3

aktivnosti na obe konferencije (nacionalne i međunarodne) u tri vremenska intervala, nešto širem (poslednjih 26 god., 1996.-2021. god.), srednjoročnom (poslednjih 9 god., 2014.-2022. god.), i nešto kraćem (poslednjih 4-5 god., 2018. – 2021(2). god.), koristeći različite statističke prikaze broja radova i autora. Na taj način želi se ukazati na opšte pravce razvoja, na njihove trendove, ali i na segmente kojima je potrebno posvetiti veću pažnju i trud u budućnosti.

II. KONFERENCIJE ETRAN/ICETRAN

Konferencije ETA/ETAN/ETRAN organizuju se godišnje, počevši od 1955. god. Prva i druga konferencija održane su u Beogradu 1955. i 1956. god., a nadalje su menjale lokacije, širom bivše Jugoslavije. Od 1992. god. održavaju se u Srbiji i Crnoj Gori, a od 2008. god. isključivo u Srbiji [2]. Od 2014. god. društvo za ETRAN svake godine organizuje dve paralelne konferencije, nacionalnu ETRAN i međunarodnu IcETRAN u nekom mestu u Srbiji. Najviše domaćinstava do sada ima Beograd 7 puta, Zlatibor 6 puta, pa Novi Sad i Niš po 4 puta. Ove 2022. god. ETRAN je prvi put u Novom Pazaru, kao mladom univerzitetskom centru.

Rad ETRAN/IcETRAN konferencija odvija se preko 16 sekcija, koje pokrivaju kompletnu oblast elektrotehnike i predstavljaju ključne teme svih konferencija. To su (po abecednom redu): Akustika (AK), Antene i prostiranja (AP), Automatika (AU), Biomedicinska tehnika (BT), Električna kola, električni sistemi i obrada signala (EK), Elektroenergetika (EE), Elektronika (EL), Metrologija (ML), Mikroelektronika i optoelektronika (MO), Mikrotalasna tehnika, tehnologije i sistemi (MT), Novi materijali (NM), Nuklearna tehnika (NT), Računarstvo (RA), Robotika i fleksibilna automatizacija (RO), Telekomunikacije (TE) i Veštačka inteligencija (VI).

Pored njih, na konferencijama se pojavljuju i radovi iz oblasti nastavne problematike, odnosno edukacije (EDU), kao i oni koji tematski obuhvataju interdisciplinarne oblasti,ili tematiku više struka, a koji su svrstani u specijalne sesije.

Na svakoj konferenciji, nekoliko radova ili predavanja se predstavljaju na plenarnim sednicama, kao uvodni ili *Key Note Lectures*. Takođe, u sklopu svake sekcije, prezentuju se pozvani radovi (*Invited Papers*) ili pozvana predavanja (*Invited Lectures*).

Uz prezentaciju radova, na konferencijama organizuju se i okrugli stolovi (*Pannel Sessions*) vezani za aktuelnu problematiku razvoja nauke u svetu ili Srbiji, kao i sednice posvećene pojedinim autorima.

III. STATISTIKA BROJA RADOVA

Pregled broja radova po svim dosadašnjim konferencijama, kako ukupan, tako i po pojedinim sekcijama, prevazilazi okvire ovog rada, jer zahteva znatno više prostora za dijagrame, objašnjenja i komentare. Da bi se ipak dobio odgovarajući prikaz, autori su odlučili da se ograniče na statistiku broja radova u tri pomenuta vremenska intervala. Treba napomenuti da su za konferencije od 1996. god. do 2021. god. u statistiku uvršteni radovi, koji su ušli u Zbornik/Proceedings (prezentovani radovi), dok su za 2022. god. obuhvaćeni prihvaćeni radovi, koji su prošli duplu recenziju.

Na Sl. 1 prikazan je pregled kretanja broja radova na konferencijama ETRAN i IcETRAN u ovom periodu. Može se videti da je kvantitativno konferencija ETRAN krajem devedesetih godina prošlog veka predstavljala jedan od najvećih, ako ne i najveći naučni skup u Srbiji. Prema podacima za 1996. i 1997. god., XL i XLI konferencija održane u junu u Budvi i na Zlatiboru, respektivno, predstavile su čak 624, odnosno 622 naučna i stručna rada [2, 4].

U narednom periodu, broj radova polako opada, tako da se može zapaziti nekoliko kvantitativnih blokova vezanih za kretanje broja radova:

1996. – 1998. god.: Između 500 – 600+ radova, prosek 588,6
1999. – 2010. god.: Između 300 – 500 radova, prosek 352,5
2011. – 2019.god.: Između 200 – 300, prosek 269,3
2020. – 2022.god.: Između 100 – 200, prosek 158,3

Poslednji blok ukazuje da je sada broj radova dosta nizak, odnosno da odgovara nivou iz početnog perioda razvoja konferencije. Tek 1975. god. na XIX konferenciji u Ohridu broj radova je prešao obim od 200 radova i tu se zadržao sve do 2019. god.Ipak, stanje za konferenciju 2022. god. ohrabruje, jer je broj radova značajno povećan (+36%).

Međutim, sadašnje stanje nije na nivou reputacije konferencije(a) i upućuje da je potrebno uložiti dodatne napore na povećanju atraktivnosti konferencije, kvaliteta radova, širem povezivanju sa privredom i snaženju uticaja u naučnoj i stručnoj javnosti Srbije i sveta.

Sl. 1. Sveobuhvatni pregled broja radova na ETRAN/IcETRAN konferencijama 1996.-2022. god.

 ISBN 978-86-7466-930-3

A. Statistika radova 2014. – 2022. god.

Iz razloga aktuelnosti i ovde će se posebno analizirati period 2014. – 2022. god. Karakteristika tog perioda je da se u njemu pojavljuju dve paralelne konferencije ETRAN, kao nacionalna i IcETRAN, kao međunarodna. To daje mogućnost autorima da svoje radove predstave na srpskom ili engleskom jeziku. Pored već pomenutih razloga internacionalizacije i bolje vidljivosti u inostranstvu, razlog za ovakvu odluku predsedništva ETRAN-a može se tražiti i u sve većem učešću naučnika iz Srbije na međunarodnim projektima, interesovanju svetskih naučnika za rezultate u Srbiji, intenziviranju značaja citiranosti za rangiranje naučnih radnika, ali i kao način snaženja uticaja i značaja konferencije u Srbiji i svetru.

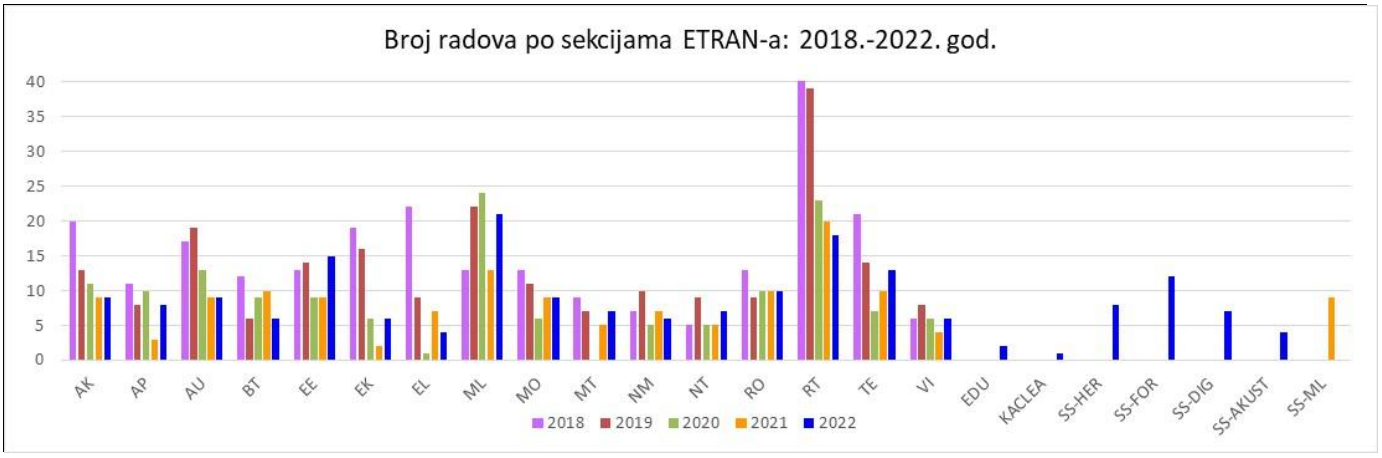
Na Sl. 2, prikazan je „zumiran“ pregled broja radova sa slike 1, na obe konferencije u analiziranom periodu, ali prikazan odvojeno, odnosno uporedno po konferencijama. Ukupno je na konferenciji ETRAN predstavljeno 847 radova, dok na konferenciji IcETRAN 1239 radova, odnosno sve zajedno na obe konferencije 2086 radova. I ovde se može uočiti napredak u 2022. god.

Poređenjem dve konferencije, vidi se da se većina autora opredeljuje za konferenciju IcETRAN (59,4%), što ukazuje na potrebu dalje internacionalizacije konferencije. Ipak, značajan broj autora prikazuje svoje rezultate i na ETRAN-u, kao nacionalnom skupu, što je dobro jer podstiče razvoj domaće misli, usvajanje adekvatne terminologije na srpskom jeziku, odnosno umanjuje efekte anglikanizacije.

Sl. 2. Pregled broja radova na konferencijama ETRAN/IcETRAN u periodu 2014. – 2022. god.

B. Statistika radova po sekcijama (2018. – 2022. god.)

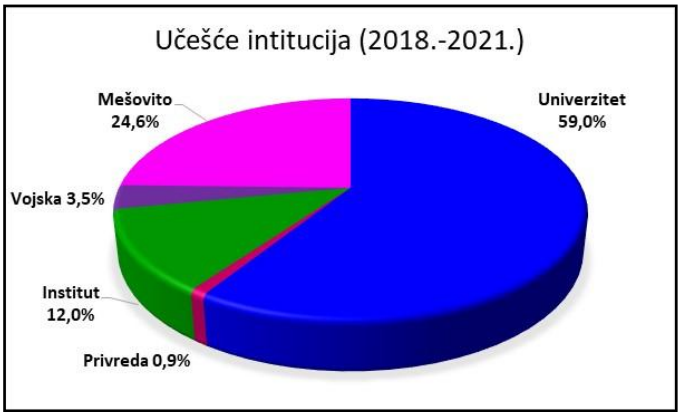
Nešto bolji uvid u rezultate istraživanja može se dobiti ako se posmatra broj radova po pojedinim sekcijama. Međutim, s obzirom na broj sekcija, predstavljanje pomoću jedinstvenih dijagrama može biti nepregledno. Iz tog razloga, autori ovog rada odlučili su se da dodatno suze opseg posmatranja na poslednjih pet godina, odnosno na period od 2018. do 2022. god.



Na Sl. 3 predstavljen je broj radova po sekcijama u tom periodu. Vidi se da su najistaknutije bile sekcije za računarstvo (RT) i metrologiju (ML), zatim automatiku i obradu signala (AU), telekomunikacije (TE), akustiku (AK) i elektroenergetiku (EE). Kod nekih sekcija može se videti značajna redukcija aktivnosti (na primer, sekcije AK, AU, EK, EL, RT), kod nekih da su konferencije u 2020. ili 2021. god. bile kritične (na primer AP, EL, EK, MT), ali se kod većine zapaža oporavak u 2022. god. Ukupnom pozitivnom rezultatu za 2022. god. dodatno doprinose radovi u EDU sesiji i specijalnim sesijama, kao i predstavljanje međunarodnog projekta KALCEA.

C. Statistika radova po institucijama

Na skupovima ETRAN/IcETRAN učestvuje veliki broj autora, najčešće sa univerziteta (fakulteta), naučnih instituta, privrede, ali i iz vojno-tehničkih i ustanova zdravstva. Naravno, mogući su i istraživački timovi kombinovani sa članovima iz različitih institucija. Kompletno sagledavanje prevazilazi obim ovog rada, pa je fokus stavljen na period 2018. – 2021. god.



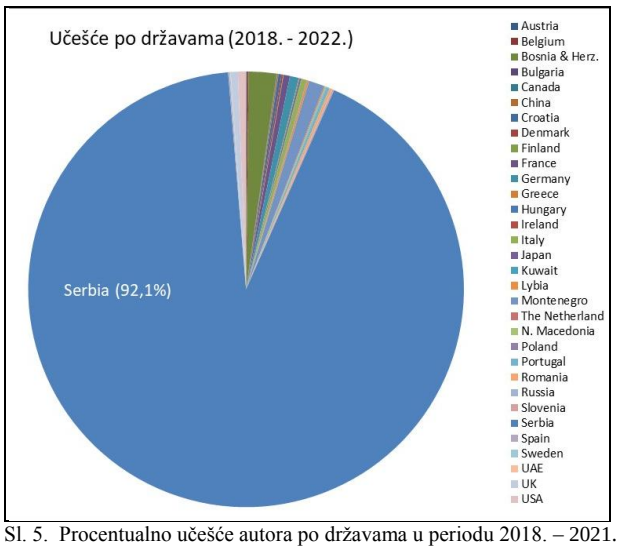
Na Sl. 4 predstavljeno je učešće broja radova po grupisanim institucijama. Vidi se da su radovi autora sa univerziteta (fakulteta) bili najviše zastupljeni (59,0%), pa zatim radovi mešovitih timova (24,6%), istraživačkih grupa sa naučnih instituta (12,0%), te vojno-tehničkih ustanova (3,5%) i privrede (0,9%). Interesantno je da nije bilo većeg učešća radova autora isključivo iz zdravstvenih ustanova, odnosno oni su se pojavljivali u sklopu mešovitih timova.

Ovaj pregled pokazuje da su skupovi ETRAN/IcETRAN prvenstveno orijentisani na učesnike iz akademskog okruženja (fakulteta ili instituta), a da je prisustvo autora iz privrede i drugih institucija nedovoljno.

Sl. 3. Pregled broja radova po sekcijama u periodu 2018.-2022. god.

 ISBN 978-86-7466-930-3

Sl. 4. Pregled učešća radova po institucijama za period 2018. – 2021. god.



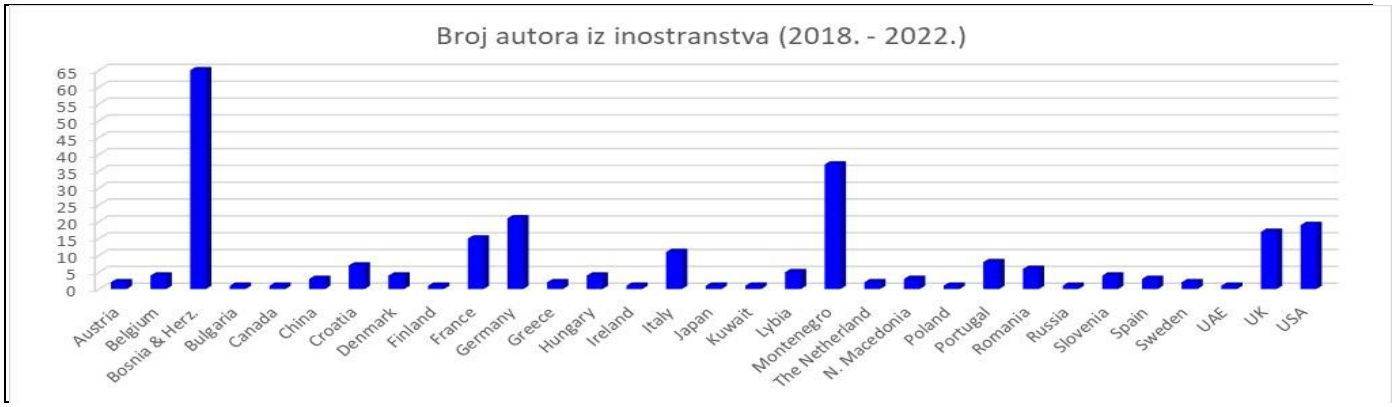
IV. STATISTIKA PO AUTORIMA

Zbog znatno složenije obrade, za statistiku po autorima koristiće se ograničeni vremenski interval od 4 odnosno 5 godina (2018. – 2021(2). god.). Na bazi iskustva i prethodnih podataka, može se odmah pretpostaviti da autori konferencijskih radova, odnosno učesnici ETRAN/IcETRAN konferencija uglavnom dolaze iz Srbije i iz akademskih institucija. Međutim, statistika ukazuje da su ove konferencije interesantne i za mnoge učesnike iz inostranstva i iz drugih institucija. Iz tih razloga interesantno je posmatrati i uporediti konferencije po nekim parametrima vezanim za autore. Ovde će se predstaviti statistika po državama iz kojih dolaze autori, odnosno u kojima se nalaze institucije i firme gde su zaposleni, zatim po pojedinačnim institucijama (mestu zaposlenja) autora, te po polu da bi se videla kakva je zastupljenost žena.

A. Autori iz inostranstva

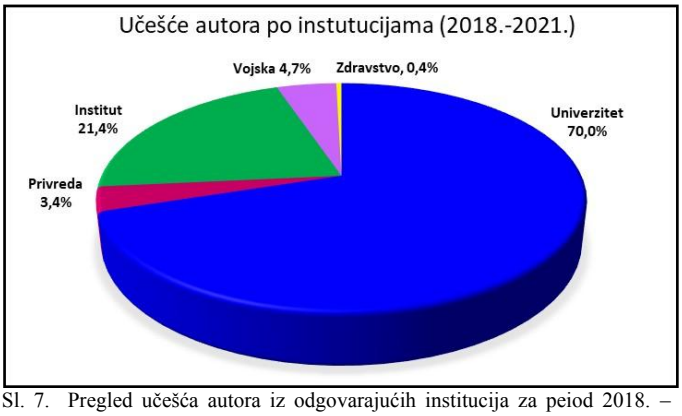
Da bi se potvrdila pomenuta pretpostavka, na Sl. 5 prikazano je procentualno učešće autora iz Srbije i iz drugih država u razmatranom periodu. Može se uočiti da velika većina, čak 92,1% dolazi iz Srbije. To je i očekivano, zbog nacionalnog karaktera konferencije ETRAN, ali i zbog toga što značajan broj autora je iz Srbije publikuju svoje rezultate na engleskom jeziku u okviru konferencije IcETRAN.

Ipak, detaljniji pregled autora pokazuje da preostalih 7,9% predstavljaju institucije iz čak 31 zemlje sveta. Da bi se jasnije videla njihova zastupljenost, na Sl. 6 predstavljena je statistika autora iz inostranih institucija. Može se uočiti da ih najviše dolazi iz Bosne i Hercegovine (uglavnom Republike



Sl. 5. Procentualno učešće autora po državama u periodu 2018. – 2021. god.

Srpske) i Crne Gore, pa zatim iz Nemačke, Velike Britanije (UK) i Sjedinjenih Američkih Država (USA). To ukazuje na dobru saradnju u regionu, jer su i autori iz Hrvatske, Slovenije i Severne Makedonije prisutni. Treba napomenuti da razlog za manje učešće tri poslednje pomenute države ex-Jugoslavije se može potražiti i u činjenici da one imaju svoje nacionalne konferencije, kojhe su potekle iz ETAN-a: KoREMA (bivša JUREMA), ELMAR (bivši ETAN u pomorstvu), ETAI i dr. Istaknuto prisustvo autora iz razvijenih, zapadnih zemalja je najvećim delom posledica aktivnosti naše naučne dijaspore, bilo u sklopu zajedničkih istraživanja sa autorima iz Srbije, bilo u sklopu timova sa svojih institucija.



B. Pregled po institucijama autora

Već je pokazano da najviše radova dolazi od autorskih timova sa univerziteta ili instituta, ali da je značajno i učešće kombinovanih timova (Sl. 4). Iz tog pregleda se ne vidi jasno pripadnost institucijama pojedinačnih autora, pa je na Sl. 7 dat pregled učešća autora po institucijama grupisanim kao na Sl. 4 za period 2018. – 2021. god. Naravno, opet je najznačajnije prisustvo autora sa univerziteta (fakulteta) 70,0%, instituta 21,4%, ali se vidi i primetno učešće autora iz vojske 4,7%, privrede 3,4% i zdravstva 0,4%. Poređenjem sa Sl. 4 može se zaključiti da su radovi mešovitih timova najčešće rezultat saradnje istraživača sa univerziteta, odnosno instituta i privrede ili vojske, i nešto manje zdravstva.

Sl. 6. Pregled broja autora iz inostranstva po državama zapuslenja za period 2018. – 2021. god.

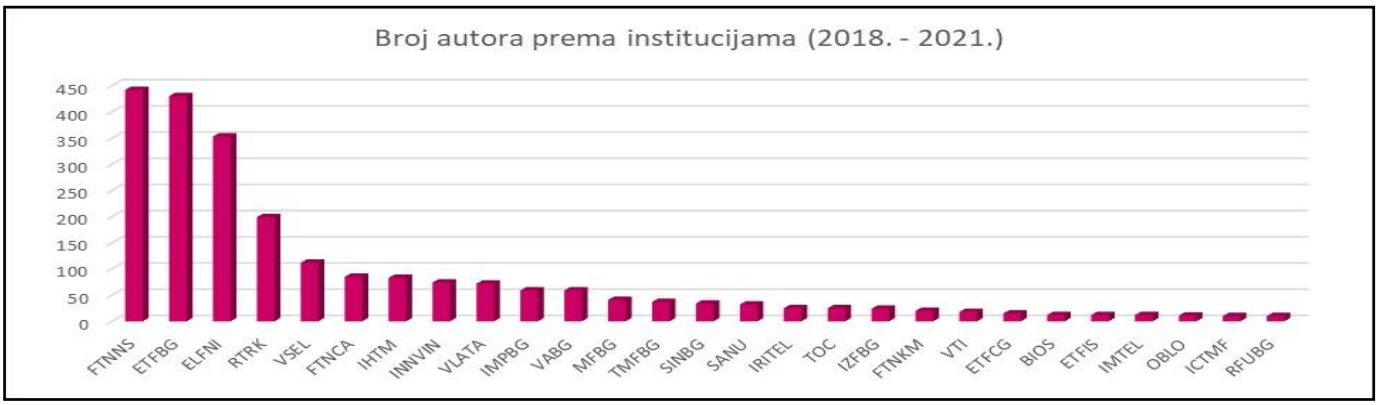
 ISBN 978-86-7466-930-3

Sl. 7. Pregled učešća autora iz odgovarajućih institucija za peiod 2018. – 2021. god.

Pored pregleda po grupisanim institucijama, interesatno je analizirati mesta zaposlenja autora, tj. napraviti pregled učešća pojedinačnih institucija. Na Sl. 8 je dat ovakav pregled za period 2018.-2021. god., uz napomenu da su u obzir uzete samo one institucije čiji autori se pojavljuju bar 3 puta. Vidi se da je najveće učešće na konferencijama ETRAN/IcETRAN od strane autora sa Fakulteta tehničkih nauka iz Novog Sada (FTNNS), zatim sa Elektrotehničkog fakulteta u Beogradu (ETFBG), te Elektronskog fakulteta u Nišu (EFNI). Zatim ide Institut RT-RK iz Novog Sada (RTRK), Visoka škola elektrotehnike i računarstva strukovnih studije Beograd (VSEL), Fakultet tehničkih nauka iz Čačka (FTNCA), te grupa instituta: Institut za hemiju, tehnologije i metalurgiju iz Beograda (IHTM), Institut za nuklearne nauke Vinča (INNVIN), Institut Vlatacom Beograd (VLATA) i Institut Mihajlo Pupin iz Beograda (IMPBG).

Ovaj pregled potvrđuje da su skupovi ETRAN/IcETRAN prvenstveno orijentisani na učesnike iz akademskog okruženja, odnosno na autore sa fakulteta i instituta u Beogradu, Novom Sadu, Nišu i Čačku, ali je značajna i prisutnost autora iz specijalizovanih firmi (industrije), kao i iz inostranstva. Međutim, prisustvo autora iz privrede, te saradnja sa zdravstvom još uvek je nedovoljna.

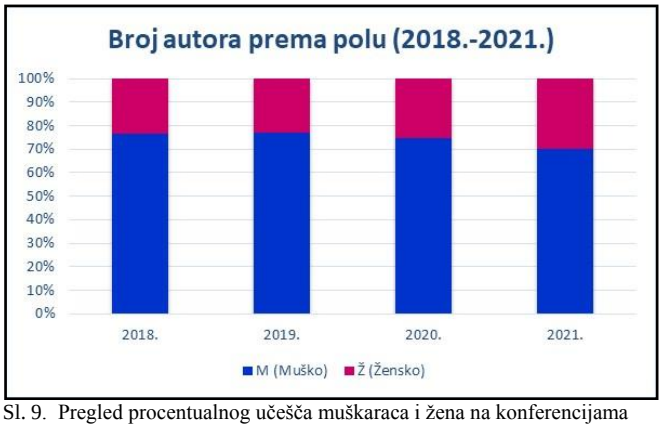
C. Pregled broja autora prema polu



U poslednje vreme sve više se govori i ulažu se dodatni napori da se poveća broj žena u inženjerskim strukama. Njihovo učešće postaje sve značajnije, pa je interesantna i statistika o njihovoj participaciji u naučnim radovima, koji se izlažu na ETRAN/IcETRAN konferencijama. Na Sl. 9 prikazan je pregled procentualnog učešća muškaraca i žena na ovim konferencijama u periodu 2018.-2021. god. Može se uočiti da je došlo do blagog povećanja učešća žena, odnosno da je ono sa 23,7% na konferencijama 2018. god. dostiglo 30% na konferencijama 2021. god. To je ohrabrujući trend, ali treba ulagati dodatne napore da se on održi.

V. ZAKLJUČAK

Konferencija ETRAN, a sada i IcETRAN, u svom dugom postojanju prošle su kroz razne faze. Poslednjih godina uočljiv je rapidan pad broja radova i smanjeno interesovanje naučnika i istraživača. Šta su razlozi i uzroci ove negativne pojave svakako zahteva dublje analize, ali se oni mogu tražiti u sveukupnoj digitalizaciji naučne produkcije, pa i svih ostalih sfera rada i života, u specifičnim zahtevima vrednovanja naučnog rada gde je fokus stavljen na naučne časopise, u potrebi za većom dinamikom naučnog rada i produkcije, pa do uticaja ograničenja u finansiranju nauke, negativnim efektima pandemije virusa Korona-19 i dr.



Ovi skupovi najčešće predstavljaju mesto prikazivanja naučnih rezultata istraživača iz akademske zajednice (fakulteta i instituta), a prisustvo privrede, vojnog i zdravstvenog sektora treba intenzivirati. Takođe, najveći broj učesnika je iz Srbije i to sa tri najveća domaća fakulteta. Međutim, značajna je i međunarodna komponenta, kroz autore iz čak 31 zemlje. Učešće žena se popravlja, ali još uvek nije adekvatno i sada iznosi 30%.

Ovogodišnje konferencije, LXVI ETRAN i IX IcETRAN nagoveštavaju preokret i bolju budućnost ovih okupljanja. Broj radova značajno je porastao (+33%), kao i očekivano učešće istraživača. Konferencija je ponovo organizovana „u živo“, a postavljeni su osnovi za intezivnije pojavljivanje *hi-tech* privrede i veze sa naučno-tehnološkim parkovima. To ukazuje da osnovni razlozi okupljanja naučnika i istraživača, a to je neposredna razmena rezultata i iskustava, dolaženje do novih ideja i zajedničko druženje i dalje predstavljaju značajan motiv za učestvovanje. Ovo i ohrabruje na nove napore za poboljšanje značaja i organizacije konferencija, povećanje atraktivnosti, uvećanje učešća naučnika, istraživača i stručnjaka iz privrede, kao i mladih doktoranata, internacionalizaciju, povezivanje sa svetskim asocijacijama (IEEE, IFAC i dr.), kao i bolju vidljivost ovih konferencija u svetskoj i domaćoj naučnoj zajednici.

Sl. 8. Pregled broja autora prema institucijama za period 2018. – 2021. god.

 ISBN 978-86-7466-930-3

Sl. 9. Pregled procentualnog učešća muškaraca i žena na konferencijama ETRAN/IcETRAN u periodu 2018.-2021. god.

ABSTRACT

The ETRAN conference is one of the oldest scientific gatherings in Serbia, which has been organized continuously for 66 years. Its international edition IcETRAN is now approaching its first decade of existence. Both conferences are successfully organized by the Society for ETRAN, whose collective members are all the most important scientific and educational institutions in Serbia and the Republika Srpska (BIH). The paper first presents the structure, as well as key topics, which are discussed at conferences. Then, the corresponding, characteristic statistical data on the number of papers and authors were observed together. They were analyzed for three periods, a broader one (last 26 years, 1996-2021), a medium-term (last 9 years, 2014-2022), and a shorter one (last 4-5 years, 2018 – 2021(2)). The numbers of papers were analyzed in aggregate, but also by individual conferences and in more detail by thematic sections, while the data on the authors were related to the country and the institution of employment, as well as to the gender of researchers. It was concluded that these gatherings usually represent the place of presenting the scientific results of researchers coming from the academia (faculties and institutes) and that the presence of the ones from industry, military, or healthcare is less noticeable. Also, the largest number of participants is from Serbia, coming from the three largest national universities. However, the international component is also significant, through authors from 31 countries. The participation of women has been improved, but it is still not adequate and amounts to 30%. These data were the fundamentals to discuss the future development of both conferences.

A Comparison of Selected Systems For Learning About SQLi Vulnerability Suitable for Academic Uses

Djordje Madic, Danko Miladinovic and Zarko Stanisavljevic

***Abstract*— In this paper five popular platforms for secure software development training are analyzed from the perspective of their suitability for academic uses. In order to compare these platforms a novel ta onomy of interactive cyber training and education systems (Cyber Ta i) is used. nly parts of the ta onomy that are relevant are included in the analysis. The analyzed platforms are also compared to iTrainer system, which was developed at the niversity of elgrade, chool of lectrical ngineering specifically to be used at the courses dealing with the injection (i) vulnerability. ased on the conducted analysis a suggestion is made regarding the requirements that a training platform should fulfill in order to be suitable for academic uses.**

***Index Terms*— i; secure software development; hands-on training.**

I. Introduction

Software engineering never had more learning resources than today, with the internet resources available at all times. It comes in many forms, as video courses, articles, e-books, and most of them are free. Most of the ones covering SQLi are structured to build theoretical knowledge while applying the knowledge and hands-on experience are missing.

On the other hand, courses covering topics like secure software development and network and system security are emerging across universities all around the world. Respectable authorities in the field of software engineering, i.e. ACM and IEEE, are issuing their recommendations regarding curriculum [1] and in these recommendations, as a rule, they state that courses covering topics from software engineering should be supported by hands-on experience for students.

There is a constant dilemma when introducing hands-on exercises at the university course, should this be done using existing technology or is there a need for a new dedicated tool to be created. In order to help teachers to resolve this dilemma regarding SQLi vulnerability as a topic to be covered at some course, in this paper analysis of five popular platforms for secure software development training is presented. These platforms are also compared to one dedicated tool for teaching SQLi vulnerability as a course topic (SQLiTrainer [2]). Based on qualitative analysis, a suggestion of requirements that a tool suitable for academic uses should fulfill is made. Finally, an example of quantitative analysis is presented. As far as the authors are aware, there are no similar studies published in open literature.

The remainder of the paper is organized as follows. The second section presents the three selected tools with hands-on SQLi exercises, one online tool with hands-on SQLi exercises, one framework for organizing secure software training, and one dedicated teaching tool. The third section compares the six selected tools using the taxonomy of interactive cyber training and education systems (Cyber Taxi) [3]. The section four describes the requirements that a tool should fulfill in order to be used in academia. The fifth section gives an example of quantitative comparison of the selected tools. The last section gives a conclusion and suggests future work.

II. Description Of The Selected Tools

Five popular platforms are selected for this research based on their availability to the authors, their popularity in the secure software development community and their coverage of the selected topic (e.g., Juice Shop [4] is an official tool of the OWASP [5] community, Avatao [9] is used for the Serbian Cyber Security Challenge, etc.).

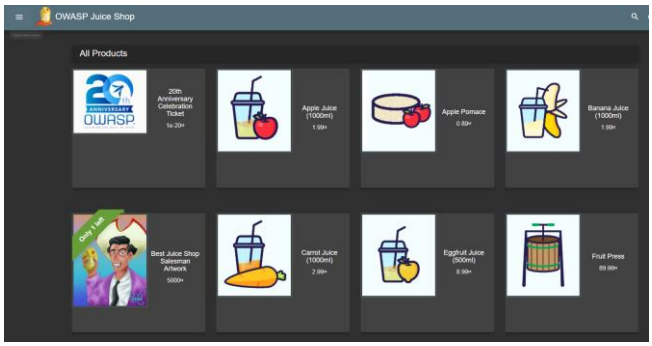

Fig. 1. OWASP Juice Shop

Juice Shop [4] (Fig. 1) is an open-source web application representing an insecure online shop. It is created by OWASP [5] organization and contains 100 challenges of varying difficulty where the user is supposed to exploit the underlying

Djordje Madic is with Zuehlke Engineering, Bul. Milutina Milankovića 1i, 11070 Novi Beograd, Serbia (e-mail: djordje.madic@zuehlke.com).

Danko Miladinovic is with University of Belgrade, School of Electrical Engineering, Bul. kralja Aleksandra 73, 11120 Belgrade, Serbia (phone: +381-63-3439-97; e-mail: danko@etf.bg.ac.rs).

Zarko Stanisavljevic is with University of Belgrade, School of Electrical Engineering, Bul. kralja Aleksandra 73, 11120 Belgrade, Serbia (phone: +381-11-3218-484; e-mail: zarko.stanisavljevic@etf.bg.ac.rs).

 ISBN 978-86-7466-930-3

vulnerabilities. SQL injection is covered by 7 of them. The application automatically detects when a challenge is solved, and progress of the user is tracked on a score board. All components of the user interface can be customized including color theme, logos, banners, links, products and other items in the database. Interactive help, hints and „challenge solved“ notifications can be turned off, while the initial set of challenges and their solutions cannot be changed. Domain of the application is well chosen, having in mind the number of online shops today. According to a study from 2017 [6] there are 800.000 registered online shops only in Europe. Juice Shop application code [7] has more than 50 contributors. Instance of the application can be started on a personal computer or one of the cloud services.

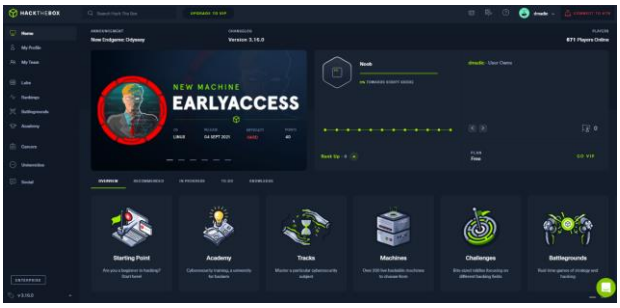

Fig. 2. Hack The Box

Hack The Box [8] (Fig. 2) is online training platform, helping individuals, companies and universities improve penetration testing skills. The platform is free for students and university professors. It includes a set of Capture The Flag (CTF) exercises grouped in 10 categories, like Web, Hardware and Reverse Engineering. Exercises are updated on weekly basis. Progress of the user is tracked and awarded with points, ranks and badges. Exercises are performed in a realistic environment, for example, against a dedicated web application instance or an executable that should be reverse engineered. Part of the exercises is followed by detailed documentation of the solutions. At the moment of writing, Web category contains 34 challenges designed as complex attacks where the user has to exploit multiple vulnerabilities to solve them. Some of them require SQLi to be solved.

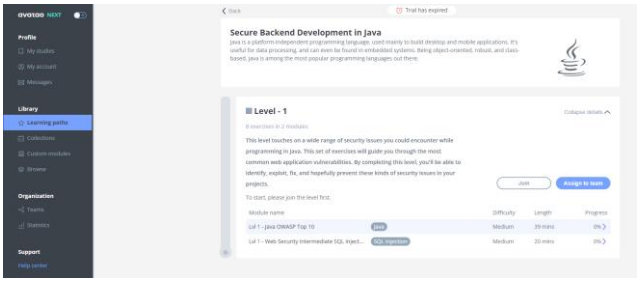

Fig. 3. Avatao

Avatao [9] (Fig. 3) is online training platform for companies created to improve security awareness of the employees and provide them with best practices for secure software development. It includes exercises in 8 programming languages, grouped in modules and learning paths. Exercises are performed in a realistic environment, for example, against a dedicated web application instance. There are 2 types of exercises, challenges and tutorials. Tutorials are interactive exercises guided by a chat bot acting as a teacher, while the challenges are designed as CTF. Most of the exercises are focused on single vulnerability, like SQLi. There are both attack and prevention oriented exercises. At the moment of writing, trial access to the platform provides 18 SQLi exercises in 5 programming languages. Many of them are different variants of SQLi Login Bypass.

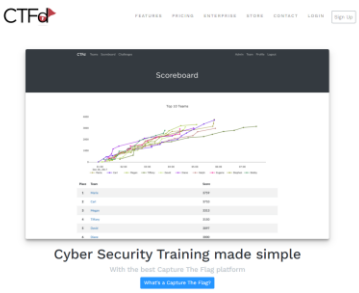

Fig. 4. CTFd Admin panel

CTFd [10] (Fig. 4) is online training framework for hosting CTF competitions and is used for helping individuals and companies improve cyber security skills using CTF challenges. Beside CTF challenges the platform supports a variety of other types of challenges such as multiple-choice and manual verification exercises. Some of these types of challenges are not available in the free version of the framework. Having said that, the framework is free, and it can be expanded by buying plugins and themes from the CTFd website. Unlike other tools, challenges do not come with the framework, but they can be added from the admin page. The admin can also add more pages, view the progress of individual users and teams on the platform and view success rate of each challenge. The framework supports individual and team competitions.

Fig. 5. PicoCTF

PicoCTF [11] (Fig. 5) is online training tool for helping users increase their hacking skills using CTF challenges. Users can register either as learners or as teachers. Learners can solve CTF challenges and join a classroom. Upon joining classrooms learners can get custom event scoreboards and track classroom member’s progress. Teachers can create

 ISBN 978-86-7466-930-3

classrooms and monitor student progress. Exercises are CTF based and are split into categories like web exploitation, cryptography, forensics, etc. There is no SQLi category, but there are around 10 SQLi challenges across all categories.

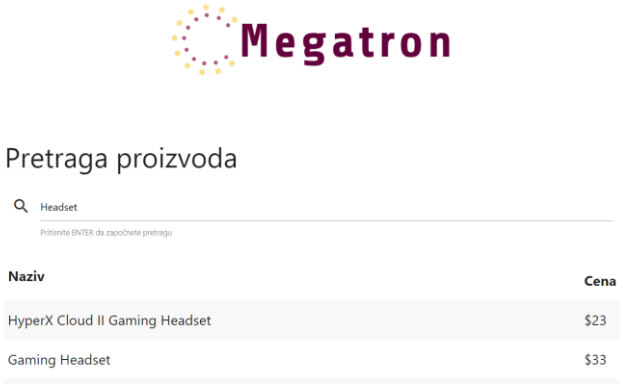

Fig. 6. SQLiTrainer

SQLiTrainer [2] (Fig. 6) represents a set of 4 vulnerable applications that can be used to demonstrate different types of SQL injection vulnerabilities. Implementation and the examples how to use the system are given in [2]. It is used for laboratory exercises at the Advanced Network and System Security course at the University of Belgrade, School of Electrical Engineering. Components of the user interface and initial state of the database can be customized. The applications can be run against different SQL databases, like MySQL and PostgreSQL, changing the solution of the exercises.

III. Comparison Of The Selected Tools

In order to compare different tools a common ground and a set of measurable parameters are needed. For the purpose of suggesting requirements that a tool should fulfill to be used in academia a novel and promising taxonomy Cyber Taxi [3] was analyzed. Most relevant parts of the taxonomy are orchestration, proficiency level, and customization level. In [3] orchestration defines the automation level, although this term can have other meanings in a different context. Having a group of students, it is a requirement to be able to set up the training environment automatically, no matter the number of participants. In case of problems, it should be simple to restart the environment and debug it. Proficiency level defines required level of knowledge. In case it is above beginner level, the tool is not relevant for academic use. In order to provide enough learning material and assess different groups of students, training should be customizable, and should be able to produce similar exercises.

Classification of the selected tools based on the relevant parts from the Cyber Taxi is presented as a table in Fig. 7. Columns of the table represent the selected tools, while rows of the table represent components of the taxonomy, grouped by more general concepts. The table is filled based on the experience of the authors with the selected tools using their publicly available, free or trial versions. All of the tools except CTFd have trainings of similar purpose and include exercises for beginners. SQLiTrainer is the only tool requiring manual effort for scoring. Hack The Box, Avatao and picoCTF are ready-to-use products, while Juice Shop, SQLiTrainer and CTFd require the training facilitator to decide on the deployment strategy and execute it. SQLiTrainer has the most customizable exercises, while Hack The Box and Avatao can customize the set of exercises a training group will receive. CTFd can be customized based on the teacher needs.

IV. Requirements

Based on the previous analysis and the authors previous experience with eLearning tools in computer engineering education, for a system to be suitable for academic uses, a recommendation can be made as a set of requirements that need to be fulfilled. Target audience of the system should be students with no previous knowledge of SQLi or other software vulnerabilities. This requires a system with exercises focused only on SQLi. Exercises combining SQLi with other vulnerabilities are out of scope, as the target audience should have knowledge of multiple vulnerabilities and understand how they can be exploited together. Further requirements can be defined using the Cyber Taxi, making it suitable for comparison with the existing tools.

Fig. 7. Clasification of the selected tools

 ISBN 978-86-7466-930-3

Audience
- Target audience: Students
- Sector: Academic
- Proficiency level: Beginner
- Purpose: Raise awareness and increase skill level

Training environment
- Training Type: Capture The Flag
- Scenario:
    - Non supervised
    - Problem- or Storyline- driven
    - Target of the challenge is application solved by exploiting SQLi vulnerability

Training setup
- Scoring: Assessment, as results of the participants should be comparable
- Roles: No specific roles
- Training mode: Team, or Individual during assessments
- Customization Level: Specific, as it should be customized for each training group

Technical setup
- Environment structure: Online platform in the sense of E-Learning platform, or hosting
- Deployment: Both On-premise and Cloud
- Orchestration: Full degree of automation with modular design of the application

Capture The Flag is the most practical training type for students. Students can be split in groups, each group having the same flag. As flags are known upfront, they can be checked automatically once the user submits them. Depending on modularity of the application, additional customization may go along, like each group having a specific user interface, initial database state, and SQL database, like PostgreSQL or MySQL.

For the selected tools to be fully compliant with the requirements, the following features should be introduced:

- Juice Shop: Customization of the exercises, providing different flags per training group
- Hack The Box: Exercises focused only on SQLi
- Avatao: More exercises focused on SQLi or customization of the existing ones
- picoCTF: introduce a specific SQLi category

As it can be seen additional effort is needed in order to use existing platforms in academia since the two very important requirements, i.e. exercises focused only on SQLi and customization of exercises cannot be expected to be fulfilled. On the other hand dedicated tools, like SQLiTrainer and frameworks, like CTFd, will fulfill all of the requirements, but will require even more effort to be created.

V. Example Of Quantitative Analysis

In this section we will give an example of a quantitative analysis using the results from the table represented in Fig. 7. and the requirements of the previous chapter. Each category in the previous mentioned table (technical setup, audience, training environment and training setup) will be graded on the scale from 1 to 5 based on how much the tools and the CTFd framework satisfy the requirements from the previous chapter.

Having that in mind we can draw a conclusion on how much each subcategory in each category weights in the final score of that category. Because all of the analyzed tools and CTFd framework satisfy the requirements of categories audience and training environment, on these two categories they all get the grade of 5.

That leaves us with two categories left to be graded, and those are training setup and technical setup. Here we can define how much each subcategory has weight in the final grade of its category based on the values for those subcategories from the previous chapter and from the table represented in Fig. 7. These specific weights are defined based on authors personal experiences with laboratory exercises on the Advanced Network and System Security course at the University of Belgrade, School of Electrical Engineering.

Training setup
- Scoring
    - Automatic assessment weights 40%
    - Manual assessment weights 20%
- Roles – 0% of the category grade
- Training mode
    - Single and team mode weights 20%
    - Only single or team mode weights 10%
- Customization Level
    - None weights 0% of the category grade
    - Ability to only pick a set of exercises for group weights 10%
    - Interface and initial database can be customized weights 20%
    - Initial database state and target database can be customized weights 30%
    - Initial database state, target database, and challenges can be customized weights 40%

Technical setup
- Environment structure
    - Noncommercial platform weights 50%
- Deployment
    - On premise and cloud weights 20%
    - Only on premise or on cloud weights 10%
- Orchestration
    - Full automation weights 30%

Based on these assessments we can see the final grade of each category and the average grade of each analyzed tool in a table represented in Fig. 8.

Fig. 8. Grades of the selected tools

VI. Conclusion

This paper presented the need for having tools to learn SQLi vulnerability in an interactive way and listed the existing tools. Selected tools were categorized based on the parts of the Cyber Taxi. The same taxonomy was used to compare the selected tools, leading to suggestion of requirements that a tool to be used in academia needs to fulfill. Conclusion is that effort needed to adapt existing tools to fulfill these requirements sometimes can exceed the effort needed to create a dedicated tool from scratch and sometimes it is even not possible to customize existing tool. However, once the requirements are clear it is always useful to check if there are existing tools that can fulfill them before starting to create a new tool. The quantitative analysis that was conducted in this paper showed how once the requirements are defined it is possible to quantify them and create a unique benchmark for each individual teacher and each individual course.

Automated grading system for picoComputer assembly codes integrated within E-Learning platform

Jovan Đukić, Vladimir Jocović, Marko Mišić, *Member, IEEE,* and Milo Tomašević

***Abstract*— btaining programming s ills is one of the most important prerequisites for a future career of every electrical or software engineer. The programming e pertise is best acquired by gradually advancing from simpler to more comple programming paradigms, architectures, and languages. That being the case, a restrictive educational computer architecture – picoComputer, along with a development environment, was developed at the niversity of elgrade, chool of lectrical ngineering to early e pose the students to the concepts of assembly language programming. aving in mind that programming s ills are successfully attained only through practical wor , such as homewor assignments, projects, and laboratory e ercises, some more contemporary picoComputer simulation environments were implemented, including essy ab des top application and a Picosim web-based solution. owever, programming courses at our school are massive and require the utilization of online learning platforms, aiming to properly achieve a scalable learning process. ence, we employed oodle - earning platform, as well as the Code unner plugin, to facilitate and accelerate the teaching and assessing processes in both of our major programming courses. Code unner plugin supports various widespread programming languages and is also highly programmable, which is why the integration of picoComputer architecture within a contemporary learning system arose as an opportunity.**

***Index Terms*— - earning; automated code assessment; oodle; picoComputer**

I. Introduction

Strong programming expertise is one of the fundamental abilities of a contemporary software engineer and a necessary quality of an electrical engineer, as well. Gaining programming practice is essential for not only solving real-world problems in software but also for memory sharpening and achieving an ability to efficiently resolve various problems that are seemingly outside of the programming scope.

Jovan Đukić is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: dj@etf.bg.ac.rs)

Vladimir Jocović is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: jocke@etf.bg.ac.rs)

Marko Mišić is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: marko.misic@etf.bg.ac.rs), (https://orcid.org/0000-0002-7369-4010).

Milo Tomašević is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: mvt@etf.bg.ac.rs)

An effective approach to adopting good programming skills requires a strong theoretical foundation, which is being acquired through traditional methods of lecturing, in addition to a practical approach, which includes homework assignments, larger projects, and laboratory exercises [1].

Programming courses at the School of Electrical Engineering, the University of Belgrade, are mandatory for all first-year students and they are organized into two one-semester courses - Programming 1 and Programming 2. Both courses are mainly focused on studying programming languages (Python and C) and introduce different programming paradigms. They start with a low-level assembly language and continue with a more complex procedural and to some extent object-oriented programming paradigm. Moreover, course topics are permeated with basic data structures and code complexity topics.

Our first-year programming courses are attended by a vast number of students (up to a thousand). These massive courses impose a lot of overhead regarding the process of qualitative assessing the students' work and administering the course contents, as well. Hence, there was a need to establish online learning platforms and other tools intending to ease the whole process of managing these huge courses, as well as disburdening the already overexerted teaching staff. Our first experiences with Moodle E-Learning platform in programming courses are described in [2]. In our previous efforts, we also had a good experience with Moodle e-learning platform for other computer engineering courses [3], as well as with other tools for student assessment [4], analysis of results [1], and source code plagiarism detection [5, 6] which are all widely used in programming education. For all those reasons, we decided to implement appropriate support for the emulation of picoComputer assembly codes in Moodle e-learning platform, as well. We describe our motivation and the details of implementation in the rest of the paper.

The second section expresses the reasons behind the choice to move mandatory programming courses to the e-learning Moodle platform and the course organization within it, as well as the examination process using CodeRunner plugin. The third section presents in more detail the in-house developed architecture for teaching assembly language programming - picoComputer (pC). The fourth section describes the present-day implemented system for compilation, execution, and evaluation of source codes written in the pC assembly language and its integration with the CodeRunner plugin within Moodle platform. The fifth section illustrates the evaluation process and the results obtained by system testing. Finally, a brief conclusion and future work are given in the last section.

 ISBN 978-86-7466-930-3

II. MOODLE PLATFORM AND CODERUNNER PLUGIN IN PROGRAMMING COURSES

The programming courses lectures at the School of Electrical Engineering are held by professors and teaching associates. The professors mostly teach the theoretical aspects of the currently studied programming topics, giving emphasis to some important essences needed for successful mastering of the practical programming tasks. Bearing that in mind, the teaching associates organize auditory exercises in a more practical manner, thus those classes are dedicated to programming practices only.

Each elementary problem and some intermediate programming tasks are conducted alongside students, aiming to strengthen and solidify their ascending programming skills, as well as to introduce new approaches to solving programming problems. Simple programming tasks were solved using an integrated development environment, such as PyCharm for Python or Microsoft Visual Studio for C, while the more complex ones were worked out on the Moodle platform using the CodeRunner plugin.

Moodle is an online learning platform that allows teachers to create courses for students and to grade their work in those courses using tests. The platform supports a variety of plugins, and we found the CodeRunner plugin the most useful for our grading purposes. This plugin introduces a new type of question, which allows teachers to assess and grade students' source codes. Correctness of the students' codes is partially verified using an automated testing process implemented by the teaching associates, who managed to appropriately configure the plugin using a custom Python script. This feature places the CodeRunner plugin at the top of the list of supported plugins. Unfortunately, some code characteristics still need to be checked manually, e.g., coding style and efficiency.

The example that demonstrates the usage of the Moodle platform is shown in Figure 1. It illustrates the exercise concerning the linked list data structure. The exercise is carried out in C programming language and consists of basic operations performed on linked lists: insertion and deletion of elements, list traverse operations, etc. Before a problem is approached practically, the topic is explained using a PowerPoint presentation. The task itself is straightforward and performed on a simple linked list of integers.

Intending to make the topic of linked lists more interesting, a big task is organized as a series of smaller tasks for a more comprehensive understanding. The task is divided into smaller task sets of varying difficulty. Former task sets consist of commonly used linked list operations and latter task sets functionally depend on the previous task sets. This way the goal is to incrementally build and test the solution and to teach students one of the most important programming principles – code reusability.

As shown in Figure 1, a question has a small table at the top of the page which contains the test input data and the expected output data. Below the test cases table, there is a text area for the code itself. The CodeRunner plugin also includes syntax coloring which is an additional advantage for the students since it can indicate the errors that would be very hard to find in a classical exam notebook.

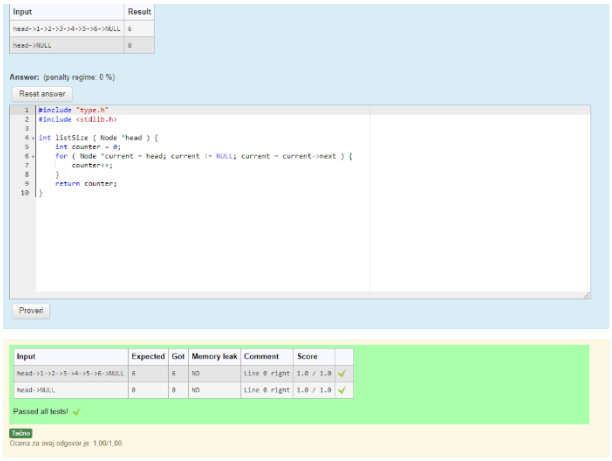

Figure 1 A CodeRunner question in C

After the required piece of code is written in the provided text area, the students can check its correctness by clicking on the check button. When the button is clicked, the contents of the text area are sent to a server dedicated to checking and grading CodeRunner questions. The server first compiles the given code and executes it using the supplied test cases. After execution, the server collects the output and compares it with the expected output.

The main advantage of the CodeRunner plugin for Moodle platform is that the entire process of code checking is configurable [7]. This is achieved through Python scripts which are executed each time a student checks the question. Furthermore, the comparison of the expected and collected output can be graded line by line, thus allowing the students to receive partial points for each successfully passed test case. After the outputs are compared, the result table, shown below the text area in Figure 1, is created giving feedback and their scores to the students, while pointing them to possible errors in the code.

In the last few years, teaching associates were able to master the craft of the plugin configuration and managed to successfully port programming tasks written in Python and C programming languages to the CodeRunner plugin. These high-level programming languages are the foundation of our mandatory first-year courses. Details of the porting process of these high-level languages and further information are presented in [2]. The CodeRunner plugin was successfully used at other universities in other contexts for Python and C++, as well [8].

However, before introducing the students to the concepts of high-level programming languages, they are taught some elementary concepts of low-level assembly programming. Being a relatively minor part of the course, it required an underlying educational architecture that would be quite restrictive, and that's why the aforementioned picoComputer architecture is envisioned and developed. Considering the nature of the low-level languages, the written assembly code can frequently be hard to read, maintain and debug. Even when the source code is syntactically correct, its possible semantic flaws could be tedious to discover. Until recently, teaching associates had to manually inspect the source code, which can devour plenty of time and energy, even for simple programming problems.

Taking these circumstances into account and having a positive experience gained from porting high-level

 ISBN 978-86-7466-930-3

programming languages such as Python and C to Moodle using the CodeRunner plugin, teaching associates decided to establish a system that could verify and test the students' solutions written in the picoComputer assembly language on the e-learning platform. Nevertheless, the task of implementing such a system is inherently harder than above mentioned porting challenges. Teaching associates had to provide not only a configured environment for executing students' source codes using test examples but also an implementation of a compiler and an emulator for a source code written in assembly language was necessary. These components were not needed in previous porting undertakings, since there are numerous compilers and interpreters for widespread programming languages, including C and Python.

III. PICOCOMPUTER

In 1989. Prof. Jozo Dujmović designed a computer architecture named picoComputer (pC) [9] and developed a DOS application *pC Assembler and Simulator* (pCAS). His intention was to facilitate the teaching and understanding of the assembly languages, which are naturally, due to their low-level nature, to some degree demanding. Since only a part of the introductory programming course is devoted to low-level programming, the pC is designed as a quite restrictive architecture as implied by its name. However, even with its restrictive scope, pC is still very useful. In order to provide more convenient environments, two tools have been recently developed at our school, MessyLab IDE [10], and a web online environment called picoSim [11].

Although the picoComputer architecture is more than 30 years old, it is still relevant nowadays. Its aim is to provide a framework for demonstrating assembly-level programming. It follows the classical Von Neumann architecture and, even though the characteristics of various components have changed throughout time and the instruction sets are getting more and more complex, the basic principles of computer structure have not changed a lot. The picoComputer generally consists of the Central Processing Unit, Random Access Memory, and Input/Output devices, which are all connected using a shared Bus, as shown in Figure 2.

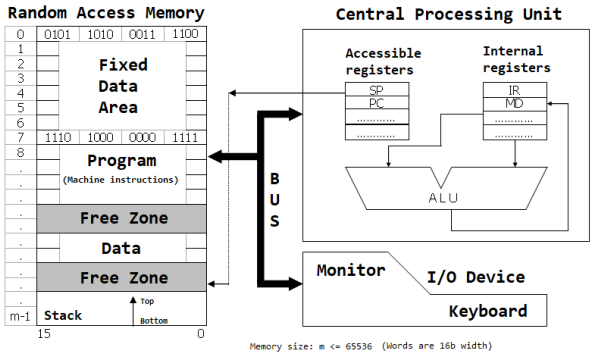

Figure 2 The picoComputer architecture

The Central Processing Unit has several internal registers, yet none of them are directly accessible as the instruction operands. Because of a limited instruction format, there are no general-purpose registers. Still, Program Counter (PC), which points to the next instruction to be executed, and Stack Pointer (SP), which indicates the top of the stack, are registers that can be indirectly manipulated by certain instructions. The value of the PC register is either incremented after an executed instruction or can be directly loaded with the branch address by a control instruction. SP register value is affected by subroutine handling instructions and.

The Random Access Memory consists of 65536 locations (memory words), which means that memory addresses are 16 bits wide, while each location is, also, 16 bits wide. The memory is logically divided into two sections: Fixed Data Area and Free Area. Fixed Data Area includes the first 8 locations, which are directly accessible through direct memory addressing. Free Zone is comprised of the remaining locations and these locations are only accessible indirectly, through another location from the Fixed Data Area, using memory indirect addressing. These locations can be used arbitrarily. The third addressing mode is the immediate addressing where the operand is found in the instruction itself.

The input device is a keyboard, and the output device is the monitor. Numerical data can be entered using a keyboard, while the screen presents the contents of certain memory locations. The input/output operations are blocking operations. Consequently, there is no need for polling a status register. However, parallelism is not supported.

Every picoComputer program consists of two sections: the directive section, and the instructions section. There are two kinds of directives: symbol definition directives and the origin directive. A symbol definition directive is used to assign numerical values to symbols to improve code readability. These symbols are replaced by their numerical values in the assembling process. Labels are an implicit means of symbol definitions, and they can be specified by an identifier attached to any instruction. The origin directive defines the starting memory location where the executable code (instruction section containing instructions following the origin directive) resides.

Every instruction is defined by its symbolic mnemonic and a variable-length comma-separated list of operands. The picoComputer format provides up to 3 operands in an arbitrary instruction. Instructions can occupy one or two memory words (16 or 32 bits). The operation code and three operand fields are encoded in four 4-bit nibbles of the first word, as shown in Figure 3.

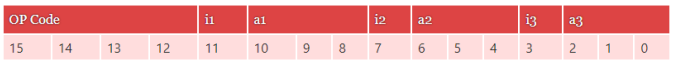

Figure 3 Typical picoComputer one-word instruction format

Hence, a maximum of 16 different operation codes are supported. Each operand specification consists of *i* field (1 bit) and *a* field (3 bits), where *i* indicates the memory addressing mode (0 for direct or 1 for indirect), while *a* field represents an address from Fixed Zone Area (0-7). The 16-bit immediate operand, when supplied, is stored in the second instruction word. The pC instruction set consists of the integer arithmetic instructions (addition, subtraction, multiplication, division), data transfer instruction (scalar or

 ISBN 978-86-7466-930-3

vector move), conditional branches, subroutine call and return, I/O instructions, and stop instruction.

IV. ASSESSMENT OF STUDENTS' PICOCOMPUTER ASSEMBLY PROGRAMS

As stated, in the second chapter, CodeRunner allows its users to provide a custom Python script for the purpose of grading and assessing. This script is executed in a preconfigured CodeRunner plugin environment, which provides numerous predefined variables. These variables can be used to obtain a variety of information about students from Moodle (i.e., student profile information) and, more importantly, the answer submitted by the student through the CodeRunner form. Given that the pC is our custom assembly language and that the answer is given in a text form, the authors had to build a custom compiler and an emulator to be able to grade and assess students' answers.

The compilation phase consists of text manipulation and performs syntax and semantic checks specified by the rules of the assembly language. During this stage, the text is split into individual lines, which are checked separately. If the process is successful, the result is a Python list data structure of integers, where each element represents an individual memory location. However, if there is an error in the code, the result of the compilation phase is a list containing descriptions of each individual erroneous line (line number and the error description). The unsuccessful compilation phase is depicted in Figure 4.

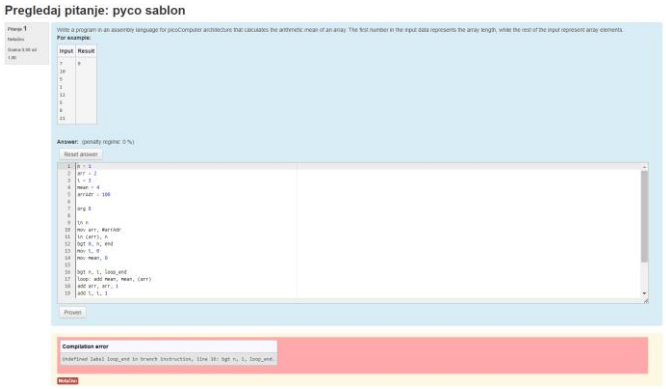

Figure 4 Unsuccessful pC compilation phase

If the compilation phase is successful, the following step is the emulation phase. The input data for the emulation phase is also a list of integers (i.e., memory locations), the address of the first instruction provided by the origin directive and a list of integers representing the input data. The emulation phase is a simple *for*-loop, which reads instructions one by one, executes them and stores their results in the memory. The exceptions to this workflow are the IN and OUT instructions. The IN instruction reads one or more numbers from the input data list, while the OUT instruction writes the content of one or more memory locations to the output list. This output list is later used for comparison with the expected results. Runtime checks are also performed during this stage. Given the restricted nature of the pC and the fact that only integer data type is supported, the only runtime check performed is the division-by-zero check. This is depicted in Figure 5.

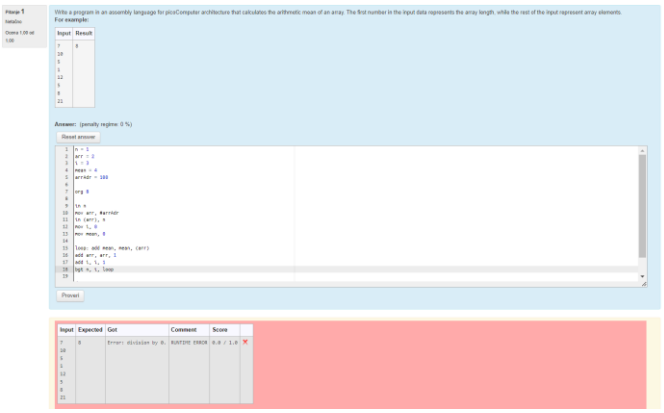

Figure 5 Runtime error checks performed

If both the compilation and the emulation phases are successful, the result of the emulation phase is compared to the expected result and the final grade is formed. The comparison is performed on a line-by-line basis, where each line gives the same number of points. Finally, the student is presented with the score table as shown in Figure 6.

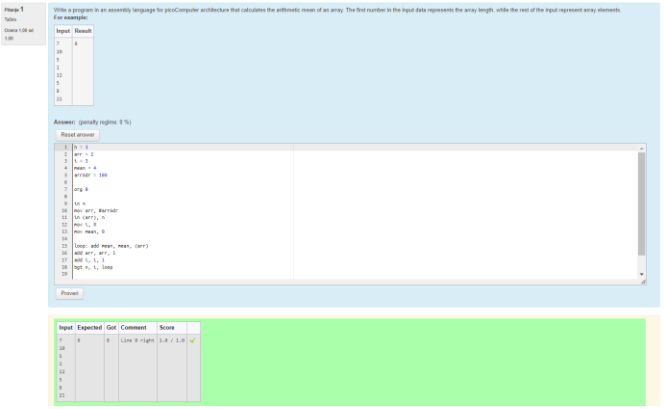

Figure 6 Score table for a program

V. SYSTEM TESTING AND EVALUATION PROCESS

During the development, the system was tested with custom-written programs, which cover all possible valid and invalid instruction formats. Valid programs consist of instructions as specified by the pC instruction format. These programs are relatively easy to write since there is a limited number of possibilities that are in accordance with the syntax and semantic rules. However, the number of invalid formats is far greater in number and, therefore, it is impossible to cover all of them. Hence, the system was also tested with the source codes of the students in the previous years.

Until recently, during exams students used the MessyLab desktop application to write and self-check their solutions. Regardless, the students used the Moodle platform to submit their answers, which were graded manually. We used these answers to perform evaluation by comparing manual scores given by the teaching associates and the scores given by the system. The system was evaluated on students' programs after the exams have passed and the results of both approaches were quite similar. We sincerely hope that the live results will be as good as these.

 ISBN 978-86-7466-930-3

VI. CONCLUSION

In this paper, we have presented the migration process of a restrictive educational picoComputer architecture to the online e-learning Moodle platform using a dedicated CodeRunner plugin for our introductory programming course. With this new feature, we have successfully fully moved all our programming activities within the Programming 1 course to the LMS. Moodle and CodeRunner are extensively used during auditory exercises in the computer lab and examination. The students reacted very positively to this innovative activity.

Having migrated all programming languages in our mandatory programming courses, it may seem that the future work lacks required matter to be considered worthy. However, the is a significant potential concerning the available possibilities to parametrize and configure these types of systems not only to achieve more sophisticated means of grading, yet also to broaden the spectrum of conceivable programming task types. In the future, we have an intention to develop various learning activities in Moodle, as well to extend our coding exercises pool with more assignments written in different programming languages. Moreover, we have in mind to migrate the rest of our programming courses to such type of learning and examining.

Pandemic Support System Modelling and Implementation as Integral Part of Computer Science Courses

Nenad Petrović

***Abstract* — In this paper, e ercises related to modelling and implementation of pandemic-tac ling systems are proposed as integral part of computer science university courses. The presented case study considers the perspective of two bachelor degree courses taught at the third year of Computer cience and Informatics track at University of Niš, Faculty of lectronic ngineering in erbia covering both hardware and software design icrocomputer ystems and Information ystems. or the first course, an indoor safety system based on Intel and additional components (251, 255 and 25) is presented. n the other side, the main topic of the second one is ava nterprise dition ( )-based information system development, while the presented e ample shows application providing efficient pandemic-related data management (coronavirus tests and vaccination).**

***Index Terms* — C ID-1 ; coronavirus; education; Intel ; ava nterprise dition ( ).**

I. Introduction

The ongoing coronavirus pandemic has brought numerous challenges not only to healthcare and medical science-related personnel, but when it comes to engineering and information sciences professionals as well. Efficient pandemic-related data management in synergy with leveraging the collected information are recognized as key factors when it comes to role of information systems in global battle against COVID-19 [1]. On the other side, IoT and embedded devices are one of crucial means for disease spread reduction (such as mask detection and contactless temperature measurement) [2]. In this paper, we introduce two exercises aiming Information Systems and IoT bachelor degree courses at Faculty of Electronic Engineering, University of Niš in Serbia. The first one covers the design and development of software leveraging pandemic data, while another is a control unit of indoor safety system. The goal is to show how students can become aware of their role as computer engineers among other professionals tackling COVID-19, while studying Java Enterprise Edition software development and programming microcontrollers, on the other side.

The exercise case studies presented in this paper are inspired by author's intensive work in area of pandemic support information technology solutions since the beginning of COVID-19 outbreak. In [3], an affordable IoT-based indoor safety system for mask check and temperature detection leveraging Raspberry Pi and Arduino Uno was introduced. Moreover, the works from [4, 5] show methodology for efficient pandemic resource planning, such as vaccine allocation and tests. Furthermore [6] shows air quality regulation system for coronavirus spread reduction, while [2] addresses green certificates checking relying on blockchain. Finally, [7] shows adoption of data mining techniques in area of post-COVID tourism. On the other side, author also introduced exercises related to coronavirus protection within Logic Design [8, 9] course and microcontroller-related part of Microcomputer Systems [9, 10].

Nenad N. Petrović is with University of Niš, Faculty of Electronic Engineering, Aleksandra Medvedeva 14, 18000 Niš, Serbia, (e-mail: nenad.petrovic@elfak.ni.ac.rs), (https://orcid.org/0000-0003-2264-7369)

II. Background

A. Information Systems Course

Information Systems is third year bachelor degree course, mainly covering Java Enterprise Edition (JEE) [11] and related technologies within practical sessions. The implementation-related assignment is homework project scored by 25% of the overall coursework. The underlying architecture is depicted in Fig. 1. In such application, user provides the corresponding input data and selects desired options via web browser-based interface. Moreover, in order to generate the expected results, business logic layer is responsible for calculations and data manipulation. Additionally, at some point it might rely on external microservices deployed within containers for some of the tasks. During this processing within business layer, objects holding the relevant data about events, users and other entities might be persisted within database or retrieved from there Finally, the outcome is shown back to the end-user inside web page. Later, the acquired data can be further leveraged for various types of predictions relevant to business goals.

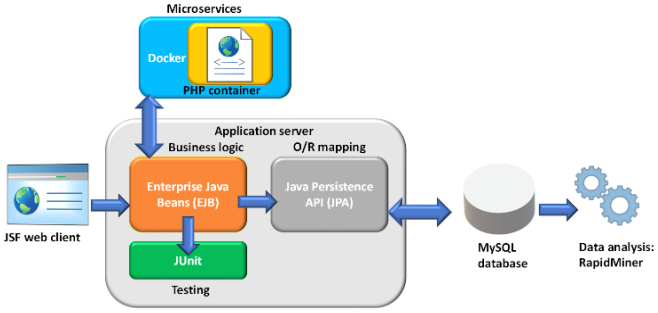

Fig. 1. Information Systems course project architecture.

An overview of components corresponding to the topics covered by the practice-oriented part of Information Systems course is given within Table 1.

TABLE I
INFORMATION SYSTEMS TOPIC OVERVIEW

Component	Type	Role
Java Server Faces (JSF) [11]	Java-based framework for web applications (front-end)	User data input and result visualization
Enterprise Java Beans (EJB) [11]	Business logic layer components for application JEE back-end	Calculations and data manipulation
JUnit [12]	Testing framework	Unit testing of business layer functionalities based on assert checking
Java Persistence API (JPA) [11]	Object-relational (O/R) mapping specification	Persistence of entities (Java class objects) in form of database rows
MySQL [13]	Relational database	Storage of relevant data within tables
Docker [14]	Containerization engine	Microservice implementation and deployment within isolated environment
RapidMiner [15]	Automated machine learning tool	Predictions using classification, regression, clustering and association rules

B. Microcomputer Systems Course

Microcomputer Systems are also obligatory third year bachelor degree course, but focused on hardware design instead. It consists of two main parts: 1) Intel 8086-based systems [16] 2) PIC16-family microcontrollers. In this paper, we focus on the first part, which represents around 30% of the overall course work, split into lab session exercises and written exam. When it comes to that topic, several additional components are also covered, as shown in Table 2.

TABLE II
MICROCOMPUTER SYSTEMS TOPIC OVERVIEW

Component	Type	Role
8086	16-bit microprocessor	Control unit and data processing
8255	Parallel data peripheral interface	Output to devices such as 7-segment displays and LEDs or input handling, such as button press
8251	Serial data transfer interface	Receive/transmit data via single line from serial devices and convert it to parallel in order to be usable by 8086
8259	Programmable Interrupt Controller	Detecting changes on interrupt lines and providing mechanism for response to events which occurred in the external environment

III. Case Studies

A. C I -1 ealthcare System for Test and accination

The goal of the project assignment is to model and implement a healthcare information system aiming to support COVID-19 testing and vaccination processes. The complete source course of the project is given within public online GiHub repository: https://github.com/penenadpi/is2022_covid.

It gives the ability to enter the related data using corresponding JSF pages, as shown within screenshot of test-related interface (Fig. 2). On the other side, it enables the storage and retrieval of relevant information about vaccination as well, such as ambulance identifier, date, vaccine type, the number of dose and person identifier.

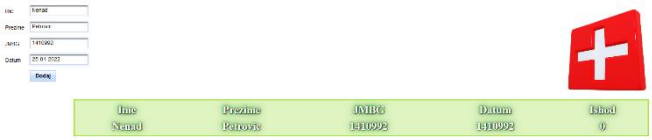

Fig. 2. JSF page for COVID-19 test records.

We can distinguish between three main types of Java class components within the application (as illustrated in Fig. 3): 1) entity classes – responsible for data persistence about relevant objects (*accination ecord* and *Test ecord*); 2) session beans services – implementation of business logic services together with their corresponding interfaces (*accinationSer ice* and *TestSer ice*); 3) controllers - functionalities related to a single JSF page (*accinationController* and *TestController*). The underlying flow can be described as follows: controllers are triggered by clicking on buttons within the JSF page, while inside them, the calls to corresponding services leveraging the data (storing or reading) and performing processing are invoked. These operations are executed against entity objects which are permanently persistent within database relying on O/R mapping.

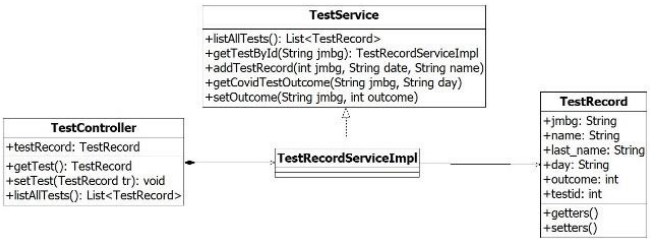

Fig. 3. Excerpt of UML class diagram for coronavirus test records.

On the other side, when it comes to testing, JUnit framework for unit testing in Java is covered by this course. Unit tests aim to check whether lowest level executable units (such as single method in object-oriented program or function) give correct result. For that purpose, test cases covering relevant features of the project are written. An example which checks whether new vaccination records are inserted correctly is given in Fig. 3. The test case consists of three main parts: 1) pre-condition: assert which needs to hold before execution of the test itself 2) test steps: the functional call to the method being tested 3) post-condition: condition which should be true after the execution of test steps. As it can be seen in Fig. 4, the precondition checks

 ISBN 978-86-7466-930-3

whether vaccination record for given person does not exist. Then, the test itself adds vaccination record. Finally, the post-condition checks if insertion had been successful by retrieving the vaccination record of provided person and testing if it is not null value.

```
@Before
public void testPrecondition()
{
    VaccinationRecord vr1=service.getVaccByPersonId(14103);
    assertNull(vr1);

}

@Test
public void testCase1()
{
    service.createVaccinationRecord(14103, 2, "Sinopharm", "13-06-2021");

}

@After
public void testPostcondition()
{
    VaccinationRecord vr1=service.getVaccByPersonId(14103);
    assertNotNull(vr1);
}
```

Fig. 4. JUnit test case implementation.

When it comes to integration with microservices, the layer of business logic (*Co idTestSer ice* session bean) interacts with PHP script deployed in a container via HTTP request. In Fig. 5, an example in context of our project assignment is shown. When it comes to insertion of COVID test results, the value of test outcome field is taken as result of PHP script deployed within web server inside Docker container. The script itself takes person identifier and current date as input, while the outcome is randomly generated (0 or 1), simulating the randomness regarding the probability of being infected.

```
public String getCovidTestOutcome(String pid, String day) throws IOException {
      String outcome="";
      URL obj = new URL("http://192.168.99.100/?pid="+pid+"&day="+day);
      HttpURLConnection con = (HttpURLConnection) obj.openConnection();
      con.setRequestMethod("GET");
      con.setRequestProperty("User-Agent", USER_AGENT);
      int responseCode = con.getResponseCode();
      System.out.println("GET Response Code :: " + responseCode);
      if (responseCode == HttpURLConnection.HTTP_OK) { // successful call
            BufferedReader in = new BufferedReader(new InputStreamReader(con.getInputStream()));
            String inputLine;
            StringBuffer response = new StringBuffer();

            while ((inputLine = in.readLine()) != null) {
                  response.append(inputLine);
            }
            in.close();
            outcome = response.toString();
            return outcome;
      } else {
            System.out.println("GET request not worked");
            return outcome;
      }

}
```

Fig. 5. Integration with Docker container microservice.

Finally, the last part of the project assignment involves leveraging the data collected by the described information system in order to make predictions which could be relevant to the pandemic support domain. For this purpose, we make use of RapidMiner tool, which gives intuitive and automated visual interface for machine learning. The presented example shows the adoption of regression, whose goal is to predict the value of numerical (continuous-valued) outcome. The layout of the underlying dataset based on the collected data is shown in Table 3. The goal is to predict vaccine demand (number of persons vaccinated) for given day. Relevant factors (input, independent variables) are day number, vaccine type, institution id and number of daily COVID-positive cases. On the other side, the predicted value (dependent variable) is the number of people who decided to take the vaccine.

TABLE III
VACCINE DEMAND PREDICTION DATASET HEADER

Day	Vaccine type	Institution	New cases	Demand

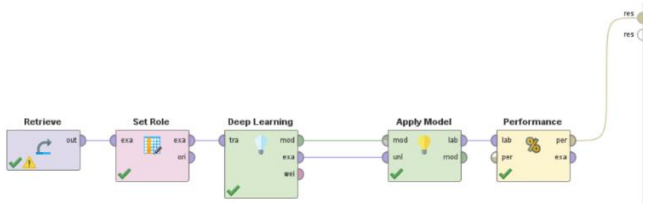

Fig. 6. Vaccination demand prediction workflow in RapidMiner.

The corresponding RapidMiner flow for regression-based prediction is shown in Fig. 6. The first step imports CSV containing all the data. After that, we select the target variable among the available columns. The third step is deep learning module which is trained to make predictions on 80% of the dataset. It contains 2 hidden layers, 30 nodes each and ReLU activation function, performs training in 10 epochs with adaptive learning rate. After that, the model is executed on test data and performance evaluated (mean relative error, which was around 4% in our case).

B. Control nit of Corona irus Indoor Safety System

On the other side, the goal of Microcomputer Systems assignment is design of control unit within COVID-19 indoor safety system (depicted in Fig. 7). Complete code with Proteus simulation is available on GitHub: https://github.com/penenadpi/8086covidsafety/blob/main/8086_8255_8259_8251_covid_safety.pdsprj

Each time new person arrives, two checks are performed by external devices: 1) temperature check – whether it is in normal range (less than 37°C) 2) mask check – if person wears mask or not. After that, the data is sent via 8251 component to the microprocessor, relying on 8259 for

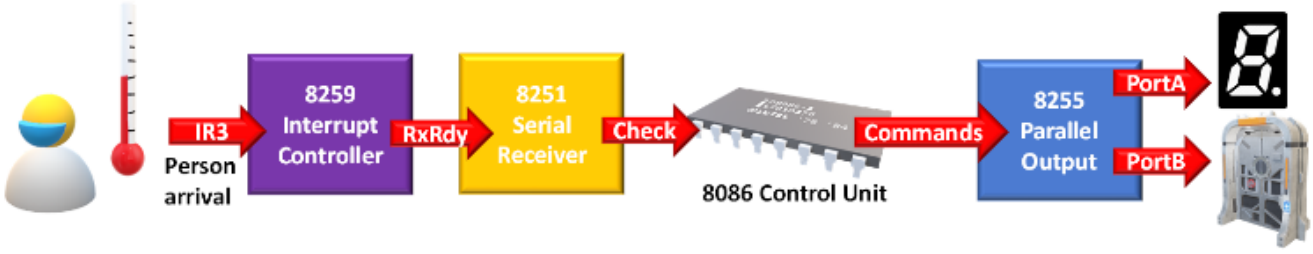

Fig. 7. 8086-based indoor coronavirus safety control system.

 ISBN 978-86-7466-930-3

interrupt handling (vector 171, line 3). In case that person passes both checks, then the door will be opened only in case that the current number of persons is in the allowed range for that room. Additional output peripheral devices are connected via ports of 8255: 1) green LED – turned on for opening door (PORTB, pin 1); 2) red LED – turned on for closing door (PORTB, pin 0); 3) 7-segment display (PORTA) – showing the current number of persons inside. However, when person leaves room, interrupt which decreases the number of persons inside the room is activated, as button on interrupt line 1, vector 169.

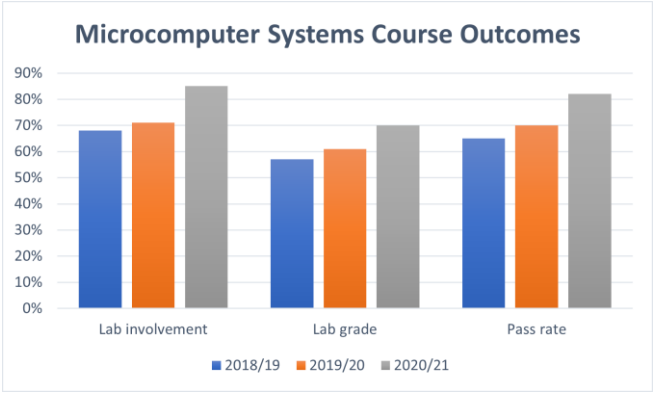

Fig. 8. 8086 interrupt procedure activated when 8251 receives data.

An excerpt of the solution containing the crucial part of the assembly code run on Intel 8086, related to interrupt triggered when new person arrives is shown in Fig. 8. As interrupt line activation means that 8251 is ready for receiving data, we set the corresponding data exchange address and receive the outcome of the entrance rules checks (mask and temperature) coming from other devices. After that, the received byte is compared against the only case which allows opening the door (MASK_TEMP_CHECK which is 18 hexadecimal). If it is not the case, the red LED will be turned on (door closed). Additionally, if person passes this check, it is also asked whether the current number of persons inside the room is below the maximum threshold (5 in this case). Only if it is true, the door will be opened (green LED turned on), the current number of persons incremented and shown on 7-segment display.

IV. Evaluation

The proposed approach of including pandemic-related exercises within computer science bachelor degree courses has been evaluated by observing the results before and after their adoption. The following aspects were considered: number of students involved into lab sessions, average lab exam grade and exam pass rate. Fig. 9a and 9b show graphical summary of results compared to previous academic years for Microcomputer and Information Systems courses, respectively.

When it comes to Microcomputer Systems, COVID-19 protection systems were also part of additional student challenges bringing bonus points which can change the whole written exam, where participation was around 15% of the total students involved.

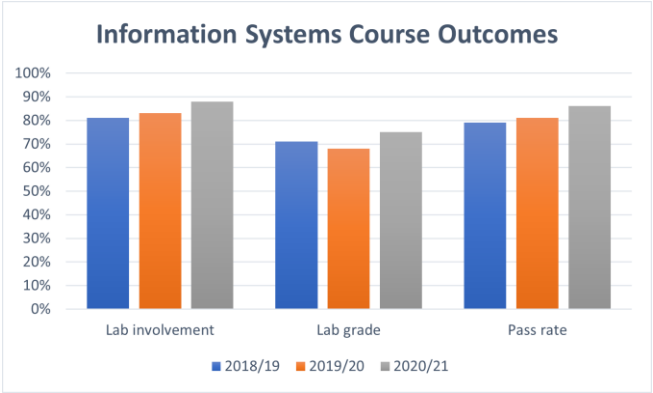

Fig. 9. Course outcomes before and after adoption of the proposed teaching methodology: a) Microcomputer Systems b) Information Systems.

V. Conclusion

In this paper, it was shown how the implementation of pandemic support solutions can be integrated within computer science university cases, considering the case studies of both hardware and software design. According to authors' observations, the adoption of such exercises in previous school year (2020/21) has shown several benefits for both of the considered courses: greater student involvement into lab sessions together with better lab

 ISBN 978-86-7466-930-3

exercise grades and higher exam pass rate. Taking into account all the considerations, the adopted teaching methodology has been slightly more effective in case of Microcomputer Systems course.

Therefore, the approach seems promising, showing that consideration of current real-world problems within computer science courses increases motivation and interest among participants, leading to better overall results.

ACKNOWLEDGMENT

This work has been supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia.

An overview of software code review tools and the possibility of their application in teaching at the School of Electrical Engineering in Belgrade

Miloš Obradović, Marija Kostić, Balša Knežević, Dražen Drašković, *Member*, IEEE

***Abstract* - The use of version control tools together with the code review techniques is the basis of modern software development. In order to introduce future software engineers to these tools, as well as the process of software development, and to better prepare them for the industry work, the course "Principles of Software Engineering" was formed at the School of Electrical Engineering at the University of Belgrade. Within this course and the team project that students are doing, all the basic stages of the development of a software system are studied. One of the biggest challenges in organizing a practical team project is finding the right tool for code review. This tool should be suitable for educating future engineers, but also enable monitoring of students' progress and evaluation of the work done. This paper presents the basic needs that a software code review tool must meet in order to be suitable for use in education. An analysis of the functionalities of some of the existing code review tools has been given, as well as the possibility of applying these tools in education at the School of Electrical Engineering. The end of the paper presents a proposal for the best way to implement a tool for code review.**

***Index terms* - teaching methodology, program code review, software development.**

I. Introduction

Software has become an indispensable part of our daily lives, and our dependence on software is constantly increasing. An organization's success and reputation depend on its ability to produce and deliver reliable software [1]. Therefore, modern software development requires engineers to not only know how to program properly and effectively but also how to develop good engineering practices to make the codebase healthy and easy to maintain [2]. One of the techniques used in industrial and open-source projects, which aims to control the quality of code added to the codebase, is called code review [3]. The main goal of code review is to improve the readability and maintainability of the codebase. It is a process in which code is reviewed during design and development by someone other than the author. According to [2], a well-designed code review process provides several benefits:

- Allows a reviewer to check the "correctness" of the code change, i.e., is it possible for the change to introduce bugs into the codebase.
- Ensures the code change is comprehensible and understandable to other engineers.
- Enforces consistency across the codebase.
- Psychological and cultural benefits such as promotion of team ownership, validation, and recognition of one's work.
- Enables knowledge sharing.
- Provides a historical record of the code review itself.

Even though it is a widely recommended technique for improving software quality and increasing developers' productivity [4], across the industry, code review is far from the universal practice [2]. Nevertheless, together with the version control systems, the code review process forms the foundation of modern software development.

Future software engineers should be familiar with the tools and processes for version control and code review. Therefore, it is important for engineering students to review each other's source code. However, surprisingly, few engineering courses in universities and colleges include code review activities [5]. The paper [6] provides an overview of the courses that have introduced code review in their practical activities (homework, projects, etc.).

At the School of Electrical Engineering at the University of Belgrade (SEE-UB), the course "Principles of Software Engineering" (PSE) was designed to introduce students to the basic concepts of software engineering. The course covers various aspects of the software life cycle: specification design and user requirements, system design, selection of the most suitable software architecture, implementation, testing, documentation writing, and basic elements of software project management. At the core of this course is a team project in which students go through all phases of the development of a software system. Their activities range from writing basic functional specification and design of the system, to the final, tested and fully functional software product, the so-called release version. The implementation phase is based on creating a web-oriented software system on a monolithic or microservice architecture, using several basic architectural

Miloš Obradović is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: milos.obradovic@etf.bg.ac.rs)

Marija Kostić is with the School of Electrical Engineering and the Innovation Center of the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: marija.kostic@etf.bg.ac.rs), (https://orcid.org/ 0000-0003-4923-3748)

Balša Knežević is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: balsa.knezevic@etf.bg.ac.rs)

Dražen Drašković is with the School of Electrical Engineering, University of Belgrade, 73 Bulevar kralja Aleksandra, 11020 Belgrade, Serbia (e-mail: drazen.draskovic@etf.bg.ac.rs), (https://orcid.org/ 0000-0003-2564-4526)

 ISBN 978-86-7466-930-3

and design patterns. In this school year, students can choose to develop their application using *CodeIgniter* or *Laravel* framework for *PHP*, or *Django* framework for *Python*.

Version control systems and code review process are studied as well. Within the team project, students learn to work in a team and to develop functional software, during the whole semester. Currently, team members are not involved in the code review and code testing process for other team members, so it is the desire of teachers that team members revise each other's program code. Thus, the author of the program code will always receive at least one or two reviews from other members of their team (or optionally members of another team).

In the third phase, students have to formally review the source code that some other team is working on. This phase aims to expand the knowledge and the programming techniques among students, both through what students see in other teams' solutions and through the feedback they receive from colleagues who have reviewed their solution.

For the course activities to be successful, it is necessary to find the best software tools that are available for use at the SEE-UB, which support the version control and code review. Several control version tools that are open-source are quite suitable for use in the course. However, it is much more difficult to find an appropriate system for code review that is publicly available, motivates students to work regularly on their project, and reduces the possibility of some team members avoiding doing their part of the project.

This paper is divided into five sections. The following section describes the process of code review and gives an overview of the functionalities of some popular code review tools. The third section outlines the basic requirements that a code review tool must fulfill to be used for teaching purposes at the SEE-UB. The fourth section presents an analysis of some existing code review tools, and the possibility of their application in teaching. The final section gives a brief conclusion of the results of this work and advice on how to independently implement software code review tools.

II. Analysis of Basic Features of Code Review Tools

Millions of software engineers around the world review source code daily. This process helps in finding and fixing bugs and increasing the quality of the codebase. Code reviews must be done in real-time and in multiple iterations. Thus, the use of the tools in the code review process must be simple and clear enough. Modern code review is characterized by being lightweight. It can be executed at many stages of software development, but it typically takes place before a code change is added to a version control codebase. Fig. 1. represents common steps of a code review process. First, the author creates a code change and submits it for review. Next, developers discuss the change and suggest fixes. This is an iterative process where the author has to deal with the suggested changes. Finally, when one or more reviewers approve the change, it can be added to the codebase. It is also possible to reject a code change [7].

Table I shows the basic features of the code review tools. Only tools that support Git version control system were considered in the analysis. Many of the analyzed tools also support other platforms. Only those functionalities related to the code review process were observed.

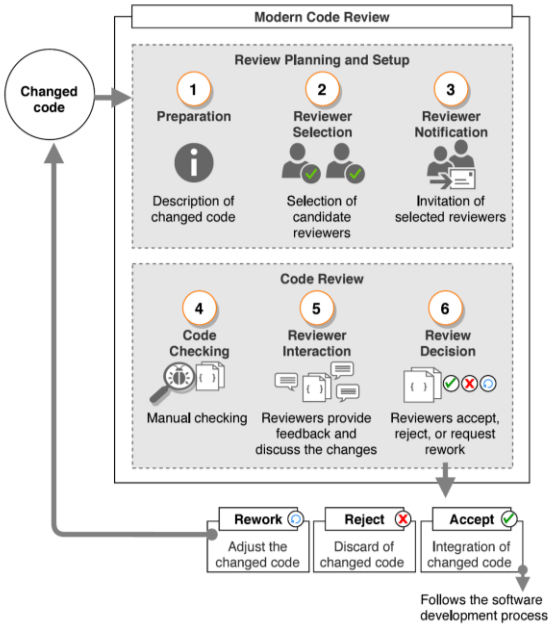

Fig. 1. Common steps of a code review process [8].

III. Necessary Code Review Tool Functionalities

This section presents in detail the basic functionalities of the code review tool that are necessary for the course. Some functionalities are important for the code review and should convey what that process looks like in practice. On the other hand, other functionalities are important for the teaching process and student collaboration on their first team project during their studies. They should motivate students to work in a team and highlight their individual programming and code review abilities. They should also provide better support for documenting a newly developed software system and commenting on different types of artifacts realized in the project phases.

As already noted, this is the first team project in their bachelor's academic studies. It is important that students cooperate well while writing a nice and readable source code, which could be upgraded later with additional modules. Currently, the team project consists of the following phases:

0. Project proposal.
1. Conceptual solution of the project with the basic functional specification.
2. Development of all use cases, one document for each functionality, and realization of the prototype in a tool for prototype development, e.g., Pencil.
3. Formal inspection of the previous phases.
4. Database modeling.
5. UML modeling of the proposed web application.
6. Implementation of a system as a web application.
7. Testing the web application.
8. Final presentation and software documentation.

 ISBN 978-86-7466-930-3

In the third phase, the formal inspection process is carried out according to the standard for formal inspection [8] and consists of six activities/steps: planning, product review, inspection meeting, realization of meeting minutes with the defect report and verification of minutes, work on corrections and final follow-up meeting to verify the corrected product. In this phase, one team of students performs a formal inspection to another team by checking all the files and documents made up to that point. The result of this phase are the reports on the formal inspection. These reports are sent to the author team for them to correct all identified shortcomings and defects, and synchronize files from the first two phases of the project. Such formal inspection could be carried out after some lather phases.

 ISBN 978-86-7466-930-3

In the sixth phase, the implementation of the software system, inspection of the source code is necessary, which has been optional so far. This paper aims to decide which software tool would be suitable for students to use in this phase. The functionalities necessary to be part of such a software tool are presented in the following subsections.

A. Availability of tools for use at the SEE-UB

The tool needs to be completely free to use or to have an academic license. Big corporations usually develop their own tools for code review, but do not make them publicly available. Other companies are actively working on the tools for software development, but their solutions are expensive, especially taking into consideration that tool will be used by several hundred students. As the code review techniques are primarily used in the industry, and less as a means of education within academic institutions [5], in the rest of this paper, only open-source tools are considered. Among the most well-known tools that offered packages with academic licenses, the following tools *GitHub*, *Atlassian Bitbucket* and *JetBrains Space* are discussed in Table 1.

B. Roles within the program code review process

The code review largely depends on the participants in the process itself. Currently, there is no universal standard in the software industry that defines exactly which people should check every change in a project [21][22]. Each company defines its own procedures for the reviewer selection process (Fig. 1, step 2). As part of the code review, there are also persons who are only in charge of checking the style of writing the program code, but not for checking the correctness of the functionality of the code [21][22].

For the course PSE there are several required functionalities related to the distribution of different roles:

- Within a single project, all students can participate in the development of the software solution, and all of them are required to review each code change, written by another team member.
- For some changes and monitoring of the program code, it should be possible to add students from other teams as code reviewers. It is necessary to enable manual addition of reviewers or addition based on the programming language/framework. As projects are developed in different programming languages (three different frameworks), it is good that the student, a member of another team, is sufficiently familiar with the syntax of that programming language, in which the authors developed their system. Comments by reviewers more familiar with the code, will be much more useful for the author [8].
- Teaching staff should be automatically added to all the teams. They should be able to just follow students' work without the obligation to review all their code changes, or with possibility to write their own reviews.

C. Possibility of anonymous code review

Research shows that significant discrimination occurs during code review when the authors of the program code or the authors of other documents are known. Discrimination can be based on gender, race, nationality, or age [22]. Additionally, in the school environment, it often happens that students with a lower average grade are afraid to criticize or point out some mistakes of students with higher grades. To motivate students to take the code review process as seriously as possible, as an important part of software development, and to reduce the effects of student discrimination and shyness, the aim is to use a tool that supports anonymous code review. Also, an anonymous review would reduce the possibility of students who know each other making personal arrangements. For example, they could decide to not find many mistakes in each other's code changes to save time they are spending on the project.

D. Ability to check the style of the program code before the code review

Static program code analysis techniques check the structure of the source code without having to execute the program itself. Their objective is to find defects early in the development process. This approach dramatically accelerates the code review process because reviewers can now focus only on the functionality and implementation of the code segment [23]. Some examples of issues that static analyzers can detect are constant expressions that overflow, uninitialized variables, tests that are never run, etc. Next to finding bugs, these tools can help verify that the code is following best practices, style guides, naming conventions, etc. in order to prevent or reduce technical debt [2]. The procedures that would be used within the project may include: writing unit tests and code coverage techniques, by each team member, for their developed parts of the program code, specific styles and precisely defined types of comments, prescribed by course teachers, etc.

As static program code analyzers reduce the cost of software development, many development environments today use them extensively. However, in the case of the course PSE, students have the freedom to choose any available development environment. A static code analyzer that supports *PHP* and *Python* programming languages is required to successfully realize the project within this course.

E. Ability to use tools to review types of files other than the program code

As already mentioned, through the course PSE, students are learning about different phases of software development. Some of the activities students face for the first time are: writing basic functional specifications, developing use case scenarios, testing web applications, and writing appropriate documentation. Next to the source code, students have to work on and produce documents of many different types. Therefore, the tool for code review should support reviewing files that are not source code. The relevant additional types of files are documents, images or specific diagrams, and other multimedia files.

 ISBN 978-86-7466-930-3

F. Ability for the teacher to access basic statistics on tool usage and change the basic code review settings

Teachers should have privileges and advanced functionalities available to them. One of these functionalities is the possibility to set up the code review process. This means that teachers should be able to form teams, control whether anonymous code reviewing is active and determine who are required reviews of some projects. Different statistics about students' work, and contributions should be also available. All this will help in further improving teaching by finding the best setup for the code review process that maximally engages students.

IV. TESTING POPULAR AND AVAILABLE CODE REVIEW TOOLS

This section shows the test results of some popular software code review tools. As explained in subsection A of the third section, for a tool to be used in teaching at the SEE-UB, it must be free for public use. The work of the following tools that meet this condition was tested in detail: *Gerrit*, *GitHub*, and *GitLab*.

Testing of three popular and publicly available tools was performed as follows. The first step is to create a project and make it available on a version control system. After that, it is necessary to do a basic review of the program code within which the tools are tested with basic files for web page structure (*html*), web page layout (*css*), program code files (*js*, *py*, and *php*) and files with commands to work with the database (*sql*). In the next step, the behavior of the code review tool is tested when files that do not contain program code were added to the project. In this step, the behavior of the tools is tested when basic document types (docx and pdf), images (*jpg* and *png*), and diagrams (*uml*) are added to the project. In the last phase of testing the software code review tool, it was checked whether the tool supports other functionalities described in the third chapter.

A. Availability, integration with Git systems, and the possibility to extend functionalities

All three tools have a basic version that is free for public use. *Gerrit* and *Gitlab* have been developed based on open-source code, which opens opportunities to independently upgrade the platform and add new functionalities per personal requirements. *GitHub*, on the other hand, is a closed-source environment, but it has a free version and offers good support for developing open-source projects. The only way to add new features to *GitHub* can be achieved through browser plugins. This is not always a good solution because it adds another item that students must install and use properly. *GitHub* also offers an academic license that brings additional functionality, but at the time of writing, the authors have not been able to go through all the necessary steps to obtain this license, so it was not possible to test its usefulness.

Code review is done through the web interface for all three tools, while support for version control is done through command line. In addition to this, the *GitHub* platform provides the ability to manage versions using the standalone application which can further facilitate the education of students in the use of software development tools. It should also be noted that the *Gerrit* platform has an interface that is not adapted for beginners and has a higher learning curve.

The *Gerrit* platform can be run on a local machine and then all data is stored on that machine. The disadvantage of this approach is that the host machine must always be available and regularly backed up data so that students do not lose their projects due to hardware failure. The advantage of this approach is the ease of adding new functionalities to the tool because the complete code is executed on a local machine.

Gerrit has a slightly different flow control compared to standard *Git* systems. Control has been simplified, which on the one hand may be good for educating new engineers, but on the other hand, it does not follow industry standards, and migrating to another code review git-based system would require adaptation.

B. Working with different file types

As expected, none of the tools had problems working with the program code. All tools provide the ability to comment on each line of program code and set the appropriate status of the comment which indicates that the code is approved or needs to be changed before getting approved.

Problems occur when the tools are used with alternative files such as documents, images, and diagrams. All three tools can display the image, but they are not able to correctly display any type of document. *Gerrit* tool provides a feature to comment on the entire file, while the other two tools do not provide this option. As a result, using *GitHub* and *GitLab*, there is no way to comment on added documents and images.

Diagrams cannot be displayed by any of these tools, but they can display the xml structure that is in the background of this file. The conclusion is that the best way to work with diagrams during software development is to attach an image with each diagram that can be commented.

C. Roles and their permissions within projects and the possibility of anonymous code review

Gerrit allows you to organize users into different groups [14]. It is possible to add users to each group individually, who will have all the authorizations assigned to that group. Using these groups, the teacher can create a project within which they will define groups and their privileges. The teacher also can create subprojects, add students to them and give them predefined group privileges.

GitLab and *GitHub* have predefined roles and access rights within the project. The roles allow the members working on the project to function well when developing software, but do not provide any additional benefits for the teacher role.

No platform has support for anonymous code review. One way to implement an anonymous code review is to make projects publicly visible. Then someone from the other team can look at the program code and submit their remarks externally to the authors of the project. Anonymous review can also be done through web plugins, but one of the problems with using anonymous review through external plugins is that all reviewers must be added to the project,

 ISBN 978-86-7466-930-3

which indicates who the potential reviewers are and reduces the effectiveness of anonymous review. Another problem is relying on the students to use external add-ons correctly, which is not easy to check, so such solutions are not the best.

All three platforms provide basic pre-processor code verification capability before review. As no style guide is currently defined in the course PSE, detailed possibilities of this functionality have not been examined in this paper and are the subject of future research.

Table II maps the functionalities required for teaching the course to the three most popular code review tools, which were publicly available.

TABLE II
ANALYSIS OF FUNCTIONALITIES OF CODE REVIEW TOOLS FOR THE NEEDS OF TEACHING THE COURSE PRINCIPLES OF SOFTWARE ENGINEERING

	Gerrit	*GitLab*	*GitHub*
Public availability	Yes	Yes	Yes
Roles in Code Review	Anonymous Change Owner, Project Owner, Registred User, Custom Gruop	Guest, Reporter, Developer, Maintainer, Owner	Read, Triage, Write, Maintain, Admin
Anonymous code review	No	No	No
Static code analysis	No	Python, PHP	Python
Review files with code	Yes	Yes	Yes
Review document, pictures and diagrams	Can comment on hole file	No	No
Automated user statistics	Available through plugins	Yes	Yes
Project configuration	Yes	Yes	Yes

V. CONCLUSION

This research provides an overview of all the commonly used code review tools in the software industry. Based on this research, the authors recommend the use of *GitLab* software, because it has user-friendly interfaces, is easy to use, has a built-in *Git* version control system, and is based on open-source code. The main disadvantage of using this platform is the limit of up to ten users per project when using the free version.

If you want to develop your code review tool and run it on a local server, then the authors recommend that you start with the *Gerrit* platform, run it on a *Linux* server and add all the features you may need locally. All analyzed tools have some shortcomings and none of them meet all the requirements for application within the course that was analyzed in this paper.

ACKNOWLEDGMENT

This paper is the result of research on the project AVANTES funded by the Science Fund of the Republic of Serbia, within the Program for the development of projects in the field of artificial intelligence. The authors are grateful for the financial support.

Automatsko snimanje amplitudno-frekventnih karakteristika primenom Arduino okruženja

Goran Dikić i Slobodan Drašković

***Apstrakt*—U radu je prikazan uređaj za automatsko snimanje amplitudno-frekventnih karakteristika elektronskih modula kao i sistema u celini. Uređaj je napravljen primenom gotovih modula za generisanje signala i merenje njihovog nivoa u radiofrekvencijskom opsegu. Proces snimanja, obrade signala kao i prikaz rezultata je automatizovan primenom Arduino NANO okruženja.**

***Ključne reči*—automatsko merenje; amplitudno-frekventne karakteristike; mikrokontroler.**

I. UVOD

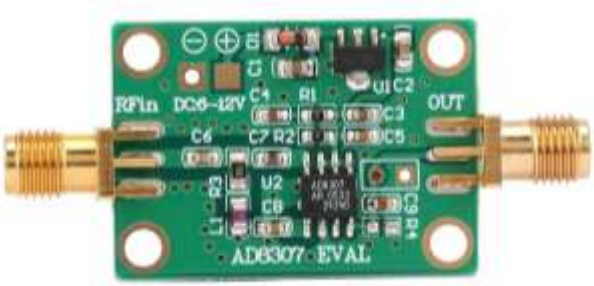
U postojećoj literaturi predložena su rešenja koja omogućavaju automatsko merenje amplitudno-frekventnih karakteristika metodom koja se zasniva na primeni modernog generatora funkcija i digitalnog osciloskopa [1] ili primenom LabVIEW integrisanog razvojnog okruženja uz obradu podataka na računaru [2].

U ovom radu je prikazan uređaj za automatsko snimanje amplitudno-frekventnih karakteristika elektronskih modula ili sistema u celini koji je nastao kao rezultat potrebe da se studentima osnovnih strukovnih studija elektrotehnike i računarstva prikaže mogućnost realizacije automatizovanih mernih sistema primenom mikrokontrolera. Imajući u vidu potrebe edukativnog procesa zahtevi u pogledu programske podrške i složenosti hardvera su optimizirani tako da se kompletna analiza kao i konačna demonstracija njegovog rada mogu realizovati tokom redovnog nastavnog procesa.

Polazeći od namene jasno je da, pored mikrokontrolera, uređaj mora da sadrži generator pobudnog signala, modul za merenje nivoa signala na izlazu ispitivanog modula ili sistema kao i da ima mogućnost prikaza amplitudno-frekventne karakteristike.

Pri odabiru hardvera pošlo se od činjenice da na tržištu postoji mnoštvo elektronskih modula koji su razvijeni za rad uz podršku mikrokontrolera. S obzirom da je pretpostavljen razvoj uređaja za snimanje amplitudno-frekventnih krakteristika u radiofrekvencijskom opsegu za merenje je odabran elektronski modul koji je realizovan primenom logaritamskog pojačavača AD8307 [3]. Jedan primer njegove primene u praksi opisan je u [4].

Goran Dikić – Akademija tehničko-umetničkih strukovnih studija Beograd, Odsek Visoka škola elektrotehnike i računarstva, Vojvode Stepe 283, 11000 Beograd, Srbija, (e-mail: goran.dikic@viser.edu.rs).



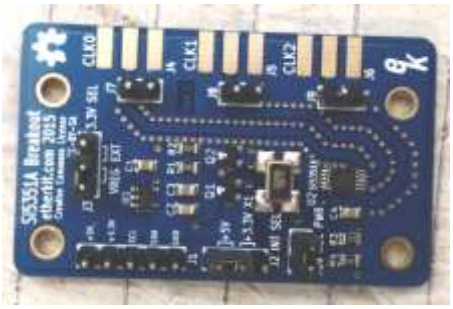
Slobodan Drašković – Akademija tehničko-umetničkih strukovnih studija Beograd, Odsek Visoka škola elektrotehnike i računarstva, Vojvode Stepe 283, 11000 Beograd, Srbija, (e-mail: slobodan.draskovic@gs.viser.edu.rs).

Za generisanje pobudnog signala odabran je modul zasnovan na primeni integrisanog kola Si5351 [5]. Primer programabilnog oscilatora na bazi ovog integrisanog kola opisan je u [6].

Imajući u vidu dostupnost i karakteristike programske podrške, posebno u pogledu mogućnosti prikaza grafičkih rezultata, za realizaciju upravljanja i obradu rezultata merenja odabrano je Arduino NANO razvojno okruženje [7].

II. OPIS UREĐAJA

Logaritamski pojačavač AD8307 omogućava konverziju nivoa merenog naizmeničnog signala u odgovarajući nivo jednosmernog napona tako da se konačni rezultat može izraziti u decibelima. U konkretnom slučaju nagib merne karakteristike odgovara nivou 25 mV/dB. Pri tome je obezbeđena linearnost u opsegu ±1 dB. Dinamički opseg pojačavača je od -75 dBm do 17 dBm. Radni napon pojačavača je u opsegu od 2.7 V do 5.5 V. Izgled modula sa ugrađenim integrisanim kolom AD8307 i pripadajućim elektronskim komponentatma dat je na slici 1.



Sl. 1. Modul sa logaritamskim pojačavačem AD8307.

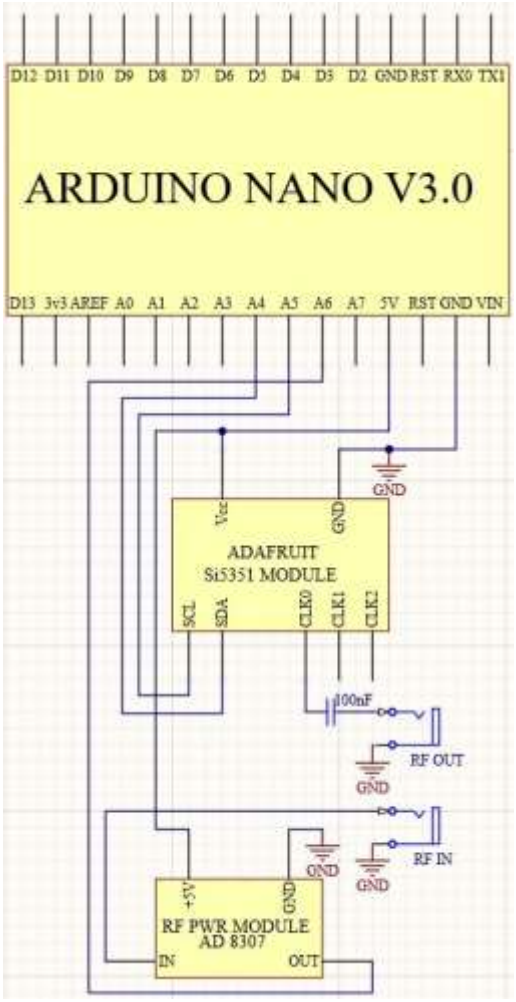
Modul za generisanje naizmeničnog pobudnog signala zasnovan na primeni integrisanog kola Si5351 može istovremeno da generiše tri signala na svojim izlazima CLK0, CLK1 i CLK2, ali se u konkretnom slučaju koristi samo CLK0. Generisani signal može imati frekvenciju u opsegu od 8 kHz do 160 MHz. Odabir radne frekvencije se vrši na osnovu kontrolnih signala koje šalje mikrokontroler. Pri tome se koristi I2C (*Inter-Integrated Circuit*) protokol. Integrisano kolo zahteva napajanje od 3.3 V. Modul je projektovan tako da se po potrebi može koristiti ovaj ili napon od 5 V. Izgled modula je prikazan na slici 2.

Rad celokupnog uređaja kontroliše mikrokontroler ATmega328P koji čini osnovu razvojnog sistema poznatog pod nazivom Arduino NANO [7]. Programska podrška koja je

 ISBN 978-86-7466-930-3

razvijena za rad sa ovim razvojnim sistemom pored razvoja i upisa programa u memoriju mikrokontrolera omogućava i upotrebu ekrana računara za grafički prikaz rezultata obrade tokom izvršenja konkretnog programa. Ova mogućnost je pojednostavila dizajn uređaja jer nije potrebno razvijati dodatnu programsku podršku da bi se omogućio prikaz amplitudno-frekventne karakteristike za ispitivani modul.

Sl. 2. Razvojni modul sa integrisanim kolom Si5351.



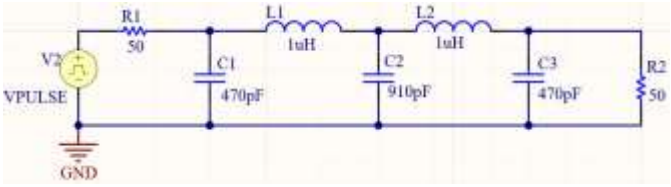
Uređaj funkcioniše tako što se u odgovarajućem programu, pre upisa u mikrokontroler, definišu početna i krajnja frekvencija na kojoj se realizuje snimanje. Veličina koraka, pri promeni frekvencije, određuje se automatski, tokom izvršenja programa, uvažavajući činjenicu da je grafička podrška dizajnirana za jednovremeni prikaz 500 tačaka na ekranu računara. Šematske veze između pojedinih modula su prikazane na slici 3.

Prenos kontrolnih signala SDA (*Serial Data and Address*) i SCL (*Serial Clock line*) ka modulu sa integrisanim kolom Si5351 ostvaruje se preko izlaza A4 i A5 Arduino NANO sistema. Na izlazu CLK0 generiše se povorka unipolarnih pravougaonih impulsa sa odnosom signal pauza u razmeri 1:1. Signal se dalje vodi preko kondenzatora od 100 nF tako da je na izlazu RF OUT potisnuta jednosmerna komponenta. Ulaz ispitivanog modula se spaja na RF OUT, a izlaz na RF IN koji zapravo predstavlja ulaz u modul sa logaritamskim pojačavačem AD8307. Izlaz ovog modula spojen je na priključak A6 Arduino NANO sistema koji predstavlja ulaz u desetobitni analogno-digitalni konvertor.

Rad uređaja, nakon upisa programa, započinje procesom definisanja neophodnih promenljivih i inicijalizacijom zahtevanih vrednosti za rad navedenih modula u skladu sa zahtevima opisanim u [3] i [5]. Realizacija i obrada svih merenja odvija se unutar programske petlje tako što se, u svakom koraku, najpre uspostavi zahtevana frekvencija signala na izlazu CLK0, a zatim sledi osam uzastopnih merenja nivoa signala na izlazu ispitivanog modula. Izmereni nivoi se obrađuju tako što se najpre saberu njihovi binarni ekvivalenti u vidu celobrojnih vrednosti. Nakon toga, dobijena vrednost se pomera unutar odgovarajućeg registra za tri mesta u desno, što odgovara deljenju sa 8. Ovim jednostavnim postupkom smanjuje se nivo šuma merenja. Dobijena vrednost se deli sa 1023 (desetobitni AD konvertor) i množi sa vrednošću referentnog napona. U ovom slučaju to je radni napon koji se dobija preko Mini-B USB (*Universal Serial Bus*) priključka Arduino NANO sistema, odnosno sa USB priključka računara. Konačna vrednost, *Vout*, koristi se za izračunavanje nivoa signala na izlazu ispitivanog modula, *PowerdB*, u decibelima:

$$PowerdB = Slope \cdot Vout - Intercept. \quad (1)$$

Pri tome *Slope* predstavlja nagib merne karakteristike, a *Intercept* vrednost presečne tačke na logaritamskoj osi [1].

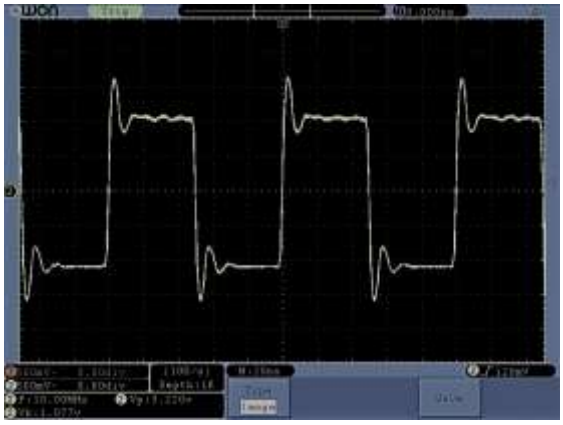


Sl. 3. Električna šema sistema za snimanje amplitudno-frekventnih karakteritika.

Rad uređaja je testiran merenjem amplitudno-frekventne karakteristike dva elektronska modula. U prvom slučaju odabran je niskopropusni LC filtar čija šema je prikazana na slici 4. Gornja granična frekvencija ovog filra je 7.2 MHz, a ulazna i izlazna impedansa su 50 Ω.

U drugom slučaju izmerena je amplutno-frekventna karakteristika kristalnog filtra 14 E 2.48 koji je proizveden u Institutu "Mihajlo Pupin", u Beogradu. Njegova centralna frekvencija je 9.0 MHz, a širina propusnog opsega, na nivou slabljenja -6 dB, iznosi ±1.2 kHz. Talasnost u propusnom opsegu je 2 dB, a slabljenje pogonskog signala nije veće od 4 dB.

 ISBN 978-86-7466-930-3

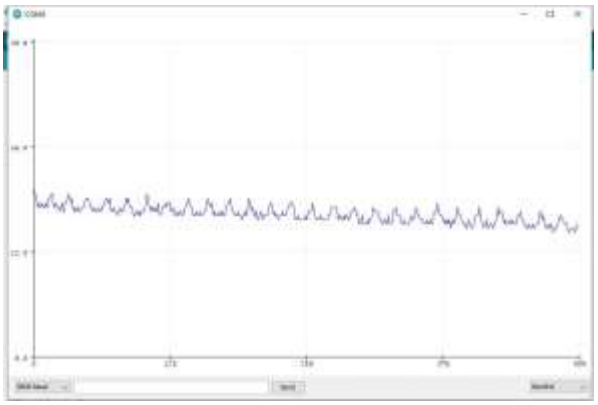


Sl. 4. Šematski prikaz niskopropusnog filtra sa graničnom frekvencijom 7,2 MHz.

Za merenje karakteristike kristalnog filtra od posebnog značaja je poznavanje njegove završne impedanse koja iznosi 390 Ω u paraleli sa kapacitivnošću od 25 pF. Važnost ovog podatka proističe iz potrebe da se obezbedi adekvatno prilagođenje impedanse kako na ulazu tako i na njegovom izlazu. U slučaju lošeg prilagođenja dobijaju se amplitudno-frekventne karakteristike koje zapravo ne odgovaraju stvarnim karakteristikama filtra (na primer velika talasnost u propusnom opsegu).

III. Rezultati eksperimenata

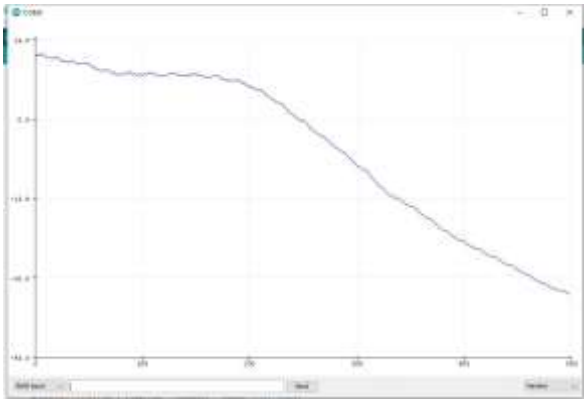
Prikupljanje eksperimentalnih rezultata započeto je analizom signala koji se dobija na izlazu CLK0 modula sa generatorm signala. Merenje je obavljeno na frekvenciji 10 MHz. Iz snimka koji se vidi na slici 5 uočava se postojanje preskoka kao i jednakost u pogledu trajanja poluperioda (odnos 1:1).



Sl. 5. Oblik signala na izlazu CLK0 (Si5351) pri frekvenciji 10 MHz.

Pravougli oblik signala nije poželjan pri merenju amplitudno-frekventnih kakrakteristika zbog činjenice da sadrži brojne harmonike, naročito kada se ima u vidu postojanje uskog i naglašenog preskoka. Sve ovo dovodi do toga da se istovremeno ostvaruje pobuda ispitivanog modula na više frekvencija pa to može uticati na kvalitet dobijenih rezultata. U svakom slučaju ovo treba imati u vidu.

U cilju sticanja uvida u nivo generisanog signala snimljena je karakteristika u opsegu 1-21 MHz, a dobijeni rezultati su prikazani na slici 6.



Snimanje je ostvareno direktnim povezivanjem izlaza RF OUT i ulaza RF IN. Uočeno je da nivo pobudnog signala neznatno opada sa porastom frekvencije i pokazuje izvesnu periodičnost u pogledu promena svog nivoa (pojava lokalnih ekstrema u pravilnim razmacima). Numeričke vrednosti na vertikalnoj osi dobijenog dijagrama predstavljaju nivo merenog signala u dBm. Pri tome numeričke vrednosti na horizontalnoj osi označavaju redni broj odbirka, a ne frekvenciju na kojoj je izvršeno testiranje. Ovo nije moguće menjati jer originalna programska podrška ne nudi mogućnost izbora vrednosti koje se koriste za označavanje na horizontalnoj osi. U slučaju "priliva" većeg broja podataka ceo dijagram se lagano pomera u levo tako da se na ekranu uvek može videti poslednjih 500 tačaka.

Sl. 6. Signal na izlazu Si5351 u opsegu od 1 MHz do 21 MHz.

A. *Izmerena karakteristika niskopropusnog filtra*

Očekuje se da karakteristika ispitivanog niskopropusnog LC filtra ima ravan ili blago talasasti oblik u propusnom opsegu. Dobijeni rezultati su prikazani na slici 7.

Sl. 7. Amplitudno-frekventna karakteristika niskopropusnog filra u opsegu od 1 MHz do 21 MHz.

Već je naglašeno da pobudni signal, zbog svog pravouglog oblika, sadrži mnoštvo harmonika. Svaki od njih, prolaskom kroz niskopropusni filtar učestvuje u formiranju nivoa izlaznog signala koji se meri. Porastom frekvencije pobudnog signala harmonici postaju sve udaljeniji u odnosu na njegovu osnovnu frekvenciju, odnosno sve dublje ulaze u područje gde

 ISBN 978-86-7466-930-3

niskopropusni filtar ostvaruje njihovo značajno slabljenje. Ovo je razlog za pojavu slabljenja (opadajući trend amplitudno-frekventne karakteristike) u početnom delu frekvencijskog opsega, bez obzira na ujednačenost nivoa pobudnog signala na ovim frekvencijama.

Nakon dovoljno visoke frekvencije pobudnog signala doprinos viših harmonika, zbog slabljenja koje unosi niskopropusni filtar, postaje zanemariv u odnosu na nivo osnovnog harmonika. Tada, karakteristika postaje približno ravna sve do prelomne frekvencije kada se, u skladu sa očekivanjem, uočava naglo slabljenje.

B. Izmerena karakteristika kristalnog filtra

S obzirom da su izlazna impedansa generatora i ulazna impedansa modula sa logaritamskim pojačavačem 50 Ω filter je spojen preko odgovarajućih transformatora sa odnosima namotaja primar sekundar u razmeri 1:8 na ulazu i 8:1 na svom izlazu. Snimanje karakteristike za kristalni filtar ostvareno je promenom frekvencije pobudnog signala u opsegu od ±5 kHz u odnosu na centralnu frekvenciju filtra (9.0 MHz). Oblik karakteristike je prikazan na slici 8.

Sl. 8. Amplitudno-frekventna karakteristika kristalnog filtra 14 E 2.48 (centralna frekvencija 9.0 MHz).

Imajući u vidu oblik karakteristike (nagli pad izvan propusnog opsega) kao i činjenicu da je snimanje vršeno unutar frekvencijskog opsega širine 10 kHz može se proceniti da širina frekvencijskog opsega takođe odgovara kataloškim podacima (±1.2 kHz u odnosu na centralnu frekvenciju). Slabljenje izvan propusnog opsega je zapravo veće u odnosu na izmereno, ali se ne može registrovati zbog ograničene dinamike samog pojačavača

IV. ZAKLJUČAK

Testiranjem su potvrđena očekivanja u pogledu problema koji mogu nastati zbog nesinusoidnog oblika pobudnog signala. Međutim, ukoliko se ima u vidu edukativna namena uređaja, predloženo rešenje nudi puno mogućnosti za povezivanje saznanja stečenih kroz izučavanje raznih predmeta i predstavlja dobru osnovu za dalji razvoj.

Za bolje rezultate trebalo bi najpre uvesti spoljni izvor referentnog napona od 2.5 V (priključak AREF na Arduino NANO modulu). Time bi se postigla bolja rezolucija, a samim tim i preciznija merenja. Bolji prikaz i očitavanje vrednosti na ekranu računara mogu se dobiti primenom MATLAB programskog okruženja (mogućnost definisanja logaritamske skale na horizontalnoj osi i ispis vrednosti koje bi označavale frekvenciju, a ne redni broj podatka). Pored toga, MATLAB omogućava dvosmernu komunikaciju tako da se zadavanje početne i krajnje frekvencije može definisati bez potrebe da se unose promene u programu koji je upisan u mikrokontroler. Naravno ovo izlazi iz okvira optimizacije koja je usvojena na početku razvoja uređaja, a odnosi se na maksimalno iskorišćenje originalnog ARDUINO programskog okruženja.

Konačno, moguće je ostvariti promene u pogledu proširenja hardvera dodavanjem LCD ekrana i obrtnog enkodera sa tasterom. Na taj način bi se pored zadavanja početne i krajnje frekvencije, uz uvođenje ogovarjućih poruka na LCD ekranu mogle uvesti i dodatne mogućnosti kao, na primer, zahtev da se ponovi snimanje ili da se uspostavi režim rada koji omogućava kalibraciju kompletnog uređaja prilikom prvog puštanja u rad.

ABSTRACT

In this paper the device for automatic recording of amplitude-frequency characteristics of electronic modules as well as whole system is presented. The device is designed applying readymade modules for signals generating and level measurement of them in radiofrequency band. Recording process, signal processing as well as presentation of results is automatized using Arduino NANO environment.

Automatic recording of amplitude-frequency characteristics using Arduino environment

Zaštita prenosa paketskog telefonskog saobraćaja upotrebom tehnologije virtuelnih privatnih mreža

Mićo Živanović, Jovan Bajčetić, Ivan Tot

***Apstrakt*—Istraživanje predstavljeno u ovom radu prikazuje jednu realizaciju zaštite paketskog telefonskog saobraćaja primenom tehnologije virtuelnih privatnih mreža kroz konfiguraciju servera za prenos paketskog telefonskog saobraćaja i zaštićeni prenos uz primenu tehnologije virtuelnih privatnih mreža u tunel modu, primenom odgovarajućeg protokola za zaštitu tajnosti, autentifikaciju, zaštitu integriteta i razmenu kriptografskih ključeva. Izvršeno je snimanje i analiza saobraćaja primenom softvera Wireshark u zaštićenom i nezaštićenom prenosu. Prikazani rezultati omogućavaju lakše razumevanje kompleksnog procesa uspostave tunela upotrebom simulacionog softvera u edukaciji.**

***Ključne reči*—paketski telefonski saobraćaj; virtuelne privatne mreže; zaštićena komunikacija; kriptografski ključ.**

I. Uvod

Stalan razvoj Interneta ima za posledicu da je Internet postao univerzalno sredstvo za komunikaciju. U toku razvoja, postavio se zahtev za bezbednošću prenošenih informacija koji se ogledao u obezbeđenju bezbednosnih servisa: autentifikacije, poverljivosti, neporecivosti i integriteta podataka [1]. Razvijeni su sistemi zaštite u tri ravni: upravljačkoj, kontrolnoj i ravni podataka. Za potrebe ovog rada biće razmotreni mehanizmi zaštite u ravni podataka koji se odnose na informacioni saobraćaj. Ravan podataka se štiti pomoću implementiranja pravila (bezbednosnih polisa) po kojima se informacioni sadržaj prenosi upotrebom mrežnih uređaja.

Jedna od tehnologija koja omogućava zaštitu prenosa podataka u ravni podataka je tehnologija virtuelnih privatnih mreža (VPN – Virtual Private Networks). Navedena tehnologija pruža sledeće mogućnosti umrežavanja:
– Intranet, umrežavanje geografski dislociranih objekata;
– Udaljeni pristup mobilnih korisnika (rad od kuće);
– Ekstranet, ograničeni pristup nekoj mreži iz drugih mreža (pristup poslovnih partnera korporativnom WAN-u) [2].

Za realizaciju virtuelne privatne mreže mogu se koristiti periferni korisnički uređaji (host, ruter ili svič), na lokaciji korisnika (CE – Customer Edge) i periferni mrežni uređaji provajdera (PE – Provider Edge).

Virtuelnu privatnu mrežu čini više udaljenih mreža koje su povezane preko Interneta. Zbog korišćenja zajedničkih resursa na Internetu, komunikacija među korisnicima virtuelne privatne mreže se mora zaštititi. Zaštita virtuelne privatne mreže se ostvaruje pomoću barijera koje implementiraju IPSec protokol u tunel modu [3].

VPN tunel je veza između dva PE rutera ili dva CE uređaja koji predstavljaju krajnje tačke tunela [2].

Prema IETF, IP VPN se mogu klasifikovati u zavisnosti od odgovornosti u pogledu upravljanja na:
– VPN kojima upravlja korisnik (Customer Provisioned VPN, CP VPN);
– VPN kojima upravlja provajder servisa (Provider Provisioned VPN, PP VPN) [2].

Prema lokaciji VPN opreme, PP VNP se mogu podeliti na:
– CE – bazirane, kod kojih su krajnje tačke VPN locirane kod korisnika;
– PE – bazirane, kod kojih su krajnje tačke VPN tunela locirane kod provajdera, na PE ruteru.

U zavisnosti od ponuđenog servisa, PE – bazirane VPN se dele na:
– PE – bazirane L2 VPN (koje pružaju servise OSI sloja 2);
– PE – bazirane L3 VPN (koje pružaju servise OSI sloja 3);
– CE – bazirane IP VPN pružaju samo servise OSI sloja 3.

Istovremeno sa razvojem bezbednosnih servisa razvijaju se arhitekture za pružanje različitih komunikacionih servisa koji koriste Internet protokol (telefonija, video, podaci, multimedijalni servisi). Prenos telefonije preko Interneta razvijao se postupno, pre svega zbog prethodno razvijenih sistema klasičnih javnih telefonskih mreža (PSTN) i digitalnih mreža sa integrisanim servisima (ISDN).

U cilju razvoja telefonije zasnovane na komutaciji paketa (VoIP telefonija), razvijene su grupe protokola za prenos VoIP telefonije i povezivanje VoIP telefonije sa telefonijom koja se prenosi u drugim sistemima prenosa (H.323 i SIP protokol) [4].

Prikaz istraživanja u ovom radu će se sastojati iz opisa načina realizacije zaštite informacije korišćenjem VPN tehnologije, a potom u jednoj realizaciji zaštite prenosa paketskog telefonskog saobraćaja upotrebom tehnologije

virtuelnih privatnih mreža, upotrebom IPSec protokola u tunel modu ka udaljenom korisniku, uz prikaz analize mrežnog saobraćaja korišćenjem programskog alata Wireshark.

II. ZAŠTITA PODATAKA PRIMENOM TEHNOLOGIJE VIRTUELNIH PRIVATNIH MREŽA

Za prenos informacionog sadržaja preko Interneta neophodno je obezbediti zaštitu u prenosu. Čest je slučaj da kompanije koriste Internet kao okosnicu za povezivanje svojih filijala ili klijenata kako bi ostvarili prenos podataka za svoje potrebe. Iz navedenog razloga nameće se potreba za zaštitu prenošenog saobraćaja. U tu svrhu koriste se različite tehnologije, od kojih je jedna - tehnologija virtuelnih privatnih mreža. Za realizaciju virtuelnih privatnih mreža na raspolaganju je više tehnologija, zavisno od toga da li se VPN realizuje kao "oblast – oblast" (site–to–site) ili kao "udaljeni pristup" (remote access). U oba navedena slučaja najčešće se koristi IPSec (IP security) protokol.

IPSec protokol štiti pakete između dva uređaja u mreži [3].

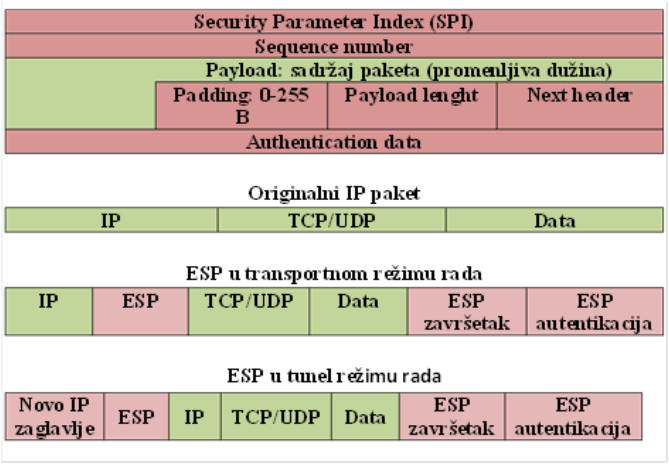
Uređaji kojima se realizuje IPSec su: server, ruteri, korisnički računari ili specijalizovani hardver. IPsec pruža dve vrste zaštite: autentifikaciju i poverljivost.

Mehanizam autentifikacije osigurava da je primljeni paket zaista poslao onaj ko je u zaglavlju paketa naveden kao izvor i da se paket nije promenio tokom prenosa, dok mehanizam poverljivosti omogućava entitetima u komunikaciji da šifruju poruke kako bi sprečili nepozvana lica da dođu do sadržaja poruka [1]. Za šifrovanje podataka se koriste simetrični algoritmi (DES, 3DES, AES), što zahteva pouzdanu razmenu ključeva strana u komunikaciji i za tu svrhu se koriste protokoli za autentifikaciju (neki od protokola iz IETF (IKE - Internet Key Exchange) standarda) [3].

Razvoj bezbednosti u arhitekturi Interneta se odvijao postepeno u čemu je značajno mesto imala Radna grupa za inženjering Interneta (IETF – Internet Engineering Task Force). Sâmo uvođenje standarda je išlo postepeno. Prvi u nizu standard IETF koji se odnosio na bezbednost u arhitekturi Interneta bio je standard RFC 1636 (Request for Comments). Standard se odnosio na osnove bezbednosti Interneta (upotreba firewall – a, servis autentifikacije, privatnost i dr.) [5].

Da bi se adekvatno razumeo način formiranja VPN sesije in a pravi način predstavio prilikom edukacije, biće razmotreno nekoliko najvažnijih dokumenata IETF kojima su definisani režimi rada VPN, mehanizam autentifikacije, razmena kriptografskih ključeva i zaštita poverljivosti.

IPSec koristi dva protokola za bezbednost: AH (Authentication Header) i ESP (Encapsulating Security Payload). Zaglavlje autentifikacije (AH) je definisano specifikacijom RFC 4302 (IP Authentication Header), dok je ESP enkapsulirajuće bezbedno pakovanje (Encapsulating Security Payload) definisan specifikacijom RFC 4303. AH i ESP podržavaju dva režima rada: transportni režim i tunelovanje.



U transportnom režimu AH autentifikuje IP koristan sadržaj i odabrane delove IP zaglavlja, dok ESP šifruje i opciono autentifikuje IP koristan sadržaj. Tunelovanje vrši zaštitu celog IP paketa. Navedeno se postiže nakon dodavanja AH i ESP polja i tretiranja celog paketa kao korisnog sadržaja novog spoljnog IP paketa sa novim IP zaglavljem.

U režimu tunelovanja ESP šifruje i opciono autentifikuje ceo unutrašnji IP paket, uključujući unutrašnje IP zaglavlje, dok AH u režimu tunelovanja autentifikuje ceo unutrašnji IP paket i odabrane delove spoljnog IP zaglavlja [1].

Redosled postupaka sa paketima za rad ESP u transportnom i tunel režimu, je sledeći:

– U transport režimu blok podataka koji se sastoji od segmenta transportnog sloja sa dodatim ESP završnim blokom se šifruje, sa dodatim zaglavljem za autentifikaciju (opciono);

– U režimu tunelovanja, ESP se koristi za šifrovanje celog IP paketa, ESP zaglavlje ide ispred paketa i šifruje se paket zajedno sa ESP završnim blokom.

Sl. 1 Opseg ESP šifrovanja u transportnom i tunel modu [6]

Sl. 1 prikazuje format jednog ESP paketa. Indeks bezbednosnih parametara (SPI) definiše jednu bezbednosnu asocijaciju kojom se određuje algoritam šifrovanja i autentifikacije, ključevi, inicijalizacione vrednosti, životni vek ključeva i vezani parametri koji se koriste uz ESP. Broj sekvence je vrednost brojača paketa kojom se sprečava ponavljanje paketa. Sadržaj paketa je promenljive dužine i predstavlja segment transportnog sloja (transport režim) ili IP paket (tunel režim). U tunel modu, celom paketu se dodaje novo IP zaglavlje koje ima dovoljno informacija za rutiranje, ali ne i za analizu saobraćaja [6].

Važan deo IPSec koji se odnosi na upravljanje ključevima obuhvata određivanje i distribuciju ključeva. Dokumentom RFC 4301 definisane su dve vrste upravljanja ključevima:

– Ručno (administrator definiše sistem sopstvenim ključevima i ključevima drugih sistema sa kojima komunicira);

– Automatizovano (omogućava generisanje ključeva za bezbednosnu asocijaciju na zahtev koji je pogodan za velike sisteme sa rastućom konfiguracijom) [7].

Protokol koji se koristi za automatizovano upravljanje ključevima za IPSec je ISAKMP (Internet Security

 ISBN 978-86-7466-930-3

Association and key Management Protocol) i definisan je dokumentom IETF RFC 2408. ISAKMP definiše procedure za kreiranje i upravljanje bezbednosnim asocijacijama, tehnike generisanja ključeva, ublažavanje pretnji (npr. od DDoS napada) [8].

ISAKMP ne nalaže konkretan algoritam za razmenu ključeva, već se sastoji od jednog skupa tipova poruka koje omogućavaju upotrebu raznovrsnih algoritama za razmenu ključeva.

Karakteristike IKE određivanja ključeva su:
– Osujećenje DDoS napada;
– Omogućava razmenu ključeva za pregovaranje oko grupe ključeva;
– Obezbeđuje od napada ponavljanjem korišćenjem jednokratnih brojeva;
– Omogućava razmenu javnih ključeva;
– Onemogućava napad tipa "čovek u sredini".

IKE potprotokol obezbeđuje dogovaranje protokola, algoritama i ključeva između učesnika u komunikaciji, proverava autentičnost učesnika koji učestvuju u postupku dogovaranja, omogućava razmenu podataka na osnovu kojih će se generisati ključevi i upravljati razmenom ključeva. IKE potprotokol obavlja se u dve faze [9].

U prvoj fazi dva učesnika uspostavljaju bezbedni komunikacioni kanal kojim će se obaviti dogovaranje bezbednosnih parametara i razmena ključeva. Dogovaranje parametara i razmena ključeva, odnosno uspostava bezbednosne asocijacije obavlja se u drugoj fazi. Za sprovođenje postupka koriste se tri načina razmene informacija, dva za prvu fazu i jedan za drugu fazu IKE potprotokola:
– Osnovni način;
– Agresivni način;
– Brzi način.

Osnovni način razmene informacija (engl. Main mode) koristi se u prvoj fazi IKE potprotokola i služi da bi se uspostavio bezbednosni komunikacioni kanal kojim će se obaviti razmena podataka potrebnih za kasniju komunikaciju AH ili ESP potprotokolima.

Agresivni način razmene, slično kao i osnovni, koristi se u prvoj fazi IKE potprotokola i služi za uspostavljanje sigurnog komunikacionog kanala za dogovor učesnika i ne obavlja se kroz bezbedni kanal. Agresivni način koristi samo tri poruke u razmeni i nešto je jednostavniji i brži od osnovnog načina, ali se dokazivanje identiteta ne vrši kroz bezbedan kanal.

Nakon uspostave bezbednog kanala primenom osnovnog ili agresivnog načina razmene, započinje druga faza IKE potprotokola. Druga faza koristi se brzim načinom razmene ključeva koja služi za dogovaranje bezbednosnih parametara komunikacije AH ili ESP potprotokolom i za razmenu tajnih simetričnih ključeva.

III. JEDNA REALIZACIJA ZAŠTITE PAKETSKOG TELEFONSKOG SAOBRAĆAJA UPOTREBOM TEHNOLOGIJE VIRTUELNIH PRIVATNIH MREŽA

U uvodu rada predstavljena je podela VPN prema tome ko je odgovoran za uspostavu zaštićene komunikacije (provajder ili korisnik), kao i koja vrsta servisa se ostvaruje (sloj 2 ili 3 OSI referentnog modela). Predloženi model koje će u nastavku biti prikazan omogućava realizaciju jedne VPN koja bi predstavljala primer uspostave zaštite VoIP putem VPN za koju je „odgovoran" provajder, na OSI sloju 3 i da se primenom programskog alata „Wireshark" snimi i analizira ostvareni saobraćaj. Za navedene potrebe je uspostavljena mrežna topologija prikazana na Sl. 2.

Ruteri predstavljaju periferne rutere provajdera na kojima se vrši konfigurisanje VPN konekcije, po modelu "oblast – oblast". Na ruteru 1 su konfigurisani i uspostavljeni VPN, VoIP i DHCP server.
VPN server je konfigurisan sledećim parametrima:
– ISAKMP razmena kripto ključeva (policy 10);
– Kripto algoritam 3DES;
– Algoritam za autentifikaciju MD5 [10];
– Rad u tunel modu.
VoIP server je određen sledećim parametrima:
– Konekcija SIP protokolom;
– Kodek g711 ulaw.

Za razumevanje rada VoIP, ukratko će biti objašnjen prenos signalizacije i kontrola saobraćaja u VoIP prenosnim sistemima, u kojima se najčešće koriste H.323 i SIP protokoli.

H.323 preporuka je deo familije ITU-T preporuka sa zajedničkom oznakom H.32x koje se odnose na multimedijalne komunikacije preko različitih mreža. H.323 definiše protokole zadužene za usluge multimedijalnih komunikacija preko mreža zasnovanih na komutaciji paketa. H.323 se najčešće koristi kao signalizacioni i kontrolni protokol u VoIP i za video konferencije, a bio je prvi standard koji je koristio RTP protokol (Real-time Transfer Protocol) za konkretni prenos audio i video signala preko mreže.

H.323 je standard koji omogućava multimedijalnu komunikaciju preko različitih mreža (usko pojasne ISDN, širokopojasne B-ISDN, lokalne računarske mreže, mreže na bazi komutacije kola). Cilj je postizanje interoperabilnosti sa različitim mrežama za prenos multimedijalnih informacija, kroz upotrebu zajedničkih preporuka, procedura i poruka, kao i uvođenjem komponente mrežnog prolaza. H.323 standard predstavlja skup protokola namenjenih za obavljanje različitih funkcija u okviru H.323 sistema i to: audio kodere i dekodere, video kodere i dekodere, signaliziranje poziva, kontrola poziva, protokol prenosa u realnom vremenu (RTP), protokol kontrole prenosa u realnom vremenu (RTCP), registraciju, pristup i status i ostale protokole za prenos podataka u realnom vremenu [4].

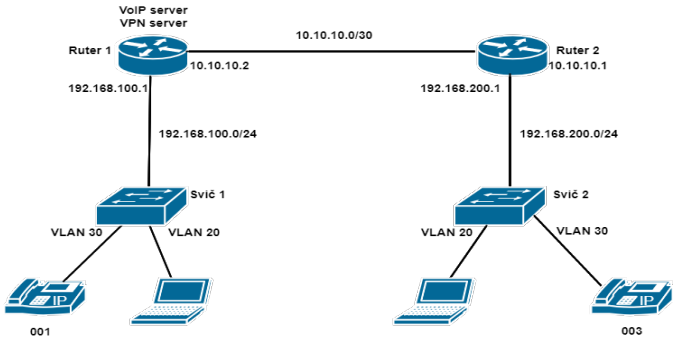
 ISBN 978-86-7466-930-3

SIP je protokol za uspostavljanje, modifikaciju i raskidanje multimedijalnih sesija u paketskim mrežama. SIP u kombinaciji sa drugim protokolima se koristi za opis karakteristika sesije potencijalnim učesnicima [11]. SIP je delo IETF (Internet Engineering Task Force) i razvijen je kao mehanizam za uspostavljanje raznovrsnih sesija, a može se koristiti za unicast i multicast komunikaciju. SIP je peer-to-peer protokol, što znači da nije centralizovan, već je servisna inteligencija izmeštena prema krajevima mreže ka krajnjim korisnicima, kao kod računarskih mreža. U okviru SIP poruka se najčešće prenosi SDP (Session Description Protocol), mada standard ostavlja otvorenim i druge mogućnosti [12].

H.323 i SIP su dva konkurentska protokola za multimedijalne komunikacije na paketskim mrežama.

SIP se odlikuje sledećim prednostima:

– Fleksibilnost (omogućava korišćenje sa različitim transportnim i drugim protokolima);
– Arhitektura i osobine mu se prirodno uklapaju Internet okruženje, dok H.323 ima neke osobine protokola fiksne telefonije;
– Poseduje mnoga proširenja potrebna za različite sisteme ličnih komunikacija (prisutnost, instant poruke, posredno upravljanje pozivom) [13].



DHCP server je uspostavljen za opseg adresa koji obezbeđuje formiranje logički odvojenih mreža sa opsegom adresa 20.20.20.0 i 30.30.30.0 u različitim virtuelnim lokalnim mrežama. Prema mrežnoj topologiji formirane su dve LAN mreže u okviru kojih je izvršeno razdvajanje saobraćaja (telefonskog i podaci), uspostavom dve VLAN na OSI sloju L2, konfigurisanjem svičeva 1 i 2 (VLAN 20 i 30), dok je po jedan interfejs na svičevima konfigurisan kao trank interfejs [14]. Nakon provere konektivnosti, uspostavljen je paketski telefonski saobraćaj bez zaštite pomoću virtuelne privatne mreže i realizovano snimanje saobraćaja, upotrebom programskog alata “Wireshark”. Rezultat i procesi analize nezaštićenog saobraćaja prikazani su u Tabeli 1. Uspostavljena je VPN sesija između dva rutera i realizovano snimanje saobraćaja u zaštićenom modu. Procesi u toku uspostave zaštićenog paketskog telefonskog saobraćaja prikazani su u Tabeli 2.

Za realizaciju mrežne topologije na slici 2 korišćena je sledeća mrežna oprema:

– CISCO 2900 ruter…….2 kom;
– CATALIST 3650 svič ……..2 kom;
– Računar sa ETH mrežnim interfejsom…. 2 kom;
– IP telefoni……..2 kom.

Procesi prikazani u Tabeli 1, a koji se odnose na uspostavu i održavanje nezaštićenog telefonskog saobraćaja prikazuju proces uspostavljanja prisutnosti uređaja u mreži i utvrđivanja mrežnih usluga (SSDP), uspostavu logičke topologije mreže i saobraćaja protokola za sprečavanje petlji (STP). Pozivanjem jednog korisnika od strane drugog korisnika ustanovljava se IP adresa pozvanog korisnika kroz broadcast upit od strane pozivajućeg korisnika (ARP proces). Kroz DNS proces se povezuju IP adresa i ime domena pozvanog korisnika. Istovremeno se šalje poruka radi utvrđivanja dostupnosti korisnika (ICMP poruka). U toku uspostave VoIP komunikacije šalje se “hello poruka” u OSPF procesu, radi konstruisanja putanje između dva rutera. Kroz SIP signalizaciju vrši se pozivanje jednog od strane drugog korisnika, nakon čega se ostvaruje TCP sesija kroz proces “trostrukog rukovanja”. U sklopu SIP procesa razlikuju se faze (traying, ringing i OK), u kojima se mogu uočiti status procesa pozivanja, koji se na kraju završava uspešnom uspostavom komunikacije. Ceo proces je praćen slanjem kontrolnih TCP poruka (ACK), kojima se određuje broj bajtova koji se može poslati pre dobijanja sledeće dozvole za slanje, kao i slanjem poruka kojima se vrši sinhronizacija uspostave TCP sesije (SYN). Poseban segment kontrole komunikacije predstavlja kontrola konektivnosti na L2 nivou (LOOP). Dalji proces komuniciranja je praćen razmenom paketa u realnom vremenu (RTP) koji nose govorni informacioni sadržaj.

Procesi prikazani u Tabeli 2, a koji se odnose na uspostavu i održavanje zaštićenog telefonskog saobraćaja, pored na početku navedenih procesa u nezaštićenom prenosu, sadrži proces razmene kripto ključeva u procesu uspostave IPSec tunela (ISAKMP). Specifično za proces prenosa u zaštićenom modu je uspostavljen trank između dva sviča na kojima su konfigurisane dve VLAN (DTP).

Sl. 2 Mrežna topologija za potrebe jedne realizacije zaštite paketskog telefonskog saobraćaja upotrebom tehnologije virtuelnih privatnih mreža

Prikazana realizacija mrežne topologije, snimanje i analiza mrežnog saobraćaja omogućava detaljno razumevanje uspostave VPN tunela, uz upotrebu simulacionog softvera, kao i praćenje procesa razmene informacionog sadržaja u realnom vremenu. Tokom procesa prenosa informacionog sadržaja u realnom vremenu, periodično se uočavaju procesi uspostavljanja prisutnosti uređaja u mreži (SSDP), obaveštavanja o nedostupnosti uređaja u slučaju prekida konektivnosti (ICMP poruke) i razmena “hello” poruka u OSPF procesu. Navedena realizacija stoga omogućava potpun uvid u sve procese u toku prenosa paketskog telefonskog saobraćaja, što može poslužiti u edukaciji i o procesima prenosa multimedijalnih informacionih sadržaja.

IV. ZAKLJUČAK

Rezultat jedne realizacije zaštite paketskog telefonskog saobraćaja, predstavljen u ovom radu prikazuje da uspostava i održavanje VPN tunela kao načina zaštite paketskog telefonskog saobraćaja podrazumeva primenu niza protokola, specifično dizajniranih za prenos informacionih sadržaja u realnom vremenu (SIP, SSDP, RTP) kao i protokola za obezbeđenje zaštite u toku prenosa (ISAKMP, IPSec). Specifično za predstavljenu realizaciju predstavlja upotreba linka za prenos različitih servisa i time korišćenje protokola kojima se omogućava konvergencija servisa u prenosu (DTP, SSDP).

ABSTRACT

The research presented in this paper addresses an example of how to execute packet telephone traffic protection using virtual private network technology through configuring servers for packet telephone traffic and also demonstrates the secure transfer with the use of virtual private network technology in tunnel mode by applying the appropriate protocols for privacy protection, authentication, integrity protection and crypto key exchange. Traffic recording and analysis has been performed using the Wireshark software in both secure and non-secure transfer. The results obtained can help better understand the complex process of setting up a tunnel through the use of simulation software in education.

Packet Telephone Traffic Transfer Protection Using Technology of Virtual Private Networks

Digitalizacija naučne građe – metode i rešenja

Zoran Zdravković

***Apstrakt* — Digitalizacija tehničke i naučne građe je prvi korak digitalizacije u nauci uopšte. Biblioteke, opšte i specijalizovane, su centralna mesta gde se nalazi postojeća naučna građa i prikuplja nova. Digitalizacija je u ovim ustanovama uveliko otpočela i nalazi se u različitim fazama razvoja. Od posebnog interesa je digitalizacija građe iz domena tehničkih nauka zbog prisustva raznorodnih tipova dokumentacije: crteža, fotografija, planova, patenata, opisa pronalazaka, video materijala i druge građe. Pored osnovnih pojmova i definicija, u radu će biti analiziran analogno / digitalni koncept, principi digitalizacije različitog tipa informacija i vrsta građe (analogni signal, tekst, slika, audio i video materijal), razmotrene posebnosti i limiti digitalizacije naučne građe. Kroz zaključna razmatranja biće prikazani svetski trendovi digitalizacije i digitalne transformacije.**

***Ključne reči* — digitalizacija naučne građe, biblioteke, digitalizacija tehničke dokumentacije**

I. UVOD

DIGITALIZACIJA - OSNOVNI POJMOVI

Analizom postojećih definicija koje na brojne načine pokušavaju da preciziraju fenomen digitlizacije, može se uočiti da termin *digitalizacija* obuhvata proces prevođenja informacije (podataka) iz originalno analognog oblika u digitalnu formu. Digitalizacija se najšire definiše kao proces prevođenja analognog u digitalni oblik, pri čemu izvor (*analogni objekat*) može biti veoma raznorodan: signal, zvuk, dokument, slika, trodimenzionalan objekat... a rezultat procesa je *digitalni objekat*, odnosno digitalna forma: hologram, digitalna fotografija, digitalni zvuk, digitalni signal..., visokog kvaliteta transformacije pri čemu se tokom procesa transformacije ne gube informacije. Najopštije, digitalizacija predstavlja beleženje analognog signala u digitalni oblik pri čemu se digitalizovana građa organizuje u digitalne kolekcije i može se pretraživati i koristiti od strane korisnika.

U digitalnom formatu informacije se organizuju u diskretne jedinice podataka – bitove, binarne podatke, koje računari i drugi digitalni uređaji (npr. digitalna kamera ili digitalni slušni aparat) mogu procesuirati.

Digitalizacija obuhvata proces snimanja analognih signala i čuvanje rezultata u digitalnom obliku. Započinje senzorima, koji registruju analogne signale poput svetla i zvuka, da bi se potom zabeležene analogne forme transformisale u ekvivalentne digitalne formate uz upotrebu čipa za analogno/digitalnu konverziju. Proces funkcioniše pretvaranjem neprekidnog toka signala i analognih tipova podataka u diskontinuirane vrednosti, koje se potom uzorkuju (sempliraju) u redovnim jednakim vremenskim intervalima kako bi rezultirali digitalizovanim izlazom. Primer su audio datoteke (najčešće frekvencije od 44,1 do 192 kHz) pri čemu se audio datoteka frekvence 48.1 kHz uzorkuje 48.000 puta u sekundi. Proces digitalizacije je efikasniji i kvalitetniji ukoliko se obavlja na višim nivoima uzorkovanja.

Tekst i slike digitalizuju se po sličnom principu: skener snima sliku ili „sliku“ teksta i pretvara je u datoteku slika – *image file*, kao što je bitmap. Program optičkog prepoznavanja karaktera (OCR) analizira svetle i tamne oblasti tekstualne površine kako bi identifikovao slovo ili numerik (cifru) pretvarjući dalje svaki takav karakter u ASCII kod.

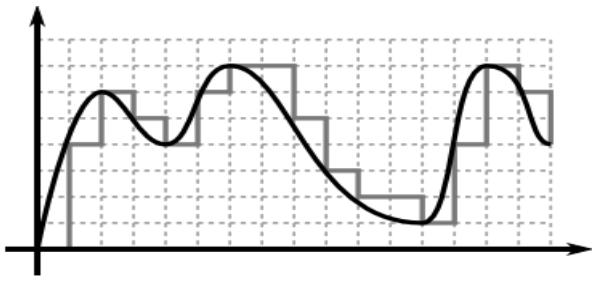
Digitalizacija audio i video materijala obavlja se konverzijom analognog u digitalni signal, pri čemu se u ovom procesu konstantno varijabilan analogni signal transformiše bez gubitka i promene bitnog sadržaja, u višeslojni (digitalni) signal.

Digitalizacija informacija olakšava njihovo čuvanje, pristup, prezentaciju i deljenje. Originalan (analogni) istorijski dokument, muzejski eksponat, rukopis u biblioteci, tehnički crtež i drugi tip naučne građe može biti dostupan jedino posećivanjem njegove fizičke lokacije, što za posledicu ima visok stepen lokalizovanosti, dok digitalizacijom postaje dostupan ljudima širom sveta, uz visok nivo demokratičnosti a nizak stepen lokalizovanosti. Digitalizacija naučne i tehničke građe, kao i naučno-istorijske baštine u celini, dobija sve više na zamahu i beleži trend porasta.

II. ANALOGNO / DIGITALNO

Odnos analognog i digitalnog predstavljanja podataka (informacija i signala) može se definisati kroz određivanje pojmova i termina *analogni* i *digitalni* oblik informacije.

Analogni oblik izvora označava neprekidan signal iz okruženja: zvučni signal, svetlost, temperaturu, vlažost vazduha, pritisak, elektromagnetno zračenje i druge fizičke fenomene i informacije iz sveta koji nas okružuje.



Digitalni oblik signala je brojčane, numeričke prirode – digitalne (od lat. Digitus: broj, cifra), i predstavljen je kontinualnim nizom nula i jedinica, binarno. Svaki digitalni podatak bez obzira na pojavni vid (tekst, slika, zvuk, animacija, film...) može se brojčano (digitalno) predstaviti celim brojevima dok se svaki pojedinačni broj može predstaviti nizom nula i jedinica, binarnim određivanjem prisustva (jedinica), odnosno odsustva (nula) signala od izvora informacija ka recipijentu.

Analogni mehanički fotoaparati, opremljeni analognom tehnologijom, koristili su analognu optiku da bi izvor svetlosti i refleksiju od fotografisanog objekta zabeležili kao sliku na fotografski film, a potom hemijske reakcije kako bi se film razvio i slika sa negativa prenela na fotografski papir. Digitalni fotoaparati koriste digitalnu tehnologiju da bi optikom, sa objetiva preneli sliku do CCD senzora (Charge-Coupled Device Sensors) sastavljenih od velikog broja fotoosetljivih elemenata pri čemu svaki mikroelement

 ISBN 978-86-7466-930-3

predstavlja jednu tačkicu slike (Pixel), čime se svetlost koja ulazi u objektiv, reflektovana sa fotografisanog objekta, pretvara u niz tačaka na određenoj površini, broj tačaka po inču (dpi – dots per inch) predstavljenih brojevima, digitalno, odnosno binarno, prikazujući prisustvo/odsustvo osvetljenja.

Analogne signale karakterišu kontinuirani podaci i informacije, celi i u neprekidnom nizu, prikazani blagim sinusoidama, pri čemu amplituda može imati bilo koju vrednost i blage prelaze od pika do pika graničnih vrednosti, uz konstantnu fluktuaciju vrednosti sa protokom vremena, dok digitalni signali nisu kontiuirani: karakterišu ih oštri „stepenici“ – skokoviti prelazi, jasno određene diskretne vrednosti, respektabilno jasno izraženi pikovi, pri čemu amplituda digitalnog signala može imati samo ograničeni broj vrednosti. Za razliku od analognog signala koji može imati bilo koju vrednost, digitalni signal može imati jedno od dva stanja prekidača: uključeno ili isključeno, uz binarnu mogućnost prisustva ili odsustva signala od izvora ka recipijentu (postoji ili ne postoji napajanje). Tako binarni kod u računarskoj primeni ima vrednost 0 ili 1; Morzeova azbuka sastavljena je od kombinacija dve veličine: tačke i crte (. i –).

Slika 1: Uporedni prikaz analognog signala (puna crna linija sa varijabilnim kvantitativnim vrednostima po protoku vremena) i digitalnog signala (stepeničasta linija sa diskretnim, određenim vrednostima) [1]

Suštinska razlika između analognog i digitalnog leži i u postojanosti kvaliteta i prednosti digitalnog signala jer se njegov kvalitet ne gubi prenosom.

Konverzija analognog u digitalni signal praćena je gubicima. I pored razvoja digitalne tehnologije i postizanja sve veće preciznosti digitalnog signala, ostaju ograničenja tehnološkim mogućnostima očitavanja i zapisivanja, brzine prenosa, frekvencije centralne procesorske jedinice (CPU), brzine procesora, kompresije zapisa, memorijskim kapacitetom i drugim tehničkim limitima. Digitalna tehnologija je postigla visok nivo kvaliteta digitalnog zapisa i unapredila ga, u meri da se ljudskim čulima, inače analognim, ne može primetiti razlika u kvalitetu i sadržaju digitalizovane verzije ostvarene konverzijom analognog objekta ili signala.

Razvoj video-monitora i ekrana omogućio je unapređenje kvaliteta prikaza tehničke građe i porast rezolucije. Rezolucija kao mera razlučivosti grafičkog sadržaja, odnosno stepen vidljivosti detalja, izražava se u tačkama po inču (dpi), odnosno pikselima po inču (ppi). Veća rezolucija donosi bolji kvalitet slike/dokumenta ali i porast veličine digitalnog fajla i zahteva veći memorijski prostor potreban za smeštaj.

Digitalizacijom se pored fajlova visoke rezolucije (300-1.200 dpi) pri skeniranju materijala za master skenove koji se trajno čuvaju, kreiraju i snimaju i digitalne datoteke tipično niske rezolucije od 72 dpi (tzv. „ekranska rezolucija“), koje se koriste samo za pregled na ekranu, uz tzv. *thumbnail* prikaz „malih sličica“, i datoteke rezolucije od 300 dpi za kreiranje digitalnih objekata u procesima digitalizacije tekstualne građe, fotografija, karata, tehničkih crteža, planova i sl. sa ciljem optimalnog smeštaja, distribucije i korišćenja digitalizovane tehničke građe.

Iako je postignut visok nivo digitalne konverzije ona ipak nije savršena i potpuno jednaka analognoj stvarnosti. Iako ljudsko oko nije u mogućnosti da razlikuje dve susedne nijanse jedne iste boje na ekranu monitora, računari moćnih performansi sa naprednim grafičkim kartama prikazuju mnogo više boja nego što se ljudskim okom može registrovati koristeći 32-bitni i viši kvalitet boja. Uobičajene vrednosti dubine boja kreću se od 1 do 64 uz bitnu osobinu da sa porastom broja informacija eksponentno raste i broj boja, ali respektivno rastu i veličina datoteke, dužina vremena za transfer i učitavanje, iscrtavanje i štampanje, ali je veći i kvalitet, izražajnost i vernost boja. Standard kvaliteta boja ekrana današnjih računara je 16-, odnosno 32-bitna dubina boje, a preporučen parametar za snimanje pri digitalizaciji tekstualne građe, fotografija, karata, planova, tehničkih crteđa i slične tehničke građe je dubina boje 8-16 bita za sivu skalu (Gray Scale) i 24-48 bita za pun kolor.

Specifični su limiti i analogne tehnologije. Oni ometaju proces komunikacije koga u slučaju jednosmernog komunikacionog kanala čine: izvor informacije (emiter) → medij prenosa podataka → prijemnik signala, informacije, tj. podataka. Faktori uticaja na komunikacioni kanal mogu biti 1) spoljni činioci: „informacioni šum“ ili „buka“ koji remete prenos signala, odnosno analogni prenos informacija, i 2) udaljenost izvora i recipijenta kada kvalitet signala i prenosa informacije opada sa udaljenošću.

Nedostaci digitalnog slanja, obrade i prijema signala potiču iz realnog okruženja koje je po prirodni analogno, ali osnovni nedostaci digitalne konverzije su:

1. potreba stalnog kodiranja i dekodiranja kako bi se informacija poslala, odnosno primila, moguća u dva smera konverzije: A/D konverzija (kodiranje analogne u digitalnu informaciju) D/A konverzija (dekodiranje digitalnog u analogni podatak, signal ili informaciju);

2. duže vreme potrebno za slanje digitalnog signala;

3. porast količine podataka u procesu digitalizacije radi izrade i postizanja kvaliteta digitalnog objekta (gustina, odnosno visoka rezolucija slike ili video zapisa, kvalitet audio zapisa i sl. – primer: istovetan audio zapis na LP gramofonskoj ploči u analognoj formi očitavan iglom staje na spiralu dugu 500 m, dok je spirala CD-a duga 6 km, uz neophodan laser kako bi se očitao audio zapis.

Otuda je kompresija podataka potencijalno dobro rešenje naročito pri transportu na daljinu, deljenje na mreži i sl. Kompresija s gubitkom (engl. Lossy Compression) je tehnologija sažimanja analognih podataka i kreiranje digitalnih podataka s prihvatljivim gubicima u odnosu na analogni izvor. Obuhvata tehnike kompresije kod kojih se gubi prihvatljiva količina podataka pri čemu se eliminišu suvišne, redundantne ili nepotrebne informacije. Najrasprostranjenija primena i upotreba je kod audio, video i multimedijalnih datoteka (JPG i TIFF su najpoznatiji formati za

 ISBN 978-86-7466-930-3

digitalne fotografije, MP3 i OGG za audio fajlove, a MPEG za video-snimke). Preporučeni formati za digitalizaciju fotografija su nekompresovan TIFF, kompresovan JPEG bez gubitka informacija i PDF format.[2]

TIFF (eng. Tagged Image File Format) nekompresovan format idealan je za smeštaj arhivskih datoteka i operisanje sa tekstualnim dokumentima i fotografijama s tim što je veličina TIFF datoteke znatno veća u odnosu na druge formate.

JPEG format (eng. Joint Photographic Experts Group Format) kao vrsta kompresovane datoteke idealno je rešenje za smeštaj kopija dokumenata i za smeštaj, transport i korišćenje dokumenata i fotografija na vebu. Veličina datoteke u JPG formatu znatno je manja od one u TIFF formatu. Kompresijom se dobija datoteka manjeg kvaliteta, ali značajno manje veličine i zauzima mnogo manje memorijskog prostora od originala (JPG fotografija tako nastala može biti manja i za više od 80% originala bez (ili sa malo) vidljivog efekta umanjnenja dok kompresovani MP3 fajl može biti jedna desetina veličine originalne audio datoteke uz neprimetnu razliku zvuka ljudskom uhu) što ovaj metod kvalifikuje kao idealan za multimedijalni sadržaj, ali isto tako i nemogućim za binarne datoteke, kod kojih ne sme doći do gubitka informacija, kada se primenjuje kompresija bez gubitka i kreiraju tzv. fajlovi bez gubitaka.

Odnos kvaliteta i veličine datoteka, odnosno kompromis umanjenja podataka originala uz balans kvaliteta, od izuzetnog značaja je za skladištenje, prenos i korišćenje sadržaja. Dobro dizajnirana tehnologija kompresije uz gubitke značajno smanjuje veličine datoteka do mere da se degradacija ne uočava. Kompromis između veličine i kvaliteta datoteke ostaje značajna stavka procesa digitalizacije naučne i tehničke građe.

Kompresija bez gubitka (engl. Lossless Compression) obuhvata tehnologiju komprimovanja digitalnih podataka kojom se mogu povratiti sve informacije originalnog sadržaja kako je izgledao pre kompresije. Kompresija podataka bez gubitaka je reverzibilna kompresija podataka jer ne degradirajući podatke, svaki bit informacije koji je izvorno bio u datoteci ostaje i nakon kompresije, a sve informacije mogu u potpunosti biti obnovljene nakon raspakivanja i dekompresije, što kod kompresije sa gubitkom nije moguće.

Ova tehnika kompresije preporučuje se i koristi kao dobar izbor za digitalizaciju tekstualnih i tabelarnih datoteka, računskih podataka, ali i kod naučnih članaka i većih tekstualnih formi (tehnička literatura, udžbenici, tehničke enciklopedije, naučni radovi, disertacije, patenti, standardi, smernice, uputstva i prateća dokumentacija) gde gubitak pojedinih delova, reči ili cifara, i grafičkih podataka može predstavljati problem. GIF digitalni format slika (engl. Graphics Interchange File) koristi se na vebu kao grafički interfejs za digitalnu kompresiju bez gubitaka. Standardni format podataka kompresije bez gubitaka su „loosless“ fajlovi, poput datoteka FLAC kodek formata – audio formata sličnog MP3 formatu samo bez gubitaka. Ovaj tip formata je najpodobniji za digitalizaciju zvuka, jer je audio kompresovan u FLAC bez gubitka kvaliteta.

Najbitnija prednost digitalnog prenosa signala leži u mogućnosti prenosa svakog mogućeg pojavnog vida informacije obuhvatajući tekst, informaciju o boji, zvuk, animaciju, video signal itd. Za razliku od analognog signala koji je po svojoj prirodi podložan ometanju, informacionom šumu i smetnjama, digitalni podatak je postojan. Svaki, pa i bilo kakav, jednom digitalizovani podatak može se čuvati, smestiti, prenositi i koristiti, istovetnog stepena kvaliteta, upravo procesima kodiranja i dekodiranja: faks uređaji prenosili su tekst i grafički sadržaj između dva telefona; računarski mrežni modem omogućavao je digitalnu MOdulaciju i DEModulaciju po principu kodiranja i dekodiranja svih pobrojanih vidova informacija između dva udaljena računara, konverzijom digitalnog signala iz računara u analogni koji može biti prenet na velike daljine postojećim analognim instalacijama, najčešće telefonskim vezama.

Motivi i razlozi za uvođenje digitalizacije između ostalih leže i u prednosti digitalizovanih podataka koji imaju mogućnost popravljanja i oporavka narušenog ili oštećenog signala, time što se može ponovo poslati i sklopiti na odredištu dopunom nedostajućih delova informacije i restaurirati.

III. SPECIFIČNOSTI DIGITALIZACIJE NAUČNE I TEHNIČKE GRAĐE

Prilikom digitalizacije naučnog materijala kao vrste građe potrebno je razmotriti materijal koji je potrebno digitalizovati, obaviti selekciju građe, racionalno sagledati neophodne hardverske i softverske resurse i planirati ljudske resurse.

Selekcija naučne građe, odnosno dokumenata i objekata koji bi bili digitalizoavni, od presudnog je značaja i obavlja se prema prioritetima:

- vrsta građe (papir, mikrofilm, tehnički crtež, plan…)
- značaj građe, (istorijsko-naučni značaj, značaj za instituciju, za istraživače...)
- stanje u kome se nalazi
- stepen oštećenja
- uslovi smeštaja
- frekventnost korišćenja
- zakonska ili druga obavezujuća regulativa digitalizacije
- obaveza arhiviranja i čuvanja tehničke dokumenatcije i sl.

Digitalizacija, proces konverzije dokumenata u digitalnu formu, zahteva definisanje ključnih elemenata koji će, pre svega, biti razmatrani pri određivanju vrste materijala – nosioca naučne informacije, odnsono tipa građe. Među najznačajnijim su veličina, oštećenost, količina, koloritet, vrsta dokumenta, tajnost, odnosno javnost dokumenta, atributi pretrage, rezolucija i tip izlaznog fajla (veličina, kompresija, broj boja, dubina boje), vid pregleda digitalnih fajlova, smeštaj i organizacija u digitalne kolekcije, a na kraju i način korišćenja digitalnih fajlova u okviru digitalne biblioteke institucije, mogućnost pristupa, dozvola za preuzimanje i autorska prava, što na kraju definiše i cenu, odnosno isplativost procesa, tj. projekkta digitalizacije.

Iamjući sve ove parametre i posebnost naučne građe kao materijala za digitalizaciju iskazuje se potreba neophodnosti kreiranja, grupisanja i ažururanja dokumentacije koja obuhvata čitav

 ISBN 978-86-7466-930-3

spektar navedenih elemenata, dokumentovanih u vidu formulara, ili dnevnika digitalizacije, za svaki digitalizovani objekat. Ovaj dokument prati čitav tok kretanja naučne dokumentacije u procesu digitalizacije. S druge strane, definiše radni zadatak operateru na skeneru a ujedno je i dokument na osnovu koga će biti kreiran finalni proizvod na zahtev korisnika, istraživača ili institucije. Ključna faza u procesu skeniranja je **kontrola kvaliteta kreiranih digitalnih fajlova.**

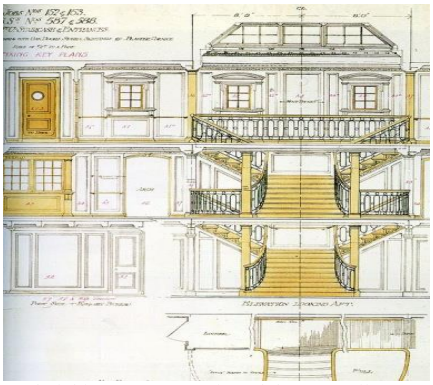
Podela prema vrsti materijala koji se digitalizuje definiše i opremu za skeniranje. Najobimnija (i najčešća) vrsta materijala na kojoj se nalazi naučna dokumentacija je ***papirna dokumentacija***, i to:

- ***papirna dokumentacija do A3 formata koja nije povezana***
  - Dokumentacija u registratorima ili kutijama (A5, A4, A3+)
  - fakture, ugovori, dosijei, predmeti i ostala razna akta
- ***papirna dokumentacija do A3 formata – osetljiva, uvezana i ne sme se razdvajati***
  - knjige, časopisi, novine, brošure, sveske…
- ***papirna dokumentacija od A3 do A1 formata uvezana ili pojedinačna***
  - osetljiva građa, povelje, plakete, grafički crteži, knjige velikih formata, posteri, plakati..
- ***papirna dokumentacija A0 formata koja nije uvezana***
  - tehnički crteži, planovi, mape, geografske karte, posteri, plakati…

Slika 2. Skeniranje papirne nepovezane građe skenerima sa ulagačima za dokumentaciju (tzv. document feeder), automatizovanim transportom i opcijom masovne digitalizacije

Masovna digitalizacija se najčešće koristi pri skeniranju i obradi poslovne dokumentacije ali se može primeniti i na naučni tip dokumenata (tzv. *protočni system obrade*). Prilikom određivanja grupe dokumenata u okviru naučne dokumentacije za masovnu digitalizaciju od značaja je *stepen automatizacije digitalizacije* koji se može primeniti. Veći stepen automatizacije direktno je srazmeran količini digitalizovane naučne dokumentacije, kvantumu i nivou obrade, respektivno i smanjenju cene, efektivnosti i ekonomičnosti/isplativosti procesa digitalizacije. Stepen automatizacije može biti poprilično visok a proces digitalizacije sofisticiran uz primenu tehnologije bar kodova, još i više uz primenu OCR tehnologije.

Naučna dokumentacija koja se ne može digitalizovati i obrađivati protočnom tehnologijom (nije moguće njeno propuštanje kroz document feeder), skenira se na *skenerima sa staklenom pločom* (ravno staklo – flatbed, ili V staklo). Ovakav vid digitalizacije naziva se *koračni postupak*, svaki dokument se ponaosob skenira, bilo ručno ili automatizovano, kao kod robot-skenera sa *robotizovanom rukom* koja automatizovano okreće strane.



Slika 3. Skeniranje papirne građe (povezane) skenerom sa staklenom pločom – flatbed skener sa kamerom i lampom odozgo (overhead)

Ova grupa naučne dokumentacije deli se prema veličini:

- dokumentacija do veličine A4 formata
- dokumentacija do veličine A3 formata
- dokumentacija do veličine A2 formata
- dokumentacija do veličine A1 formata
- plakati i tehnički crteži do veličine A0 formata.

Posebno specifičan detalj vezan za tehničku dokumentaciju je da je ona *koncipirana kao jedinstven oblik*: jedan predmet koji se sastoji od tehničkih crteža, ali i od poslovne prateće dokumentacije A4 i A3 formata koja opisuje detalje tehničkog crteža, razne dozvole i ostalu pravnu dokumentaciju kao prateći material. Specifičnost ove grupe dokumenata je da završni digitalizovan fajl imora biti jedinstven fajl i ne može se razdvajati. Za ovakav tip tehničke i naučne građe koristi se hibridna tehnologija digitalizacije, skeniranja i softvera koji omogućavaju praćenje hronologije dokumentacije u predmetima prilikom skeniranja i jednostavne izmene skenera kojima će se obrađivati dokumentacija. Za tehničke crteže koriste se najsavremenija oprema i uređaji, a kada se u predmetu naiđe na manju dokumentaciju u softveru se izvršava odabir drugog skenera, nastavlja skeniranje i obrađuje, odnosno snima u jedinstven fajl. Ovakvim konceptom digitalizacije zastupljene su i prisutne sve vrste zapisa (papir, negativi, mikrofilmovi), objedinjene kao sastavni deo jedinstvenog dosijea.

Slika 4. Tehnički crtež sa pratećiom dokumentacijom kao celina

OCR - OPTIČKO PREPOZNAVANJE KARAKTERA

Osnovni zadatak OCR softvera je pretvaranje digitalnih slika (JPEG, TIFF, PNG…) na kojima su skenirani tekstovi sa matričnih štampača, kucaćih mašina, iz knjiga, novina, časopisa ili tehničke dokumentacije, u promenljive digitalne tekstualne forme, tako što se iz rastera tačaka sa slika, softverski prepoznaju slova, reči i čitavi tekstovi.

 ISBN 978-86-7466-930-3

Cilj OCR-ovanja je dematerijalizacija papirnih dokumenata, pri čemu se primenjuju sledeće discipline:

- masovna digitalizacija, kada se postiže velika brzina na velikom zahvatu
- automatizovana separacija dokumenata, auto-sortiranje, strukturiranje dokumenata i sadržaja
- Optical Character Recognition, Inteligent Document Recognition, indexiranje
- kompresija dokumenata i digitalnih slika.

Vektorizacija tehničkih crteža

Pri digitalizaciji tekstualne građe i poslovne dokumentacije primenjuje se tehnologija optičkog prepoznavanja karaktera (OCR procesuiranje) u procesu transformacije "slika teksta" u editabilan tekst, dok se kod digitalizacije tehničke dokumentacije koristi proces vektorizacije za transformaciju linija iz rastera tačaka u vektorski oblik. Sam proces OCR-a smanjuje potrebu za prekucavanjem tekstova sa digitalnih slika, a vektorizacija respektivno smanjuje potrebu za precrtavanjem tehničkih crteža.

(izvor: https://www.dass.rs/images/1/vektorski%20oblik.png)

IV. ZAKLJUČNA RAZMATRANJA – GLOBALNI TRENDOVI U DIGITALNOJ TRANSFORMACIJI

Iako je digitalizacija u poodmaklom stadijumu još nije kasno da se uvede minimum opštih zahteva i zajedničkih kriterijuma koji bi bili poštovani u daljem toku procesa digitalizacije naučne građe i u nauci uopšte. Imajući u vidu savremena kretanja na polju digitalizacije navodimo *10 ključnih globalnih trendova u digitalnoj transformaciji*, kao budućim stremljenjima naučnih institucija i društva u celini**:** [3]

1. Internet of Things (IoT)

IoT je najbrže rastući koncept na Internetu (procene su najavljivale više od 8 miljiardi „Things (stvari)'' na Internetu u prvim godinama od pojavljivanja, da bi do 2020. godine broj dostigao i više od 30 milijardi), imajući u vidu da nisu samo stvari na Internetu u pitanju, već način na koji se koriste, povezuju, analiziraju i unapređuju digitalnu transformaciju. Pametni gradovi, kuće i zdravstvo su primeri oblasti koje najbolje demonstriraju značaj i primenu IoT-a. Pored neminovnosti daljeg razvoja i napretka u ovoj oblasti, dinamika rasta i razvoja će zavisiti i od IoT sigurnosti i ograničavanja rizika koji se javljaju u primeni. IoT je danas ključni digitalni trend, u osnovi je sledeća 3 globalna trenda, i biće njihov katalizator u budućnosti.

2. Analitika – Big Data

Ogromna količina informacija kreirana kroz IoT postaje snaga promena koje iz korena menjaju društvo, od proizvodnje do zdravstva, čak i načina funkcionisanja gradova, omogućavajući im da povećaju svoju efikasnost i profitabilnost. Slični rezultati se postižu i očekuju i u drugim oblastima, naročito kada su podaci naučnih istraživanja u pitanju.

3. Edge Computing

Trend koji postepeno preuzima primat od Cloud Computing-a: obrada podataka u realnom vremenu (real-time) postaje sve važnija sa drastičnim porastom količine podataka koje proizvodi rastući IoT. Pametni dronovi, autonomna vozila i AI pametni uređaji zahtevaju trenutno povezivanje i komunikaciju kroz IoT, što prevazilazi sadašnje mogućnosti Cloud Computing-a. I pored toga Cloud neće biti zamenjen u svim, bar ne u doglednom narednom periodu – još uvek će biti opravdana opcija u većini procesa.

4. 5G

Usled sve većeg pritiska narastajućeg kvantuma broja podataka kroz opet rastući IoT, mobilni provajderi se odlučuju za uvođenje 5G mreže i usluga. Prelazak na 5G se neće desiti preko noći: do 2025. godine 5G mreža će pokriti trećinu svetske populacije i omogućiti suštinsku i realnu digitalizaciju brojnih oblasti poslovanja i života.

5. Blockchain

Tehnologija poznatija po svojoj primeni u kriptovalutama i najčešće spominjana kao alat u finansijskom sektoru, postaje sve šira u raznorodnim oblastima: zdravstvena industrija i industrija zabave su samo neke od oblasti koje se priključuju primeni ove tehnologije, uz očekivanja su da će se posle 2020. godine više od 20% svetske finansijske trgovine odvijati na ovoj platformi.

6. Artificial Intelegence (AI)

Koncept koji predstavlja sposobnost mašina da učeći imitiraju intelegentno ponašanje ljudi opravdavaju očekivanja da će u budućnosti transport, proizvodnja i druge oblasti života biti digitalizovane i automatizovane uz pomoć veštačke inteligencije (AI). Poslovanje sve većeg broja kompanija oslanja se na podršku AI-a u marketingu, analitici, odnosu sa korisnicima, robotici i drugim oblastima. Ključne softverske kompanije ubrzano integrišu AI u svoje platforme sa jasnim ciljevima: ubrzavanje, ekonomičnija i pametnija automatizacija i digitalizacija procesa (u širokom dujapazonu primena od e-mailova, preko kreiranja sadržaja do industrijske proizvodnje).

7. Virtual (VR) i Augmented Reality (AR)

Uvećana stvarnost (AR) u profesionalnom kontekstu pokazuje bolje rezultate od virtuelne realnosti (VR), naročito usled povoljnije i jednostavnije primene, pogotovi u oblastima marketinga, edukaciji i dizajniranju novih proizvoda, gde se prednost daje AR-u u odnosu na VR. Puna komercijalna primena u globalno najlukrativnijoj kreativnoj industriji video igara potvrdiće se u narednim godinama.

8. Upravljanje glasom

Pretraživanje, obrada i upravljanje glasom rezultat je velikog napretka u nauci, naročito na polju analitike i hardverskim rešenjima pri čemu se ostvaruje novi nivo korisničkog iskustva kroz intearkciju sa digitalnim platformama: pametne kancelarije, kuće i digitalni

 ISBN 978-86-7466-930-3

asistenti su neki od primera u ovoj oblasti koja se bazira na napretku tehnologije prepoznavanja glasa i veštačke inteligencije.

9. Učenje na greškama

Failure-as-a-Service koncept po kome neuspeh postaje sam po sebi nova usluga, a učenje na greškama postaje alat u brzom prilagodjavanju digitalnim uslovima poslovanja i omogućava dalji razvoj društva. Brzi neuspeh pomaže efikasnom prilagođavanju novom poslovnom okruženju, pre svega pri izradi prototipova novih proizvoda. Prepoznavanje grešaka i njihovo brzo ispravljanje postaju esencijalni deo uspešne digitalne transformacije, kao i inovativnog pristupa kreiranju novih proizvoda i usluga.

10. Digitalna transformacija kao preduslov opstanka

Porastom broja novih tehnologija koje se uvode u sve više oblasti ljudskog društva respektivno raste i brzina potreba za promenama. Naučne instiucije i kompanije koje su ih prihvatile, i pored prisutnih ograničenja sa kojima se suočavaju, ostvaruju tržišnu prednost i povećavaju šanse za dalji razvoj. Dolazak digitalne transformacije i uvođenje nove poslovne kulture u brojnim institucijama postaje ključna prepreka: institucije koje su sposobne da se brzo i uspešno prilagode novim okolnostima imaju veće šanse za opstanak i uspeh.

ABSTRACT

Digitization of technical and scientific material is the first step of digitalization in science in general. Libraries, general and specialized, are central places where existing scientific material is located and new ones are collected. In these institutions, digitization has largely begun and is in various stages of development. Of special interest is the digitization of material from the domain of technical sciences due to the presence of various types of documentation: drawings, photographs, plans, patents, descriptions of inventions, videos and other materials. After basic terms and definitions of digitization, the paper will analyze the analog / digital concept, principles of digitization of different types of information and types of material (analog signal, text, images, audio and video material) and consider features, also limits, of scientific material digitization. Concluding remarks will present global trends in digitization and digital transformation.

Key words - digitization of scientific materials; libraries; digitization of technical documentation

Digitization of scientific material - methods and solutions

Jedinica za snimanje podataka u ispitivanju vanrednih železničkih događaja

Sanja Jevtić, Marija Vukšić Popović, Nada Ratković Kovačević, Sonja Ketin

***A stra t*— (uridical ecording nit – jedinica za snimanje *ra n* podata a) je ao sistem za snimanje na vozilu odgovoran za sa upljanje podata a, a ujedno je obavezni element opreme na savremenom vozilu. tandarni principi i procedure u ispitivanju sleda događaja u situcijama koje se na železnici nazivaju vanrednim događajima će sa ovim uređajem dobiti drugu perspe tivu.**

***Ključne reči*—Juridical recording unit; vanredni događaj, sistem jedinstvenog vremena**

I. UVOD

Vanrednim događajima na železnici se smatraju udesi u kojima je jedno ili više lica poginulo ili teže povređeno, u kome je nastala znatna materijalna šteta i u kome je nastao veći prekid u železničkom saobraćaju, ili nezgoda u kojoj je jedno ili više lica lakše povređeno, nastala manja materijala šteta, kraći prekid železničkog saobraćaja, nastalo ugrožavanje, ili otežano odvijanje železničkog saobraćaja. [1,2]. Izraz vanredni događaj se odomaćio na železnici iako su više puta menjani važeći pravilnici koji se bave ovom tematikom [3,4]. Ovi događaji se evidentiraju i statistički prate i objavljuju po vrstama, uzrocima, mestu nastanka i posledicama.

Rekonstrukcije pruga i čitavih sistema nameću skok u tehnološkim rešenjima. Digitalizacijom svih procesa železničkog saobraćaja postižu se znatno veće brzine, što zahteva i dodatne prateće sisteme, koji će brinuti ne samo o bezbednosti i sigurnosti, već i o arhiviranju ključnih podataka u slučaju spornih situacija.

II. ETCS SISTEM I UREĐAJ ZA SNIMANJE NA VOZILU

ETCS (European Train Control System – Evropski sistem kontrole vozova) sistem podrazumeva da se na samom vozilu sve akcije koje preduzima oprema i mašinovođa dešavaju u okvirima trenutnog nivoa rada kao i režima rada. Nivo rada podrazumeva nivo opreme duž pruge i na vozilu, čime se postavljaju okviri za funkcionisanje sistema. Režim rada podrazumeva dinamičnu podelu odgovornosti za rad između opreme i mašinovođe i vezan je za fleksibilno prilagođavanje potrebama saobraćaja, npr režimi FS (Full Supervision – Puna odgovornost), LS (Limited Supervision – Ograničena odgovornonost), SH (Shunting – Manevrisanje), UN (Unfitted – Neopremljenost), OS (On Sight – Vožnja po viđenju), TR (Trip – Put kočenja, bezbednosno kočenje)[5].

Kao što se može pretpostaviti iz navedenih režima rada mašinovođa u neke od režima može ući samo pod određenim uslovima i uz jasne potvrde sa pruge, čime se jasno zna i usaglašava podela odgovornosti za određene akcije u režimu rada između mašinovođe i opreme.

Velike brzine, mnoštvo akcija i oštri uslovi rada na železnici, zahtevaju uređaj koji će nedvosmisleno obezbeđivati podatke o toku događaja i kauzalnosti u spornim situacijama.

Principi rada JRU definisani su dokumentima tipa FIS (Functional Interface Specification – funkcionalne specifikacije interfejsa), u okviru TSI (Technical Specification of Interoperability – Tehničke specifikacije interoperabilnosti). ETCS oprema je deo većeg Sistema ERTMS/ETCS (European Railway Train Management System – Evropski sistem upravljanja železničkim saobraćajem) oprema na vozilu će detektovati pojavu specifičnih događaja čime će se poslati odgovarajuća poruka uređaju za snimanje na vozilu. Ono što će se tom prilikom zabeležiti podrazumeva: datum i vreme pojave događaja, koristeći UTC (Universal Time Co-ordinated – univerzalni vremenski standard – u kom se svaka vremenska zona definiše svojim pomerajem od ovog vremena) zapis, pozicija voza i brzina prilikom pojave događaja, kao i verziju operativnog sistema, nivo rada i režim rada opreme u trenutku pojave događaja [6]. Vreme i datum će učestvovati u formiranju takozvanog vremenskog pečata date poruke koja se šalje preko interfejsa JRU (za manje od 5s nakon događaja). Ukoliko se nekoliko događaja šalje u vezi sa istim okidačkim događajem, enkapsulirani podaci će biti konzistentni jedni sa drugima u vezi sa vremenskim pečatom. Spisak svih poruka koje se šalju JRU dat je u [7], kao i spisak svih okidačkih događaja (imaju istu strukturu sa zajedničkim zaglavljem i setom promenljivih u zavisnosti od poruke).

JRU snima sve informacije koje se prosleđuju ka/od EVC (European Vital Computer – Evropski vitalni računar ili kernel), kao i interakcije između mašinovođe i sistema preko DMI (Driver Machine Interface – Interfejs mašinovođa-

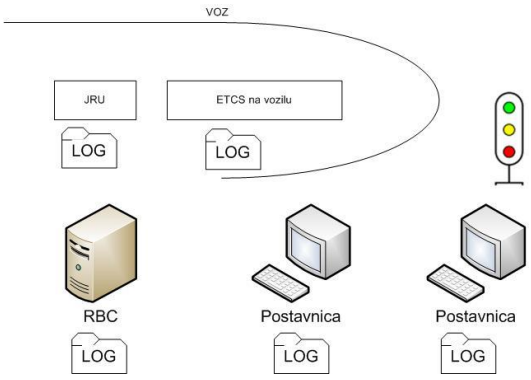
 ISBN 978-86-7466-930-3

mašina). Ipak, sve što se prezentuje mašinovođi na DMI-u je u lokalnom vremenu. Sam JRU uređaj je obavezan ali nije deo ERTSM/ETCS opreme na vozilu [7] – Sl.1 prikazuje deo ETCS opreme na vozilu i drugu opremu.



Sl. 1. ETCS oprema na vozilu i duž pruge, uključujući i JRU, gde je JRU prikazan kao uređaj koji je obavezan, ali nije deo ETCS opreme (uređaj za snimanje na vozilu). Ka njemu je referentnim dokumentom (subset-027) definisan samo interfejs i podaci koji se njime prenose. Slika daje i presek svih subset dokumenata koja definišu slične interfejse [5,7]

Sam JRU sadrži i interfejs za preuzimanje snimljenih materijala pomoću DT alatke (*downloading tool*). Informacije se prenose od EVC-a, bez promene. JRU snima svoje podatke na privremeni memorijski uređaj i to tako da je taj uređaj u stanju da snimi minimalno operacije u okviru 24 h. JRU mora biti u stanju da snimi redukovani skup podataka za najmanje poslednjih osam dana. Vreme za koje je JRU u mogućnosti da zadrži podatke je najmanje sedam dana (misli se na vreme bez napajanja). Privremeni memorijski uređaj je moguće lako izvaditi iz sklopa, kako bi se omogućio prenos podataka nakon akcidenata [7-9].

III. SIGNALNO-SIGURNOSNI SISTEMI

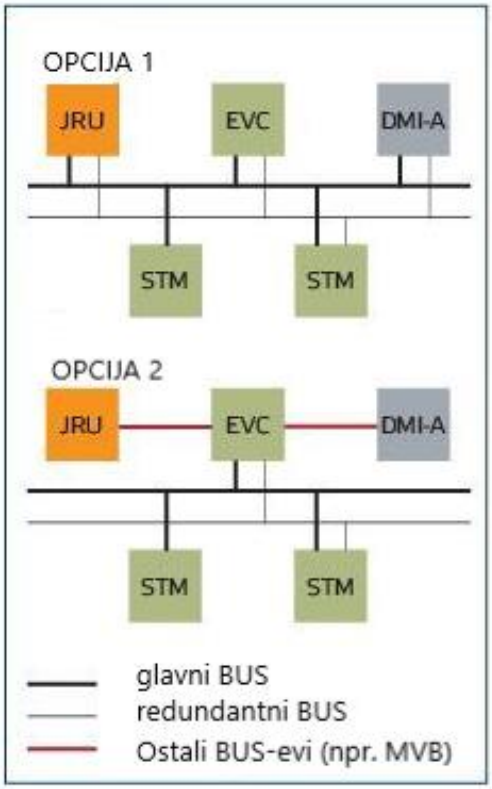
Nesreće i nezgode [3] na železnici su u velikoj meri u korelaciji sa radom signalno-sigurnosnih uređaja i sistema (sudari, iskliznuća, nesreće na putnim prelazima, požari, izbegnuti sudari, pogrešno pokazivanje signalnih znakova, prolazak pored signalnog znaka koji zabranjuje dalju vožnju,..). Iz ovoga se vidi da nije samo JRU uređaj koji će beležiti određene situacije. Sl. 2 prikazuje neke od sistema od interesa za ovaj rad koji će imati svoje logove (evidenciju događaja/statusa/alarma i sl. sa vremenskim pečatima). ETCS kao sistem se svrstava u ATP/ATC sisteme (Automatic train protection/Automatic train control – sistemi za automatsku zaštitu i kontrolu voza). IXL (interlocking) predstavlja sistem elektronskih postavnica, koji ne pripada ETCS-u, ali je sa njim spregnut. RBC (Radio Block Center – radio blok centar) je obavezni deo sistema ETCS nivoa 2, sa kojim je vozilo u pokretu u konstantnoj vezi, preko GSM-R (GSM for Railway – GSM sistem za železnice).

Svi sistemi na slici će imati i vezu sa intranet mrežom na železnici od koje će dobijati i signal tačnog vremena. Ovaj signal će se iz jedne ili nekoliko tačaka (rezervne lokacije) sa prijemnikom tačnog vremena (GPS – Global positioning system – sistem globalnog pozicioniranja, koji sadrži i tačno vreme) prosleđivati svim računarskim sistemima na zemlji. Svi logovi svih sistema će imati isto vreme u svojim vremenskim pečatima.

Sl. 2. Prikaz zapisa različitih podsistema u ETCS-u nivoa 2 i van njega.

Ukratko – svi sistemi koji učestvuju u formiranju puta vožnje, njegovom osiguranju i praćenju ostaviće neki oblik traga u ovim logovima. Uz vremenske pečate i činjenicu da sve akcije signalno-sigurnosnih sistema ostavljaju trag u obliku logova će istraživanje vanrednih događaja učiniti lakšim.

IV. JRU KAO CRNA KUTIJA



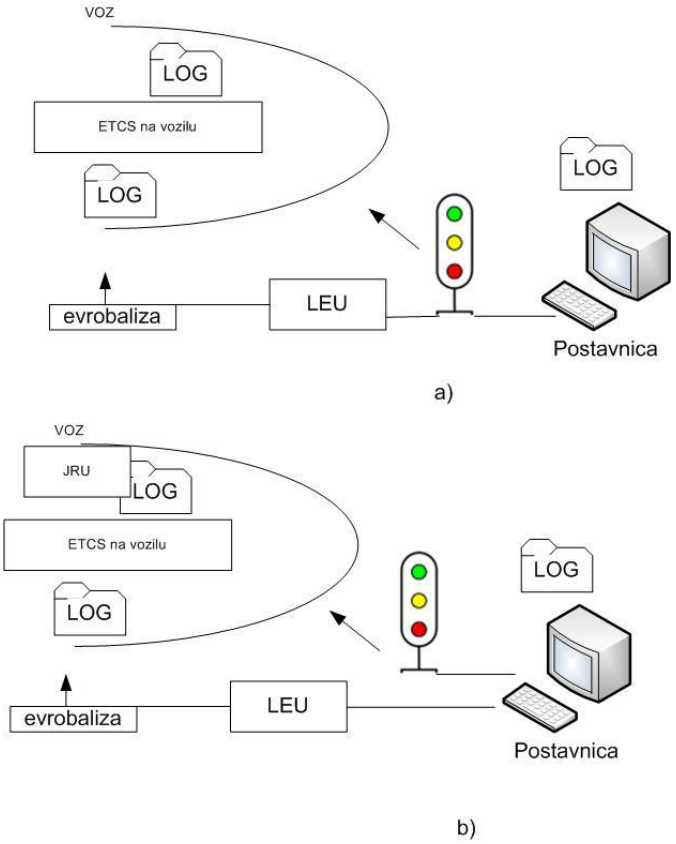
JRU se u vozilu sa ostalim elementima povezuje nekom od standardnih bus konfiguracija, od kojih su najčešće: PROFIBUS (Process Field BUS), CAN (Controller Area Network) ili MVB (Multifunctional Vehicle Bus) bus konfiguracija (Sl.3), ali i Ethernet u nekim slučajevima. STM (Specific Transmission Module – element koji dozvoljava povezivanje sa nacionalnim sistemima klase B na vozilu), će takođe biti povezan u sistem (Sl.1).

Neki od relevantnih standarda čije se ispunjenje zahteva za ovu opremu su EN 50155, IEEE 1482.1. Prvi definiše mehaničke i aspekte okruženja, dok je drugi u vezi sa ojačanjem memorijskih modula u uslovima oštećenja, kao i bezbednosne aspekte.

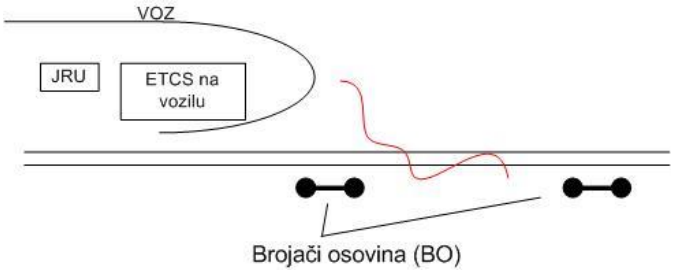
Iz prethodnog se vidi da je još u postupku dizajna i razvoja setovan put ka tome da JRU ima ulogu black box-a (crne kutije) na železničkim vozilima (slični principi, uređaji i standardi se koriste kako u vodenom, vazdušnom, tako i u

 ISBN 978-86-7466-930-3

drumskom saobraćaju).



Sl. 3. Primeri bus konfiguracija na vozilu [8].



Kako je njegov rad i čuvanje podataka siguran proces, ostaje samo da se u svakodnevnom radu prepoznaju situacije u kojima je dvomislenost neizbežna. Jedan od primera je i rad na ETCS nivou 1 u kom se zahteva da mašinovođa prati i signalizaciju duž pruge, a ne samo kabinsku (Sl.4).

U ovom primeru pod a) je data situacija u kojoj se stanje sa signala replicira preko LEU (Lineside Electronic Unit – Pružna elektronska jedinica) ili b) kada postoje dve nezavisne linije (jedna do signala, a druga do LEU i evrobalize). Telegram koji formira LEU je isti signalni kriterijum sa pružnog signala, koji se zatim preko evrobalize prosleđuje vozilu u pokretu. Kabinska signalizacija može u ovim slučajevima dati kriterijume različite od onih duž pruge, a u slučaju da je propisano da mašinovođa prati i pružnu signalizaciju dvosmislenost je neizbežna.

Osim ovoga može se uočiti i primer u kom brojači osovina (BO) pokazuju da je prostorni odsek prazan, ali ne mogu da detektuju postojanje prepreke na pruzi ili objekta koji zadire u slobodan profil pruge (Sl.5). U ovakvim slučajevima će se mašinovođa u skladu sa svojim ovlašćenjima i trenutnim režimom rada prebaciti u onaj režim koji zahteva situacija, imaće niz akcija koje će ostati zabeležene, a radi veće kontrole moraće da operiše u režimima koji mu daju veće mogućnosti, ali i odgovornost. Ovo se može shvatiti kao predupređivanje dvosmislenih situacija jer je ovakav slučaj već pokriven operativnim pravilima.

Sl. 4. Situacije u realizaciji signalizacije na ETCS nivou 1, koje potencijalno mogu dovesti do različitih zapisa u logovima uređaja.

Sl.5. Situacija u kojoj oprema duž pruge ne registruje opasnost, ali mašinovođa ima mogućnost da se prilagodi novonastaloj situaciji.

V. ZAKLJUČAK

JRU će značajno uticati na proceduru isleđivanja i ispitivanja procesa koji su prethodili vanrednim događajima. Specijalno će uticati na razumevanje sleda akcija i interakcija mašinovođa-mašina u aktivnoj kabini. Sistem jedinstvenog vremena u intranet mreži će umnogome raslojiti otkaze uređaja kao i greške usled ljudskog faktora. Podela odgovornosti između mašinovođe i mašine u svakom od ETCS režima rada, operativna pravila, procedure i regulativa koja će tek biti formirana u narednom periodu, će sigurno naići i na određene prepreke.

Možda na prvi pogled izgleda da je sve u vezi sa JRU pozitivno, međutim sam uređaj i njegovo korišćenje će biti dotaknuto i takozvanim otvorenim pitanjima. Neka od njih su i tehnička i operativna ekspertiza, kao i važeća regulativa koja

 ISBN 978-86-7466-930-3

se sporo menja.

Upavljanje resursima svakog preduzeća podrazumeva i konstantno ažuriranje tehnologija rada. Kao i kod svakog sistema i ovde će se u eksploataciji naći situacije koje se mogu smatrati dvosmislenim. Napredak u tehničkom smislu će uticati i na ustaljene procedure.

ABSTRACT

JRU (Juridical Recording Unit) is as a system for data recording on vehicle, responsible for collection of data, and at the same time it is a mandatory element of the contemporary on-board equipment. Standard principles and procedures in sequence of events investigation in railway knowna as extraordinary events will with this device gain a different perspective.

Merenje digitalizacije i IKT sektora – parametri i metode kvantifikacije razvoja društva

Zoran Zdravković

***Apstrakt* — Digitalizacija kao sveobuhvatan i sveprisutan fenomen zabeležen je u skoro svim oblastima savremenog društva. Tokom poslednje dve decenije digitalizacija se nakon otpočinjanja i progresivnog razvoja nalazi u različitim fazama realizacije u brojnim institucijama iz različitih sfera. U radu će biti sagledan značaj i uticaj informaciono-komunikacionih tehnologija i digitalizacije na sveukupan razvoj društva. Biće razmotrene mogućnosti kvantifikacije kroz analizu parametara i metoda merenja digitalizacije. U radu će biti predstavljeni *Indeks digitallizacije* u procesu kvantifikacije digitalizacije, *Indeks IKT razvijenosti* kao mera stepena razvoja informacionog društva, i drugi parametri kojim bi se mogao meriti razvoj ekonomije i društva. Zaključni deo rada obuhvata osvrt na digitalne agende, akcione planove i strategije digitalizacije u daljem razvoju informacionog društva.**

***Ključne reči* — digitalizacija; merenje digitalizacije; Indeks digitalizacije; Indeks IKT razvijenosti**

I. Uvod

Uticaj informaciono-komunikacionih tehnologija (IKT) na društvo je toliki da u znatnoj meri određuje tokove i transformiše ekonomske i društvene aktivnosti savremenog društva. Informacione tehnologije značajno su sredstvo koje omogućava i pospešuje kapacitete za razvoj društva. Način, intenzitet i upotreba informacionih tehnologija određuju nivo razvoja društva i uz inovacije bazirane na znanju pozitivno utiču na unapređenje društva, podizanje društvenog standarda, modernizaciju i opšti napredak društva.

Značaj primene savremenih informacionih tehnologija kao ključnog faktora razvoja društva nameće potrebu kvantifikacije uticaja informacionih i komunikacionih tehnologija na društvo. Stepen napretka društva može se meriti *Indeksom IKT razvijenosti* koji je razvila Međunarodna telekomunikaciona unija, i kompozitnim *Indeksom digitalizacije* (Digitization Index) – konceptom koji je prihvaćen za meru nivoa digitalizovanosti zemalja, razvijenim u Booz&Company konsultantskoj kući.

INDEKS IKT RAZVIJENOSTI

Indeks IKT razvijenosti – IDI (ICT Development Index) razvila je Međunarodna telekomunikaciona unija (ITU, International Telecommunication Union), specijalizovana agencija Ujedinjenih nacija za informacione i komunikacione tehnologije u Ženevi, sa ciljem praćenja napretka razvoja i primene informacionih i komunikacionih tehnologija kako u zemljama u razvoju tako i u ekonomski razvijenim zemljama. Druga moguća primena IKT indeksa je sagledavanje i merenje globalnog digitalnog jaza i razvojnog potencijala koje zemlje imaju korišćenjem informacionih i komunikacionih tehnologija. IKT indeks je koristan i značajan alat za vrednovanje, poređenje, evaluaciju i benčmarking najvažnijih pokazatelja za merenje informacionog društva. Standardni je alat koji vlade, operateri, razvojne agencije, istraživači i institucije mogu koristiti za merenje digitalnog jaza i upoređivanje IKT performansi unutar jedne, ali i unakrsno između više zemalja, jer i pored pozitivnog trenda da informaciono-komunikacione tehnologije postaju sve više dostupne i standard u društvu, i dalje postoji izražen informacioni i digitalni jaz među zemljama u razvoju i ekonomsko-tehnološki razvijenih zemalja.

Indeks razvoja IKT je kompozitni indeks: sačinjen je od 11 indikatora ukombinovanih u jedinstvenu referentnu meru koja služi u svrhe praćenja i poređenja razvoja informaciono-komunikacionih tehnologija. Indeks IKT temelji se na sistemu od 11 pokazatelja svrstanih u tri podsistema:

1. Podsistem pristupa (obuhvata pet indikatora koji se odnose na infrastrukturu i pristup),

2. Podsistem korišćenja (sačinjen od tri indikatora koji se odnose na intenzitet upotrebe IKT), i

3. Podsistem veština (tri indidkatora koji se odnose na bazične pokazatelje o nivou sposobnosti i veština za ovladavanje IKT). [1]

Razvijen od strane članica Međunarodne unije za telekomunikacije 2008. godine indeks razvoja IKT prvi put je predstavljen 2009. godine u Izveštaju merenja informacionog društva (Measuring the Information Society Report) za više od 160 ekonomija u svetu, u izdanju ITU, i od tada se redovno godišnje objavljuje. Izveštaj merenja informacionog društva od 2015. godine prikazuje nivo IKT razvoja u 167 privreda u svetu, poredi napredak i ističe zemlje koje su a) najbrže, b) najdinamičnije i c) najviše, ili d) ukupno, poboljšali svoju poziciju na rang listi od 2010. godine, uz prikaz i analizu korišćenja fiksne i mobilne telefonske mreže i širokopojasne Internet mreže, kao i najnovije događaje u sferi Internet stvari (IoT, Internet of Things).

Prema izveštaju merenja stanja i napretka informacionog društva prvih pet zemalja koje imaju najviši nivo ili su najviše napredovale su: Republika Južna Koreja, Danska, Island, Ujedinjeno kraljevstvo i Švedska. [2]

Korišćenjem indeksa razvoja informaciono-komunikacionih tehnologija utvrđen je i stepen razvoja društva po kome 2015. godine Kineski Hong Kong, Norveška i Japan zauzimaju od devetog do jedanaestog mesta, dok Srbija zauzima pedesetprvo mesto, nalazeći se ispod Slovenije (koja je na 33. mestu) i Hrvatske (na 42. mestu), a iznad Makedonije (60. mesto), Crne Gore (65. mesto) i Bosne i Hercegovine koja zauzima 77. mesto.

 ISBN 978-86-7466-930-3

INDEKS DIGITALIZACIJE

Merenje razvijenosti informaciono-komunikacionih tehnologija pojedine zemlje i uticaj na društvo mogu se odrediti i posredno predstaviti Indeksom digitalizacije. Indeks digitalizovanosti (Digitization Index) razvila je kompanija „Strategy&“ (ranije „Booz&Company“) kao kompozitni indeks koji se sastoji od 23 indikatora prikazanih u Tabeli 1. [3]

Tabela1: Lista indikatora i izvora Indeksa digitalizacije [4]

INDIKATOR	IZVOR
Tarifa za fiksne telefonske linije	ITU
Tarifa za priključenje fiksne telefonske linije	ITU
Tarifa za mobilni pripejd	ITU
Tarifa za mobilni pripejd priključak	ITU
Tarifa za fiksni širokopojasni pristup Internetu	ITU
Investicije po telekom preplatniku (mobilni, širokiopojasni i fiksni priključak)	Svetska banka
Penetracija fiksnih širokopojasnih priključaka	ITU
Penetracija mobilne telefonije	ITU
Stanovništvo pokriveno mrežom mobilne telefonije	ITU
Procenat populacije koja koristi PC računar	ITU
3G Penetracija	WirelessIntelligence
Međunarodni internet protok (bitova u sekundi / internet korisnik)	ITU
Širokopojasne brzine (% iznad 2 Mbps)	Akamai
Internet maloprodaja (procenat Internet maloprodaje od ukupne malopprodaje)	Euromonitor
E-uprava, indeks spremnosti za e-upravu	UN
Procenat pojedinačnih korisnika Interneta	ITU
Prosečan prihod po korisniku bežičnih mreža	WirelessIntelligence
Broj jedinstvenih poseta društvenih mreža na Internetu po stanovniku	Internet World Stats
Upotreba SMS-a (prosečan broja SMS-ova po korisniku)	WirelessIntelligence
Inženjeri (procenat od ukupnog stanovništva)	Svetska banka
Kvalifikovanost radne snage (procentualni udeo radne snage sa višim obrazovanjem od srednjoškolskog, od ukupne, u ukupnoj radnoj snazi)	Svetska banka

Indeks se od 2004. godine upotrebljava kao prihvaćena mera nivoa digitalizovanosti zemalja, obuhvataući 150 država. Zemlje su podeljene prema nivou digitalizovanosti u četiri grupe, pri čemu vrednost indeksa digitalizacije može biti u rasponu 0-100 na skali, pri čemu je vrednost 100 maksimalna vrednost indeksa digitalizacije. Prema rasponu vrednosti indeksa digitalizacije (0-25, 25-30, 30-40 i 40-100) ekonomije države se mogu grupisati na sledeći način:

1. Nerazvijene ekonomije (indeks digitalizacije <25): Avganistan, Alžir, Angola, Aruba, Bangladeš, Belize, Bolivija, ..., Vijetnam, Zambija.

2. Ekonomije u razvoju, sa indeksom digitalizacije 25-30: Albanija, Antigva i Barbuda, Jermenija, Azerbejdžan, Bosna i Hercegovina, Bocvana, Brazil, Kostarika, Ekvador, ..., Makedonija, Trinidad i Tobago, Venecuela.

3. Ekonomije u tranziciji sa indeksom digitalizacije 30-40 su Argentina, Bahrein, Barbados, Bugarska, Čile, Kolumbija, Hrvatska, Kipar, Estonija, Iran, Jordan, Letonija, Makao, Malezija, Malta, Mauricijus, Meksiko, …, Crna Gora, Oman, Filipini, Srbija, Sejšeli, Turska, Ukrajina, Urugvaj.

4. Razvijene ekonomije (indeks digitalizacije >40): Australija, Austrija, Belgija, Češka, Danska, Finska, Francuska, Nemačka, Grčka, Hongkong, Mađarska, Island, Irska, Izrael, Italija, Japan, Južna Koreja, Kanada, Litvanija, Holandija, Novi Zeland, Norveška, Poljska, Portugalija, Rumunija, Rusija, SAD, Singapur, Slovačka, Slovenija, Španija, Švedska, Švajcarska, Tajvan, Ujedinjeni Arapski Emirati, Velika Britanija i dr.

II. OSTALE KVANTITATIVNE METODE I PARAMETRI MERENJA DIGITALIZACIJE I INFORMACIONO-KOMUNIKACIONIH TEHNOLOGIJA

Razvoj IT sektora i digitalizacije u korelaciji je sa stepenom razvijenosti društva. Jedan od merljivih pokazatelja razvijenosti društva je **finansijsko ulaganje u IT sector po stanovniku**. U Srbiji ulaganje u IT industriju iznosi 62 evra po stanovniku, što je u rangu Rumunije i Bugarske; u Hrvatskoj ulaganje u IT iznosi 200 evra po stanovniku, dok je prosek ulaganja Evropske unije u IT 800 evra po glavi stanovnika. [5]

Merenje digitalizacije može se pratiti kvantitativnim metodama i indirektno, praćenjem i analizom statističkih vrednosti merljivih pokazatelja digitalizacije, počev od trenutnog stanja i baznih vrednosti, preko referentnih, do ciljanih vrednosti zacrtanih planovima i strategijama.

Kvantitativni parametri digitalizacije i upotrebe informaciono-komunikacionih tehnologija mogu biti merljive, odnosno sledeće izmerene vrednosti:

- **Broj, cifra**: broj digitalno pismenih građana, broj institucija koje obavljaju obuku i unapređenje digitalne pismenosti, broj visokoškolskih programa iz oblasti digitalizacije, broj institucija koje nude visokoškolske programe IKT oblasti, broj studenata upisanih na programe digitalizacije, broj diplomiranih, specijalista, mastera ili doktoranada iz oblasti digitalizacije i informaciono-komunikacionih tehnologija…;

- **Procentualna vrednost** – procenat digitalno opismenjenih građana, pojedinih grupa ili određene populacije stanovništva, npr: 2018. godine u Republici Srbiji je 51% lica starosti od 15 i više godina kompjuterski nepismeno, odnosno 34,2% lica kompjuterski pismeno, dok je 14,8% delimično kompjuterski pismeno;

- **Odnos**, tj. racio određenih parametara: npr. zastupljenost tehničkih uređaja prema broju korisnika računara, broj digitalnih prenosivih uređaja u domaćinstvu u odnosu na celokupnu populaciju;

 ISBN 978-86-7466-930-3

- **Vreme, interval** – npr. vreme provedeno na digitalnim platformama ili aplikacijama državne uprave (u minutima ili satima po danu);

- **Stanje** – upotreba elektronskih servisa, stanje e-trgovine ili e-uprave i sl. kroz broj pruženih ili upotrebljenih digitalnih usluga, broj korisnika usluga, broj pružalaca usluga i sl. (izraženo brojčano ili procentualno); kao i

- **Trend** (porast ili opadanje) određenih parametara (izražen u procentualnom iznosu) na osnovu ranije izmerenog stanja i projektovanog, odnosno ostvarenog stanja, npr: razvoj digitalnih veština, unapređenje IKT i digitalnih kompetenecija ili porast korišćenja širokopojasnog pristupa kroz broj domaćinstava, broj institucija i preduzeća sa širokopojasnim Internet priključkom i sl.

Praćenje promena i statistika vrednosti navedenih parametara dobar su **osnov za kvantitativno merenje stepena digitalizacije društva i upotrebe informaciono-komunikacionih tehnologija**, počev od pojedinaca i domaćinstava, preko sektora privrede, do nivoa celokupne ekonomije društva u zadatom srednjoročnom (trogodišnji) ili dugoročnom (desetogodišnjem) periodu.

III. DIGITALNE AGENDE, AKCIONI PLANOVI I STRATEGIJE DIGITALIZACIJE U DALJEM RAZVOJU INFORMACIONOG DRUŠTVA

Uloga i značaj digitalizacije i savremenih informaciono-komunikacionih tehnologija prepoznati su kao značajni faktori u razvoju društva, ekonomiji, privredi, kulturi i obrazovanju, procesima državne uprave i drugim društvenim sferama. Stoga se kroz donošenje inicijativa u digitalnoj sferi, usvajanje smernica, akcionih planova i strategija razvoja informacionog društva pristupa budućem uređenju digitalnog društva sa ciljem napretka i razvoja celokupnog društva. Dugoročnim planiranjem, poput ciljeva Strategije „**Evropa 2020**“ predviđa se mogućnost stvaranja novih radnih mesta i unapređenje životnih uslova uz ostvarivanje pametnog, održivog i inkluzivnog rasta i održive budućnosti u Evropi.

Evropska komisija predložila je pet merljivih ciljeva Evropske unije planiranih za 2020. godinu, kao osnovu za utvrđivanje nacionalnih ciljeva i pravac kojim Evropska unija teži da se krene – proces održivog rasta i postizanje društvenog uspeha, u sledećim domenima:

- zapošljavanje;
- istraživanje i inovacije;
- klimatske promene i energetika;
- obrazovanje;
- borba protiv siromaštva.

U okviru Evropske unije IKT i digitalizacija su prepoznati kao činioci od značaja za ekonomski, društveni rast i inovativnost kao generatora razvoja društva.[6] Evropska komisija predložila je sedam ključnih inicijativa sa ciljem podsticanja napretka svake prioritetne oblasti:

1. „Uniju inovacija“
2. Inicijativu „Mladi u pokretu“
3. **„Digitalna agendu za Evropu“**
4. „Evropa koja efikasno koristi resurse“
5. „Industrijska politika za eru globalizacije“
6. „Agenda za nove veštine i nova radna mesta“
7. „Evropska platforma za borbu protiv siromaštva“.

Poseban značaj među sedam vodećih inicijativa ekonomske strategije „Evropa 2020“ ima *Digitalna agenda za Evropu*, kao ključna inicijativa, čime se ukazuje na značaj koji digitalizacija i informaciono-komunikacione tehnologije imaju u razvoju savremene ekonomije. Poseban akcenat stavlja se na razvoj širokopojasnog pristupa Internetu činjenicom da velike brzine širokopojasnog pristupa omogućavaju građanima i preduzećima bržu komunikaciju i efikasniju proizvodnju. Evropska komisija usaglasila je svoj dugoročni plan za razvoj informaciono-komunikacionih tehnologija u periodu od 2010. do 2020. godine:

1) da sva domaćinstva u Evropskoj uniji do 2020. godine dobiju mogućnost pristupa Internetu brzinom 30 Mb/s,

2) da najmanje polovina stanovnika Evrope može da koristi brzinu 100 Mb/s,

3) finansiranje izgradnje zajedničke optičke mreže i podsticanje država članica, privatnog sektora i javnih preduzeća da izgrade sopstvene mreže koje bi se na nju nadovezale. [6]

Metod kvantifikacije se može primeniti i pri **merenju rasta bruto društvenog prihoda u korelaciji sa ulaganjem u IKT sektor**. Prema istraživanjima međunarodne Organizacije za ekonomsku saradanju i razvoj (OECD) porast ulaganja u oblast elektronskih komunikacija od 8% omogućava rast bruto društvenog proizvoda od 1%, a na osnovu istraživanja Svetske banke povećanjem penetracije širokopojasnih priključaka za 10% obezbeđuje se rast bruto društvenog proizvoda od 1,38% u zemljama u razvoju, odnosno 1,21% u razvijenom zemljama. [7]

IKT sektor je direktno zaslužan za 5% bruto nacionalnog prihoda (BNP) u Evropi, uz znatni doprinos rastu produktivnosti (20% dolazi direktno iz sektora IKT a 30% iz investicija u IKT) usled visoke dinamičnosti i inovativnosti ovog sektora kao i promeni načina poslovanja u drugim sektorima koju donosi. [7]

Pored međunarodnih i regionalnih strategija poput strategije Evropa 2020, pojedine zemlje i na nacionalnom nivou donose sopstvene smernice, digitalne agende i strategije razvoja digitalnog društva. Primer nacionalnih i regionalnih inicijativa država sa dobrom EU praksom su: Francuski digitalni plan iz 2010. godine, Širokopojasna strategija u Nemačkoj (Deutschland Digital 2015), grčki FTTH program javno-privatnog partnerstva, Program Digital Britain iz 2012. godine na teritoriji Velike Britanije i Plan vlade italijanske oblasti Trentino.

U nacionalnim okvirima u Republici Srbiji organizaciono su definisane nadležnosti i aktivnosti u procesima digitalizacije kulturnog nasleđa. U okviru Ministarstva kulture i informisanja određeni su sektori zaduženi za sprovođenje definisanih nadležnosti. Sektor za digitalizaciju kulturnog nasleđa i savremenog stvaralaštva Ministarstva kulture i informisanja Republike Srbije obavlja „ ... koordinaciono-organizacione, razvojne i tehnološko-operativne aktivnosti koje za cilj imaju izradu nacionalne strategije i planova digitalizacije, definisanje tehnoloških, pravnih i organizacionih okvira za izgradnju digitalne istraživačke infrastrukture; koordinaciju sa međunarodnim organizacijama i institucijama kao i koordinaciju na nacionalnom nivou svih učesnika u ovom procesu sa ciljem izgradnje digitalne istraživačke infrastrukture, koja kao izrazito važnu ima komponentu zaštite kulturnog nasleđa u nadležnosti Vlade Republike Srbije uz sprovođenje vertikalne, horizontalne i međunarodne koordinacije ukupnih aktivnosti na izgradnji digitalne istraživačke infrastrukture“ [8].

Nacionalna digitalna agenda Republike Srbije sistemski i planski određuje pravce i ciljeve digitalizacije u svim sferama

 ISBN 978-86-7466-930-3

društva i definisana je planovima i strateškim dokumentima obuhvaćenih sledećim **nacionalnim strategijama**:

- Strategija razvoja kulture Republike Srbije 2020-2029. godine sa Akcionim planom
- Predlog Strategije razvoja kulture Republike Srbije 2017-2027. godine
- Strategija razvoja elektronskih komunikacija u Republici Srbiji 2010-2020. godine
- Strategija razvoja širokopojasnog pristupa u Republici Srbiji do 2012. godine
- Strategija razvoja veštačke inteligencije u Republici Srbiji za period 2020-2025. godine
- Strategija razvoja industrije informacionih tehnologija za period 2017-2020. godine
- Strategija razvoja širokopojasnih mreža i servisa u Republici Srbiji do 2016. godine
- Strategija razvoja elektronskih komunikacija u Republici Srbiji 2010-2020. godine
- Strategija razvoja informacionog društva u Republici Srbiji do 2020. godine
- Strategija razvoja kulture Republike Srbije 2017-2027. godine
- Strategija naučnog i tehnološkog razvoja Republike Srbije u periodu 2010-2015. godine.

Informaciono društvo sagledano je i u **akcionim planovima lokalnih samouprava** u Srbiji kojim se definiše digitalizacija u bitnim društvenim sferama poput:

- elektronskih komunikacija
- e-Uprave
- e-Zdravstva
- e-Pravosuđa
- informaciono-komunikacionih tehnologija u obrazovanju, nauci i kulturi
- elektronske trgovine
- poslovnog sektora IKT i
- informacione bezbednosti.

ABSTRACT

Digitization as a comprehensive and ubiquitous phenomenon is present in almost all areas of modern society. During the last two decades, after its beginning and progressive development, digitalization is in the phase of realization in numerous institutions and areas. The paper will consider the importance and impact of information and communication technologies and digitization on the overall development of society. The possibilities of quantification through the analysis of parameters and methods of digitization measurement will be considered. The paper will present the Digitization Index in the process of quantification of digitization, the ICT Development Index as a measure of the degree of development of the information society, and other parameters that could measure the development of the economy and society. As the conclusion paper will provide an overview of digital agendas, action plans and digitization strategies in the further development of the information society.

Keywords - digitization; digitization measurement; Digitization index; ICT Development Index

Digitization and the ICT sector measuring – society development parameters and quantification methods

Neki savremeni aspekti upotrebe luminescentnih efekata

Milanka Pećanac [1,2], Bećko Kasalica [1]

Apstra t – Možda će merenja veoma slabe luminescencije ljudske kože u budućnosti premostiti jaz između tradicionalne istočne i konvencionalne zapadne medicine. Za sada, merenja luminescencije i istraživanja u toj oblasti, potvrđuju vezu između bioloških ritmova i emisije elektromagnetnog zračenja živih jedinki. Danas se mnogo literature o luminescenciji, sa frazom „potencijalne primene'', treba da origuje u „postojeće primene'', jer je luminescencija učvrstila svoje mesto u mnogim primenama od medicine, metrologije, heritologije, forenzi e. Može se govoriti o sintezi materijla, razvoju uređaja i metoda koji će lumineiscentne efe te bolje i potpunije opisati valitativno i vantitativno, učiniti jasnijim i informativnijim. Razvoj aparatura znači razvoj svakog od glavnih podsistema, od eksitacije do detekcije. Posebno je važan podsistem obrade, gde se obrađuju formirani signali i uključuje određeni namens i pisani program za dobijanje rezultata u sredinama, gde je potreban samo podatak o određenoj veličini, oju dobijamo metodom primene luminescentne tehni e. Određivanje prisustva nekih materija može zahtevati merenja sa velikom osetljivošću (tragovi telesnih tečnosti, amino iselina u otis u prsta, e splozivnih materija). setljivost dete cije može se postići različitim načinima transformacije energije korištenjem luminescentnih tehni a, uz druge tretmane. umineiscentni efe ti jedinjenja lantanida (terbijum, europijum, itrijum i dr.), mogu se pojačati kombinovanjem sa ligandima koji te efekte promovišu. Materijali sa retkim zemljama, zbog jedinstvenih optičkih osobina, interesantni su i u oblasti zaštite. I tu se radi na prahovima, bojama, rastvorima, a o bi se dobili produkti čiji se luminescentni profili teško oponašaju. Karakteristična vremena luminescentnih efekata su različita (vreme reakcije, rela sacije, i dr.) i zavise od vrste pobude, pa informacije oje se tako dobijaju imaju višestruka značenja, na osnovu ojih se, iz jedne serije merenja, uz pogodan razvoj ele trons e podrške, može istovremeno meriti i situacija sa složenim skupom elektromagnetskog, nuklearnog zračenja. Ti efekti su posebno važni jer se omogućuje i kvalitativna i kvantitativna analiza elemenata u tragovima. uminescencija ima svoju istoriju, te mnogo poznatih rezultata potiče iz starijih generacija mernih sistema, što direktno dovodi do potrebe za digitalizacijom u cilju mogućnosti njihove upotrebe u proširenju baze podataka za automats o brzo pretraživanje.

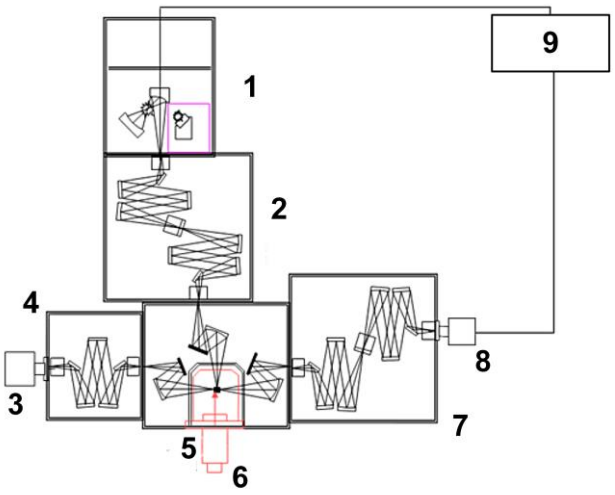
Ključne reči - luminescentni efe ti, forenzi a, dete cija materija, retke zemlje, pojačanje efekata.

I. UVOD

Praćenje dinamike raznih procesa u mikrosvetu je vezano za transformaciju raznih vrsta energije, koje poseduju mikročestice u najširem smislu, polazeći od atomske, molekularne strukture ili od ulaženja u atom i zahvatanja drugih teorijskih modela, koji opisuju procese u jezgru. Postoje različite podele spektroskopija prema ciljnoj sredini koja se proučava, analizira, poredi; merne tehnike nose sopstvene formalizme, a često se i u oblasti jedne spektroskopije pojavljuju različite notacije. Drugi prilaz mernih tehnika bi bio vezan za izabrane snopove, koji potiču od definisanih izvora: elektrona, jona, fotona iz različitih delova elektromagnetnog spektra, od radiotalasa / mikrotalasa, do X i γ-zračenja. S obzirom na odnose energija *mikročestica*, koje čine snop, za testiranje i impulse, postoji mnogo opisa procesa kojima će različite sredine da reaguju i prema odnosu karakterističnih veličina (parametara merenja) može da se vidi u kom području su procesi rasejanja (Rayleigh, Brillouin, Raman), apsorpcije, refleksije ili luminescentne prirode. Detaljnim praćenjem vremenskih opisa procesa i karakteristikama raznih vremenskih konstanti (vremena relaksacije i dr.) *mikročestica* mete, kojoj ulazni snop menja energetska stanja (pobuđuje) prelaskom na više nivoe, vremenom su materijali dobijali razne kategorije i imena sa kratkim ili dugim zadržavanjima u novim stanjima. Savremeni trend i nagomilana iskustva istraživanja su dovela do novih konstatacija, da su ,,klasične" spektroskopije dobile *takmace* kroz kategoriju nelinearnih spektroskopija [1-6]. Postoje i podele na spektroskopije vezane za elektromagnetno zračenje, ali za koherentno i nekoherentno zračenje. Prema problemu kome se okrećemo, u smislu deskripcije materijala normalnog stanja i perturbovanog, u smislu proizvođenja nove dinamike i njegove relaksaciju, takođe postoji izbor više mogućh komplementarnih (ili ne) rešenja, mada u edukativnom metrološkom prilazu postoji preferirana metoda za definiciju energetskih stanja u svetu elektrona, atoma, molekula, rešetke čvrstog tela. Svesno je konstatovano stanje haotičnih kretanja u vezi sa gasovitim stanjem i čvrstim stanjem, a tečno ima svoje probleme upravo zato što nije uslovno vezano za stroge stavove kod čvrstog stanja i haotične sudare kod gasovitog.

Luminescentni procesi [7] imaju svoju bogatu istoriju i u vezi teorije i u vezi tehničke podrške i kompleksnosti aparature koja ih meri. U osnovi, radi se o rešavanju izvora pobude i kvantitativnoj deskripciji transformacijom u signale. U prošlosti je glavna tendencija tražila prebacivanje na električne signale, pa su i detektori bili tog profila.

U ovom radu će predmet istraživanja biti okrenut retkim zemljama [8] i termodinamičkim procesima, koji će pokriti eksplicitno temperaturne zavisnosti izbora karakterističnih parametara. Poznavanjem početnih materijala [9,10] i u definisanom temperaturnom opsegu dinamike izabranih parametara, materijali uzeti kao uzorci mogu imati različite primene od funkcije detektora, daljinskog (beskontaktnog) merača temperature, komponente za smese sa posebnim spektralnim znakom... [13 - 15]



II. EKSPERIMENTALNI DEO

Luminescentna termometrija [11] ima više *arijanti* komercijalnog tipa, (slika 1) koji su prema nameni sa manjim ili većim modifikacijama, vezanim za mesto gde se postavljaju uzorci, specifične držače uzoraka ili posudice,

[1] Fizički fakultet Univerziteta u Beogradu, [2] Deseta gimnazija "Mihajlo Pupin".

 ISBN 978-86-7466-930-3

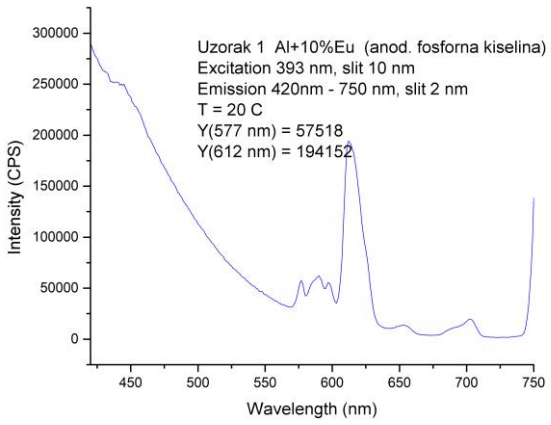
sisteme tipa termostata za precizno održavanje u vremenu zadate temperature, koji zavisno od intenziteta razvijenih luminescentnih procesa odgovaraju pragovima detekcionog dela. Posle prijemnika zračenja, koji treba da pokriva oblast ultraljubičaste / ljubičaste do kraja vidljivog dela i zahvat infracrvenog dela, sledi sistem elektronskih rešenja pojačanja i oblikovanja signala, koji priprema signale za odgovarajuću obradu.

Slika 1. Šema spektrofluorometra: 1 – Xe impulsna ili kontinualna lampa ili laser, 2 – ekscitacioni monohromator, 3 – detektor, 4 - emisioni monohromator, 5 – ćelija sa uzorkom, 6 – emisioni monohromator, 7 – detektor, 8 – računar sa softverom za obradu podataka.

Za svrhe eksperimenata, korišćenih u ovom radu, radilo se o koherentnom izvoru – laseru, koji ima mogućnost podešavanja talasne dužine. Detektore su predstavljali fotomultiplikatori, podaci su prikazivani kao grafici i u ASCII zapisu u fajlovima. Makroskopski izgled jedne formacije eksperimenata je na slici 2.

Slika 2. Izgled dela laboratorije sa postavkom za merenje luminescentnih spektara, detalj sa računarom za obradu podataka.

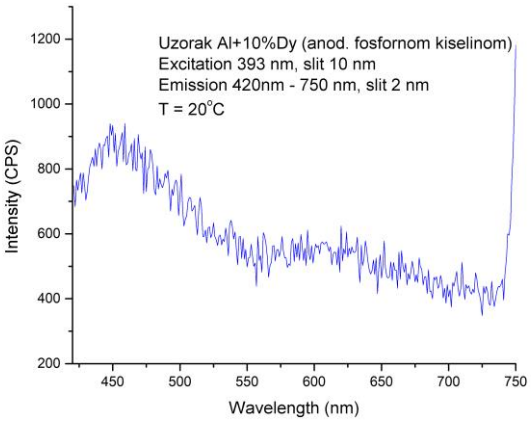
A. Uzorci



Na jednom tipu spektrometara analizirani su uzorci, koji su laboratorijski pripremani na bazi aluminijuma dopiranog retkim zemljama (Eu ili Dy), u koncentracijama 10%, koji su anodizirani fosfornom, oksalnom, sumpornom, hromnom ili bornom kiselinom, dimenzija uzoraka reda cm i debljine do mm.

Na drugom tipu spektrometra su specifično pravljeni uzorci sa polaznim prahovima rodamina, na pločici aluminijuma, anodiziranog u fosfornoj kiselini, na kojoj je nanošen rastvor rodamina RH D:110=1:9. Oba tipa uzoraka su bili sličnih gabarita, radi lakšeg poređenja u odnosu na intenzitet ekscitovanih procesa. Pored toga, vođeno je računa da se organizuju eksperimenti sa istim parametrima ekscitacije u odnosu na vremenske i prostorne parametre izvora ili da se prave modifikacije intenziteta ili geometrije ekscitacije. Temperatura koja je menjana je na jednom tipu uzoraka bila u opsegu od 20-70◦C, a u drugom se radilo o niskim temperaturama od 10-150 K, pošto je bilo od interesa analizirati uzorke sa polaskom od sobnih temperatura ili u opsegu daleko od uobičajnih temperatura ambijenta. Pitanje promene temperature se relativno jednostavno rešavalo (kod niskih temperatura krio sistemima). Ekscitacija uzoraka bez obzira na koherentnu ili nekoherentnu pobudu je vršena po celoj površini uzorka.

Ekscitacioni snop lasera je propušten u jednoj seriji merenja kroz prorez 10 nm, a u drugoj, kod OPO lasera, monohromator sadrži dve difrakcione rešetke: od 300 i od 1800 zareza/mm, koji se mogu birati zavisno od željene rezolucije. Podsećamo da rešetka 1800 zareza/mm daje višu spektralnu rezoluciju, ali je signal nekoliko puta slabiji.



III. Rezultati

Rezultati vezani za uzorke tipa aluminijumskih pločica, anodiziranih različitim kiselinama, koji sadrže retke zemlje su prikazani na slici 3.

a)

 ISBN 978-86-7466-930-3

b)

Slika 3. Emisioni spektri uzoraka anodiziranog dopiranog Al u funkciji temperature, ekscitovani laserom: a) emisioni spektar uzorka Al dopiranog sa 10% Eu; anodiziranje fosfornom kiselinom, sa eksitacijom na 393 nm, snimljen na 20°C, b) emisioni spektar uzorka Al dopiranog sa 10% Dy; anodiziranje fosfornom kiselinom, sa eksitacijom na 393 nm, snimljen na 20°C.

Više je faktora koji utiču na to da dobijeni podaci odstupaju od očekivanih, onih koji se sreću u bazama podataka ili da su rezultati merenja, jednostavno, neupotrebljivi. Najčešće je to zastarelost opreme, „grubost" aparature, problem sa podešavanjem ili prosto pojava šuma. Na slici 3 b) informativno je dat spektar koji je neupotrebljiv zbog pojave šuma i „grubosti" aparature. O uslovima merenja je potrebno posebno voditi računa.

Spektri su istog tipa ili se razlikuju prema broju vrhova / pikova. Razlikuju se širine vrhova za slučaj pobude lampom ili laserom.

Od interesa je sprovesti eksitacije drugim tipovima koherentnih i nekoherentnih izvora i uporediti strmine spektara čime se može naći ili proceniti eventualno ko je ekscitovao neki nepoznati spektar za te uzorke. Od interesa je i promeniti gradijent temperature pri zagrevanju i diskutovati o optimalnom merenju temperature uzorka.

Uopšteno je potrebno voditi računa i o okolnostima:

- uniformnosti ekscitacije uzorka,
- broj ciklusa merenja posle kojih se pogoršava luminesentni odziv,
- variranje vremena ekscitacije i odgovarajućih izlaza,
- promena koncentracije i dopiranja.

IV. ZAKLJUČAK

Procesi luminescencije materijala imaju široku upotrebu u mnogo oblasti. Kako je nauka o materijalima danas prepoznata kao jedna od najpropulzivnijih oblasti, postoji stalan trend da se dalje radi na luminescentnim materijalima i na poređenju ekscitacija u kategorijama koherentnih / nekoherentnih izvora. Pored toga što se luminescencija koristila ili koristi u svrhe detekcije i merenja, postoje trendovi da se formirani materijali dalje izlažu drugim pobudama, koje će samo da povise stepen intenziteta luminescencije. Kako su aktivni materijali kod kvantnih generatora vezani za promene koncentracije, čiji se prelazi prate već dugo, rađeno je na poboljšanju koeficijenta korisnog dejstva, izlaganjem aktivnih materijala definisanim snopovima elektromagnetnog zračenja u raznim dijapazonima spektra, nuklearnim zračenjima ili na drugi način.

Postoji velika količina starih spektara „klasičnih" materijala i sa „klasičnim uslovima", za koje je potrebno da budu ubačeni u baze podataka i da se dalje obrađuju i/ili porede raznim algoritmima ili se vrše transformacije u digitalni zapis za uključenje provere teoretskih modela. (9) To dovodi do potrebe za pretvaranjem starih snimaka u digitalnu formu, sa zapisom koji daje mogućnost za dalju obradu.

Pored toga, same tehnike merenja [12] mogu da budu od interesa i za konkretne forenzičke metode.

ABSTRACT

Perhaps measurements of very low luminescence of human s in in the future will bridge the gap between traditional astern and conventional Western medicine. or now, luminescence measurements and research in this area confirm the connection between biological rhythms and the emission of electromagnetic radiation from living individuals. Today, a lot of literature on luminescence, with the phrase „potential application'', needs to be corrected into „existing applications'', because luminescence has strengthened its place in many applications from medicine, metrology, heritology, forensics. We can tal about the synthesis of materials, the development of devices and methods that will better and more

 ISBN 978-86-7466-930-3

completely describe the luminescent effects qualitatively and quantitatively to ma e them clearer and more informative. Apparatus development means the development of each of the major subsystems from e citation to detection. specially important is the processing subsystem where the formed signals are processed and includes a specific dedicated written program for obtaining results in environments where only data on a certain size is needed, which is obtained by the method of luminescent technique. , amino acids in fingerprint, e plosives). Detection sensitivity can be achieved by different ways of energy transformation using luminescent techniques along with other treatments. The luminescent effects of lanthanide compounds (terbium, europium, yttrium, etc.) can be enhanced by combining with ligands that promote these effects. aterials with rare earths, due to their unique optical properties, are also interesting in the field of protection. And here we wor on powders, paints, solutions, in order to obtain products whose luminescent profiles are difficult to imitate. Characteristic times of luminescent effects are different (reaction time, rela ation, etc.) and depend on the type of e citation, so the information obtained in this way has multiple meanings based on which, from one series of measurements, with the appropriate development of electronic support, the situation with a comple set of electromagnetic, nuclear radiation, can also be measured simultaneously. These effects are particularly important because both qualitative and quantitative analysis of trace elements is enabled. uminescence has its own history, and many nown results come from older generations of measuring systems, which directly leads to the need for digitization in order to be able to use them in e panding the database for automatic fast search.

ey words - luminescent effects, forensics, matter detection, rare earths, amplification effects.

Изазови у настави на рачунарима током пандемије Covid 19 на предмету Нацртна геометрија са рачунарским цртањем

Магдалена Драговић, Александар Чучаковић, Светлана Чичевић, Александар Трифуновић, Анастасија Мартиненко

***Апстракт*—Савремени приступи у високошколској едукацији, са употребом рачунара, као алата за прецизно цртање и 3Д моделовање, комбиновани са формом *online* предавања, су настали као резултат потреба инжењерске струке и актуелних услова живота за време пандемије Covid 19. Комбинована форма наставе, где се предавања реализују као својеврсни вебинари, а вежбе спроводе уживо у учионицама, на рачунарима, носе одређене специфичности и изазове како за наставнике, тако и за студенте. Кроз овај рад аутори ће приказати карактеристике оваквог типа наставе и њене изазове у реализацији, која је спровођена на Грађевинском факултету Универзитета у Београду током школске 2021/22 године, на предмету Нацртна геометрија са рачунарским цртањем. Након завршеног зимског семестра, после реализована два узастопна испитна рока (у јануару и фебруару), спроведена је анкета са студентима, који су положили испит. Анкету, су креирали наставници на предмету. Резултати делова анкете, у контексту теме рада, су приказани кроз графике и дескриптивну статистику.**

Кључне речи — едукација, *online* настава, нацртна геометрија, рачунарско цртање, софтвер Auto CAD.

I. УВОД

Специфичности времена у коме живимо, развој технологије и рачунарских алата за рад стручњака инжењерске струке, диктирају континуиране промене у едукацији студената, како у концепту, тако и садржају и начину реализације. Већ дужи временски период, у настави су опште присутне презентације са слајдовима у PowerPoint апликацији, као помоћни „алат“ за предавања, пошавши од основно-школског нивоа едукације до високошколских установа, које постају један од основних материјала за учење [1]. Комбиновање типа предавања, које се реализује уз слајдове са сажетим информацијама и сликама-цртежима о наставној теми, са *online* вебинаром, као главним средством за живу комуникацију између наставника и студента, је једна од актуелних метода у настави спровођеној током ванредних услова - пандемије Covid 19 . Настава подржана различитим видовима информационо-комуникацијске технологије се приближила *e-learning*-у, типу реализације наставног процеса на даљину, који је током интернет ере добио и своје појмовне варијетете (електронско учење, учење путем интернета, *online* учење...)[2]. Услови живота које је диктирала пандемија и специфичности предмета који студент учи су актуелизовале и друге типове материјала: снимљена предавања, видео клипови, додатни писани, или цртани материјали у електронској форми и сл.

Предмет Нацртна геометрија са рачунарским цртањем, који је део новог курикулума будућих грађевинских инжењера на Грађевинском факултету Универзитета у Београду (у даљем тексту ГРФ), је креиран 2021. год. као курс у новом циклусу акредитације ове високошколске установе [3]. Специфичност приступа је у том смислу што комбинује овладавање вештинама цртања и моделовања на рачунару, у софтверу који има 3Д радно окружење, са применом научних принципа нацртне геометрије. Управа факултета се одлучила за примену комбинованог вида наставе (практични део наставе је организован у рачунарским учионицама, на факултету, а предавања су се одвијала *online*), у складу са нешто блажим епидемиолошким мерама и прописима. Обзиром да су студенти прве године читаву годину пре уписа учили у комплетном *online* режиму, оваква одлука је осигурала квалитет реализације и подигла атрактивност наставе.

Нацртна геометрија је научна дисциплина настала као резултат потребе да се 3Д простор на адекватан начин прикаже на 2Д цртежу, а њен креатор је француски војни инжењер и математичар Гаспар Монж (Gaspard Monge 1746-1818). Монж је креирао систем приказивања просторних елемената у две комплементарне ортогоналне пројекције, које је користио за приказе војних утврђења и решавање њихових специфичних потреба алатима геометрије [4]. Нацртна геометрија има две кључне улоге - представљања и анализирања 3Д објекта (одатле потиче и назив „дескриптивна“ – описна). У едукацији доноси као резултат способност геометријске апстракције различитих геометријских облика и геометријско резоновање [5]. Она даје скуп принципа и поступака који омогућавају решавање геометријских задатака у простору

 ISBN 978-86-7466-930-3

цртањем на 2Д папиру, или пак на рачунару, што је случај са модерном нацртном геометријом. Као таква је у потпуности специфична и носи широку палету путања у поступку решавања једног геометријског задатка, дајући слободу аутору цртежа да различитим идејама дође до решења. Представља високо захтевну научну дисциплину која развија просторну имагинацију, а специфично је важна за струке које се тичу дизајна, инжењерства и архитектуре [5,6]. Често није популарна међу студентима, јер је добар број њих склон тражењу обрасца за решење („корак по корак“ исцртавање линија на цртежу) који се може меморисати. Утисак који деле аутори овог рада, стечен на основу вишегодишњег рада са студентима је да мањи број студената настоји да „освести“ везу између 2Д цртежа (као пројекције) и 3Д простора. Стога, допуна наставе нацртне геометрије технолошким решењима – цртачким алатима, у форми софтверских апликација, које поседују 3Д радно окружење, представља искорак ка бољој визуелизацији просторних елемената, прецизнијем и ефикаснијем цртању, као и њиховом атрактивнијем приказу [6].

Међу савременим рачунарским софтверским решењима постоји низ апликација које служе као цртачки алат, како за 2Д, тако и 3Д цртање. У тренутку када се укључи и просторност – тродимензионалност, поступак цртања постаје моделовање[1]. Ова могућност је отворила врата новим приступима у едукацији инжењера. Тако се низ софтверских решења које се користе у сврхе основне геометријске едукације, протеже од SketchUp-a, Rhinoceros-a, GeoGebra-e и сл. до озбиљних инжењерских софтвера за потребе струке, какав је AutoCAD, ArchiCAD, Revit и други. Могућност да студент једним „кликом“ миша из „3Д простора“ пређе у 2Д пројекцију наизглед је била идеална за оне студенте који теже схватају шта цртеж нацртан на папиру заиста представља у простору. Осим тога, приказ било ког објекта, грађевинског, или чисто геометријског, у форми која визуелно даје просторну представу, студенту даје сигурност препознавања објекта који црта. Различити начини приказа просторног модела (жичани, површински, пуни, провидни и сл.) доприносе квалитету визуелизације, који се савременим софтверским алатима лако изводе. Коначно, генерације студената које долазе су одрасле уз 3Д видео игре, које су већ утицале на њихов ниво технолошке „писмености“ и спремност на изазов да у сличном окружењу уче и припремају се за професију. Руковођени овим идејама академски наставници, на ГРФ, су увели 3Д окружење у наставу на предмету Нацртна геометрија још од 2015. год, тада у форми 3Д решења задатака, која су пратила 2Д цртеже, извођене на практичним вежбама, у класичном систему наставе [7]. Данас је то прерасло у комплементарно - 2Д/3Д цртање на рачунару, употпуњено моделовањем.

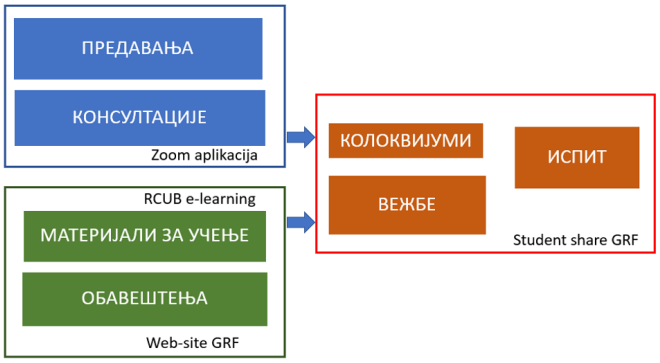
У раду ће бити приказани аспекти изазова техничког (реализација наставе) и едукационог (нови модалитет радног окружења) типа, који су се појавили током наставе на ГРФ-у, са студентима прве године, на курсу Нацртна геометрија са рачунарским цртањем, током школске 2021/22. године.

II. УСЛОВИ ИЗВОЂЕЊА НАСТАВЕ

Реализација наставе и то дела практичних вежбања на предмету Нацртна геометрија са рачунарским цртањем, на ГРФ, је спровођена паралелно у 4 рачунарске учионице које укупно броје 94 (24, 30, 20 и 20 места) расположива рачунара за студенте[2]. У условима пандемије, према прописима о максималној квадратури простора по једном студенту (4м^2), то је значило да се број студената у учионици креће од 10-12, у мањим учионицама, до 17, у већој учионици. Верзија софтвера која је коришћена у настави је AutoCAD 2022 (најактуелнија верзија бесплатно доступна студентима за рад и вежбу код куће). Број студената за који је настава оргнизована у току школске 2021/22 године је оквирно 350. Наставу је до краја редовно похађало око 300 студената. Фонд часова на предмету је 2+3 (предавања + вежбања) током петнаестонедељног зимског семестра. Практичне вежбе су се реализовале под вођством једног наставника и једног студента демонстратора у две суседне учионице (како би наставник могао да надзире обе групе студената). Свако од 11 реализованих вежбања је оцењивано оценом од 1-10, што је у укупној оцени на курсу представљало 30 поена (од максималних 100), док је услов за потпис семестра износио мин. 16.5 остварених поена са вежбања.

Перформансе рачунара који су коришћени у раду са студентима су следеће: Intel I5 процесор, 3.30GHz, 32GB RAM, hard disk 500GB M2, NVIDIA GeForce GT 730 – графичка карта, под 64-bit Windows оперативним системом. Познато је да је софтвер AutoCAD један од захтевнијих софтвера када је у питању графика, чиме се омогућава изузетна прецизност код цртања, као и интеракција-манипулација са 3Д објектом (померање, ротација, увеличавање и др.). У складу са тим, поседује палете алата (палета *snap*) који омогућавају реализацију прецизног цртежа, као и алате за раванску и просторну манипулацију (*pan*, *orbit* и *zoom).*

Упознавање студената са процедурама коришћења рачунара (логовање на рачунаре са корисничким именом и лозинком) и рачунарске инфраструктуре факултета је спроведено кроз форму обавештења постављених на предметној табли, у оквиру факултетског web-сајта www.grf.bg.ac.rs. Упутства о приступу подлогама за вежбе у оквиру факултетске инфраструктуре, са подручја *student share,* креирању личне фасцикле на D-диску појединачних рачунара и личне датотеке – цртежа у AutoCAD (*.dwg) формату, уз одговарајући назив и идентификацију студента, су такође представљена студентима у писаној и електронској форми, током уводних часова.



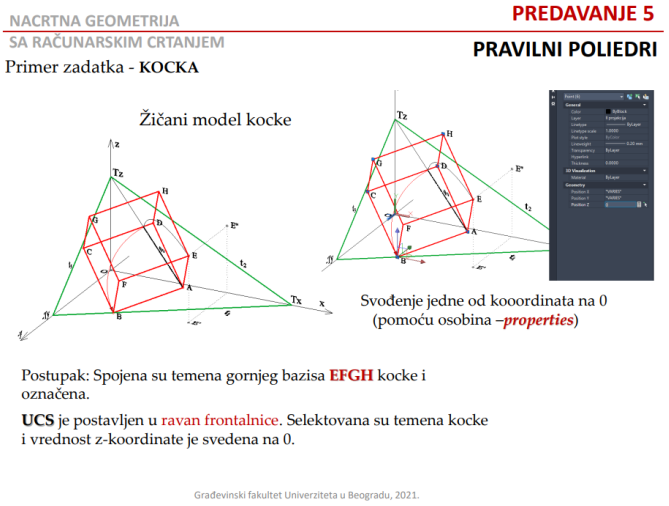
[1] Реч „моделовање“ се користи у много контекста, али када је реч о геометријском поступку, најчешће значи – креирање просторног модела неког тела мање, или веће сложености.

[2] Сваки студент ради самостално на једном од рачунара у учионици (у начелу, студенти су настојали да раде увек на истом рачунару, како би им били доступни и претходни радови-вежбе).

 ISBN 978-86-7466-930-3

III. МЕТОДОЛОГИЈА НАСТАВЕ

За разлику од актуелних светских тенденција ка Project Based Learning-у (PBL), или „обрнутој учионици“, у наставном процесу [8], на ГРФ је још увек активна методологија која примењује теоретску наставу (наставник излаже предвиђену тему), која претходи практичном делу – вежбањима (на основу предавања студент се припрема за вежбање код куће и решава задатке на факултету, у рачунарској учионици). Целокупна структура извођења наставе, коришћења наставних материјала и комуникацијско-информационих окружења се може испратити помоћу графика (сл. 1).



Сл. 1. Дијаграм структуре извођења наставе са радним комуникацијско-информационим радним окружењима

Потреба да се студентима образложе теме које покрива научна дисциплина нацртне геометрије, а која има директну примену у грађевинарству, спроведена је кроз предавања у форми *Power Point* презентација (сл.2) и пратећа објашњења која наставник говори уживо на вебинару (Zoom апликација). Слике – цртежи појединих наставних тема, у оквиру презентације су дате у форми ортогоналних, или аксонометријских слика, тј. приказа дела екрана рачунара (*print screen* опција) са исцртаним цртежом у 2Д, или 3Д приказу. Слике су по потреби креиране у неколико фаза извођења задатка, како би се лакше пратио сукцесивни поступак решавања-цртања, или моделовања, што је пракса показала као веома користан метод [6][3].

Специфично, имајући на уму да студент има двоструки задатак - да савлада геометријска знања и оспособи се за рад адекватним цртачким алатом- софтвером Auto CAD, креирани су и допунски материјали у писаној форми (појашњење поступка), као и појединци видео клипови (комплетан, или део поступка[4] у изради задатка), ради боље припреме студената за реализацију практичних вежби.

[3] Претходна искуства на предмету Нацртна геометрија, где су студенти добијали решења задатака у форми AutoCAD цртежа (2Д и 3Д) са фазама израде задатка – „корак по корак“, које су дефинисане сукцесивним укључивањем лејера, показала су да је одређени број студената на предмету користио овај олакшани вид учења „процедуре“ и да им је помагао да се на адекватни начин припреме за вежбање.

[4] Припремљени су материјали за оне сложене поступке где је у спровођењу команди потребно извести више корака, односно, изабрати одређене опције које се нуде у командној линији.

Сл. 2. Приказ слајда *Power Point* презентације са предавања који приказује поступак и делом команде у поступку извођења геометријског задатка

Обзиром да је учење рада у софтверу предмет курсева који су доступни јавности у стручним и лиценцираним институцијама и да постоје бројни приручници (како штампани, тако и у форми интернет упутстава и подршке [9]), наставне теме су пратила концизна упутства којим се командама (куцаним у командној линији, или коришћењем алатке на палети алата) треба служити да би се на одговарајући начин нацртао цртеж – решио дати геометријски задатак. Кратка упутства о радном окружењу софтвера AutoCAD су дата у форми једног-уводног предавања и писаног материјала постављеног на предметној табли факултетског web-сајта, а истој теми је посвећено и уводно вежбање (без оцењивања).

За потребе архивирања материјала за учење и припрему вежби на *e-learning* платформи Рачунарског центра Универзитета у Београду (РЦУБ – у даљем тексту) је креиран налог предмета у оквиру ширег налога ГРФ. На одлично организованој платформи која омогућава распоред материјала по радним недељама, интеракцију са студентима кроз оцењивање радова и повратна упутства о грешкама, архивирани су додатни материјали за учење: видео снимак предавања и ppt - презентација, текст задатка за вежбу, закључано решење вежбе AutoCAD формата, пратећи писани материјал за поступак израде, као и поставка вежбе (постављена по завршетку недеље текуће вежбе).

Научни принципи и методе које користи Нацртна геометрија су, сходно расположивом времену у семестру, приказани у сведенијем обиму, него што је то класични приступ подразумевао. Један од практичних разлога за то је што софтвер AutoCAD има своје процедуре (команде) решења геометријских задатака, која се изводе много ефикасније и прецизније. Наиме, перформансе софтвера су омогућиле да се неки геометријски поступци изоставе – те да рачунар „сам реши“ геометријски задатак применом једне или више команди, било да се ради о задатку у коме се тражи продор праве кроз раван, или продор два геометријска тела-солида.

 ISBN 978-86-7466-930-3

IV. ИЗАЗОВИ У РЕАЛИЗАЦИЈИ НАСТАВЕ

Током реализације практичних вежбања, у учионицама, на рачунарима, наставници, као и студенти су се суочавали са два типа изазова: технички – који су везани за рачунаре, опрему и рачунарску инфраструктуру факултета и теоријски - везани за саму нацртну геометрију и примену AutoCAD алата (вештина и брзина цртања). И наставници и студенти су били суочени са изазовом брзине одвијања наставе, њених временских оквира (2+3часа) и усвајања вештина цртања и неопходних геометријских знања, у контексту успешне реализације курса.

Неколико изазова које су наставници на предмету уочили у оваквом типу наставе су:

-недостатак визуелног контакта са студентима (немогућност да се студент током предавања препозна и ликом);

- немогућност да се поједини студенти укључе и гласовно у комуникацију (проблеми са опремом);

-повремено укључивање и ометање предавања спољним звуцима или гласовима[5];

-свако мењање документа који се приказује подразумева низ корака у апликацији, што успорава ток и ритам предавања, захтевајући извесну вештину предавача;

-студенти су мање активни („храбри“) у комуникацији;

-студенти су значајно више комуницирали путем “chat” опције него гласовно, што је од предавача захтевало излазак из фокуса предавања и пр**а**ћење *chat*-а;

Везано за образложену проблематику, на крају семестра је спроведена анкета, која укључује питања о неколико типова изазова. Анкетирани су студенти који су положили испит у једном од два испитна рока јануар/фебруар. У анкети је учествовало 53 студента, од чега је 58.5% женских и 41.5% мушких испитаника. Око ¾ (75.5%) овог броја студената припада популацији која је завршила гимназију, док је 22.6% завршило неку од техничких школа.

Студенти су реаговали на понуђене опције (или више њих) у контексту личних изазове током рада на рачунарима, што у крајњем исходу може указати на правац побољшања квалитета наставе у наредним годинама. У кратким цртама, у наредном тексту су описани поједини изазови који су пратили реализацију наставе, а у наставку су резултати студентске анкете са појединим питањима обрађеним за потребе овог рада.

А. Изазови са опремом-рачунаром

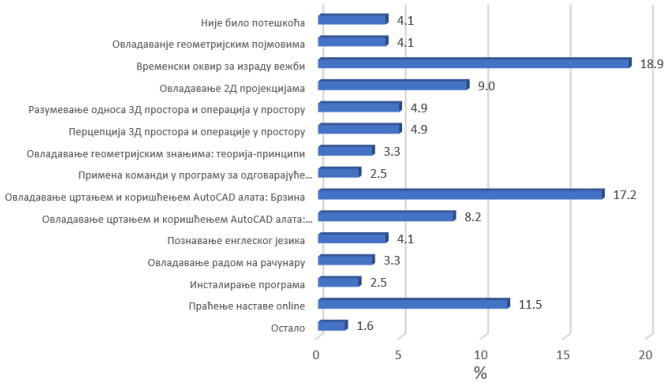
Обзиром на старост и перформансе рачунара и помоћне опреме (миш и тастатура, понекад и екран), долазило је до проблема у ефикасности извођења-цртања студената на вежбама. Неисправна опрема је успоравала, или у потпуности онемогућавала рад. Такође, специфично за софтвер AutoCAD, дешавало се да графичка картица рачунара не подржи команду манипулације „*3D Orbit“* и да усред поступка дође до терминалне грешке, па су студенти „губили“ нацртане задатке и били принуђени да раде цртеж од почетка.

Б. Изазови са рачунарском инфраструктуром и процедурама

Посебно изражени, у првих месец дана наставе, су били заступљени проблеми активирања студентских налога на рачунарима (форма одбијене лозинке), који често нису могли да се реше у току самог вежбања. Брзина и неискуство студената у раду са датотекама на мрежи (копирање, чување и именовање датотеке) су готово до последњег термина вежбања чинили да студенти активирају поставке вежби на самој мрежи, чиме би осујетили приступ поставци осталим студентима и угрозили анонимност личног рада. Могућност да било ко од студената по завршетку и предаји вежбе може да приступи туђем раду су учинили да студенти падну у искушење да копирају туђи задатак, преименују, па чак и обришу цео рад.

V. РЕЗУЛТАТИ АНКЕТЕ

Резултати спроведене анкете су показали да је скоро 2/3 студента (66.5%) имало проблем са нефункционалном, или преосетљивом опремом (углавном „миш“); затим, 42.5% испитаника је пријавило „пуцање“ софтвера у току рада, те нестанак дела урађеног цртежа, док је 10,5% пријавило и потпуни губитак рада; коначно, 3.8% испитаника је пријавило некоректну „крађу“ комплетног рада, или појединих цртежа. Свега 1.9% студената није имало лични рачунар, а 5.7% је имало потешкоће око инсталирања софтвера (сл.3). У ери дигиталних справа које су углавном подешене за коришћење на енглеском језику, 9.4% студената је имало изазове са значењем и називима команди које су главна спона корисника и рачунара. На графику (сл. 3) су дати и остали резултати анкете који презентују заступљеност потешкоћа које су студенти имали у праћењу, или реализацији наставе на рачунарима, као и разумевању геометријских поступака на релацији 2Д/3Д.



Као противтежа потешкоћама, студенти су се у анкети изјаснили о позитивним утисцима (сл. 4) и погодностима које је донео рад на рачунару. Највећи број студената (64.2%) је показао задовољство због рада у 3Д радном окружењу, а једнако оценио квалитет цртежа који се остварује цртањем на рачунару (62.3%). Такође је значајан проценат студената (52.8%) који оцењује квалитет софтвера - да се делови цртежа могу уклонити/сакрити са екрана (без брисања).

Део анкете, који упућује на то које су материјале студенти користили у поступку учења и припреми вежби или испита, показује да је 96% испитаника користило платформу РЦУБ-а, а 54% је користило предметну таблу на web сајту факултета и материјале који су на њима постављани; мањи број студената (69.8%) је као

[5]Иако су извршена подешавања у апликацији, неретко се дешавало да се звук са локације где се налазе студенти чује преко гласа наставника и ремети ток предавања.

 ISBN 978-86-7466-930-3

литературу користио уџбенике, а 41.6% је користило и личне белешке.

Сл. 3. Резултати анкете: приказ заступљености изазова које су анкетирани студенти имали током реализације наставе на рачунарима

Сл. 4. Резултати анкете: приказ позитивних утисака које су анкетирани студенти имали током реализације наставе на рачунарима

VI. ЗАКЉУЧАК

Сумирајући резултате спроведене анкете и утиске током реализације наставног процеса на предмету Нацртна геометрија са рачунарским цртањем, може се рећи да је наставни процес у коме су важну улогу имали рачунари, њихова опрема, рачунарска инфраструктура и платформе за његову реализацију, на нивоу актуелности, ефикасности и адекватности испунио очекивања наставника. Студенти су активно користили већину садржаја – наставних материјала која је припремљена у релативно кратком временском периоду (око 6 месеци) и успешно положили испит. Остварен резултат током два испитна рока, у којима је положило 157 студената: у јануару - 112 (просечна оцена 8.81) и фебруару - 45 (просечна оцена 7.84), од укупног броја од око 320 студената (који су редовно похађали наставу), показује да је њихово интересовање за предмет и мотивација да га положе у првим испитним роковима одговарала одговорима приказаним у анкети. Резултати су на нивоу резултата претходних генерација студената, који су слушали класичан курс Нацртне геометрије.

Изазови који су пратили наставни процес, а специфично они који су се дешавали у рачунарским учионицама, дају смернице за неопходност побољшања расположиве опреме и рачунара, у функцији квалитета извођења наставе, као и смањења нивоа стреса, како за студенте, тако и за наставнике. Очито је највећи изазов био временски оквир за реализацију вежби, што се може тумачити мањком вештина у манипулацији рачунарском опремом (као и њеним квалитетом) и недовољним искуством у раду на рачунарима, уз надасве потребно знање геометрије и поступака у софтверу AutoCAD.

Несумњиво је да је искуство студената прве године факултета сасвим различито од искустава студената са виших година студија, јер је брзина и моћ адаптирања на новине у режиму студирања (у односу на средњошколску наставу), један од детерминишућих фактора успешности. Ипак, студенти су показали да врло добро владају савременим комуникационим платформама које су активно користили и са њих преузимали електронске материјале за учење.

ЗАХВАЛНОСТ

Овај рад је спроведен у оквиру реализације научних пројеката, које је финансирало Министарство науке и технолошког развоја Републике Србије под редним бројевима ТР 36027, ТР 36006, 200092.

ABSTRACT

Contemporary academic educational trends, based on utilization of computer tools for accurate drawing and 3D modelling, and additionally combined with online lectures, arose as a consequence of engineering practical needs and a

life-style limitation during pandemic COVID-19. The combined method of teaching, where the lectures are realized in the form of webinars, while the practical exercises took part in the classrooms, on desktop computers, brought specific challenges, both for lecturers and students. In this research authors will present characteristics of such teaching methodology along with its challenges, which is applied at the Faculty of Civil Engineering, University of Belgrade, during 2021/22 school year, at the Descriptive geometry with computational drawing course. After the winter semester and two realized exam terms (in January and February), a questionnaire was conducted among students who passed the exam. The lecturers created their own set of questions for the purposes of this research. Some results of this questionnaire, due to the context of the paper, are presented in graphics and descriptive statistics.

Challenges in the realization of computer added teaching process during COVID 19 pandemic at Descriptive Geometry course

Aktuelni problemi digitalizacije u državnoj administraciji

Nikola Popović, Julijana Mirčevski

Apstrakt --Tekuće stanje procesa digitalizacije u Srbiji počinje da ispoljava prve, jasne znakove protivrečnih pojava. Uvodi se značajan broj sistema za upravljanje dokumentima, posebno u sistemu državne administracije. Uz sasvim očite pogodnosti, ispoljavaju se problemi kompatibilnosti novih sistema sa postojećim sistemom rada sa papirima. Harmonizacija dostupnosti dokumenata i načina rada je otežana. Jedan deo dokumenata i pored digitalne verzije mora i dalje da ostane na papiru. Troškovi digitalizacije su visoki, a navedeni problemi izazivaju značajna kašnjenja implementacije. U radu su naznačena moguća tehnološka rešenja koja omogućavaju održivost procesa digitalizacije kroz niže troškove.

Ključne reči -- digitalizacija; održivost; metodologija digitalizacije; državna uprava.

I. Uvod

Analiza metapodataka koji su u propisima predvidjeni za opis digitalnih dokumenata ukazala je da je strategija digitalizacije zasnovana na klasičnim principima rada sa papirom. Regulativu u većini čine propisi koji se tiču zaštite digitalnih dokumenata. Usvojen je klasični princip grupisanja dokumenata hijerarhijskom klasifikacionom šemom. Nismo uočili da se iko bavio sadržajem dokumenata, semantikom i odgovarajućim aspektima jezika.

Težište digitalizacije je usmereno na zadovoljavanje potreba građana i preduzetnika. Od državnih organa se primarno zahteva i očekuje znatno veća efikasnost i uštede. Masovno se pominje primena "najboljih praksi" (eng. best practices), ali bez navodjenja čije prakse i konteksta te prakse. Procesi izrade studija stanja (eng. feasibility study) se sprovode/zamenjuju prostim anketiranjem. Izučavanje kompleksnih, heterogenih procesa u državnoj administraciji ne može da se izvodi anketiranjem. Unifikacija radnih procesa je nekada opravdana, ali u nekim nedovoljno analiziranim situacijama može da dovode do gubitka bitnih podataka i nemogućnosti generisanja novih informacija. Ciljevi digitalizacije, kako su postavljeni, ne uzimaju dovoljno u obzir potrebe organizacije rada u državnim organima. Regulativa je orijentisana na što bržu digitalizaciju u domenu finansija i bankarstva. U tom domenu najveći procenat dokumenata čine strukturirani dokumenti. Državna administracija u najvećem procentu radi sa nestruktuiranim dokumentima. Procesi rada sa struktuiranim i nestruktuiranim dokumentima se suštinski razlikuju. Radni procesi u državnim organima često zahtevaju organizovanje kompleksa podataka i metapodataka, koji omogućava složenu konsolidaciju informacionih resursa, u cilju donošenja racionalnih dokumentovanih odluka. U takvim slučajevima često je nužno formiranje ad-hoc klastera dokumenata radi sagledavanja sadržaja i obima problema. Jednostavan primer je ažuriranje podsetnika za posetu ministra stranoj zemlji. Osim novih podataka potrebno je proveriti i revidirati arhivske podatke (istorijat) radi njihovog sagledavanja (prikazivanja ili ne) u kontekstu tekućih zbivanja. Ovi postupci uslovljavaju pristup mnogo većem broju dokumenata, u vremenskom i tematskom domenu. U državnoj administraciji masovno se uvodi "Document management system" - DMS. DMS po definiciji ima sam dokument u centru pažnje (eng. document centric approach), što znači da ne odgovara uvek značajnim procesima informisanja u državnoj administraciji.

Nikola Popović, stalni sudski veštak za informacione tehnologije, e-mail: nikola.popovic@eunet.rs, nikola.popovic@mfa.rs, Beograd

Julijana Mirčevski, stalni sudski veštak za informaciono-komunikacionu tehnologiju, julijana.mir@gmail.com, Beograd

II. Kontradikcije metoda

Usvojen je koncept visoko centralizovane digitalizacije. U stranoj literaturi odavno su prepoznati problemi koji se javljaju u tom kontekstu [1], [2] . Nije uočeno da se posebno analizirao problem pristupa podacima u kontekstu dualiteta digitalni-papirni dokument. Strategija i taktika su svedeni na pominjanje zakona o arhivskoj građi, obavezno navodjenje pojma „najbolje prakse“, i očekivanje brze digitalizacije kompletnog sistema državnih organa.

U početnoj fazi uvodjenja DMS-a neprekidno se govori o značaju mogućnosti pronalaženja bilo kog dokumenta, bilo gde, u državnom organu. U kasnijim fazama realizacije počinje se sa ograničavanjem pristupa saradnicima organa državne uprave. Uvode se ograničenja - filteri za dokumenta koje pojedine niže organizacione jedinice i pojedini saradnici mogu i treba da vide. Naknadna analiza ograničenja pristupa pokazuje da su umesto sveobuhvatnog „wide-range“ DMS-a, često mogli da se primene znatno jednostavniji (tj. jeftiniji) sistemi sa istom funkcionalnošću. Navodimo:

1. Svi isporučioci DMS-a redovno ističu kao "glavnu" prednost korišćenja DMS-a mogućnost da svako vidi sve dokumente u DMS-u. Uopšte ne postoji potreba da svako vidi sve dokumente u DMS-u. Administrator DMS-a po funkciji može da ima pristup svim dokumentima, ali isključivo iz tehničkih razloga upravljanja repozitorijumima dokumenata.

2. Donosilac odluka suviše kasno shvata problem iz tačke 1. i onda uvodi restrikcije pristupa, koje su ustvari restrikcije na osnovne funkcije DMS-a. Cena pogrešne primarne odluke je previsoka.

3. Problem pronalaženja bilo kog dokumenta u klasičnom sistemu papirne dokumentacije, neposredno ukazuje na lošu

 ISBN 978-86-7466-930-3

organizaciju posla u državnom organu. Nije zadatak DMS-a da koriguje lošu organizaciju posla. Dokument pogrešno dislociran u DMS je veoma teško pronaći (na primer: pogrešno imenovan fajl u pogrešnom folderu).

III. SPECIFIČNOSTI DIGITALNIH DOKUMENATA

Ovde nije mesto za analizu razlike izmedju struktuiranih i nestruktuiranih dokumenata. Dokumenti u domenu finansija i upravljanja kadrovima su u velikom procentu strukturirani. Dokumenti u ostalim domenima nisu strukturirani (note, dopisi, informacije, analize itd.). DMS softveri koji se u ovom trenutku uvode u državnoj administraciji po pravilu ne vode računa o ovoj razlici. Po našim saznanjima prodavci softvera insistiraju na iskustvima softverskog sistema SAP (Systems Applications and Products in Data Processing) koji zahteva obimno, suštinsko prilagodjavanje i unifikaciju poslovanja u posmatranoj organizacionoj celini. Državna administracija je po pravilu tematski organizovana (pravosudje, finansije, zdravstvo, spoljni poslovi itd.). Praksa je pokazala da implementacija "univerzalnog" DMS-a po definiciji usmerenog na rad sa dokumentima kao baznim elementima, generiše nove, neočekivane probleme. Tematski orijentisana organizacija državnog organa zahteva značajno precizniju studiju izvodljivosti (eng. feasibility study). Prodavci DMS-a izbegavaju izradu studije stanja jer ima visoku cenu po vremenu a i zahteva iskusne ljudske resurse. Pokušaj zamene studije stanja anketom ne može da obezbedi pouzdan uvid u organizaciju rada u državnom organu niti da identifikuje bitne probleme.

Korisnički orijentisan pristup (eng. user-centric approach) u implementaciji DMS-a je u osnovi ispravan. Medjutim, organizacija prostora dokumenata u državnoj administraciji i pojedinačnim agencijama ne može da bude korisnički orijentisana (eng. user-centric approach) već tematski orijentisana (eng. topic-centric approach). Insistiranje na zadovoljavanju potreba gradjana i uštedama u državnoj administraciji je jedan aspekt problema. Drugi a značajniji aspekt je da digitalizacija mora da obezbedi uslove za rešavanje potreba državnih organa kako bi oni stvarno mogli da budu efikasniji. Ovo je ključna protivrečnost koja se pojavljuje u usvojenom procesu digitalizacije u državnoj administraciji. Korisnički orijentisan pristup digitalizaciji i tematski orijentisan pristup digitalizaciji su suštinski različiti. Olakšavanje rada korisnika korišćenjem DMS-a ne treba da se svede na “štednju papira” i “smenjenje šetanja po hodnicima”. DMS mora da korisniku obezbedi efikasno raspolaganje informacionim resursima državnog organa odnosno svake niže organizacione jedinice. Nužno je efikasno pretraživanje i mogućnost fleksibilnog, multiaspektnog povezivanja dokumenata. To je uslov za generisanje novih informacija iz raspoloživih dokumenata.

Praktično iskustvo pokazuje da prodavci ne vode računa o bitnim elementima:

kvalitetu skeniranih dokumenata,

koriste proizvod kako bi primarno smanjili svoje troškove organizacije implementacije i održavanja.

Isporučioci ove vrste softvera tvrde da obavljaju OCR (Optical Character Recognition) proces na unetim dokumentima ali u nekim slučajevima je ustanovljeno da se ne radi. Ovo je još jedna bitna protivrečnost digitalizacije u državnim organima. I dalje postoji promet papirnih dokumenata koje je, u postojećim uslovima, nemoguće koristiti samo u digitalnoj formi. Proces OCR-a generiše odredjen manji procenat grešaka u prepoznatom tekstualnom sadržaju dokumenta. U našoj državnoj administraciji uobičajeno se koristi font Times New Roman koji je značajno nepovoljan za proces OCR-a. Pored toga prodavci se ne upuštaju u kvalitet procesa digitalizacije papirnih dokumenata. Slike serijski skeniranih dokumenata po pravilu odstupaju od vertikalne osovine, što zahteva primenu automatske korekcije linearnosti redova teksta (eng. deskewing). Osvetljenost i kontrast slike se drži na prosečnim vrednostima. Prodavci tekstualni sadržaj dobijen OCR-om implementiraju neposredno u PDF dokument, bez provere ispravnosti teksta spelling checkerom. Pošto je tekst dobijen OCR-om ugradjen u PDF nije ga moguće ni vizuelno kontrolisati. Takvi digitalni dokumenti ne mogu da budu priznati za valjanu arhivsku gradju. Ispouručioci softverskih alata u sklopu DMS-a pažljivo ćute o ovim problemima.

Metapodaci implementirani u PDF dokument su i dalje minimalni iako postoje efikasni softveri za generisanje self-contained dokumenata sa znatno većim brojem metapodataka.

U kancelarijskom poslovanju državne administracije uobičajeno je da se uz izlazni dokument dostavlja dopis koji sadrži opis sadržaja dokumenta, razlog za dostavljanje dokumenta, identifikaciju dokumenta itd. Sam dokument koji se prosledjuje je po pravilu prilog. U praksi dokument često ima više priloga. Prodavci uobičajeno povezuju jedan identifikacioni opis dokumenta sa jednim dokumentom (najčešće u PDF formatu u državnoj administraciji). Ovo već sada stvara značajne tehničke i administrativne probleme. Više priloga se pakuje u jedan PDF dokument čime se gubi struktura paketa dokumenata. Gube se veze izmedju dokumenata ili se unose naknadni podaci o vezama. Problem je što tekuće izvedbe DMS sistema ne dozvoljavaju formiranje ad-hoc klastera dokumenata po jednoj ili više tema. U upotrebi je samo jedna unapred propisana klasifikacija, što je jasno sa stanovišta spoljašnjeg korisnika usluga državnog organa. Potreba za organizovanjem prostora dokumenata prema stvarnim, dinamičkim potrebama internog korisnika nije nigde sagledana. Ovakva koncepcija DMS-a bez ikakve potrebe smanjuje upotrebljivost repozitorijuma dokumenata. Iskustvo pokazuje da odredjeni open source programi ove opcije omogućavaju.

Korišćenje novih metoda izdvajanja ključnih reči, nezavisnih od jezika dokumenta i bez kontrolisanog rečnika, stvorilo je nešto veću mogućnost logičkog povezivanja dokumenata u procesu pretraživanja. Značaj se ogleda u tome što se ne zahteva rad profesionalnog indeksera dokumenata, a koji nisu ni predvidjeni za rad u državnoj administraciji. Hijerarhijska klasifikacija dokumenata predvidjena Uredbom o kancelarijskom poslovanju je ispod nivoa potreba rada sa digitalnim repozitorijumima dokumenata.

 ISBN 978-86-7466-930-3

IV. MOGUĆI PRAVCI PRIMENE DIGITALIZACIJE

Praktično ispitivanje mogućnosti aktuelnih softverskih paketa ukazalo je na moguće pravce razvoja. Logika dodeljivanja privilegija pristupa ukazala je da za segmente ograničene nadležnostima organizacionih jedinica može da se koristi Wordpress [6] u ulozi mikro DMS-a. Na primer arhivske fascikle mogu da se reprezentuju u formi Wordpress web sajta. Pri radu sa udaljenim filijalama (na primer diplomatsko konzularna predstavništva) mogu efikasno da koriste post opcije Wordpress-a, uz obezbedjenje sigurne komunikacije.

Uzroci nemogućnosti pronalaska nekog dokumenta u organu državne administracije prvenstveno leže u slaboj organizaciji rada. Pravila rada (pravilnici) ili nisu ažurirana, ili su loše definisana, ili se jednostavno ne poštuju. Primena glomaznih i veoma skupih DMS sistema sasvim sigurno ne može da reši navedene probleme.

Lista testiranih softverskih modula koji mogu da realizuju funkcionalnosti DMS u manjim organizacionim celinama:

Wordpress - open source CMS software [2] [6]

nuBuilder - Rapid Application Developer, sada ima priključak na Wordpress. Koristi relacionu baza podataka MySQL [6]

Tematres - softver za izradu tezaurusa i taksonomija i prikazivanje strukture repozitorijuma dokumenata [7]

Tesseract free open source softver za OCR (Optical Character Recognition) [8]

ScreenReader (komponenta programa ABBYY Fine Reader) koristi se za preuzimanje teksta sa ekrana

YAKE algoritam za ekstrakciju ključnih reči iz dokumenata (bez nadzora - eng. unsupervised method). Za nas je veoma važna karakteritika da rad algoritma ne zavisi od jezika algoritma. Koristi se u verziji programskog jezika ***Python*** bez dodatnog programiranja. [9] spelling checker za srpski jezik (bilo koja implementacija, preporučljivo je da se za rad koristi NoSQL verzija baze podataka na primer MySQL v.8 i dalje). Odredjena regulacija karakteristika može da se postigne izmenom liste tzv. stop reči.

KNIME (open-source data analytics, reporting and integration platform) izuzetno koristan "free machine learning" softver u domenu vizuelnog programiranja (topic aggregation, documents clustering for information consolidation, automatizing workflow itd.) [10]

Praktični eksperimenti ukazuju da već uz minimum programerskih kapaciteta (dva do tri programera srednjeg nivoa obučenosti za programske jezike PHP i Javascript), navedena grupacija open source softvera može da generiše prototipove DMS-a manjih dimenzija, ali bolje prilagodjenih potrebama državne administracije sa aspekta organizovanja prostora dokumenata. U stvari u pitanju su mikro DMS sistemi odnosno mikro CMS sistemi koji mogu da formiraju mrežu za razmenu podataka u slučaju potrebe.

Dosadašnje praktično iskustvo autora ukazuje da sveobuhvatni (eng. large scale) DMS sistemi koji se trenutno implementiraju u državnoj administraciji ne ispunjavaju više bitnih uslova za pouzdanu organizaciju prostora dokumenata u državnoj administraciji.

Posebno konstatujemo da je istraživačka delatnost je praktično onemogućena. Izmene može da radi samo prodavac. Već na kratki rok pojaviće se ozbiljni problemi u funkcionalnosti implementiranih DMS-ova. Velike agregacije dokumenata neće biti fleksibilne i podložne reorganizaciji usled fiksne strukture DMS-ova. Uporno se ponavlja mantra "skalabilnosti", ali se nigde ne pominje da je u pitanju aspekt "fizičke skalabilnosti" (po fizičkim dimenzijama repozitorijuma dokumenata) a ne i "logičke skalabilnosti" (problem generisanja novih informacija, problem konsolidacije informacija vidi Saračević et all. [8]).

Kompanije proizvođači i isporučioci ove vrste softverskih proizvoda redovno zaštićuju svoje proizvode autorskim pravima. Postavlja se pitanje zaštite vlasništva nad podacima i posebno mogućnosti upravljanja podacima od strane državnih organa. U ugovorima se problem migracije na drugi, noviji sistem ostavlja za "buduće vreme". Prodavci izbegavaju ozbiljan razgovor o temi migracije. Korišćenje usluga *Data centara* još uvek nije dovoljno precizirano, posebno u domenu softvera za upravljanje upravljanje podacima - šta se dešava sa softverom ? Pitanje urgentne mobilnosti podataka i posebno DMS-a se retko postavlja iako nas bliska istorija (1999. godina) upozorava na veoma stvarne probleme čuvanja i očuvanja podataka državnih organa.

V. DIGITALIZACIJA I SRPSKI JEZIK

Jezički aspekti digitalizacije su izostavljeni iz strategija digitalizacije. Information Retrieval problem se uopšte ne pominje u strategijama a neposredno je vezan za jezik i pismo, posebno u domenu državne uprave. Do sada istraživani metodi automatskog indeksiranja dokumenata nisu dali ni približno zadovoljavajuće - pozitivne rezultate. U korpusu dokumenata u domenu državne administracije koristi se jezik u formi koja najverovatnije nije pogodna za proces indeksiranja ("administrativni jezik"). Testiranja su obavljana na Open source softverima, ali veoma je velika verovatnoća da ni komercijalna rešenja ne mogu da daju bolji rezultat. Osnovni problem je što su postojeći jezički alati za srpski jezik veoma ograničenih mogućnosti ili ne postoje u potrebnoj formi (službeni rečnici pojmova, POS tageri, itd.). Na primer u programu Microsoft Word postoji modul Grammar koji izuzetno dobro koriguje pravopisne i gramatičke greške korisnika engleskog jezika i još nekoliko jezika koji su zastupljeni u svetu. Za srpski jezik ne postoji ništa slično čak ni u nagoveštaju. Nedostatak ključnih softverskih komponenti iz domena lingvistike i odgovarajućih jezičkih korpusa dovodi do toga da čitav sistem digitalizacije neće moći da se odvija onom dinamikom kojom se zamišlja. Vidljivost dokumenata i uopšte informacija, drastično je ograničena time što se kasni za tzv. jezičkom industrijom u svetu. Ovo je segment u kome su neophodne inovacije iz domena namenskog softvera, u veoma kratkom roku, a mladi istraživači se već pojavljuju[13] ali im je neophodna promptna podrška države.

 ISBN 978-86-7466-930-3

VI. ZAKLJUČAK

Uzevši u obzir dugogodišnje iskustvo u radu na parcijalnim procesima digitalizacije u državnim organima, savremeni trend razvoja informatike, tendenciju odvajanja softvera od hardvera, primenu metoda veštačke inteligencije u pretraživanju i druge tekuće prisutne pojave u razvoju informacionog društva, može se zaključiti da je neophodno poštovati sledeće bitne okvire:

- digitalizacija u okviru pojma održivog razvoja,
- digitalizacija treba da se implementira na *open source* softverskim platformama,
- digitalizaciju mora da prati razvoj informatičkog instrumentarijuma za domen srpskog jezika i pisma.

To zahteva angažovanje više specijalista za softver i hardver ali znatno olakšava rešavanje problema interoperabilnosti informatičke podrške tokom dužeg vremena i na raztličitim hardverskim platformama.

Digitalizacija u državnoj administraciji je složen proces. U radu su naznačene primedbe nastale na osnovu praktičnog iskustva i saznanja tokom uvodjenja DMS-a u više institucija. Primedbe se odnose na procese koji generišu nove probleme. Očekivanja da će samo ishitrenom digitalizacijom u državnim organima da se ostvare uštede i ubrzanja rada nisu realna. Potvrdjuje se ispravnost odavno poznatog pristupa evolucionog razvoja sistema. *Outsourcing* razvoja IT sistema i dalje ima visoku cenu.

Trend odvajanja softvera od hardvera, bezbednost podataka i otvorena softverska rešenja prilagodljiva rastućim potrebama korisnika, treba da ostanu postulati razvoja digitalizacije.

Nepoštovanje ove činjenice redovno dovodi do značajnih kašnjenja u implementaciji sistema i nekontrolisanog rasta cena projekata u celini.

Abstract - The current state of the digitalization process in Serbia is beginning to show the first, clear signs of contradictory phenomena. A significant number of document management systems are being introduced, especially in the state administration system. With obvious advantages, there are problems with the compatibility of new systems with the existing paperwork system. Harmonization of document availability and mode of operation is difficult. One part of the documents, in addition to the digital version, must still remain on paper. The costs of digitization are high, and these problems cause significant delays in implementation. The paper identifies possible technological solutions that can improve the sustainability of the digitization process.

Index Terms - digitalization; sustainability; methodology of digitalization; state administration.

Current problems of digitalization in state administration

Potencijal SMS komunikacije u mobilnom zdravstvu

Gordana Jelić, Danica Mamula Tartalja, i Enis Osmani

Apstrakt— Dobra komunikacija među učesnicima u zdravstvenoj zaštiti je jedan od osnovnih preduslova pozitivnih ishoda različitih intervencija u ovoj oblasti. Razmena tekstualnih poruka ili usluga kratkih poruka SMS (*Short Messages Service*), odnosno alfanumeričkih poruka od 160 ili manje znakova, nalazi se među najčešće korišćenim alatima mobilnog zdravstva. Cilj ovog rada je da se prikaže kratak pregled postojećih studija i literature o upotrebi SMS poruka u zdravstvene svrhe, fokusirajući se na pragmatički aspekat diskursa kratkih poruka. Analizirajući primere poruka na gramatičkom, leksičkom i komunikološkom nivou, ukazaćamo na jezička sredstva koja predstavnici zdravstvenog sistema (lekari, institucije) upotrebljavaju kako bi ostvarili željeno tumačenje poruke i postigli efekat kod ciljne grupe. Upotrebom efikasnih načina za poboljšanje modalnosti jezičkog izraza,komunikacija kratkim porukama nadmašuje tehnološka ograničenja ovog komunikacionog medijuma.

***Ključne reči*—mobilno zdravstvo, komunikacija, SMS poruke**

I. Uvod

Pametni telefoni i mobilne platforme za razmenu zdravstvenih poruka menjaju način na koji upravljaju zdravstvenim programima stanovništva. Prema Međunarodoj uniji za telekomunikacije gotovo polovina svetske populacije još uvek nije povezana na internet, ali 97% globalne populacije, ili sedam milijardi ljudi, živi u području pokrivenom mrežom mobilnih telefona [1]. Zbog sveprisutne dostupnosti mobilnih telefona i mogućnosti za interaktivnu komunikaciju kao i komunikaciju u realnom vremenu, tokom protekle decenije došlo je do brzog širenja intervencija u mobilnom zdravstvu (*mHealth*) kako bi se pomoglo u rešavanju dispariteta u pristupu zdravstvenim uslugama i poboljšanju zdravstvenih ishoda. Dobra komunikacija omogućava da se saznaju informacije neophodne za tačnu dijagnozu problema, da lekari bolje razumeju potrebe svojih pacijenata i što efikasnije dovedu do ozdravljenja ili ublažavanja simptoma bolesti. Takođe, doprinosi boljem razumevanju problema od strane pacijenata, pridržavanje preporučenim terapijama i lekovima i daje pozitivne efekte na troškove zdravstvene zaštite (smanjenje dijagnostičkih testova, upućivanje u bolnicu i dužinu boravka u njoj). SMS poruke, u poređenju sa tradicionalnim telefonskim pozivom, obezbeđuje nisku cenu, trenutni prenos informacija i bolju dostupnost [2]. Mobilna zdravstvena tehnologija pruža različitim kategorijama korisnika non-stop pristup visokokvalitetnim informacijama po niskoj ceni putem tekstualnih poruka i mobilnih aplikacija.

Razmena tekstualnih poruka TMI (*Text-messaging Intervention*) je popularna jer se kratke poruke mogu slati, čuvati, može se odgovarati na njih i mogu se preuzimati po potrebi korisnika; relativno je jeftina i pritom dostupna za bilo koju vrstu telefona. Sa slanjem poruka i e-poštom koje prevazilaze telefonske pozive kao najpopularniji način komunikacije, provajderi mogu kreirati personalizovane, sadržajno bogate, čak i interaktivne poruke koje podstiču angažovanje [10].

Interaktivne SMS poruke smanjuju verovatnoću prekomernog opijanja kod mladih odraslih osoba. Postoje usluge koje pružaju informacije o mentalnim bolestima kao što su šizofrenija, depresija, anksioznost i stres. SMS poruke se šalju u primarne, privatne „sandučiće" učesnika i mogu se lako primiti i odložiti; ovo bi mogao biti jedan od razloga za njihovu efikasnost kao intervencije mHealth. SMS mHealth intervencije se takođe smatraju anonimnim i stoga ruše određene barijere pristupu zdravstvenoj zaštiti. [9]

Primeri zdravstvenih programa stanovništva zasnovanih na tehnologijama mobilnog zdrastva su brojni. Oni uključuju programe tekstualnih poruka koji ciljaju na probleme javnog zdravlja, kao što su pušenje, zdravlje majke/bebe, gubitak težine, fizička aktivnost, anksioznost/depresija i slično. Drugi programi podsećaju ljude da zakažu velnes termine, vakcinaciju, ili su usmereni na populacije sa hroničnim bolestima. Složeniji programi uključuju interaktivne platforme i cilj su im pacijenti otpušteni iz bolnice, oni kojima je potrebna naknadna nega, ili hronični bolesnici, kojima je potrebna nega između poseta ordinaciji. Ove platforme mogu uključivati upitnike koji, kada se na njih odgovori, nude put do informacija o upravljanju negom ili pokreću upozorenja koja podstiču praćenje od tima za negu.

Pravovremeno pružanje informacija i upozoravanje ljudi u realnom vremenu je važno u svim segmentima zdravstvene zaštite. Komunikacija putem SMS poruka pokazala se kao bitna komponenta m zdravstva u borbi protiv pandemije COVID19. Platforme za praćenje pomoću SMS poruka pokazale se se kao koristan sistem ranog upozorenja za

Gordana Jelić – Akademija tehničko-umetničkih strukovnih studija Beograd, Odsek Visoka škola za informacione i komunikacione tehnologije, Zdravka Čelara 16, 11000 Beograd, Srbija (e-mail: gordana.jelic@ict.edu.rs).

Danica Mamula Tartalja – Akademija tehničko-umetničkih strukovnih studija Beograd, Odsek Visoka škola za informacione i komunikacione tehnologije, Zdravka Čelara 16, 11000 Beograd, Srbija (e-mail: danica.mamula@ict.edu.rs).

Enis Osmani – Akademija tehničko-umetničkih strukovnih studija Beograd, Odsek Visoka škola za informacione i komunikacione tehnologije, Zdravka Čelara 16, 11000 Beograd, Srbija (e-mail: enis.osmani.26.19@ict.edu.rs).

 ISBN 978-86-7466-930-3

upućivanje pacijenata sa pogoršanim kliničkim statusom na bolničku negu ili dodatni savet lekara. [2, 3]. Takođe, veoma korisnim se pokazalo slanje jednosmernih SMS poruka (obaveštenja, preporuke, upozorenja) od strane zvaničnih zdravstvenih ustanova i ministarstava.

Na vrhu piramide nalaze se programi za koordinaciju nege koji crpe podatke iz elektronskog zdravstvenog kartona kako bi razvili personalizovane poruke koje usmeravaju pacijenta na određene resurse, upravljaju receptima ili šalju podatke nazad, pružaocu usluge, za naknadnu negu. Najčešće, ove programe razvijaju i pokreću zdravstveni radnici koji žele da poboljšaju upravljanje brigom za pacijente kod kuće, uključujući one koji su nedavno otpušteni i takozvane „*frequent flyers*“ — pacijente sa više hroničnih stanja kojima su potrebne svakodnevne ili skoro svakodnevne intervencije kako bi upravljali svojim zdravljem i pritom ih držati van bolnice.

SMS projekti u mobilnom zdravstvu imaju za cilj poboljšanje u praćenju pacijenata i razmeni informacija. Takođe omogućavaju prikupljanje podataka, vođenje evidencije i komunikaciju sa novim pacijentima. Mobilno zdravstvo nije ograničeno na intervencije ili podsetnike putem SMS poruka. Mogućnosti pružanja usluga višestruko su porasle, posebno od pojave IoT (*Internet of Things*). To takođe znači da su mogućnosti, ali i tehnički zahtevi, mnogostruki. Starije generacije i druge kategorije primalaca zdravstvenih usluga često se teško prilagođavaju tehnološkom razvoju, pa su stoga isključene iz inovacija koje bi im mogle biti od koristi. Pitanje je da li je legitimno isključiti ljude iz usluga zato što ne mogu ili ne žele da koriste određene aplikacije, s obzirom na to da su SMS poruke su pogodne da se, što šire, dopre do svih delova stanovništva svake zemlje u borbi protiv bolesti.

II. Teorijski okvir i metode istraživanja

Razlozi za upotrebu komunikacije putem SMS poruka u oblasti zdravstva su višestruki, a same poruke se mogu podeliti u dve grupe, u zavisnosti od toga da li su jednosmerne (monološke) ili interaktivne (dijaloške). Jednosmerne poruke ne zahtevaju odgovor i obuhvataju podsetnike, motivacione poruke koje imaju za cilj da pruže podršku pacijentu ili da ga podstaknu na akciju. Dijaloške poruke predstavljaju interakciju lekar-pacijent u pisanom obliku i u najvećem broju slučajeva su nastavak komunikacije koja je započeta ili u ordinaciji kao razgovor licem u lice ili putem telefona, i kao takva odnosi se na praćenje stanja pacijenta, primenu i efekte terapije, analizu rezultata testova i ispitivanja i slično.

U skladu sa obimom ovog rada, prevashodno su razmatrane jednosmerne SMS poruke, odnosno koja jezička sredstva se koriste da bi se poruka prenela na najbolji mogući način. Naime, poruka mora da bude kratka i jasna, relevantna, fokusirana i razumljiva primaocu poruke. Komunikacija lekar/zdravstveni sistem-pacijent pripada institucionalnom diskursu (engl. *institutional talk*) gde je komunikaciona moć nejednako raspoređena. Heritidž [3] ističe da je jedna od osnovnih karakteristika institucionalne komunikacije asimetrija, koja se ogleda na više ravni, kao što su učešće u interakciji, odnos prema problemu, znanje, kao i pravo na posedovanje znanja. Drugim rečima, u medicinskom susretu lekar je taj koji ima profesionalno znanje i poseduje moć u komunikaciji. Međutim, kada se ova interakcija prenese u pisani oblik ta moć se polako gubi. U nedostatku neverbalne komunikacije i pravovremene reakcije (*feedback*) od strane pacijenta, lekar kao pisac SMS poruke mora da, pored svog stručnog znanja, uloži dodatni trud da kroz upotrebu odgovarajućih jezičkih sredstava obezbedi razumevanje, a samim tim i željeno tumačenje poruke i ostvarivanje planiranog cilja.

U komunikologiji se struktura poruke definiše kroz informaciju (novostečeno znanje) i redundantni sadržaj, odnosno postojeće znanje bez kog razumevanje ne bi bilo moguće. Koristeći kvalitativne metode analize konverzacije [4, 5], a uzimajući u obzir osnovne principe kritičke analize diskursa [6], induktivnim pristupom opisaćemo jezičke elemente koje smo uočili u primerima kratkih poruka.

III. Studije slučaja

TMI se može koristiti u različitim vrstama intervencija mobilnog zdravlja. Poruke se kategorizuju prema različitim kriterijumima: komunikacija o promeni ponašanja (npr. podsetnici za preglede i lekove, promocija zdravlja kao što je prestanak pušenja, mobilizacija zajednice); prikupljanje podataka ili informacija (npr. prikupljanje i izveštavanje o zdravstvenim informacijama i pružanje usluga, praćenje vitalnih događaja, kao što su epidemije); upravljanje logistikom ili lancem snabdevanja (npr. obezbeđivanje osnovnih zaliha i lekova na zalihama u različitim zdravstvenim ustanovama). Mnoge studije ukazuju na to da TMI značajno poboljšava različite situacije u zdravstvu, kao što su uzimanje lekova, prisustvo lekarskim pregledima i ishode promene ponašanja, samokontrolu dijabetesa, prestanak pušenja, gubitak težine, povećanje fizičke aktivnosti.

Nažalost, zdravstveni sistemi u Republici Srbiji, kako državni tako i privatni, veoma malo koriste SMS komunikaciju sa korisnicima svojih usluga. Zapaženo je pojedinačno angažovanje lekara na društvenim mrežama (*Twitter*, *Facebook*), koji direktno odgovaraju na zdravstvena pitanja svojih pratilaca. Međutim, kako i dalje veliki deo stanovništva ne koristi društvene mreže, ovim radom mi želimo da ukažemo na potrebu i značaj uspostavljanja SMS komunikacije na institucionalnom nivou, kao najpogodnijeg vida komunikacije koji može da dopre do najvećeg broja korisnika. Takođe, paralelno sa razvojem tehničke podrške, potrebno je ukazati lekarima na specifičnosti jezičke upotrebe u medijumu kakav je SMS komunikacija, s obzirom na jezgrovitost i preciznost kratkih poruka, kao i na specifična obeležja pisanog jezika u odnosu na govor.

Kao ilustraciju, uzećemo za primer poruku – poziv na vakcinaciju - koju je poslao Institut za javno zdravlje Srbije „Dr Milan Jovanović Batut” 16. novembra 2021. godine. Ovo je prva SMS poruka koju je neki zdravstveni sistem poslao svim građanima Srbije, angažujući sve mobilne operatere koji su

 ISBN 978-86-7466-930-3

poruku poslali svojim korisnicima. Prvo što možemo uočiti jeste da ova poruka nema epistolarnu formu, koja je tipična za SMS poruke prilikom prvog obraćanja. Dakle, nema uspostavljanja kontakta u formi oslovljavanja. Zanimljiva je i upotreba lične deikse (grč. *deixis=pokazivanje, ukazivanje*), lingvističke kategorije koja označava skup jezičkih elemenata koji upućuju na lica, odnosno na učesnike u komunikacionom činu [8]. Ovde je lična deiksa iskazana upotrebom *inkluzivnog mi* (govornik i sagovornik), odnosno glagolima u prvom licu množine: *„borimo se"* i *„imamo"*. Direktnim obraćanjem u drugom licu jednine, što je u skladu sa suštinski ličnom prirodom SMS komunikacije, bilo upotrebom lične zamenice „*Tvoja vakcina čeka na tebe"* ili imperativa *„Dođi, vakciniši se i pridruži se"*, uspostavlja se bliskost i osećanje empatije. Na tri mesta u poruci upotrebljen je oblik superlativa prideva: *„najjače oružje", „u najbližem domu zdravlja", „prema sebi i svojim najbližima"*. Umesto pozdrava, poruka završava pozivom na akciju *„Na tebe je red."*. Dakle, poruka je napisana veoma biranim jezičkim sredstvima koja imaju za cilj da izvrše emocionalni i psihološki uticaj na primaoce poruke i da ih podstaknu na delovanje.

Na sajtu Svetske zdravstvene organizacije (*WHO – World Health Organization*) nalazi se dokument sa svim SMS porukama koje je ova organizacija pripremala u skladu sa epidemiološkim okolnostima izazvanim COVID-19. Zemlje članice SZO su pozvane da prevedu poruke sa engleskog jezika na svoj jezik, da prilagode sadržaje poruka i da ih distribuiraju svom stanovništvu i na taj način iskoriste prednosti elektronske komunikacije kako bi spasili živote od ove zarazne bolesti. Na listi se nalazi 50 SMS poruka koje su grupisane tematski (prevencija, simptomi, samoizolacija, mentalno zdravlje, itd.).

Sintaksička struktura ovih poruka je jednostavna, uglavnom su to naporedne rečenice u kojima su nosioci značenja glagoli u imperativu, glagolskom načinu koji ima za cilj da iskaže sugestiju, molbu, zapovest, zabranu i slično. Izrazima poput *'wash your hands; avoid touching your eyes; cover your mouth; dispose of used tissues; keep 1 meter distance; be active; quit smoking to reduce your risk; have fun; contact your friends and family*' na jasan, koncizan i sugestivan način ostvaruje se komunikaciona namera poruke.

Uočili smo i određeni broj uslovnih i namernih zavisnih rečenica, kojima se dodatno ističe odgovornost primaoca poruke ukoliko se ne ponaša u skladu sa preporukama. U najvećem broju poruka, pošiljalac se direktno obraća primaocu poruke, osim u slučajevima kada se sadržaj odnosi na posebne kategorije stanovništva (deca, stariji ljudi, ljudi sa invaliditetom) i tada se o njima govori kao o „trećoj strani".

Ako analiziramo SMS poruke koje Istitut za transfuziju krvi Srbije po potrebi šalje na više adresa, možemo uočiti kako se pažljivim izborom leksike pozivaju potencijalni davaoci krvi na ovaj humani gest. Rečima i sintagmama, kao što su *„pokažimo solidarnost", „Da život pobedi!", „Sreća je veća kada se deli sa drugima!"* primaoci poruka se podstiču na akciju. Iz teksta objavljenog na sajtu BudiDavalacKrvi, napisanog prema izvorima iz časopisa *ScienceAlert* i *The Independent*, saznajemo da je i u razvijenim zemljama poput Velike Britanije i Švedske, zbog pada u broju novih davalaca krvi, razvijen automatizovani servis za tekstualne poruke sa ciljem da podstakne stanovništvo da donira i nastavi sa doniranjem krvi, i da ih obaveštava tačno kada je njihova krv upotrebljena za lečenje pacijenta.

IV. Zaključak

U želji da dopru do što većeg broja korisnika, zdravstveni sistemi u svetu opredeljuju se za komunikaciju SMS porukama jer su zbog dometa i veze sa internetom sigurniji da će poruka biti primljena, ali i pročitana, s obzirom da se uopšteno govoreći manje razmenjuju SMS poruke u odnosu na komunikaciju pomoću aplikacija kao što su *Viber* ili *WhatsApp*. Multimedijalnost, odnosno vizuelni aspekat komunikacije zamenjuje ili dopunjuje tekstualne SMS poruke kada postoji potreba da se slanjem slike postigne bolje razumevanje i efekat sadržaja poruke.

Komunikacija lekar-pacijent je složena interakcija koja, pored ispunjenja različitih zahteva, podrazumeva razumevanje emocionalnog stanja pacijenta. Zbog toga je važno povećati svest lekara o tome kako njihove negativne emocije mogu uticati na pacijente, što se ogleda u njihovim stavovima prema pacijentima, ali i u načinu na koji ih pacijenti doživljavaju.

Medijum SMS komunikacije je, sam po sebi, ograničen u mnogim aspektima i zahteva dobro promišljenu i oblikovanu poruku koja će biti na odgovarajućem nivou razumevanja ciljne grupe pacijenata (*health literacy*). Upravo zbog toga, potrebno je posvetiti više pažnje pragmatičkoj analizi jezika kratkih poruka. Pragmatička perspektiva diskursa je posebno usmerena na one aspekte diskursa koji su iako nenapisani ili neizrečeni, uspešno komunikativno preneseni [8]. Buduća istraživanja upotrebe jezika kratkih poruka u oblasti mobilnog zdravstva trebalo bi da predlože različita jezička i nejezička semiotička sredstva kojima se mogu izraziti stavovi, namera i odnos prema sagovorniku, odnosno da definišu lingvističke i diskursne strategije koje bi lekari mogli da koriste u cilju uspešnije komunikacije sa svojim pacijentima.

U zemljama sa više jezika, pismenost može da varira u zavisnosti od jezika, a neophodna su razmatranja u vezi sa odgovorima na više jezika. Jedinstvena razmatranja i prilagođavanja mogu biti neophodni ako se koristi nelatinično pismo na telefonima. Iako postoje relativno napredni softverski alati za obradu prirodnog jezika, odnosno za tumačenje jezika kao što je engleski, mnogo manje alata je razvijeno za autohtone jezike [9]

ABSTRACT

On the Potential of SMS Text Messaging in mHealth

Gordana Jelić, Danica Mamula Tartalja, Enis Osmani

Good communication among participants in health care is one of the basic preconditions for positive outcomes of various interventions in this area. Text messaging or Short Messages Service (SMS), or an alphanumeric message of 160 characters or less, is one of the most commonly used mobile health tools. This paper aims to present a brief review of contemporary studies and literature on the use of SMS messages for health purposes, focusing on the pragmatic aspect of the discourse of short messages. Analyzing examples of messages at the grammatical, lexical and communicative level, we point out the language tools that representatives of the health system (doctors, institutions) use to achieve the desired interpretation of the message and achieve the effect on the target group. By using effective ways to improve the modality of linguistic expression, short message communication goes beyond the technological limitations of this communication medium.

Key words: mobile health, communication, SMS

Forenzičke metode za identifikaciju lica: juče, danas, sutra

Snežana Stojičić, Radovan Radovanović, Nataša Petrović i Milesa Srećković

Apstrakt—**Identifikacija lica je bila, jeste i biće izazov za oji se ontinuirano nalaze rešenja koja pružaju tehnološki odgovor u ovoj oblasti, posebno zasnovanih na upotrebi biometrijs ih podata a u ele trons om obli u i primene principa i is ustava najbolje pra se ele trons og poslovanja uopšte. potreba podata a u ele trons om obli u, smeštenih u određenim bazama podata a, sredstava ele trons e komunikacije i elektronske obrade velike količine podataka u obavljanju poslovnih procesa identifi acije lica je evidentno u porastu, ao odgovor na izazove oje ele trons o poslovanje donosi, neophodno je usaglašavanje razvoja normativnog o vira ako u domenu povećanja efikasnosti poslovanja ta o i izazova oje digitalna era sa sobom nosi. Izazov, sa forenzičkog aspekta, kao odgovor na potencijalno narušavanje i nepoštovanje pravnih normi, uslovljava razvoj i primenu novih procedura i alata u ovoj oblasti. Danas je evidentna potreba stalnog praćenja razvoja i primene novih metoda za identifi aciju lica, a posebno onih, oje mogu biti vezane za forenzičke aspekte u digitalnom svetu. Predmet razmatranja su upravo ova pitanja, oja se odnose na izazove u identifi aciji lica u digitalnoj eri.**

***Ključne reči*—Forenziče metode; idetifikacija lica; biometrijs i podaci.**

I. Uvod

Za sisteme za biometrijsku identifikaciju se može reći da imaju više generacija, koje se zasnivaju na tehnološkim rešenjima, odnosno prate razvoj tehnologije, koja uslovljava i omogućava identifikaciju lica zasnovan na biometrijskim podacima. Savremeno digitalno okruženje, stvara nove izazove i mogućnosti za počinioce krivičnih dela, ali i službe, koje utiču u rasvetljavanju istih. Tako proces digitalizacije i modernizacije poslovnih procesa, neophodno prati i razvoj adekvatnog odgovora sa aspekta primene metoda za identifikaciju lica sa aspekta forenzike.

II. Prve generacije biometrijskih tehnologija

Biometrijske tehnologije prve generacije bile su fokusirane na jaku biometriju i jedinstvenost identifikacija ili autentikacija određenih pojedinaca (fizičkih lica). Prvi slučajevi upotrebe velikih razmera, počeli su kasnih 1990-ih u SAD, sa povećanjem primene posebno posle uvođenja biometrijskih pasoša, koji sadrže otiske prstiju, fotografiju i podatke o licu. Od tada, biometrijske tehnologije su postale robusnije i naprednije, značajno smanjujući stope grešaka uz pomoć razvoja računarske tehnologije i primenjenih rešenja, a naročito u tehnologijama za prepoznavanje lica.

Prve primene biometrije i razvijenih alata za brzu i pouzdanu identifikaciju ili autentikaciju, našle su širok spektar konteksta primene, uključujući potrebe sprovođenja zakona. Primena se zayim proširila i na privatni sektor, uključujući rešenja kao što su ona za otključavanje pametnih telefona ili prepoznavanje VIP-a kupaca. Rešenja zasnovana na biometriji u nekim slučajevima zamenjuju tradicionalne lozinke, posebno imajući u vidu da sa najnovijim tehnologijama za prepoznavanje lica moguća je identifikaciju za manje od jedne sekunde.

Ne manji značaj imaju i takozvane “slabe” biometrijske metode, kao biometrijske metode druge generacije, kao što su motoričke veštine, osobenosti položaja tela, hod i način interakcije sa okruženjem [1]. Ova druga generacija biometrije se naziva i „biometrija ponašanja“, jer je digitalno fizičko i kognitivno ponašanje ljudi analizira, a ne relativno statičke karakteristike, kao što su otisci prstiju. Posebno je od interesa, to što druga generacija biometrijskih sistema, pruža nove mogućnosti automstizacije poslovnih procesa u organima za sprovođenje zakona, vršenju granične kontrole, omogućavajući, na primer, otkrivanje lica sumnjivog ponašanja koje bi moglo da ukaže na nameru da počini krivično delo.

Da bi se povećala tačnost, biometrijske tehnologije prve generacije se redovno kombinuju u multimodalne sisteme. Ovi sistemi kombinuju nekoliko biometrijskih identifikatora za identifikaciju jedne osobe. Multimodalni sistemi mogu minimizirati rizike od pojave grešaka i pomoći u prevazilaženju poteškoća uzrokovanih lošim kvalitetom podataka ili podacima koji nedostaju, istovremeno povećavajući mogućnosti i u drugim aspektima, kao što je etički.

Tehničko tehnološki napredak omogućava sve veću primenu sistema video nadzora, kojima se omogućava upotreba biometrijskih tehnika i veštačke inteligencije za identifikaciju lica u javnim prostorima, što implicira potrebu da se striktno reguliše upotreba ovih sistema. Napredak tehnologije i potreba za normativnim uređenjem primene savremenih tehnoloških rešenja predstavlja stalni izazov, posebno imajući u vidu komparativnost ovih oblasti korišćanja biometrije, kako na nacionalnom, tako i na međunarodnom planu.

 ISBN 978-86-7466-930-3

Pošto su aktivnosti mozga merljivi biološki signali, one se takođe smatraju biometrijskim. S obzirom na poteškoće u hvatanju elektrohemijskih signala mozga i njihovu složenost, relevantnost moždanih aktivnosti je dugo vremena bila ograničena na medicinski sektor. Međutim, poslednjih godina, elektroencefalografija (EEG), koja snima električne aktivacije mozga postavljanjem elektroda na skalp i takozvani interfejsi mozak-kompjuter (BCI), koji mogu da prevedu aktivnost mozga u mašinski čitljivi unos, postali su pristupačniji [2] i čak su integrisani u proizvodima širo biometrijske autentikacijeke potrošnje[1].

III. Dalji pravci razvoja metoda identifikacije lica

Predlog regulatornog okvira o veštačkoj inteligenciji[2], Evropska komisija je usvojila u prvoj polovini 2021. godine, kao novi pravni okvir za primenu veštačke inteligencije. Predlog uredbe ima za cilj da programerima, onima koji koriste veštačku inteligenciju i korisnicima, pruži jasne zahteve i obaveze u vezi sa specifičnom upotrebom AI[3]. U isto vreme, predlog uredbe obuhvata i aspect usmeren ka smanjenju administrativnih i finansijskih opterećenja za preduzeća, posebno za mala i srednja preduzeća (MSP) [3, 4].

Predlog je deo šireg paketa, koji se odnosi na veštačku inteligenciju, a koji je posvećen jačanju, prihvatanju, ulaganju i inovacijana u oblasti AI u EU.

Zašto su nam potrebna pravila o AI? Predloženi propis o veštačkoj inteligenciji obezbeđuje da se izgradi poverenje u ono što veštačka inteligencija može da ponudi. Dok većina sistema veštačke inteligencije predstavlja ograničen rizik i može doprineti rešavanju mnogih društvenih izazova, određeni sistemi veštačke inteligencije stvaraju rizike, koji se moraju rešavati, kako bi se izbegli neželjeni ishodi.

Važno je istaći da iako postojeće zakonodavstvo pruža određeni okvir, procenjuje se da je nedovoljno da se odgovori na specifične izazove, koje donose sistemi veštačke inteligencije.

Predložena pravila će se baviti rizicima, koje posebno stvaraju AI aplikacije, predložiti listu visokorizičnih aplikacija, postaviti jasne zahteve za AI sisteme za aplikacije visokog rizika; definisati posebne obaveze za korisnike veštačke inteligencije i provajdere visokorizičnih aplikacija; predložiti ocenu usaglašenosti, pre nego što se sistem veštačke inteligencije stavi u upotrebu ili stavi na tržište; predložiti način praćenja pošto se takav AI sistem stavi na tržište; i predložiti strukturu upravljanja na evropskom i nacionalnom nivou [4].

Opis stanja biometrijskih tehnologija sa aspekta EDPS[4] (European Data Protection Supervisor), indukuje da broj uređaja koji se primenjuju za obradu biometrijskih podataka raste neverovatnom brzinom. Mnogi pametni telefoni koriste slike lica i otiske prstiju za autentikaciju svojih korisnika. Virtuelni glasovni asistenti obrađuju glasovne podatke kao odgovore na zahteve korisnika. Sistemi video nadzora mogu se koristiti za identifikaciju ili klasifikaciju pojedinaca/lica. Pametni satovi i fitnes narukvice mogu pratiti i obrađivati podatke o fiziološkom statusu (kao što su otkucaji srca i navike spavanja). Sistemi video nadzora su imali značajnu ulogu i sa aspekta pandemije COVID-19, podrška korišćenju prepoznavanja lica i veštačke inteligencije za praćenje socijalnog distanciranja ili pravilne upotrebe maski za lice, kao i upotrebe osetljivih termovizijskih kamera i prepoznavanja lica, koja se mogu na osnovu povišene temperature identifikovati, kao potencijalno zaražen, korona virusom.

Poseban domen primene i korišćenja biomtrijskih podataka čine informacioni sistemi velikih razmera, kao što su tri velika IT sistema u oblastima azila i migracija, koji su trenutno operativni i uključuju korišćenje biometrijskih podataka: Vizni informacioni sistem (VIS), Šengenski informacioni sistem (SIS II) i EURODAC (European Asylum Dactyloscopy Database), sistem koji obrađuje podatke o tražiocima azila.

Pored toga u pripremi su, još tri nova evropske informaciona sistema, velikih razmera, od kojih će dva obrađivati biometrijske podatke: Ulazno-izlazni sistem (EES) i Evropski informacioni sistem krivičnih evidencija za državljane trećih zemlja (ECRIS-TCN). Iako su ovi informacioni sistemi razvijeni nezavisno, nova regulativa interoperabilnosti[5], definiše četiri osnovne komponente interoperabilnosti koje bi trebalo da omogućavaju međusobnu interakciju. Među njima, i rešenje za zajedničko upoređivanje biometrije - (sBMS) odnosno otisaka i slika lica kroz različite sisteme [5].

Međutim, uz očekivan porast primene, važno je paralelno sprovoditi i aktivnosti na podizanju svest o izazovima koje biometrijske tehnologije donose, a posebno sa aspekta izgradnje poverenja u tehnološka rešenja [6].

Takođe, javljaju se izazovi i nove mogućnosti zloupotreba novih tehnologija, kao što je kompanija koja se bavi obradom fotorgafija lica, Clearview AI, koja je preuzela oko 3 milijarde slika, prikupljenih sa miliona web lokacija, uključujući Fejsbuk, Tviter i Jutjub, i prodaje svoje usluge organima za sprovođenje zakona, ili poljska platforma PimEyes, koja je na sličan način došla do podataka i koristi ih za sticanje dobiti [7,8]. Povećana upotreba biometrijskih podataka uz nemogućnost promene fizioloških osobina, donosi povećanu zabrinutost za bezbednost biometrijskih podataka.

Ukoliko se u razvoju Sistema yasnovanih na biometrijskim podacima ne primenjuju odgovarajuće mere zaštite, posledice povrede ličnih podataka mogle bi biti veoma ozbiljne. Upravo iz tog razloga, nastali su međunarodni standardi, kao što su ISO/IEC 24745 ISO/IEC 24745:2011 Information technology — Security techniques — Biometric information protection i standard u oblasti mehanizama zaštite biometrijskih šablona (BTP), a aktuelnost potvrđuje ISO/IEC 24745:2022, Information security, cybersecurity and privacy protection — Biometric information protection, revizija koja pokriva zaštitu biometrijskih informacija pod različitim zahtevima za

 ISBN 978-86-7466-930-3

poverljivost, integritet i obnovljivost/opoziv, tokom skladištenja i prenosa. Standard identifikuje zahteve i daje preporuke za bezbedno upravljanje i obradu biometrijskih informacija u skladu sa pravilima privatnosti[6].

Međutim, neizvesno je u kojoj meri, se pri razvoju biometrijskih sistema prate i primenjuju standard. S obzirom da je otkriveno da je postojao pristup preko 27,8 miliona zapisa nezaštićenih i uglavnom nešifrovanih[7], a da za razliku od kompromitovanja lozinki, kada se to dogodi sa otiscima prstiju, ne postoji mogućnost da promenite otisak prsta. Baza podataka se odnosila na Biostar 2, system, koji je razvila kompanija za obezbeđenje Suprema [8, 9].

Početkom marta 2022. godine objavljeno je da je Samsung potvrdio kršenje bezbednosti pošto što su hakeri pristupili i preuzeli skoro 200 gigabajta poverljivih podataka, uključujući izvorni kod za različite tehnologije i algoritme za operacije biometrijskog otključavanja. Hakerska grupa Lapsus, preuzela je odgovornost i objavila da su preuzeli izvorni kod koji Samsung telefoni koriste za obavljanje osetljivih operacija, algoritme za sve otključavanje na osnovu biometrije [10].

Osetljiva priroda biometrijskih podataka prepoznata je i u okviru pravnog okvira EU, kao i u okviru Modernizovane konvencije Saveta Evrope 108+, podleže posebnoj zaštiti i može se reći da je obrada biometrijskih podataka zabranjena u principu i postoji samo ograničen broj uslova pod kojima takva obrada je zakonita, tako da u okviru svojih zadataka nadzora i sprovođenja, EDPS sprovodi između ostalog i redovne revizije velikih IT sistema EU.

Svakako, prethodno pitanje pre svake primene, treba da bude vezano za procenu neophodnosti i proporcionalnosti. Ne treba da koristimo savršen system, koji nam nije potreban ili koji obrađuje biometrijske podatke na nesrazmeran način. Obrada biometrijskih podataka treba striktno da se pridržava principa ograničenja svrhe. Ograničenje svrhe je posebno relevantno u ovom kontekstu, zbog tipova biometrijskih podataka, koji omogućavaju zaključivanje o drugim ličnim podacima.

Prilokom obrade biometrijskih podataka preporučljivo je u potpunosti primenjivati princip minimalizacije prikupljanja podataka. Prilikom procene koje biometrijske tehnologije koristiti, potrebno je ograničiti obradu biometrijskih podatka, na ono što je neophodno za ostvarivanje određenog zadatka. Uvažavajući činjenicu da bi multimodalni biometrijski sistemi mogli biti sigurniji i tačniji od običnih biometrijskih sistema, takva vrsta obrade koja uključuje više biometrijskih podataka donosi i veće rizike za osnovna prava pojedinaca. Kada se razmatra obrada više od jedne vrste biometrijskih podataka, potrebno je, proceniti njihovu neophodnost i proporcionalnost, balansirajući očekivane koristi sa rizicima.

Poverenje u biometrijske sisteme, zahteva tačnost, jasanoću i direktan pristup u saopštavanju prednosti i ograničenja svake biometrije tehnologije, predstavljanje mogućnosti i rizika. Percepcija javnosti o rizicima je razlog zašto milioni korisnika dobrovoljno odlučuje da koriste biometrijske podatke za autentikaciju kada koriste svoje pametne telefone, dok je sve veće protivljenje upotrebi biometrijske identifikacije u javnim prostorima.

Podaci, kao što su otisci prstiju i DNK, generalno su jedinstveni za pojedinca i tako mogu potvrditi nečiji identitet i prisustvo na mestu zločina, odnosno imati forenzički značaj. Takođe, može pomoći da se dokaže nevinost osumnjičenog. Posebno na međunarodnom nivou, forenzički podaci mogu se koristiti i za povezivanje niza transnacionalnih krivičnih dela, imajući u vidu da se otisci prstiju mogu brzo proveriti, naročito, ako osumnjičeni prelazi granicu. Ne manji značaj, imaju ovi podaci, sa aspekta korišćenja za identifikaciju žrtava velikih katastrofa.

Najbrži razvoj, ostvaren je u oblasti identifikacije na osnovu prepoznavanja fotografije lica i time otvara mnoge nove mogućnosti, za identifikaciju pojedinaca i pronalaženje počinioca krivičnih dela. U ovom smislu forenzička ekspertiza i podaci su od vitalnog značaja za sprovođenje istraga na nacionalnom nivou, kao i ostvarivanje učešća u međunarodnim istragama u skladu sa normativnim okvirom i nadležnoatima [9].

Posebna oblast primene su biometrijske autentikacije, kao siguran i praktičan alternativni način autentikacije putem lozinki. Međutim, i u ovom, slučaju, pojavljuju se izazovi, koje je potrebno imati u vidu, kao što je očuvanje privatnosti lica, obezbeđivanje bezbednosti i poverljivosti biometriskih podataka pri prenosu i skladištenju, kao i činjenica da se za razliku od lozinki biometrijske osobine ne mogu poništiti i ponovo je izdati. Ukoliko dođe do kompromitovanja, korišćenog biometrijskog podatka, s obzirom da se ne može promeniti, isti se ne može dalje korisititi u svrhu autentikacije [11]. U ovom smislu Cloud tehnologija može da iskoristi prednosti biometrijske tehnologije i obrnuto. Biometrija sa svojim jakim svojstvima autentikacije, može da se iskoristi da poboljša bezbednost Cloud sistema i ponudi novi modeli usluga (tj. biometrijska autentikacija kao jedna od usluga u Cloud-u. S druge strane, Cloud omogućava svojim resursima fleksibilnosti, skalabilnost i smanjenje troškova za rad biometrijskih Sistema (tj. procesorsku snagu ili skladištenje podataka), kao i da omogući poboljšanje performansi biometrijskih sistema [11].

Standardi omogućavaju efikasan razvoj biometrijskih sistema, uspostavljanjem zajedničkih kriterijuma i postavljanjem smernica za zaštitu privatnosti (Eversheds Sutherland, 2022). Sporazumi o formatima podataka i interfejsima aplikativnog softvera mogu pomoći će da se smanje troškovi razvoja sistema. Razvoj standarda za primenu biometrije i za testiranje tačnosti, doprinosi razjašnjavanju ranjivosti i usmerava ka pronalaženju rešenja.

Imajući u vidu da ljudska faktor i slabe lozinke, prema proceni iz Imageware analize, čine 52% narušavanja bezbednosti podataka, što se može smatrati indikatorom potrebe da se tradicionalne metode autentikacije zamene novijom biometrijskom tehnologijom, kao što su specijalizovani hardverski senzori u mobilnim telefonima, skeneri otiska prsta, kamere za prepoznavanje lica (2D/3D) ili

[6] https://www.iso.org/

[7] https://www.securitymagazine.com/articles/90731-more-than-27-million-biometric-records-exposed-in-a-public-database

 ISBN 978-86-7466-930-3

prepoznavanje irisa oka [11]. Biometrijske tehnologije postaju sve popularnije, posebno sa pojavom dvofaktorske autentikacije za *online* usluge. Pregled prednosti i nedostataka multifaktorske autentikacije dat je u Tabeli 1. Na osnovu analiza tržišta procenjuje se da će se u narednim godinama tržište biometrijskih tehnologija dostići 55,42 milijarde dolara do 2027. godine, tržište kamera za video nadzor sa procenama predviđanja rasta na 44 milijarde dolara do 2025. godine [11].

TABELA I
MULTIFAKTORSKA AUTENTIKACIJA ZA I PROTIV (PRATT, 2021)

Prednosti	**edostaci**	**ere**
Teško se hakuju ili repliciraju	Nepovratna neopozivost u slučaju kompromitovanja	Više faktora je dostupno za MFA
Konformno za korisnike	Povećan rizik od zloupotrebe	Zahteva povećane mere zaštite
Manja zavisnost od medija	Značajne investicije za velike sisteme	Minimalizacija podataka
Manja zavisnost od mrežne povezanosti	Novo i nedovoljno dokazano u praksi	Raspodela rizika
Proširivost novim elementima	Pristrasnost, greške, lažno pozitivni rezultati	Edukacija i uključenost korisnika

Svedoci smo porasta upotrebe biometrijskih tehnologija za različite oblasti primene, ovakav napredak otvara i nove mogućnosti za dalja istraživanja i razvoj. Posebno imaju se u vidu niz fundamentalnih otvorenih pitanja i izazova kojima će se baviti istraživanja u oblasti primene biometrije u svim sverama savremenog života [12-15].

To svakako prati i aspekt bezbednosti, pošto je sve više podataka u opticaju, u digitalnom obliku, uključujući biometrijske podatke, koje pojedinci ostavljaju na web-u i u ličnim elektronskim uređajima, kao što su pametni telefoni i drugi mobilni uređaji. Posebno, imajući u vidu dostupnost digitalnih senzora i kapacitet uređaja za skladištenje podataka, i tu je i činjenica da se identifikacije osoba sve više zasnivaju na digitalnim procesima [16].

IV. ZAKLJUČAK

Osim što su univerzalne i jedinstvene, biometrijske karakteristike treba da budu relativno trajne i lake za prikupljanje i korišćenje. Biometrijski sistem treba da bude u mogućnosti da pruži što tačnije rezultate u različitim okolnostima i uslovima. Svakako važan, a možda i najvažniji aspekt biometrijskog sistema je prihvatanje od strane javnosti. Iako se DNK smatra konačnom biometrijom za identifikaciju osobe (osim jednojajčanih blizanaca), podudaranje DNK je previše invazivno za široku upotrebu u autentikaciji identiteta. Termografija lica, koja otkriva toplotne obrasce, koje stvaraju krvni sudovi i emituju iz kože, nije invazivna metoda, ali je cena previse visoka. Među biometrijskim podacima koji se trenutno razmatraju za buduću primenu su puls, miris tela, sastav kože, šara noktiju, hod i oblik uha. Potrebno je više istraživanja za dalju ocenu prihvatljivosti za širu upotrebu.

Sistem, koji se koristi, treba da bude siguran, obezbeđuje privatnost i daje tačne rezultate. Sistem koji je nesiguran, nepouzdan ili invazivan, s druge strane, može doprineti narušavanju poverenja javnosti, što na kraju može dovesti do otpora u prihvatanju tehnika biometrijskog prepoznavanja. Ključna strategija u garantovanju odgovarajućeg izbora i upotrebe biometrijskih metoda je razvoj međunarodnih standarda. Tokom poslednje decenije, napravljen je ogroman napredak u poboljšanju biometrijskih senzora, algoritama i procedura, ali i dalje, postoje slabosti i ranjivosti, koje treba rešavati. Potreba za zaštitom privatnosti i čuvanjem osetljivih biometrijskih podataka, ostaje i dalje fundamentalna.

ZAHVALNICA

Aurori se zahvaljuju organizacionom odboru konferencije ETRAN 2022 na prepoznatom značaju oblasti forenzike, prostoru i vremenu datom za izlaganje i diskusiju.

ABSTRACT

Identification of persons has been, is and will be a challenge for conductiong, as question which solutions best fit to the purpose and is it provided technological response on adequate level. Especially this one based on the use of biometric data in electronic form and application of principles and experiences of best e-business practice in general. The use of data in electronic form stored in certain databases, issues of electronic communication and electronic processing of large amounts of data in performing business identification processes is evidently increasing, in response to the challenges of e-business, it is necessary to harmonize the development of normative framework as well the business efficiency are the challenges that the digital age brings. Challenges from the forensic aspect in response to potential violations and non-compliance with legal norms, which requires the development and application of new procedures and tools in this area. There is also an evident need for constant monitoring of the development and application of new methods for personal identification, especially those that may be related to forensic aspects in the digital world. The subject of consideration are precisely these issues that relate to the challenges in identifying persons in the digital age.

Sigurnosni uređaji za proveru oružja u funkciji forenzičko-balističkih ispitivanja

Kristijan Đujić, Radovan Radovanović, Saša Milić, Martin Matijašević, Aleksandar Ivković

Apstrakt—Sigurnosni uređaji za proveru oružja tzv. "hvatači projektila" namenjeni su bezbednom proveravanju različitih vrsta vatrenog oružja i dizajnirani su, pre svega, za zaposlene u sektoru bezbednosti. Ovi uređaji sastoje se iz metalne konstrukcije dizajnirane za minimiziranje olova u vazduhu, rampe niskog ugla, kružne komore i posude. Njihova konstukcija sadrži posebnu bezbednosnu funkciju koja sprečava da oružje eksplodira prema licu korisnika. Čak i ako korisnik ispaljuje projektil pod uglom, sve prisutne osobe u okruženju će biti bezbedne. Povratni udarni talas se kreće turbulentno unutar sigurnosnog uređaja za proveru oružja, a plamen se preusmerava od korisnika koji vrši opaljivanje. Sistem hvatača uključuje rampe sa malim uglom koje odbijaju projektil umesto da ga razbijaju, minimizirajući olovnu prašinu. Projektil se odbija o kružnu komoru za usporavanje, gde usporava sve do zaustavljanja. U funkcionalnom smislu sigurnosni uređaj za proveru oružja se može postaviti na sto ili zid u bilo kojoj prostoriji, pa je idealan za laboratorijska ispitivanja. U radu se analiziraju karakteristike sigurnosnih uređaja za proveru oružja kroz forenzički eksperiment sproveden na modelu kompanije *Savange Range systems GT Tabletop Gunsmith* u cilju utvrđivanja potencijala za primenu u forenzičkim i balističkim ispitivanjima.

Ključne reči — Forenzička ispitivanja; balistička ispitivanja; putanja projektila; bezbednost; vatreno oružje; fizički pregled; klasifikacija; probna paljba.

I. UVOD

TEORIJSKO razmatranje problematike forenzike, balistike i razvoja sprava za merenje i registraciju u fokusu je različitih naučnih disciplina. Prva knjiga o forenzičkoj medicini objavljena je davne 1400. godine u Kini [1], značajne su i naučne analize Leonarda da Vinčija usmerene na let projektila i međuzavisnost dužine i prečnika cevi. I dalje su kao osnov balistike od značaja razmatranja Nikolo Tartalja (1538. godine) koji zaključuje da slobodni let projektila nije pravolinijski, Galileo 1638. opisuje putanju leta kao parabolu, a Njutn 1684. uvodi u razmatranje i otpor vazduha. Tokom XVIII veka Francuz B. Belidor nalazi eksperimentalno da je najbolji odnos težine baruta i projektila 1:3, a Englez Bendžamin Robins stvara balističko klatno. Leonard Ojler rešava matematički sistem jednačina kretanja projektila, koji ima i danas značaj za brzine ispod 240 m/s. Ojler uvodi i sistem postupnog rešenja sistema jednačina po sukcesivnim lukovima, koji se koristi i danas. Tokom XIX veka uvodi se krešer za merenje pritiska gasova u cevi, i hronograf za merenje brzine projektila. Utvrđena je zavisnost sile baruta, gustine punjenja, i razvijenog pritiska gasova u komori konstantne zapremine poznata kao Ejbel-Noublov zakon. Nađen je i zakon otpora sredine, od kojih je Gavrov korišćen do Prvog svetskog rata. Italijan Anđelo Sijači sa razradama P. Šarbonijea daje metod rešavanja jednačina kretanja u konačnom obliku [2].

Od posebnog značaja u forenzičko-balističkim ispitivanjima i izvođenjima logičkih zaključaka je forenzička analiza materijala pronađena nakon ispaljivanja projektila. U Američkom građanskom ratu čuven je primer smrti generala Unije, Džona Sedžvika. On je prekorio svoje ljude, jer se savijao od snajperiste Konfederacije, koji se ispaljivao projektil sa udaljenosti od 1000 metara, a njegove poslednje reči bile su: "Sa ove razdaljine ne bi mogli ni slona da pogode", kada ga je pogodio projektil u glavu. Objašnjenje je pronađeno kada je projektil uklonjen iz njegove glave, odnosno, tada je otkriveno da je heksagonalnog oblika. Došlo se do zaključka da je mogao biti samo opaljen iz britanske puške Vitvort, oružja sposobnog za izuzetnu preciznost, za to vreme, i koja je prodata u velikom broju vojsci Konfederacije.

Prvi dokumentovani slučaj forenzičke balistike u Velikoj Britaniji zabeležen je 1835. godine. Tad je Henri Godard, službenik metropolitanske policije, istraživao ubistvo gde je žrtva upucana projektilom sa olovnom kuglom. Nakon pregleda pronađenog projektila, Godard je primetio trag od livenja koji je ostavio kalup koji je formirao olovni "projektil". Osumnjičeni je bio identifikovan, a kalup od projektila pronađen u njegovoj kući. Testiranje uzorka kalupa u poređenju sa tragovima livenja na pronađenom projektilu dozvolilo je Godardu da potvrdi da je smrtonosni projektil proizveden iz kalupa osumnjičenog. Osumnjičeni je osuđen za ubistvo.

U Velikoj Britaniji, ono što bismo sada prepoznali kao forenzičku balistiku, počelo je da se razvija 1920-ih kada su dva pionira, Robert Čerčil i major Džerald Barard, analizirali ispaljene metke i čaure sa ciljem da ih povežu sa sa određenim oružjem. Jedan od prvih slučajeva ubistva u Velikoj Britaniji, koje je rešeno primenom forenzičke balistike, je bilo zloglasno ubistvo PC Vilijama Gateridža 1927. godine. Robert Čerčil je uspeo da brzo uporedi metke sa pištoljem pronađenim u kući osumnjičenog. Iako su uporedni mikroskopi bili grubi prema današnjim standardima, fundamentalne postulate su dali rani pioniri na

 ISBN 978-86-7466-930-3

principima uporedne mikroskopije. Posle Drugog svetskog rata, Služba forenzičke nauke je objedinila sva ispitivanja vatrenog oružja u Engleskoj i Velsu. Ova služba je u velikoj meri zaslužna za postavljanje temelja za moderne forenzičko balističke preglede u Velikoj Britaniji. Ipak, iako je tehnologija imala uticaj na istraživački rad, omogućavajući na primer, brzo traženje projektila i čaura, većina forenzičkih balističkih radova dala je malo doprinosa od onog koji su Čerčil i Burard praktikovali pre skoro 100 godina [3].

Balistika je proučavanje projektila u letu. Ova reč je izvedena iz grčkog, ballein, što znači 'baciti'. Forenzička balistika je opšte prihvaćena naučno-tehnološko-istražna disciplina koja u opštem smislu predstavlja svaki naučni pregled koji se odnosi na vatreno oružje i koji se obavlja u cilju prezentovanja nalaza na sudu. Ovo obično uključuje davanje mišljenja o tome da li komponente municije mogu biti povezane sa oružjem koje ih je ispraznilo, utvrđivanje dometa vatre, identifikovanje ulaznih i izlaznih rana, tumačenje pričinjene štete pucnjavom i ispitivanjem mehaničkog stanja oružja. Ironično, računajući svojstva metka ili projektila u letu [4]. Osnovna podela balistike je na unutrašnju i spoljnu [5], dok je danas kao podgrana balistike razvijena kriminalistička (sudska) balistika, odnosno forenzička balistika.

Rešavanje osnovnog zadatka unutrašnje balistike podrazumeva primenu kompjuterskih programa. U sistem jednačina unutrašnje balistike (1-5), unose se osnovni podaci:

1. Karakteristike cevi
2. Karakteristike projektila
3. Karakteristike baruta.

Unutrašnjebalistički ciklus je opisan jednačinama energije, sagorevanja baruta i kretanja projektila:

$(1-T/Tv)fmb\psi/\Theta=\varphi MpV\ 2\ /2$ ..... (1)

$\Psi=\kappa 1z(1+\lambda 1z)$ ..... (2)

$\sigma=1+2\theta 1z$ ..... (3)

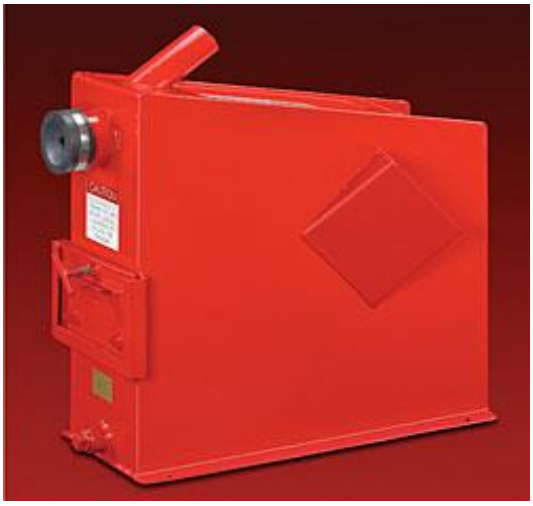
$u=de/dt=uo+pn+bk=uop$ ..... (4)

$\varphi Mpv(dv/dt)=sp$ ..... (5)

Gde je: φ[/] − koeficijent fiktivnosti; f[kJ/kg] − sila baruta; mb[kg] − masa baruta; Mp[kg] − masa projektila; ψ[/] – relativni deo sagorelog barutnog punjenja; z[/ −] relativna debljina sagorelog svoda; σ[/] − relativna sagorela površina baruta; κ1,λ1 − karakteristike oblika barutnog zrna; T[K] − temperatura barutnih gasova; Tv[K] − temperatura sagorevanja baruta pri konstantnoj zapremini; v[m/s] − brzina kretanja projektila; u[m/s] – brzina sagorevanja baruta; uo[m/s.bar] − jedinična brzina sagorevanja baruta; p[bar] − pritisak barutnih gasova; Θ=cp/cv-1; e[m] − svod barutnog punjenja; S[m 2] − površina poprečnog preseka kanala cevi oružja; n[/ − e] eksponent u izrazu za brzinu sagorevanja; bk[m/s] − konstanta u izrazu za brzinu sagorevanja [6].

U kontekstu forenzičko balističkih ispitivanja sprovedenih posredstvom sigurnosnih uređaja za proveru oružja može se ispitati [7]:

1. ponašanje oružja tokom procesa opaljenja
2. dužina trzanja
3. potpunost sagorevanja baruta
4. količina i boja dima
5. postojanje plamena na ustima cevi
6. jačina pucnja



II. KARAKTERISTIKE SIGURNOSNOG UREĐAJA ZA PROVERU ORUŽJA - MODEL GT GUNSMITH

Sigurnosni uređaj za proveru oružja *GT Gunsmith* je po konstrukcionim karakteristikama izdržljiva, jednostavna za upotrebu i samostalna jedinica sa osnovnom funkcijom hvatanja projektila. *Gunsmith* serija proizvođača *Savange Range* systems koristi *Vet Snail*® tehnologiju za minimiziranje olova u vazduhu. Rampe niskog ugla pomažu da se projektil skrene u kružnu komoru gde gubi energiju i pada u posudu za sakupljanje [8].

TABELA I
KARAKTERISTIKE MODELA GT GUNSMITH

Opis	Karakteristike
Proizvod	tabletop Gunsmith
Model	GT
Veličina	610mm visina; 280mm širina; 610mm dužina
Otvor zamke	prečnika 75 mm
Težina	70 kilograma
Upotreba	provera oružja

Uređaj je konstruisan od potpuno zavarene jednodelne konstrukcije i čeličnih tela, debljine 5mm. Unutar uređaja je komora za usporavanje za bezbedno i „čisto“ zaustavljanje projektila koje eliminiše opasnosti od olovne prašine. Dizajniran je za testiranje funkcija u neposrednoj blizini i jednostvana je za održavanje [9].

Sl. 1. Model GT Gunsmith

III. FORENZIČKI I BALISTIČKI POTENCIJAL MODELA GT GUNSMITH

Osnovna i primarna funkcija modela *GT Gunsmith* je u sposobnosti upoređivanja oružja korišćenog u izvršenju krivičnog dela, prazne čaure, projektile i municije. Eksperimentalnu proveru je potrebno realizovati s ciljem dobijanja stvarnih podataka o svojstvima sigurnosnog uređaja za proveru oružja modela *GT Gunsmith* u cilju utvrđivanja njegovih forenzičkih i balističkih potencijala.

 ISBN 978-86-7466-930-3

Eksperiment je realizovan u laboratorijskim uslovima, opaljivanje je izvršeno iz pištolja Zastava CZ 99, kalibra 9mm.

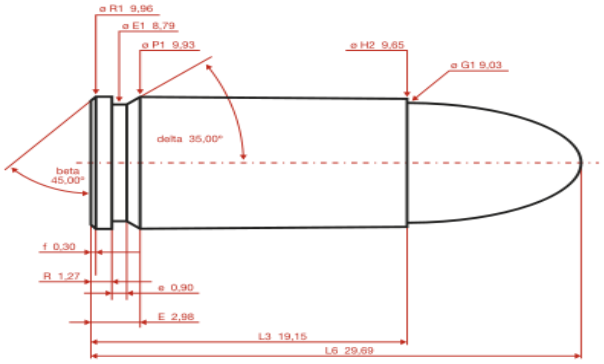


TABELA II
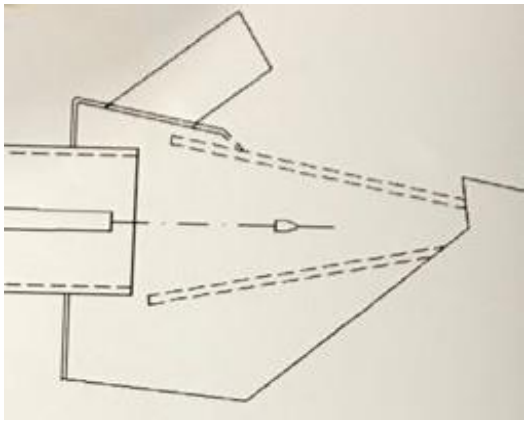
TEHNIČKI PODACI MODEL CZ 99

Opis	Tehnički podaci
Kalibar	9mm
Dužina	190mm
Visina	140mm
Debljina preko korica	37mm
Masa bez okvira	860gr.
Masa - prazan okvir	965gr.
Masa - pun okvir	1145gr.
Kapacitet okvira	15 kom.

Sl. 2. Model CZ 99

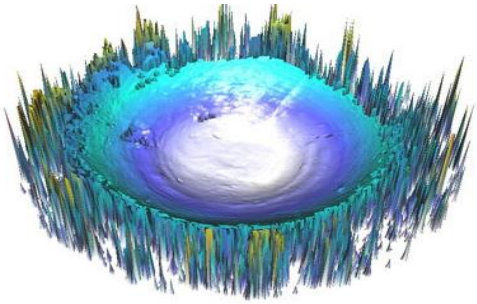


Ovaj model [10] ima najčešću upotrebu u vojno-policijskim formacijama i sektoru privatnog obezbeđenja na našim prostorima.

Sl. 3. Dimenzije kalibra 9mm

Sposobnost upoređivanja ispaljenog zrna sa oružjem je osnovno svojstvo ovog uređaja [11].

Prisiljavanjem projektila da se okreće dok putuje niz cev oružja, preciznost se znatno povećava. Istovremeno, narezivanje ostavlja tragove na projektilu koji ukazuju na tu cev, odnosno predstavlja jedinstveni forenzički otisak cevi. Pre masovne proizvodnje vatrenog oružja, svaku cev i kalup za projektil ručno su pravili oružari, što ih čini jedinstvenim [12]. Svaki projektil ispaljen iz određene cevi bi bio odštampan sa istim oznakama, omogućavajući istražiteljima da identifikuju oružje koje je ispalilo određeni projektil [13].



Sl. 4. Putanja zrna kroz model GT Gunsmith

Sl. 5. Zrno kalibra 9mm posle ispaljivanja

Preliminarnim pregledom projektila u bazi ispitivanja opštih karakteristika pronađenog projektila, može se isključiti veliki broj oružja. Određivanjem opštih aspekata ispaljene municije, izvestan broj oružja može se odmah isključiti kao nesposoban za ispaljivanje te vrste projektila.

Sl. 4. 3D prikaz Zrno posle ispaljivanja

Da bi uporedili pojedinačne pruge u samom eksperimentu, morali smo da dobijemo poznati uzorak koristeći (poznato oružje u ovom slučaju CZ 99, a u realnim forenzičkim istragama zaplenjeno oružje. Za projektile sa sporijim kretanjem, kao što su pištolji ili revolveri, poznati primerci projektila nastaju ispaljivanjem oružja u sigurnosni uređaj za proveru oružja (hvatač projektila) [14]. Potrošeni projektil se može povratiti, netaknut, pošto uređaj usporava projektil pre nego što stigne do zida uređaja. Ovaj uređaj se može koristiti i za brže leteće projektile, kao što su oni ispaljeni iz pušaka velike snage i oružja za vojnu primenu, dok se recimo rezervoari za vodu ne mogu koristiti, jer rezervoar neće obezbediti dovoljnu moć zaustavljanja projektila [15].

Kada se proizvede poznati primerak, uzorak dokaza se može uporediti sa poznatim ispitivanjem na bazi komparativne analize i u isto vreme uporednim mikroskopom. Stranice koje se porede se pažljivije ispituju, tražeći više uzastopnih tragova. Ne postoji određeni broj

 ISBN 978-86-7466-930-3

uzastopnih poklapanja koji je jednak deklaraciji o podudaranju, a ispitivači su obučeni da koriste forenzičku metodu „dovoljnog slaganja“. Stepen do kojeg ispitivač može da donese tu odluku zasniva se na njihovoj obučenosti i stručnosti [16]. Svi nalazi forenzičara podležu ispitivanju obe strane, tužilaštva i odbrane, tokom krivičnog postupka.

Marka i model oružja se takođe mogu zaključiti iz kombinacije karakteristika različitih klasa koje su zajedničke za određene proizvođače [17]. Tri glavne karakteristike klase svih projektila su tlo i žlebovi, kalibar metka, i preokret za narezivanje. Sva tri se mogu direktno vezati za tip cevi koji je korišćen za ispaljivanje projektila.

IV. ZAKLJUČAK

Rad daje teorijsko - eksperimentalnu analizu procesa opaljenja u sigurnosni uređaj za opaljivanje projektila (hvatač metka), koji očuva zrno za dalja eksperimentalna istraživanja i numeričko modeliranje na računaru. Eksperimentom se došlo do saznanja da uređaj očuva zrno u meri dovoljnoj za dalje optimalne ulazno-izlazne parametre i prihvatljive rezultate za konkretno oružje [18]. Rezultati eksperimenata potvrđuju da je ovaj jedinstveno dizajniran uređaj idealan i za testiranje funkcionalnosti različitih vrsta vatrenog oružja. Tehnologija koju koristi u komori za usporavanje praktično eliminiše čestice olova koje mogu nastati pre nego što se unesu u vazduh i udišu. Ovaj jedinstveni sistem koristi OSHA standarde, štiteći zaposlene u laboratoriji i ispitivače. Patentirani niski ugao ulazne rampe skreće projektil u komoru za usporavanje gde se projektil okreće, gubi energiju, a zatim upada u posudu za sakupljanje zrna. Uređaj je značajan i kod ispitivanja barutnih čestica. Nakon izlaska iz cevi oružja, barutne čestice se zadržavaju u okolini ulaznog otvora na prvoj prepreci na koju je projektil naišao. Za kriminalističku praksu su važne situacije kada je pomenuta prepreka odeća ili telo čoveka [19], pa se mogu vršiti različite simulacije.

Ovaj uređaj je relativno jednostavan i može se koristiti kao prenosni sistem za izvlačenje projektila za balističko poređenje. Eksperiment je pokazao da uređajem mogu da rukuju i da ga prenose samo dve osobe, pa se testiranje može vršiti i na samom mestu krivičnog dela. Uređaj očuva zrno za balističko poređenje, bezbedno vrši hvatanje svih projektila, ima brzi ciklus „pucaj i sakupljaj“ kraći od 60 sekundi i realtivno je lak za održavanje.

Security devices for checking weapons in the function of forensic-ballistic tests

Kristijan Đujić, Radovan Radovanović, Saša Milić, Martin Matijašević, Aleksandar Ivković

Abstract — Security devices for checking weapons, the so-called "Projectile catchers" are intended for safe screening of various types of firearms and are designed primarily for employees in the security sector. These devices consist of a metal construction, technology to minimize lead in the air, a low-angle ramp, a circular chamber and a vessel. Their construction contains a special safety function that prevents the weapon from exploding towards the user's face. Even if the user fires a projectile at an angle, all persons present in the environment will be safe. The return shock wave rotates turbulently inside the safety device for checking the weapon and the flame is redirected by the user who performs the firing. The catcher system includes small-angle ramps that repel the projectile instead of shattering it, minimizing lead dust. The projectile bounces into the circular deceleration chamber, where it decelerates until it stops. In functional terms, a security device for checking weapons can be placed on a table or wall in any room, so it is ideal for laboratory tests. The paper analyzes the characteristics of security devices for weapons testing through an experiment conducted on the model of Savange Range systems GT Tabletop Gunsmith in order to determine the potential for application in forensic and ballistic tests.

Keywords — Forensic examinations; ballistic tests; projectile trajectory; security; firearms; physical examination; classification; trial fire.

Примена форензичких алата у класификацији инцидената и несрећа у комерцијалном ваздушном саобраћају по EASA методологији

Александар Ивковић[1], Радован Радовановић[1], Саша Милић[2], Душан Ивковић[3], Кристијан Ђујић[1]

[1]*Криминалистичко полицијски универзитет – департман форензичког инжењерства*
[2]*Факултет за дипломатију и безбедност*
[3]*Војнотехнички институт, сектор за ваздухопловство*

Абстракт - У раду је наведено више случајева који су довели до несрећа у авио саобраћају и један симулиран сценарио без фаталног исхода уз селекцију више кључних параметара на бази којих је извршена детаљна анализа полазних претпоставки и потенцијалног решења. Моделовање сценарија потенцијалног нежељеног догађаја је извршено на бази искустава стечених кроз реалне догађаје и засновано је на постојећим типовима ваздухоплова и на реално могућој конфигурацији и изгледу аеродрома. Основа сценарија и резултати анализе се уклапају, како у међународне, тако и у националне правне оквире. На узорку од 1000 фаталних несрећа у периоду од 1950. до 2010. се може уочити да је до највећег броја несрећа дошло грешком пилота, уз напомену да је у неким случајевима то била последица реакција на изразито лоше временске услове или техничке кварове. У осталим случајевима то су пропусти контроле летења или особља одговорног за одржавање и механичких отказа.

Кључне речи - форензика у ваздушном саобраћају, инциденти, EASA, менаџмент безбедности

УВОД

Форензика је дефинисана правним оквиром који јој даје Кривични Закон и основна улога коју има је у оквиру кривичног поступка и прикупљања доказног материјала, као и његовог стручног тумачења. Методе и технике које користи форензика су компатабилене са познатим и општеприхваћеним научно-истраживачким методама, а методологије које користи су у сталној примени у природним наукама (по потреби и друштвеним) и без ограничења које повремено намећу специјализоване научне дисциплине. Форензика као наука је интердисциплинарна и обухвата распон од прикупљања и анализе архивске грађе, правилника, упутстава, препорука, анализе обичаја и културних утицаја па до технологија израде, врсте материјала техника и технологија израде, утицаја окружења, па до медицинских података.

Овај рад је илустративан приказ једног дела кога форензика, као интердисциплинарна наука, може да пружи када нема нежељеног сценарија који подразумева ангажовање тужилаштва и судских органа. У раду су аутори приказали истраживања из области ваздушног саобраћаја.

Након несрећа у комерцијалном ваздухопловству прође доста времена док се све чињенице не сазнају и док се не дође до одговора зашто и како се нешто десило. Чак и када се догоде несреће то је због низа независних догађаја који су коинцидирали у до тада непредвиђеним околностима, односно, нико их није раније предвидео. Да би форензичке анализе добиле на пуном значају, неопходно је прикупити податке и анализирати их, а по потреби и проверили кроз симулиране сценарије где би се тестирала њихова поузданост и на тај начин предвидели и предупредили нежељени исходи.

ТЕХНИЧКИ АСПЕКТИ

У раду је наведено више случајева који су довели до несрећа и један симулиран сценарио без фаталног исхода. Симулиран сценарио је, након анализе, понудио одговоре на то зашто се и како нешто десило, па па до указивања на кривца и предлога побољшања. Сценарио је базиран на могућим догађајима и релним типовима ваздухоплова и аеродрома. Основ сценарија и резултати анализе су у међународном и националном правном оквиру. Вођено је рачуна да се не изађе из оквира статистике несрећа са фаталним исходом.

На узорку од 1000 фаталних несрећа у периоду од 1950. до 2010. можемо видети да је до највећег броја несрећа дошло грешком пилота, понекад као реакција на изразито лоше временске услове или техничке кварове. У осталим случајевима то су пропусти контроле летења или особља одговорног за одржавање и наравно због механичких отказа. Проценти су следећи[1]: грешка пилота 32%, отказ механичке природе 20%, грешке пилота узроковане/провоциране временским условима 16%, сами временски услови 12%, саботажа 8%, људска грешка осталих учесника 6%, грешка пилота везана за технику 5%, сви остали узроци 1%.

Да се из прикупљених података учи и да је прикупљање и ажурирање данас неопходност показује и разлика у вероватноћи да се фатална несрећа догоди на комерцијалном лету од просечно 4,3 жртве на сваких милион сати налета, што је у преносном значењу 115 година летења. У општој авијацији, где су нижи стандард и

 ISBN 978-86-7466-930-3

чињеница је да лете аматери, имамо 22,43 жртве летења на сваких милион сати налета.

Одличан показатељ је и укупан број несрећа који и поред годишњег пораста броја сати налета од 3-5% константно опада и у апсолутним бројевима је са свог пика седамдесетих од 42 несреће годишње 2016. пао на 6 несрећа годишње, при томе треба имати на уму да је по подацима ICAO-a[2] и годишњем извештају европске комисије о европском ваздухопловном тржишту за 2016 годину из марта 2017. и поред неколико нафтних, тржишних и политичких криза од седамдесетих на овамо дошло до огромног пораста саобраћаја. За то су заслужни не само авиони новије генерације са већим бројем седишта, односно повећаном носивости, већ и повећан обим и фреквенција полетања. Комерцијална авијација по броју превезених путника са нешто испод 400.000.000 путника 1975. данас је на 3.500.000.000 особа, што је повећање капацитета флоте, односно броја летова за готово 9 пута, са скоком од 2003. до 2010. од 53%. Обим превоза робе је доживео и већи пораст, на њему се нећемо задржавати пошто са собом носи мањи друштвени ризик, већи број летова се обавља у време када је нижи обим саобраћаја и ноћу, у авиону је само посада, висинска ограничења практично не постоје итд.

У 2015. години кроз аеродроме у свету је прошло 7 милијарди путника, а само европски превозиоци су имали профит од 7,4 милијарде долара. Овакав скок, поред чињенице да авијација прати тржишна дешавања и подложна је кризама, није забележен на другим пољима саобраћајне и транспортне индустрије.

РЕАЛНЕ НЕСРЕЋЕ И СИМУЛИРАН СЦЕНАРИО

Осмог марта 1974. непосредно након полетања из Париза за Лондон авион DC-10 компаније Turkish Airlines лет 981 пао је због проблема са забрављивањем врата теретног одељка.

Дванаестог августа 1985. Japan Airlines Боинг 747ср лет 123 из Токија за Осаку је 12 минута након полетања на удаљености око 100 km имао експлозивну декомпресију приликом које је изгубио репни део авиона, погинло је 15 чланова посаде и 505 од 509 путника. Ово остаје до данас најсмртоноснија несрећа у којој је учествовао само један авион. Разлог пада: лоше урађено одржавање авиона.

Двадесет шестог маја 1991. Боинг 767-300ER компаније Lauda Air лет 004 на лету из Банкока за Беч пада у ковит и при том гине свих 213 путника и 10 чланова посаде. Разлог пада је активирање реверзног потиска у лету, уређаја иначе дизајнираног за помоћ при кочењу након слетања. Разлог је техничка грешка, тј. пропуст у конструкцији и сигурносној опреми која је касније отклоњена.

Током деведесетих низ инцидената са Боингом 737 резултованих непоузданим или чек супротним отклоном у односу на командовани правац кормила довео је до неколико несрећа. У две одвојене несреће погинуло је 157 људи док проблем није коначно детектован и наредбом америчких ваздухопловних власти FAA[3], коначно отклоњен. Проблем је био у електро магнетном вентилу, који је на ниским температурама, или по повратку на више температуре реаговао непоуздано или чак супротно од командованог. Авиони иначе лете на висинама где је температура током целе године око -52ºC.

Недавни случајеви, који показују да и поред најбоље воље систем обавезног пријављивања, прикупљања, дистрибуције и релевантне анализе података није заживео везани су за Боинг 737 MAX генерације.

Два догађаја за које ће се брзо испоставити да су повезана су пад LionAir лета 610 29. октобра 2018. и Ethiopian Airlanes лет 302 10. марта 2019. на ова два лета је било 346 жртава а појединачно су највеће несреће у историји поменутих компанија. Када су коначно потврђени подаци и установљено да су оба ваздухоплова пала из истог разлога FAA је 13. марта 2019. донела одлуку о приземљењу типа и до 18, марта 2019. године свих 387 примерака је било приземљено. Интересантно је да је још пре 13. марта 51 ваздухопловна власт донела одлуку о приземљењу конкретног типа ваздухоплова. Забрана је трајала до децембра 2020. и након поновне сертификације пловидбености типа, враћен је у оперативну употребу. Оно што је страшно у овим случајевима је чињеница да тенденција да обара нос авиона у погрешном тренутку је била софтверска грешка уочена много пре несреће које су се догодиле, нажалост без одговарајуће реакције произвођача.

Сличан проблем и понашање је примећено и код ваздухоплова другог произвођача исте генерација Ербаса 320 NEO. Међутим EASA је низом тестова у симулатору утврдила да се померањем тежишта (тако што се задњи редови седишта ће попуњавати) ваздухоплов може и даље користити, уз поменуто ограничење. На крају је и на овом типу грешка исправљена.

Моделован сценарио се одвија на замишљеном аеродрому са две писте које се укрштају и различите су дужине и капацитета, пројектоване за истовремену употребу. У сценарију/симулацији након низа пропуста ваздухоплов средње величине излеће са писте и након мањег оштећења и лакших повреда две особе успоставља се нормалан рад аеродрома. Након неколико техничких анализа понашања делолва система одрађена су и безбедносна, сходно препорукама, али и правна у складу са националним прописима. Због обима анализа, овде наводимо само закључке.

Након форензичких и истражних радњи спроведених после удеса дошло се до закључка да се већина несрећа

 ISBN 978-86-7466-930-3

могла спречити. Пружаоци услуга у ваздухопловству примарно, а потом и произвођачи, почињу са класификацијом и обрадом података о ситуацијама које нису довеле до несреће, али се могу сврстати у инциденте.

КЛАСИФИКАЦИЈА ПРЕМА EASA

Стратегија и принципи Европске агенције за безбедност ваздушне пловидбе се заснивају практично на смерницама које је поставио ICAO тако да је све универзално применљиво. EASA и њено поље деловања је далеко шире од саме Европе и простире се дуж комплетног Медитерана и делимично на Блиском Истоку и Азији. Смернице ICAO су водиље за целу планету па се овом приликом у скраћеном облику упознајемо са њима.

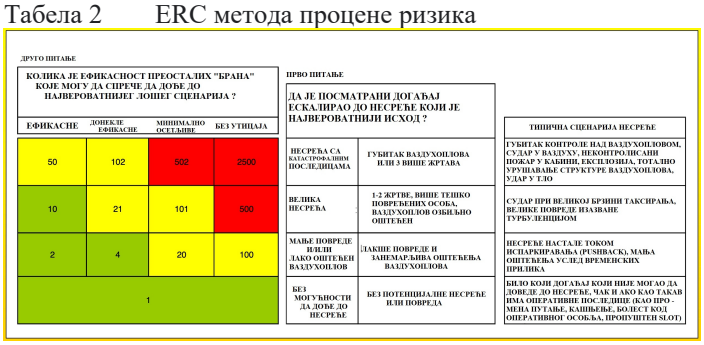
Процена безбедносног ризика или система управљања безбедношћу увелико зависи од избора методе, тачније од адекватности методе за процену ризика и потребе за правилним разумевањем циљева процене ризика. Оцена безбедносног ризика догађаја је препозната као један од главних приоритета у контексту система управљања безбедношћу. Мерење нивоа ризика практично одређује приоритете. Квантитативне вредности ризика су релативне вредности ризика између догађаја, израчунавају се или пореде на различите начине. Инцидент или пропуст је нешто где нас поступци, вештина, обука или сигурносни системи нису заштитили, већ „срећна околност“. Ово уједно представља најстарији, традиционални метод за процену који се користи од почетка комерцијалног ваздухопловства. У овој методи се безбедносни учинак представља и приказује бројем (или стопом) различитих категорија догађаја, тачније њиховом учесталошћу, а његова три главна недостатка су: а) квалитативни учинак ограничен на највише 3 категорије, б) нема квантитативне вредности ризика и в) фокус је на очигледним последицама а занемарује се потенцијал ризика. Данас када су несреће веома ретки догађаји (мање од 3 на 10 милиона летова), ова метода постаје неупотрбљивља из перспективе пружаоца услуга који су у обавези да квантификују своје перформансе.

МЕТОДЕ ЗА ПРОЦЕНУ РИЗИКА

ICAO матрица ризика

ICAO матрица ризика је метода процене ризика заснована на „пројектованој вероватноћи и озбиљности последица могућих исхода постојеће опасности или безбедносног случаја“. Иако се овај метод успешно користи за процену ризика безбедносних проблема, он има видљива ограничења и није довољно осетљив за појединачне процене ризика. Овај метод карактерише прилагођена матрица без разумевања Коксове теореме матрикса (Табела 1)[4].

БЕЗБЕДНОСНИ РИЗИК	ОЗБИЉНОСТ				
ВЕРОВАТНОЋА	КАТАСТРОФАЛНО A	ОПАСНО B	ВЕЛИКА НЕСРЕЋА C	МАЊА НЕСРЕЋА D	ЗАНЕМАРЉИВО E
УЧЕСТАЛО 5	5A	5B	5C	5D	5E
ПОВРЕМЕНО 4	4A	4B	4C	4D	4E
РЕТКО 3	3A	3B	3C	3D	3E
МАЛО ВЕРОВАТНО 2	2A	2B	2C	2D	2E
ГОТОВО НЕМОГУЋЕ 1	1A	1B	1C	1D	1E



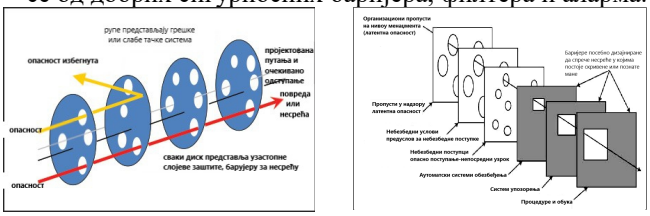
Табела 1 Коксова матрица

ERC метода процене ризика

Кључни циљеви методе класификације ризика догађаја према ERC методи[5] (Табела 2) коју је развила радна група ARMS[6] су превазилажење ограничења ICAO-ове матрице и смањење субјективности аналитичара у погледу вероватноће догађаја и последица истог. За разлику од ICAO матрице где се процена ризика заснива на свим сличним догађајима истог типа (догађаји који су последица истог ризичног догађаја), ERC метод се заснива на концепту „нивоа ризика заснованог на самом догађају“ где се ризиком догађаја сматра ризик који је постојао када се догађај десио. Класификација ризика односно процена ризика коју носи догађај се врши коришћењем ERC матрице где се од стручњака за безбедност тражи да одговори на два питања:

1. Да је овај догађај ескалирао у несрећу, који би био највероватнији исход?
2. Која је била ефикасност преосталих баријера између овог догађаја и исхода са највећом вероватноћом?

Табела 2 ERC метода процене ризика



Питања која се односе на процену озбиљности слично приступу ICAO матрице ризика, и на вероватноћу исхода, заснивају се на процени преосталих баријера које спречавају ескалацију догађаја до несреће. Овај приступ прати модел узрочности несреће „швајцарски сир“ који је развио Џејмс Рисон[7](Слика 1).

Следеће одговоре на друго питање предлаже група ARMS:

Нису ефикасни: Несрећа се догодила или је могла бити спречена само чистом срећом или вештином пилота или другог одговорног лица (котролор лета и сл.).

 ISBN 978-86-7466-930-3

1. Минимално ефикасне: баријере су постојале, али је њихова укупна ефикасност била минимална
2. Ограничено ефикасне: ефикасност преосталих безбедносних баријера је ограничена. Ово је ванредна ситуација, која је захтевнија за превазилажење, али са значајном преосталом сигурносном маргином
3. Ефикасне: сигурносна маргина је одговарајућа и састоји се од добрих сигурносних баријера, филтера и аларма.

Слика 1 Рисонов модел „швајцарког сира“

ERC модел има два излаза:

1. Толеранција на ризик: вредности боја указују на поступке у вези са догађајем.
2. Индекс ризика: квантитативна вредност ризика у опсегу од 1 до 2.500 погодна за мерење безбедносних перформанси.

Неколико аутора је предложило побољшане верзије матрице са бољим резолуцијама (Jochen Mickel[8]), али о овим моделима овде неће бити речи јер следе исте принципе који су претходно наведении.

EASA ERCS метода за процену ризика

EASA ERCS (European Risk Classification Schema)[9] метода за процену ризика (Табела 3) је најкомплекснија од свих до сада обрађених и представља њихову еволуцију, а да ли представља квалитативни помак и стварни напредак, показаће време.

Европска шема класификације ризика ERCS прати основне принципе методе класификације ризика догађаја и то: 1) Поцена нивоа ризика на основу догађаја, 2) Процена вероватноће заснована на ефикасности заустављања и преосталих баријера и 3) Квалитативна и квантитативна оцена ризика по безбедност догађаја, без уласка у стварне последице. У поређењу са ERC класификацијом ризика догађаја, EASA ERCS метода уводи идентификацију кључних области ризика (укључујући поређење међусобних нивоа ризика) и усклађен приступ за утврђивање озбиљности догађаја и вероватноће, па је стога и много сложенија. Примена *ERCS* подразумева следеће кораке: 1) утврђивање највероватније врсте несреће, 2) одређивање категорије несреће, 3) оцена озбиљности, 4) идентификовање заустављање баријере из *ERCS* модела баријере, 5) идентификација ефикасности преосталих баријера, 6) израчунавање суме тежине баријере и одговарајућег резултата баријере и 7) одабир безбедносног скора и одговарајуће вредности ризика из ЕРЦС матрице.

Табела 3 EASA ERCS метода процене ризика

ПРОЦЕНА ОЧЕКИВАНОГ РИЗИКА

ЗАКЉУЧАК

На симулираном моделу може се видети да независно од модела који користимо за процену ризика резултати више варирају у односу на обученост лица него од врсте примењеног модела, док најмању разлику даје управо EASA модел. Најмање одступање је практично везано за детаљну аналитичку методу доделе бројне вредности испитиваном догађају, односно његове квантификације. Нажалост метода је временски захтевна и код необученог корисника могла би да да погрешан резултат, док су друге поменуте методе интуитивније и захтевају много краћи период за усаглашавање са поступком. Резултати и сценарио симулације су даљи предмет истраживачког рада, овде је нагласак на поређења поменутих метода процене ризика.

Нуклеарна форензика – методе за откривање процеса производње, прометовања и кријумчарења недозвољених фисионих материјала

Срећко Илић[1], Радован Радовановић[1], Саша Милић[2], Александар Алексић[2], Александар Ивковић[1]

[1] *Криминалистичко-полицијскиуниверзитет – департман форензичког инжењерства*

[2] *Факултет за дипломатију и безбедност*

Апстракт. Савремена технологија са собом доноси савремена и моћна оружја, али и бојазан да она могу бити употребљена ван међународних договора, протокола и обичаја ратовања. Као последица развоја нуклеарних технологија, појавио се нуклеарни тероризам, а нуклеарна форензика је област форензичког инжењерства која се, у садејству са другим традиционалним форензичким методама, бави реконструкцијом догађаја који су претходили неком нуклеарном инциденту или катастрофи. Методологије и мерне методе нуклерне форензике се користе за откривање кријумчарења и недозвољене производње специјалних фисионих материјала, који су основе језгара у атомским и хидрогенским бомбама. У раду ће бити разматрано више метода са циљем њихове категоризације и систематизације, а детаљно ће бити описане гама-спектрометријска метода, различите методе масене спектрометрије и рендгенска флуоресцентна спектрометрија. Циљ рада је да укаже на значај нуклеарне форензике у имплементацији нуклеарних безбедносних режима, како на локалном, тако и на глобалном нивоу.

Кључне речи: нуклеарна форензика, тероризам, оружје, криминал, инциденти, безбедност

Увод

Открићем нуклеарног наоружања и његовом применом на бојном пољу, у јапанским градовима Хирошима и Нагасаки променио је погледе на обичаје ратовања али и политику и дипломатију.Управо због ове чињенице, данашњи актери на међународној дипломатско-политичкој сцени морају да се обраћају бираним речима једни другима и да њихова дела буду умерена колико год је то могуће. Државе које имају програме нуклеарног наоружања, у једном моменту су, схвативши опасност у којој се свет налази, иницирале механизме за заустављање ширења нуклеарног наоружања. Тек неколико држава је након тога успело у намери да зварши већ започет нуклеарни програм. Те државе су, заједно са свим осталим које немају нуклеарно наоружање, под будним оком међународне заједнице и МААЕ – Међународне агенције за атомску енергију (*енг.* "IAEA – International Atomic Energy Agency" [1]), проблем је у томе што правни оквири нису у потпуности обавезујући, па су механизми за деловање МААЕ веома сужени.

Чињеница да смо пар држава има нуклеарно наоружање и да је оно инсталирано на територијама неколико других, рекло би се да смо прилично безбедни, али тај простор је попунио нуклеарни тероризам, као стална претњу за безбедност незаштићеног становништва било где у свету. У домену је фантастике да терористи могу да дођу до нуклеарног оружја, али они нуклеарне материјале користе у друге сврхе, о чему ће даље у раду бити речи.

Анализом нуклеарних материјала форензичари настоје да установе како, када или где су материјали направљени, односно за шта су коришћени [3, 4]. Треба истаћи да су нуклеарни форензички алати веома значајни за нуклеарне инспекторе приликом у откривања изотопа који се користе приликом констуисања нуклеарног оружја. Ово се односи на инспекцијске надзоре приликом испитивања тврдњи да ли је нека држава покушала да развије или тестира нуклеарни борбени програм и тиме нарушила неки од споразума које је потписала или обогаћује материјал за производњу електричне енергије.

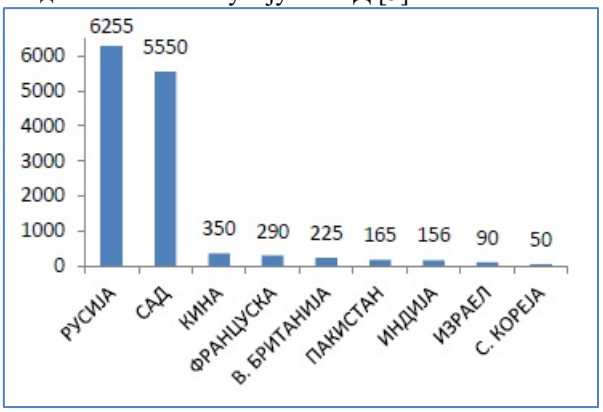
Међународни споразуми о нешириењу нуклеарног наоружања

Најзначајнији споразум у домену забране нуклеарне безбедности је Споразум о забрани ширења нуклеарног наоружања (*енг.* "NPT – Non-Proliferation Treaty"). Донет је 1968. године, а

 ISBN 978-86-7466-930-3

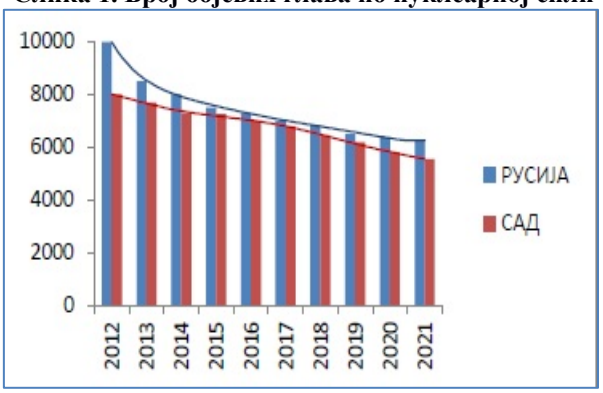
ступио је на снагу 1970. године. Споразумом је као најважније издвојено да је предвиђено да дође до престанка ширења нуклеарног оружја, да дође до укидања ове врсте наоружања и да се појача свеобухватна сарадња у циљу ширења знања везаних за мирнодопске примене нукеарне енергије. Такође, предвиђено је да МААЕ има улогу у контроли спровођења тачака и контроле коришћења нуклеарне енергије. Ово је веома битна ставка за нуклеарну форензику. Наиме, све потписнице се обавезују да ће МААЕ обезбедити увид у нуклеарна истраживања и производњу и размену фисионих материјала у мирнодопске сврхе. Ове ставке указују на то да би се контрола спроводила управо коришћењем нуклеарних форензичких метода, јер се радионуклиди који се за производњу наоружања (недозвољени фисиони материјали) разликују од оних који се користе у мирнодопске сврхе (дозвољени), те би се форензичком контролом и инспекцијским надзором врло лако могло открити уколико нека држава под велом производње нуклеарне енергије тежи да развије нуклеарни борбени програм.

Други по важности је Свеобухватни споразум о забрани нуклеарних проба (*енг.* – "CTBT - Comprehensive Nuclear-Test-Ban Treaty"). Споразуму су претходили неки о делимичној забрани нуклеарних проба, али је овим Споразумом који је донет 1996. године и дефинитивно завршено са нуклеарним пробама. Било је ту и тамо неколико инцидената, односно кршења Споразума, понајвише од стране С. Кореје, али су нуклеарне пробе од стране оних који су их највише изводили и дефинитивно престале.



Поред ова два споразума постоји низ билатералних споразума између САД и Русије. Свим тим споразумима се подразумева редуковање нуклеарног наоружања. Сваки од њих је одиграо неку улогу, али се заправо ништа круцијално, по питању укидања нуклеарног оружја, до данас није десило.

За ову тему значајан акт је свакако Међународна конвенција о спречавању аката нуклеарног тероризма (*енг.* "CNT – International Convention for the Suppression of Acts of Nuclear Terrorism") из 2005. године. Конвенцијом је дефинисан низ аката који се сматрају нуклеарним тероризмом, али је и гарантована помоћ МААЕ у сузбијању ове врсте тероризма, као и решавању кризних ситуација и уклањању непожељних материјала са територије угрожене државе.



Безбедносни акти које нисмо посебно описали, редом према времену доношења или предлагања, су: Повеља о Антарктику (1959), Споразум о делимичној забрани нуклеарних проба (1963), Споразум о космосу (1967), Споразум о забрани смештања нуклеарног и другог оружја за масовно уништење на дно мора и океана и у њихово подземље (1971), Споразум о Месецу (1979) и Споразум о забрани одређених фисионих материјала (1993).

Тренутно стање у вези са бројем нуклеарних бојевих глава у свету

Од открића нуклеарног наоружања, кроз читав "Хладни рат", па све до данас, Русија и САД су биле водеће војне силе гледано према квантитету нуклеарних бојевих глава. Тренутни тренд у вези са бројем нуклеарних глава у свету можемо видети на графику [5]. Што се тиче тренда раста или опадања, праћењем квантитета бојевих глава у свету, може се уочити да Русија и САД из године у годину смањују број бојевих глава, док остале нуклеарне силе повећавају своје нуклеарне арсенале. Међутим, како остале нуклеарне силе у збиру имају око 10 пута мање бојевих глава од САД и Русије заједно, а тај однос је раније умео да буде и дупло већи, јасно је да је нуклеарно разоружавање у рукама две водеће силе и зато су нам оне, у смислу анализе, најбољи показатељ параметара раста или пада. Тренд опадања везано за Русију и САД [5].

Слика 1. Број бојевих глава по нуклеарној сили

Слика 2. Однос нуклеарних бојевих глава Русије и САД током последњих 10 година

Систем инспекцијског надзора у оквиру Међународне агенције за атомску енергију

Оснивањем Међународне агенције за атомску енергију и изгласавањем њеног Статута 1957. године, било је предвиђено да постоји инспекцијски надзор који би обухватао низ техничких мера којима се врши праћење обавеза држава да не користе нуклеарне мирнодопске системе за развој нуклеарног наоружања, што је забрањено тачком 5. става А, члана 3. Статута. Инспекторски систем на неки начин представља извршно тело у оквиру нуклеарних безбедносних режима. На оснивање инспекцијског система се чекало две године. Договорен је у Канади 1959. године, међутим, документ који је регулисао рад овог тела се чекао још толико. Године 1961. потписан је први документ који је регулисао процедуре за аплицирање и упутства за рад „IAEA“ инспектора. Овај документ је познат под називом „INFCIRC/26“, а након допуне, 1965. године, заведен је под називом „INFCIRC/66“. Када је 1970. године на снагу ступио Споразум о забрани ширења нуклеарног наоружања, створили су се услови за „озбиљније“ деловање Агенције, што је 1971. године, довело до увођења новог „INFCIRC/153“ документа о инспекцији, који је пре свега увео Свеобухватан инспекцијски надзор (*енг.* CSA – Comprehensive Safeguards Agreements). Он је дефинисао начин сарадње између Агенције и држава потписница и то, пре свих, држава које нису декларисане нуклеарне силе, а имају установе које користе нуклеарну енергију у мирнодопске сврхе. Ове државе су се, потписивањем документа, обавезале на свеобухватан инспекцијски надзор од стране „IAEA“ на својој територији, те да ће омогућити инспекторима све податке који су у вези са нуклеарним постројењима и применом радионуклида у било којој области. У оквиру истог акта дефинише се Протокол о малим количинама, који се односи на државе које не поседују велика нуклеарна постројења него имају јако мале количине нуклеарних материјала или их немају уопште. Наиме, њиме се уређује да у државама које потпишу Протокол Агенција нема сталан инспекторски надзор. С друге стране, Протокол не искључује установљене обавезе према Агенцији и разним потписаним споразумима. Дакле, држава која је приступила Протоколу се одриче великих нуклеарних истраживања, што је чини изузетом од сталне инспекторске контроле, али мора да пошаље извештај Агенцији о свим радионуклидима које поседује или жели да набави, као и да одговори на све прописане захтеве „IAEA“ уколико за тим постоји потреба.

Деловање инспектора Агенције у циљу спречавања ширења нуклеарног наоружања у основи се може поделити у четири групе,сакупљање и процена информација, унапређење сарадње са државама, планирање, спровођење и унапређење свих активности, укључујући и рад на терену, као и деловање командног центра у Бечу и доношење закључака и њихово представљање.

Агенција у окивру инспекторских послова прикупља велики број информација. Извори из којих се долази до њих могу се поделити у три гупе:

1) информације које је обезбедила сама држава у којој се врши надзор (извештај државе о нуклеарним активностима и радиоактивним материјалима),

2) информације које су произашле из података са терена (прикупљени узорци) и обраде у командном центру (подаци из прикупљених узорака, али и они добијени помоћу детектора и камера постављених у нуклеарним постројењима широм света),

3) информације из других релевантних извора као што су отворени извори (интернет и други) и они које је доставила трећа страна.

Информације из свих извора морају бити међусобно конзистентне. У супротном Агенција је принуђена да са државом превазилази проблем кроз низ консултација, али и увођењем посебних мера уколико је то неопходно.

Услед немогућности Агенције да, заједно са својим инспекторима, одговори на изазове који су пред њу постављени, дошло је до потребе да се уведе Додатни протокол (INFCIRC/540) у окивру механизама који се спроводе у циљу поштовања Споразума о забрани ширења нуклеарног наоружања. Овај Протокол Агенцији и њеним инспекторима проширује овлашћења и омогућава већа права на информације од значаја, те лакше откривање забрањених нуклеарних активности. Додатни протокол је донет 1997. године.

Нуклеарна форензика – организације, лабораторије и методе

Нуклеарна форензика је релативно млада област форензике. Свој нагли развој је почела да доживљава развојем нових технологија и то крајем прошлог века, да би у 21. веку доживела потпуни процват. Далеко од тога да неке методе које она

 ISBN 978-86-7466-930-3

користи нису постојале и раније и далеко од тога да нису постојали начини за откриће забрањених нуклеарно-безбедносних акитвности, али она тада просто није била установљена као дисциплина, а њене методе нису биле свеобухватне као данас. У нека страрија времена, просто су се користиле методе нуклеарне физике у циљу откривања недозвољених активности. Данас постоји низ организација широм света које раде на јачању ове научне дисциплине, а једна од њих је и МААЕ. Нуклеарна форензика је једини практичан механизам којим се може деловати у циљу спречавања кршења нуклеарних безбедносних режима и ширења нуклеарног наоружања.

Релевантне организације

Иако је МААЕ кровна организација по питању нуклеарне безбедности, она ипак није кровна организација која ради на примени и развоју нуклеарне форензике. Најрелевантнија организација на светском нивоу је МТРГ – Међународна техничка радна група за нуклеарну форензику (*енг.* "ITWG – The Nuclear Forensics International Technical Working Group"). Сматра се да је Радна група основана 1995. године, иако је активно учешће у развоју програма узела тек двадесетак година касније (2016.). Она броји више од 50 земаља потписница, међу којима је и Србија, као и 11 релевантних међународних организација, међу којима је и МААЕ, али и ИНТЕРПОЛ, ЕУРОПОЛ и ОЕБС. Такође, на списку организација је и Глобална иницијатива за борбу против нуклеарног теоризма (*енг.* "GICNT – Global Initiative to Combat Nuclear Terrorism") која се убраја у значајне чиниоце у борби против злоупотребе нуклеарних материјала, а самим тим и у развоју нуклеарне форензике и њених метода. Ова организација се састоји од три групе, од којих је једна Радна група за нуклеарну форензику (*eng.* "NFWG – Nuclear Forensics Working Group") чији главни циљеви леже у охрабрењу држава да формирају националне нуклеарно-форензичке лабораторије и националне нуклеарно-форензичке библиотеке [6].

Међународна техничка радна група је подељена у више мањих група. Свака група има своје деловање. Поред Групе за прикупљање доказа, веома је активна и Група за вежбе. Примарни циљ овог сектора је повећање спремности лабораторија за поступање у случају потреба. Пре договореног састанка Групе, свака лабораторија добија радиоактивни узорак за који треба да изврши анализу коришћењем метода нуклеарне форензике. Група инсистира на анализама које се врше у року од 24 часа од добијања узорка, затим након 7 дана и последња након 2 месеца. Након тога се сви учесници састају и размењују искуства уз дискусију. Постоје још и Група за смернице, која ради на развоју техничких докумената ове организације, затим Група за формирање националних библиотека за нуклеарну форензику и Група за тренинге, која пружа помоћ у развоју нуклеарне форензике државама и организацијама које то затраже [6].

Методе нуклеарне форензике

У различитим литературама постоје различите категоризације нуклеарних форензичких метода. Оне су углавном извршене према различитим критеријумима. Чак је и "ITWG" у документу бр. 2 серије докумената Међународне агенције за атомску енергију под насловом "Нуклеарна безбедност", дала предлог редоследа метода којим би требало да се приступа у случају вршења нуклеарно-форензичког испитивања, а који се може сматрати одличном категоризацијом датих метода, пре свега према времену испитивања, али и врсти испитивања у смислу избора научне методе.

Високо-резолутивна гама спектрометрија (*енг.* "HRGS – High-Resolution Gamma Spectrometry"). Обично се користи у почетној фази испитивања. Неинвазивна је и прилично поуздана за почетни стадијум испитивања, па се користи као незаобилазна метода за добијање смерница за даље испитивање. Заснива се на детектовању γ-фотона и њиховом идентификовању у датом спектру. γ-кванти настају када језгро, након распада, прелази из енергетски побуђеног у неко ниже енергетско стање. Како је енергија γ-фотона једнака разлици енергија које је језгро имало и које има након емисије кванта, јасно је да се тумачењем спектра може доћи до закључка до ког распада је дошло.

Разне врсте масене спектрометрије (*енг.* "MS – Mass Spectrometry"). Масена спектрометрија је веома распрострањена метода. Поуздана је и осетљива, али је и инвазивна, јер узорак пре употребе мора да прође кроз одређене физичко-хемијске припреме. Користи се углавном за одређивање састава неке супстанце. Сепарација појединачних елемената се врши на основу њихове масе. Овде се користи чињеница да наелектрисане честице када се нађу у хомогеном магнетном пољу, почињу да се крећу по кружној путањи. Што је већа маса честице, већи је и полупречник кружне путање. То нас води до тога да ће се честице различите масе различито понашати у магнетном пољу, оне са мањом масом ће описивати кругове мањег полупречника и обрнуто.

 ISBN 978-86-7466-930-3

У нуклеарној форензици се често користе методе чија је основа масена спектрометрија, али поред ове методе обухватају још неки вид додатне анализе. Од ових метода најчешће се користе:
Масена спектрометрија са индуковано спрегнутом плазмом (*енг.* "ICP-MS"), **Масена спектрометрија термалном јонизацијом** (*енг.* "TIMS"), **Масена спектрометрија раствора изотопа** (*енг.* "IDMS"), **Гасна хроматографија – масена спектрометрија** (*енг.* "GS/MS"), **Масена спектрометрија секундарним јонима** (*енг.* "SIMS"), **Масена спектрометрија акцелератором** (*енг.* "AMS"). Надоградњом методе "ICP-MS" додатним алатима, добијају се још неке сложеније варијанте ове методе, као што су: **Ласерска аблација масена спектрометрија са индуковано спрегнутом плазмом** (*енг.* "LA-ICP-MS") и **Мулти-колекторска масена спектрометрија са индуковано спрегнутом плазмом** (*енг.* "MC-ICP-MS") [3, 7].

Поред претходно побројаних метода, у нуклеарној форензици су присутне и следеће методе: **Скенирајућа електронска микроскопија** (*енг.* "SEM"), **Трансмисиона електронска микроскопија** (*енг.* "TEM"), **Рендгенска флуоресценција** (*енг.* "XRF"), **Рендгенска дифракција** (*енг.* "XRD"), **Инфрацрвена спектроскопија Фуријеовим трансформацијама** (*енг.* "FTIR"), **Оптичка емисиона спектрометрија са индуковано спрегнутом плазмом** (*енг.* "ICP-OES"), **Ласерски индукована спектроскопија пробоја** (*енг.* "LIBS"), **α-спектрометрија** (*енг.* "AS"), **Микро-Раман Спектроскопија** (*енг.* "micro Raman Spectroscopy"), као и комбиноване "SEM/XRF", али и "SEM/EDX" или "SEM/WDX" [3, 7].

Све набројане методе су аналитичке и представљају срж нуклеарно-форензичких испитивања. На овај начин добијени подаци се сврставају у категорију која се на енглеском назива "ESS – Environmental Sampling for Safeguards"). Поред њих се користе и методе конвенционалне форензике, нпр. ДНК анализе и узимање отисака прстију. Осим тога, користе се и разне методе мониторинга, праћења итд. Те методе су: откривање недозвољених материјала **вишеканалним анализаторима** (*енг.* "MCA"), откривање недозвољених материјала **детекторима легура** (*енг.* "ALEX"), коришћење **инструмената за праћење промена у животној средини** (*енг.* "Environmental monitoring instruments"), коришћење система **дигиталног видео надзора** (*енг.* "Digital video surveillance sytems"), коришћење **сателитског снимања** (*енг.* "Satellite imagery"), коришћење **инспекцијске базе података** (*енг.* "Inspection Database"). У ову групу метода спадају и софтвери који се користе у ове сврхе, а то су: **Скуп неуралних мрежа** (*енг.* "CNN"), **Морфолошка анализа за атрибуцију материјала** (*енг.* "MAMA") [7, 8].

Табела 1. даје поделу према времену коришћења и према групи у коју дата метода спада.

Табела 1 Редослед корака који треба предузети приликом испитивања узорка, према упутству (ITWG) [4]

Врста методе	24 h	7 дана	2 месеца
Радиолошки метод	Брзина дозе (α, β, γ, n) Површинска контаминација Радиографија		
Физичка карактеризација	Визуелни преглед Фотографисање Утврђивање масе и димензија Оптичка микроскопија Густина	Микроструктура Морфологија SEM XRD	Наноструктура Морфологија TEM
Анализа изотопа	HRGS	TIMS ICP-MS	SIMS Технике радиоактивног бројања
Радиохронометрија	HRGS (за Pu)	TIMS ICP-MS	HRGS (за U) α-Spectrpmetry
Хемијски састав	XRF	ICP-MS Хемијско испитивање FTIR SEM IDMS	GC-MS
Традиционалне форензичке методе	Примена традиционалних форензичких дисциплина (отисак прста, ДНК анализа власи итд.)		

У табели 2. је дат преглед метода према томе у коју сврху се користе. Табела није преузета, али су подаци у њој систематизовани коришћењем података одређеног извора [8]. Ови подаци су приказани табеларно ради веће прегледности. У табели 3. су дате методе према врсти алата у које се убрајају. У табели 4. подела је према величини узорка и информацијама које се о узорку добијају.

Табела 2 Подела метода према томе у коју сврху се користе [8]

Информације које се добијају из дате методе	Врста методе
Елементарни и молекуларни потписи	ICP-MS ICP-OES LA (LA-ICP-MS) LIBS (за мале количине узорка) μRaman Spectroscopy
Карактеризација изотопа	MC-ICP-MS TIMS AMS SIMS
Датирање	SIMS MC-ICP-MS
Информације о нехомогености недозвољених нуклеарних материјала	LA-MC-ICP-MS SIMS XRF SEM/EDX SEM/WDX μRaman Spectroscopy
Морфологија у нуклеарној форензици	MAMA CNN

Табела 3 Врста алата и метода у оквиру алата [9]

Врста алата	Метода
Алати за анализу елемента или изотопа	Радиометријске технике (α, β и γ спектрометрија) Масена спектрометрија (TIMS, ICP-MS) Хемијски огледи Радиохемијске методе XRF XRD GC/MS
Алати за визуелну анализу	Визуелно осматрање и фотографија Ауторадиографија Оптичка микроскопија SEM TEM
Алати за микроанализу	Рендгенске микроанализе (SEM/EDX и SEM/WDX) SIMS ИЦ спектроскопија μРаман спектроскопија

 ISBN 978-86-7466-930-3

Табела 4 Карактеризација према величини узорка и границама детекције [6]

Врста алата	Метода	Врста информације о материјалу	Границе детекције	Просторна резолуција
Алати за анализу елемента или изотопа	HRGS	Изотопске	ng-µg	
	Хемијски огледи	Елементарне	mg	
	Радиохемијске/ Радиометријске методе	Изотопске/ Елементарне	fg-pg	
	TIMS	Изотопске/ Елементарне	pg-ng	
	ICP-MS	Изотопске/ Елементарне	pg-ng	
	XRF	Елементарне	10 ppm	
	XRD	Молекуларне	~ 1 at%	
	GS/MS	Молекуларне	ppm	
Алати за визуелну анализу	Визуелна инспекција	Макроскопске		0.1 mm
	Ауторадиографија	Микроскопске		10 – 50 µm
	Оптичка микроскопија	Микроскопске		1 µm
	SEM	Микроскопске		1 nm
	TEM	Микроскопске		0.1 nm
Алати за микроанализу	SIMS	Елементарне/ Изотопске	0.1 ppb – 10 ppm	0.1 – 1 µm
	SEM/EDX (WDX)	Елементарне	0.1 – 2 mu %	1 µm
	FTIR	Молекуларне	0.1 – 1 mu %	10 µm
	µРаман	Молекуларне	~ 1 mu %	1 µm

Закључак

Развојем нуклеарно-форензичких метода, нуклеарна безбедност је подигнута на виши ниво. Нуклеарни безбедносни режими су без ових алата немоћни. Постојање метода, значајно је допринело заустављању ширења нуклеарног наоружања, нуклеарног тероризма и недозвољене производње и употребе оружја које се везује за атомску и нуклеарну енергију. Ипак, и поред ових озбиљних метода није дошло до онога чему се тежи, а то је да се у потпуности укине нуклеарно наоружање, које би у некој будућој ескалацији сукоба између сила довело до престанка света каквим га познајемо. Међутим, кривица је у политици, а методе су моћан алат у имплементацији споразума.

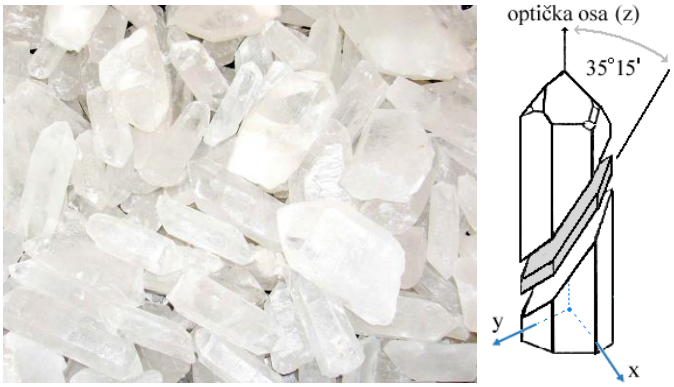
Stabilnost frekvencije kvarcnih oscilatora

Miodrag Malović, Ljiljana Brajović, Tomislav Šekara

***Apstrakt*—Oscilatorna kola su neizbežni deo praktično svih elektronskih uređaja. Najčešće se koriste kola na bazi kvarcnih kristala. Prikazan je proces proizvodnje i princip rada kvarcnih oscilatora, kao i podele kristala i oscilatornih kola. Analizirane su metode kvantitativnog opisivanja greške odnosno nestabilnosti frekvencije. Efekti koji utiču na promene frekvencije su klasifikovani po fizičkom poreklu i vremenskom periodu u kom se dešavaju.**

***Ključne reči*—Kvarcni kristal, oscilator, frekvencija, vreme, stabilnost, preciznost**



I. Uvod

Piezoelektricitet je pojava međuzavisnosti između normalnog napona, koji izaziva mehaničku deformaciju, i naelektrisanja na krajevima materijala. Pritisak na materijal izaziva električnu polarizaciju, i obrnuto, primena električnog napona izaziva deformaciju materijala. Piezoelektrični oscilatori su električna kola koja koriste piezoelektrične karakteristike kvarcnih kristala ili drugih materijala da stvore električni signal približno konstantne frekvencije. U današnje vreme piezoelektrični, uglavnom kvarcni, oscilatori su glavni izvor takta u elektronskim napravama, a praktično ne postoji elektronski uređaj bez oscilatora. Alternative kvarcu su drugi kristali (npr. turmalin, topaz ili kalijum-natrijum tartarat) ili neke vrste keramike. Keramički materijali, dobijeni sinterovanjem, i pored nekih prednosti, imaju mnogo nestabilniju frekvenciju oscilovanja [1].

U novije vreme javljaju se i MEMS oscilatori koji ne moraju raditi na piezoelektričnom principu. I pored značajnog poboljšanja nekih karakteristika, prvenstveno stabilnosti frekvencije [2], MEMS oscilatori su još uvek daleko od preuzimanja primata kvarcnim oscilatorima, jer imaju i veću cenu i veću potrošnju energije (bitno kod baterijski napajanih sistema). S obzirom na tendencije razvoja u pravcu smanjenja potrošnje i cene, izgleda da će se kvarcni oscilatori koristiti još dugo godina.

II. Kvarcni kristali

Kvarc, koji predstavlja kristalni oblik silicijum dioksida, se najčešće dobija iz površinskih kopova u raznim delovima sveta. Kristali su uglavnom providni i bezbojni, a mogu biti i u različitim nijansama u zavisnosti od primesa. Prirodni kristali kvarca (Sl. 1a) se mrve, rastvaraju, i ponovo kristališu pod kontrolisanim uslovima. Veštački uzgojeni kristali (veličine u santimetrima) zahtevaju par meseci rasta pod strogo kontrolisanim uslovima (na visokoj temperaturi i pritisku). Komadići kristala pravilnog oblika, veličine tipično nekoliko milimetara, isečeni iz njih na različite, strogo definisane načine koji se nazivaju rezovi (*cuts*), koriste se kao osnove elektronskih oscilatornih kola. U odnosu na RLC kola, kvarcni oscilatori imaju manji koeficijent prigušenja, odnosno manje gubitke, te zahtevaju vrlo malo snage za održavanje oscilacija.

Sl. 1. a) Prirodni kristali kvarca; b) AT rez; električna osa (x) spaja naspramne uglove heksagonalnog preseka, a mehanička (y) je normalna na naspramne površine; svaki kristal ima tri x i tri y ose.

Rezonantne frekvencije kvarcnih kristala su u praksi u većini slučajeva u opsegu od kHz do više stotina MHz. Rezonantna učestanost primarno zavisi od vrste, oblika i veličine kristala (reza), i primenjenih statičkih sila.

Izborom pogodnih oblika kristala dobijaju se oscilatori relativno stabilni u odnosu na temperaturske promene (koje su glavni izvor kratkoročnih fluktuacija frekvencije). Najčešće korišćeni oblik kristala je tzv. AT rez. AT pločice se seku kao isečci pod uglom od 35º 15’ u odnosu na optičku osu, kao na Sl. 1b (x ose se poklapaju).

Osim AT reza, evo kratkog opisa nekih od mnogobrojnih drugih tipova:

- BT rez: manje temperaturno stabilan ali se za visoke frekvencije lakše proizvodi (jeftiniji je); seče se pod uglom od 49º u odnosu na optičku osu

- SC rez: izvedeno od „stres kompenzacije“; kompleksnijeg procesa proizvodnje, koristi se u temperaturski kompenzovanim oscilatorima, sa većom stabilnošću frekvencije u odnosu na temperaturu i mehaničke uticaje; seče se pod strogo definisanim uglom ne samo u odnosu na optičku (35º 15’, kao AT), već i na električnu osu (21º 54’); slični

Miodrag Malović – Univerzitet u Beogradu, Inovacioni centar Tehnološko-metalurškog fakulteta, Karnegijeva 4, 11120 Beograd (e-mail: ofiss@malovic.in.rs) (https://orcid.org/0000-0002-0691-4626).

Ljiljana Brajović – Univerzitet u Beogradu, Građevinski fakultet, Bulevar kralja Aleksandra 73, 11120 Beograd (e-mail: brajovic@grf.rs) (https://orcid.org/0000-0002-2265-7308).

 ISBN 978-86-7466-930-3

rezovi se nazivaju dvostruko rotirani rezovi

- XY rez: koristi se za manje frekvencije, tipično za 32768 Hz (popularna kao 2^{15}, tako da se 1 sekunda registruje prenosom 15-bitnog brojača); često korišćeni *tuning fork* kristali (u obliku zvučne viljuške) koriste ovaj tip reza; seče se poprečno ili skoro poprečno u odnosu na optičku osu (u xy ravni)

Geometrija oscilovanja kvarcnog kristala varira. Najčešće imamo pojavu tzv. *thickness-shear* (smicanje po debljini) oscilovanja, što znači da gornja i donja površina pločice osciluju longitudinalno u različitim smerovima, kao što je grafički prikazano na Sl. 2, dole desno. Ovo je uobičajeni režim rada za AT rezove. Sledeći najčešći modovi oscilovanja su: longitudinalni (*length* ili *extensional*) i transverzalni (*flexure*), ekvivalentno poznatim režimima oscilovanja žica i štapova, kao i režim smicanja po površini (*face-shear*). Transverzalne oscilacije su tipične za XY rez.

Sl. 2. Najčešći modovi oscilovanja kvarcnih kristala.

Smicanje po površini je na Sl. 2 prikazano odozgo (za kvadratnu pločicu manje debljine) a ostali modovi sa strane. Ovo su najčešće geometrije, ali postoje varijacije i na ovaj raspored dimenzija. Takođe, postoje i drugi modovi oscilovanja (npr. torzioni), kao i drugi oblici pločica (npr. disk), koji se ređe koriste.

III. MATEMATIČKO OPISIVANJE FLUKTUACIJA FREKVENCIJE

Preciznost i tačnost frekvencije su dva pojma koja treba razlikovati. Greška je razlika između stvarne frekvencije, koju je nemoguće savršeno odrediti, i nominalne (deklarisane) frekvencije. Tačnost je obrnuto proporcionalna greški. Preciznost ili stabilnost oscilatora je inverzna mera varijacije frekvencije. Uređaj može biti tačan ali neprecizan ako mu je srednja frekvencija blizu nominalne ali pokazivanje više varira, ili netačan a precizan ako frekvencija nije dobro podešena ali manje varira u vremenu.

Stabilnost se obično deli na kratkoročnu i dugoročnu, mada je ponekad u upotrebi i izraz srednjoročna stabilnost. Ne postoji striktna vremenska podela na kratkoročne i dugoročne promene frekvencije u smislu apsolutne vrednosti vremena. Kratkoročna stabilnost označava promene u toku vremena reda veličine sekundi ili minuta (u toku jedne sesije rada sa uređajem, recimo), dok se dugoročna stabilnost odnosi na periode reda veličine meseci ili godina. Često se reč stabilnost koristi isključivo da opiše kratkoročnu preciznost, dok se dugoročne promene opisuju pojmom „starenje“.

Kod starenja, za kvantitativnu meru stabilnosti uzimamo jednostavno relativni odnos apsolutne promene frekvencije i njene početne, krajnje ili nominalne vrednosti (koje su približno jednake, a stabilnost ne zahteva toliko preciznu deklaraciju, pa možemo upotrebiti bilo koju od njih).

Za opisivanje kratkoročne stabilnosti koriste se različite metričke funkcije. Peak-to-peak devijacija predstavlja razliku između maksimalne i minimalne izmerene frekvencije u nekom vremenskom intervalu, i može se izražavati u apsolutnim ili relativnim jedinicama:

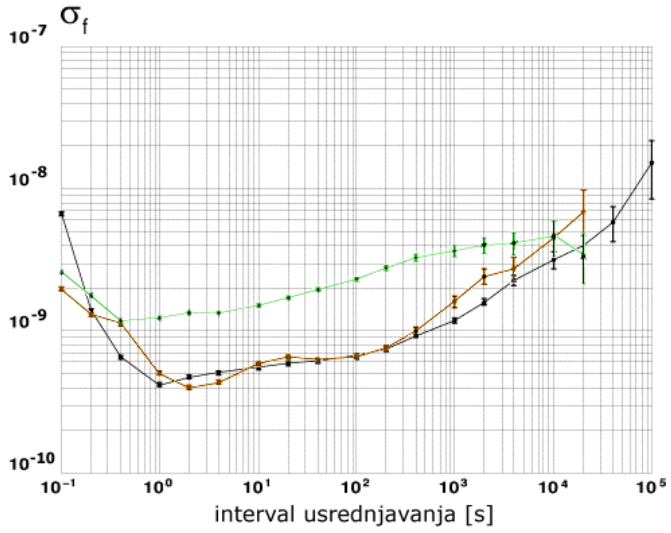
$$\Delta f_{\text{p-p}} = f_{\max} - f_{\min}$$
$$\delta f_{\text{p-p}} = \frac{f_{\max} - f_{\min}}{\bar{f}} \tag{1}$$

Standardna devijacija predstavlja koren iz srednjeg kvadrata razlike u odnosu na srednju vrednost (varijanse):

$$\sigma f = \sqrt{\frac{\sum_{1}^{N} (f_N - \bar{f})^2}{N}} \tag{2}$$

i takođe se često deli sa srednjom vrednošću frekvencije da bi se izrazila u relativnim jedinicama. Ipak, ako se drugačije ne naglasi, u metrologiji se najčešće podrazumeva da se koristi Alanova devijacija:

$$\sigma_f(t) = \sqrt{\frac{\sum_{1}^{N-1} (\bar{f}(\mathrm{t}_{i+1}) - \bar{f}(\mathrm{t}_i))^2}{2(N-1)}} \tag{3}$$



Alanova devijacija je funkcija vremenskog intervala (koji se najčešće naziva interval usrednjavanja) t, i uzima u obzir usrednjene frekvencije u isključivo susednim intervalima tog trajanja. Da bismo, na primer, odredili Alanovu devijaciju frekvencije za interval usrednjavanja od 1 s, izbrojaćemo impulse u N susednih sekundi (najmanje dve) i podeliti broj impulsa sa vremenom (tj. 1 s; za određivanje protoka vremena koristi se tačniji, etalonski sat) da bismo dobili f_{sr} za svaki period. Zatim određujemo Alanovu devijaciju kao koren iz srednjeg kvadrata razlika isključivo susednih članova, podeljenog sa dva. Bitno je zapaziti da na ovaj način driftovi frekvencije izvan intervala za koji se stabilnost deklariše ne utiču na rezultat, što nije slučaj sa standardnom devijacijom ili peak-to-peak vrednošću. Alanova devijacija se, kao i standardna, često izražava u relativnim jedinicama (podeljena sa srednjom vrednošću).

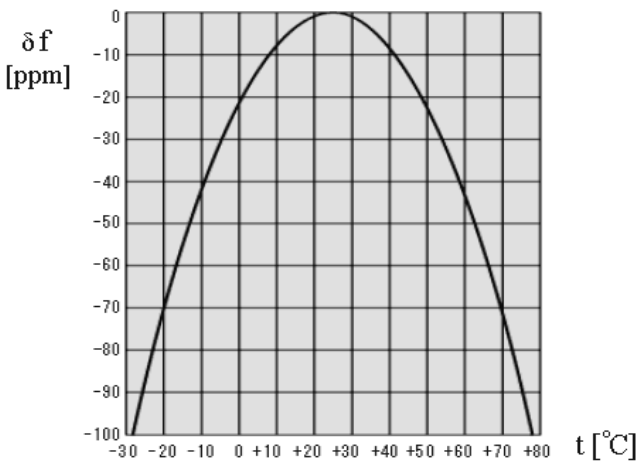
Renomirani proizvođači određuju stabilnost frekvencije laboratorijski i predstavljaju tipične rezultate kao Alanovu devijaciju u zavisnosti od perioda posmatranja. Radi se o

 ISBN 978-86-7466-930-3

šumu frekvencije, bez merljive promene spoljašnjih faktora, dakle pod konstantnim laboratorijskim uslovima. Stabilnost se predstavlja na logaritamskom grafiku, najčešće za periode od dela sekunde do 10^4 ili 10^5 sekundi. Stabilnost je slabija za manje intervale, i poboljšava se sa povećanjem perioda posmatranja kao posledica usrednjavanja, do optimalne vrednosti za periode reda veličine 1 s. Sa povećavanjem kvaliteta oscilatora, raste i vreme za koje se javlja maksimum stabilnosti (ide i preko 10^4 s kod najkvalitetnijih kontrolisanih oscilatora) [3]. Pri daljem povećanju perioda usrednjavanja, nestabilnosti temperature, napajanja, i dr, preuzimaju dominantni uticaj, pa opet dolazi do (nešto sporijeg) pogoršanja. Za najkvalitetnije kvarcne oscilatore, stabilnost može imati vrednost ekstremuma (numerički minimum, odnosno kvalitativno maksimum) reda veličine i boljeg od 10^{-13} (dok je uobičajeno nekoliko redova veličine lošija), u relativnim jedinicama [4].

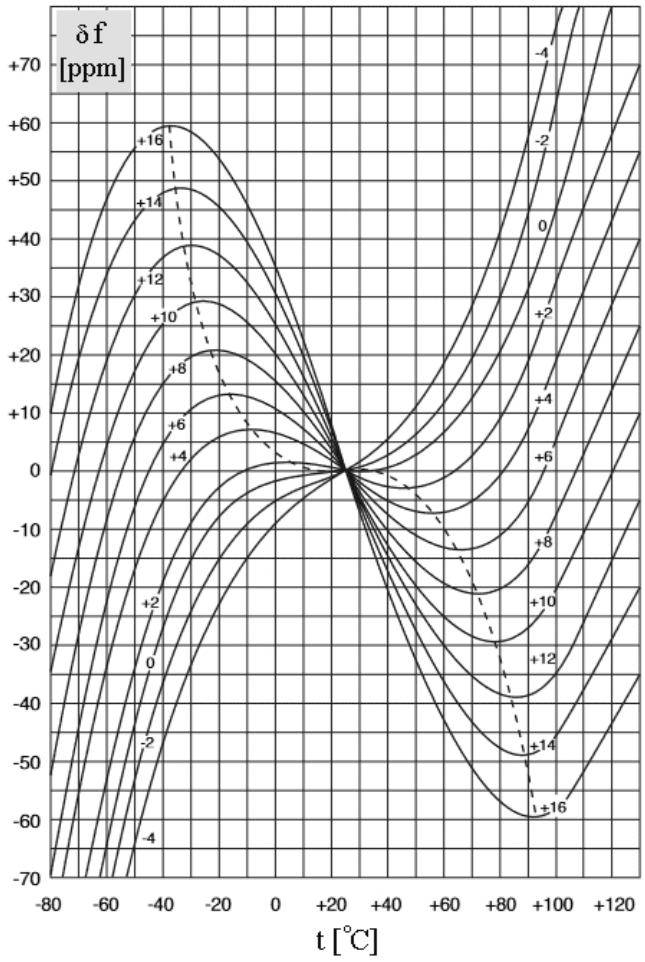
Na Sl. 3 je prikazan primer dijagrama vremenske stabilnosti za tri eksperimentalno testirana komada TCXO oscilatora modela HTV2 proizvođača Connor-Winfield [5].

Sl. 3. Eksperimentalno određena stabilnost frekvencije tri komada temperaturski kompenzovanih oscilatora *Connor-Winfield* HTV2 [5].



IV. IZVORI KRATKOROČNE I DUGOROČNE NESTABILNOSTI FREKVENCIJE

Od kratkoročnih varijacija najčešće su one izazvane promenama temperature, mada i mnogobrojni drugi fizički efekti doprinose stalnim kako skokovitim tako i laganim promenama (driftovima) rezonantne frekvencije [6]. U njih spadaju šokovi (fizički udarci), promena položaja, vibracije, promena napona napajanja, elektromagnetske smetnje, radioaktivnost, itd.



Mnoge od ovih pojava imaju izražen histerezis, a prvenstveno temperatura i napajanje. Pojava skokovite promene frekvencije prilikom gašenja i ponovnog paljenja uređaja se naziva *retrace* efekat. Regularne vibracije, promene položaja, i napona napajanja uglavnom ne proizvode intenzitet relativne promene frekvencije veći od 10^{-9}. Ritrejs ili jači šokovi mogu imati nešto veći efekat, obično oko 10^{-8} [7].

Zavisnost frekvencije od temperature je parabolična sa negativnim koeficijentom (kao na Sl. 4), tj. ima maksimum na željenoj radnoj temperaturi kod većine rezova:

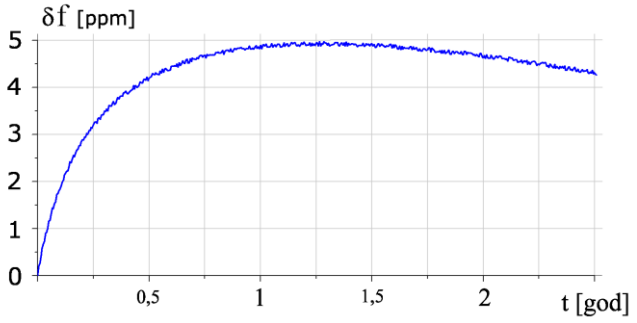
$$f(t) = f_0(1 - k(t - t_0)^2) \quad (4)$$

Sl. 4. Parabolična zavisnost $f(t)$ za BT, XY, i mnoge druge tipove rezova kvarcnog kristala.

Sl. 5. Skup funkcija $f(t)$ za AT tipove kristala sa različitim uglom rezanja.

 ISBN 978-86-7466-930-3

dok AT i SC tipovi kristala imaju približno kubnu zavisnost rezonantne frekvencije od temperature:



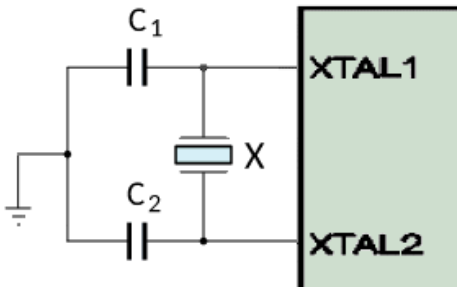
$$f(t) = f_o(1 + k_1(t - t_o) + k_2(t - t_o)^2 + k_3(t - t_o)^3) \quad (5)$$

Središnji deo obe krive obično se nalazi na sobnoj temperaturi ($t_o \approx 25$ ºC), pošto je to ciljna temperatura rada većine kristala, dok je nešto više kod SC rezova (65-95 ºC), koji se koriste u kontrolisanim, zagrejanim komorama. Kod uobičajenog AT reza pod optimalnim uglom od oko 35º 15', imamo slabu zavisnost od temperature (relativne promene reda veličine ppm, tj. 10^{-6}, za ceo opseg temperatura 0-50 ºC).

Pri promeni ugla rezanja, vidimo da dolazi do krivljenja funkcije (na Sl. 5 imamo po jednu nacrtanu krivu na svaka 2 minuta promene ugla reza). Tačke lokalnih ekstremuma kubne zavisnosti, koji se javljaju u ovom slučaju, nazivaju se LTTP i UTTP (*lower temperature turning point* odnosno *upper temperature turning point*), i spojene su isprekidanim linijama na slici. Kristali se nekada koriste i u ovom režimu (oko ovih temperatura).

Kod kristala ekonomske klase, varijacije rezonantne frekvencije posmatrane između različitih komada kristala, istog modela, iznose tipično oko 10^{-5}, a retko preko 10^{-4}.

Dugoročne promene frekvencije se odnose na duže periode koji su reda veličine meseci ili godina. Uzrok dugoročnih promena su kretanja molekula primesa unutar kristala, i fizičkih promena oblika samog kristala kao i delova sa kojima je doveden u dodir (postolja). Naravno, kvalitet izrade kristala i oscilatora određuje ove parametre - čistoća kako materijala tako i punjenja kutije oscilatora od inertnog gasa, i kvalitet zaptivanja povećavaju stabilnost frekvencije. Tipična kriva promene frekvencije kvarcnog kristala usled starenja data je na Sl. 6. Eksponencijalna komponenta, dominantna na početku života kristala, uglavnom potiče od promena oblika (tzv. *stress relief* odnosno ublažavanje naprezanja, ili sleganje), dok sporo opadajuća komponenta koja preuzima primat u kasnijim godinama predstavlja efekte kontaminacije (kretanje molekula primesa) [8].



Sl. 6. Tipična promena rezonantne frekvencije kvarcnog kristala usled starenja.

Starenja većine komercijalnih oscilatora su reda veličine 10^{-6} do 10^{-5} na nivou više godina. U literaturi se može sresti i podela starenja na aktivno i pasivno. Pod aktivnim starenjem se podrazumeva starenje u toku rada, dok je pasivno starenje „na polici" tj. kada se kristal ne koristi. Moguće je i eksperimentalno ubrzano starenje kristala. Ovo se izvodi aktivno, na većoj temperaturi. Smatra se da rad na 85 ºC od mesec dana do 1000 sati, ili rad na 105 ºC nedelju dana, proizvodi efekte starenja kao i regularna operacija na sobnoj temperaturi tokom jedne godine. Ubrzano starenje na temperaturama od 125-150 ºC često ispoljava izmene nagiba opadajuće dugoročne komponente, dakle postoje promene u fizici procesa kontaminacije, te se ne može smatrati za tačnu repliku originalnog procesa i ovakva testiranja nemaju veliku vrednost [9].

V. TIPOVI OSCILATORA

Kao što je već rečeno, kvarcni kristali se koriste kao osnovni elementi u oscilatornim kolima (oscilatorima). Oscilatori mogu imati komponente koje služe za stabilizaciju frekvencije, kao i kola za multiplikaciju frekvencije, kojima se osnovna frekvencija kristala povećava ceo broj puta (najčešće 2^n).

Najprostiji tip oscilatora se dobija vezivanjem dva kondenzatora između krajeva kristala i mase, i koristi se za davanje takta mikroprocesorima, kao što je ilustrovano na Sl. 7. Malo kompleksniji modeli poznati su iz analogne i digitalne elektronike, kao što su Kolpicov i Piersov oscilator [10].

Sl. 7. Uobičajeni način vezivanja kvarcnog kristala (X) na CPU - mikroprocesorski oscilator.

Osnovna podela oscilatora je na tri kategorije: RTXO, TCXO i OCXO (gde kovanica XO označava kristalni oscilator), a postoje i druge skraćenice od kojih ćemo neke spomenuti.

Jednostavna kola koja ne vrše nikakvu kompenzaciju temperaturskih promena spadaju u kategoriju RTXO (*room temperature crystal oscillators*). Većina ekonomskih uređaja koriste RTXO kola, ne samo zbog manje cene, već i zbog znatno niže potrošnje energije, što je važan faktor u projektovanju baterijski napajanih uređaja.

TCXO (*temperature compensated crystal oscillators*) sadrže termometre, mere temperaturu, i uvode korekcije da bi se rezonantna frekvencija učinila stabilnijom. Uobičajeni princip rada TCXO je VCXO: *voltage controlled crystal oscillator*. VCXO je nešto širi pojam, koji obuhvata sve kristalne oscilatore čija se frekvencija kontroliše naponom (ne samo one kod kojih je cilj postizanje stabilne frekvencije). Kod TCXO sa VCXO (takođe zvanih i VC-TCXO),

 ISBN 978-86-7466-930-3

kontroliše se napon napajanja kristala tako da se kompenzuju promene frekvencije koje potiču od promene temperature (koja se monitoriše). Digitalni TCXO se referenciraju i imenima DCXO - *digitally controlled crystal oscillators* ili MCXO - *microprocessor controlled crystal oscillators*.

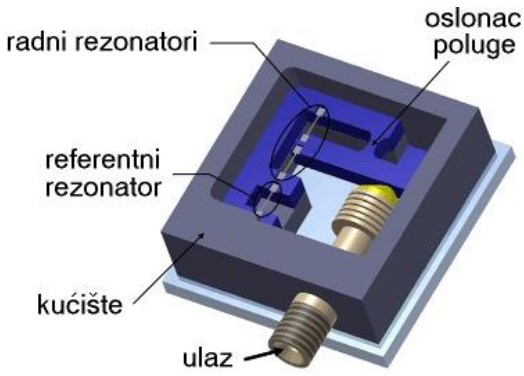
Kod OCXO (*oven controlled crystal oscillators*) se kolo grejanjem održava na konstantnoj temperaturi, u kućištu koje predstavlja zatvorenu temperatursku komoru (*oven*), tako da su temperaturski uticaji zanemarljivi. Ovo je još skuplji i energetski zahtevniji tip oscilatora. U ekstremnim slučajevima, koriste se još skuplji, krupniji i snažniji DOCXO (dupli OCXO), koji rade istu stvar u dva koraka - imaju spoljnu i unutrašnju komoru, i umesto standardne stabilnosti frekvencije za OCXO reda veličine 10^{-8} relativno na dnevnom nivou, postižu uobičajenu standardnu stabilnost reda veličine 10^{-11} i bolje [11].

VI. GPS DISCIPLINOVANI OSCILATORI

Kombinovanjem OCXO, a ređe i TCXO, koji ne moraju biti striktno bazirani na kvarcu (mada kvarc jeste jedan od osnovnih tipova kristala koji se koriste), sa GPS prijemnikom, dobijamo u novije vreme popularnu kategoriju GPS disciplinovanih oscilatora (GPSDO) [12].

Sl. 8. GPSDO modul, bez prijemnika, proizvođača *Acquisys* [14].

GPS (*global positioning system*) servis pruža uslugu takozvanog PPS-a, odnosno *pulse per second*. Iako PPS ne pruža informaciju o fizičkom vremenu (vreme-datumu), on daje pouzdanu informaciju o protoku jedne sekunde, koja se konstantno usklađuje sa referentnim laboratorijama najvišeg nivoa tačnosti na zemlji. Istina je da u prijemu PPS signala postoji značajna neodređenost, uslovljena procesom prenosa signala sa satelita do prijemnika u uređaju (nesavršenosti elektronike transmitera i prijemnika, kao i neodređenost putanje prenosa kroz sredinu promenljivih karakteristika), što čini da je kratkoročna stabilnost PPS frekvencije mala (čak i do 10^{-6}). Međutim, dugoročna stabilnost ovog signala je superiorna u odnosu na sve samostalne oscilatore, i GPS disciplinovani oscilatori (koji predstavljaju kompleksne elektronske uređaje sa sofisticiranim softverom) kombinuju ovu stabilnost sa superiornom kratkoročnom stabilnošću OCXO oscilatora. Procesor monitoriše frekvenciju PPS i OCXO signala, i izvodi neophodne korekcije da bi izlaz oscilatora uskladio sa dugoročno analiziranim PPS signalima. Budući da se radi o softverskoj kontroli, GPSDO lako izlazi na kraj sa propuštenim PPS signalima. Promene rezonantne frekvencije kristala nastale kao posledica starenja se pamte pa možemo reći da se izvodi kontinualna kalibracija frekvencije.



Jedna od mana ove vrste oscilatora (osim očiglednih: veličine, potrošnje i cene, koja je za bolje modele preko hiljadu dolara) je nemogućnost da se radi na mestima gde ne postoji dostupnost GPS signala (bez dodatnog antenskog sistema), a ovaj je poznat po svojoj slaboj prodornosti u zatvorene prostore [13].

Primer GPSDO modula (bez prijemnika), proizvođača Acquisys [14], prikazan je na Sl. 8. Dimenzije modula iznose $10{,}4 \times 7{,}0 \times 2{,}6$ cm.

VII. SENZORI NA BAZI VARIJABILNOSTI FREKVENCIJE

Promenljivost frekvencije oscilovanja kristala je pojava koju možemo i iskoristiti. Neki senzori rade tako što prate promene rezonantne frekvencije u funkciji posmatrane fizičke veličine. Naravno, kvalitet ovih senzora je limitiran zavisnošću iste frekvencije od drugih faktora. Jedan od metoda koji se koriste za eliminaciju zavisnosti od neželjenih parametara jeste upotreba još jednog, referentnog kvarcnog kristala, koji se izlaže koliko je moguće identičnim uslovima, osim pobude. U ovom slučaju izlaz senzora predstavlja razliku između frekvencija oscilovanja pobuđenog i referentnog kristala.

Jedan od takvih sistema, za merenje pritiska, realizovan je na univerzitetu u Ksi Anu, u Kini [15]. Šema je prikazana na Sl. 9. Ideja je slična Vitstonovom mostu sa poluprovodničkim mernim trakama: dva rezonatora koji se istežu u suprotnim smerovima povećavaju osetljivost, dok treći služi za kompenzaciju temperaturnih i drugih efekata.

Sl. 9. Šema senzora pritiska razvijenog na Univerzitetu u Ksi Anu, Kina [15].

Integrisani senzori ubrzanja na principu promenljive frekvencije kvarcnog rezonatora su u upotrebi od osamdesetih godina prošlog veka, ali su u početku bili višekomponentni, tj. probna masa se sastavljala sa kućištem i kristalom (koji je obično bio tipa DETF - *double ended tuning fork*, odnosno zvučna viljuška spojena na oba kraja). Ovakvi sistemi su termalno nehomogeni, tj. unose grešku po osnovu različitih koeficijenata termalnog širenja različitih materijala od kojih se sastoje. Zato se u novije vreme proizvode tzv. monolitni MEMS senzori koji su u potpunosti izgrađeni od kvarca [16].

 ISBN 978-86-7466-930-3

QCM - *quartz crystal microbalance*, predstavlja kategoriju merenja koja se zasnivaju na promeni mase kvarcnog kristala, koja uzrokuje promenu rezonantne frekvencije [17]. Dodavanjem slojeva materijala na kvarc, frekvencija oscilovanja se smanjuje. QCM kvarcni kristali, po pravilu oblika okrugle pločice (diska), imaju tanak film kojim su obloženi, a koji menja masu putem interakcije sa sredinom u kojoj se nalazi. Najčešće se vrši detekcija gasova, koji stupaju u hemijsku ili fizičku interakciju sa slojem, koja uzrokuje promenu njegove mase. Naravno, neophodno je da ova interakcija bude reverzibilna. Jedna od čestih primena QCM je merenje vlažnosti (upijanjem molekula vode od strane sloja materijala kao što je grafen).

Merenja viskoznosti tečnosti uranjanjem celog kristala ili, češće, njegovog dela u tečnost poznate gustine takođe se svrstavaju u kategoriju QCM. Teškoća u primeni ovih tehnika je činjenica da dolazi do velike promene u faktoru prigušenja što izaziva dodatnu nestabilnost frekvencije, pa čak i mogućnost prestanka oscilovanja. U novije vreme koriste se senzorski sistemi u kojima se određuju dimenzije kapljica tečnosti koje se zatim spuštaju na površinu kristala čija se frekvencija meri [18]. Istina je da je automatizacija ovakvog procesa teško izvodljiva, ali kontinualna terenska merenja viskoznosti su retko potrebna.

VIII. ZAKLJUČAK

Opisani su kvarcni kristali i oscilatori koji ih koriste kao svoje komponente. Analizirani su faktori koji utiču na promene rezonantne frekvencije, odnosno njene kratkoročne i dugoročne nestabilnosti. Dat je i kratak pregled savremenih senzora koji koriste promene rezonantne frekvencije za merenje različitih fizičkih veličina.

Iako su u novije vreme razvijeni MEMS oscilatori sa boljom stabilnošću frekvencije, mala potrošnja i cena će definitivno uticati na to da kvarcni kristali ostanu osnova većine oscilatornih kola u doglednoj budućnosti.

ABSTRACT

This paper presents a short review of quartz oscillators frequency stability issues. Quartz crystals are a base building block of majority of oscillator circuits, which are unavoidable part of practically any modern electronic device. The principle of operation, process of production, and classification of crystals were described briefly. Metrics for mathematical description of frequency error and stability were analysed. Phenomena affecting frequency fluctuations were classified by their physical origin and the time scale on which they occur. Several types of sensors employing the effect of frequency variability were also described.

Natural Polymers As Nanocapsule Carriers

Danijela Rajić, Srđan Vuković, Svetlana Pelemiš, Milesa Srećković

***Abstract*— Natural polymers obtained from renewable sources have recently been increasingly considered as suitable carriers, in the form of nanocapsules, for various active components. They enable the formation of a system for the delivery of active substances so that it is possible to encapsulate, protect, and release bioactive substances in drugs and food. Encapsulation of active components also enables the protection of sensitive and easily volatile components. Particular attention is paid to their application in the food industry for the production of functional foods, which, in addition to being nutritional, also have a certain therapeutic effect. In the pharmaceutical industry, more and more research is being devoted to them in the area of long-release drugs. Nanocapsules outperform most other colloidal carriers because of their small size, greater encapsulation potential, greater encapsulation power, and targeted action. Most of the existing carriers based on natural proteins used in the food and pharmaceutical industries are hydrophilic, so the encapsulation of hydrophobic active substances is a special challenge. This paper presents an overview of natural polymers used as suitable carriers and the possibilities of their use in the synthesis of nanocapsules for various uses.**

***Index Terms*— natural polymers; renewable sources; nanocapsule carriers; drugs; active components.**

I. Introduction

Natural polymers derived from food are considered desirable materials for constructing delivery systems to encapsulate, protect, and release bioactive components in nutraceuticals, pharmaceuticals and food [1]. Food proteins are of particular interest in the design of delivery systems, due to their high nutritional value, abundant sources, structural versatility and considerable functional properties [2, 3]. Nanoparticles constructed of food proteins have suitable physicochemical properties and functional attributes, which allow them to entrap both hydrophilic and hydrophobic bioactive compounds. They are increasingly being applied as delivery systems in the food industry to improve the stability and oral bioavailability of bioactive components [4]. Nanocapsules have an advantage over most of the other colloidal carriers due to their smaller size, higher encapsulation efficiency, more effective penetration ability and targetability [5]. Nanobiotechnology have wide range of application [6]. Nanocapsules were first developed around 1970. They were initially devised as carrier for vaccines and anticancer. Over the past few decades, there has been considerable interest in developing biodegradable nanocapsules (liposome, virus like particle (VLP), protein, etc.) as effective food and drug delivery device [2].

Nanocapsules have become an important area of research in the field of food and drug delivery vehicles [7].Scientific community working at the interface of chemistry and biology is always on the lookout for biopolymers from natural and sustainable sources to generate newer structures which could be used for applications ranging from product structuring to the in vivo delivery of bioactives. Since, most of the biopolymers approved and been used for food and pharmaceutical applications (such as gelatin, casein, dextran, etc.) are water soluble in nature; it becomes necessary to involve steps of physical and chemical alterations like cross-linking and hydrophobic modifications in order to generate colloidal particles from these materials [8].

Nanocapsules have an advantage over hydrogels, organogels, liposome, and microparticles due to their smaller particle size, higher encapsulation efficiency, more effective penetration ability and targetability. Nanocapsules are usually fabricated from varieties of natural polymers, mainly including food- grade proteins and polysaccharides, because they are biocompatible, biodegradable, and non-toxic properties, such as soy protein lactoferrin, gelatin, chitosan and alginate [5]. Nanocapsules generally vary in size from 10 to 1000 nm [9,10]. Recently protein nanoparticles have been shown efficacy as biodegradable carrier which can incorporate variety of drugs in relatively non-specific fashion [11]. The food or drug is dissolved, entrapped, encapsulated or attached to a nanoparticles matrix and depending upon the method of preparation, nanoparticles, nanospheres or nanocapsule can be obtained. Nanocapsules are vesicular systems in which the drug is confined to a cavity surrounded by a unique polymer membrane, while nanospheres are matrix systems in which the drug is physically and uniformly dispersed [7,9]. Figure 1 shows the schematic diagram of nanocapsulated and nanosphere particles loaded with food or drug.

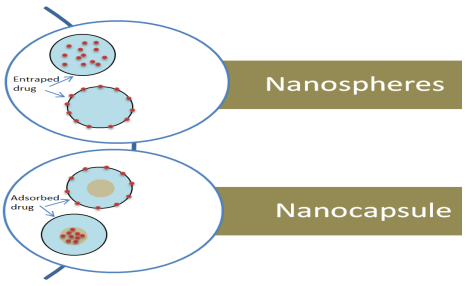

Fig. 1. Schematic diagram of nanospheres and nanocapsules

Among these colloidal system those based on protein may be vary promising since they are biodegradable and non-antigenic relatively easy to prepared and their size distribution can be monitored easily [12]. A wide variety of drugs can be delivered using nanoparticulate carriers via a number of routes. Food-borne diseases are becoming one of the serious problems faced by humans along with environmental contamination and because of that technological innovations in food safety related to consumer confidence and human health are becoming extremely urgent [13].

II. PLANT PROTEINS

Among various natural or synthetic polymer-based particulate systems potentially available to food applications, plant protein-based micro- and nanoparticles are preferably used for nutrient or drug delivery because they offer advantages over other materials in terms of biodegradability, abundant renewable sources, safety status in vivo, and many useful functional properties [14-18]. Additionally, they also exhibit high loading capacity of various bioactives due to their amphiphilic structure, multiple binding sites, and a variety of possible binding mechanisms include electrostatic attractions, hydrophobic interactions, hydrogen and covalent bonding. Due to the known characteristics of microencapsulation, easy surface modification and scale-up feasibilities, particulate systems in micron and nanometre scales provide better opportunities for targeted delivery of bioactive ingredients [16, 19, 20]. The plant proteins most commonly used in the production of nanocapsules are zein, soy, and wheat proteins, and they will be discussed in this paper.

A. Zein

Zein is a protein classified within the group of prolamins. It is attractive for use in nanotechnology as a polymer matrix and is classified as Generally Recognized As Safe (GRAS) by the U.S. Food and Drug Administration (FDA). In addition, zein has promising characteristics, such as biocompatibility, biodegradability, and low toxicity. It is widely used in that it can encapsulate generally different insoluble compounds in water to provide stability and control of release when is in the GastroIntestinal Tract (GIT) [14, 21]. Zein is the main form of protein storage contained in the endosperm tissue of corn and comprises almost 80% of the whole protein content in the corn. In the past, zein was considered more of a by-product of corn processing industries; the consensus indicated zein to be a low-valued material without important potential technological uses. However, due to several recent methodologies and developing processes allowing applications in different fields, nowadays, there is new thought related to zein and zein-based materials towards considering them as more valuable materials. Potential applications of zein include uses as biodegradable plastics, fibers, adhesives, coatings, ceramics, inks, cosmetics, textiles and chewing gum [14, 22, 23, 24].

B. Soy proteins

Soy proteins, the by-product of soy oil processing, is now one of the most widely used protein ingredients in food processing. When different processing methods are conducted, soy protein aggregates with different structures and functionalities could be formed along different pathways [25]. In addition to zein, soy protein-based particles are also promising candidates as delivery systems for nutraceuticals or drugs. Due to the ligand binding properties, soy proteins can serve as an effective carrier for various bioactive molecules. They can bind these molecules to form complexes in nanoscale through physical interactions, mainly hydrophobic interactions, hydrogen bonds and van der Waals attraction. Recent studies suggest that soy proteins have the potential to be used as carriers for both hydrophobic and hydrophilic bioactive compounds, such as vitamin B12, cranberry polyphenols, curcumin, resveratrol (RES), and polyphenols from Concord grape pomace, to improve their water solubility, stability and bioavailability [14].

C. Wheat gliadins

Nanocapsules made from gliadin, a component of wheat gluten, have been prepared for nutrient/drug delivery and controlled release applications. For example, gliadin nanocapsules has been used as carriers for all-trans-retinoic acid (RA) [26]. Gliadin nanocapsules (450–475 nm) were showed to be a suitable delivery and controlled release system for nutrients and drugs with different polarity (hydrophobic and amphiphilic). It was found that the amounts of the entrapped drug increased with an increase in the drug hydrophobicity, confirming a strong interaction between gliadins and apolar compounds. Their essential feature is low price and availability [14, 26].

III. PREPARATION METHODS

Protein nanocapsules can be obtained by different methods [11]. Protein nanocapsules have been extensively studied as suitable for drug delivery since they are biodegradable, non-toxic and non antigenic, because of their defined primary structure and high content of charged amino acids (that is, lysine). The protein-based nanocapsules could allow the electrostatic adsorption of positively or negatively charged molecules without the requirements of other compounds. In addition, protein nanocapsules can be easily prepared under soft condition, by coacervation or controlled desolvation processes [2]. Among the available potential colloidal drug carrier systems covering the size range described, protein-based nanocapsules play an important role [11]. Biopolymers, such as proteins, are commonly used to encapsulate oil-in-water emulsions. Simple and complex coacervation, spray drying and heat denaturation represent three major microencapsulation techniques based on proteins. Their principles are quite similar: emulsification of the core material (oil) is followed by microcapsules wall formation induced by environmental conditions changing. Concerning simple coacervation method, the protein precipitation around

 ISBN 978-86-7466-930-3

oil droplets is obtained by changing pH and temperature or by the "salting-out" technique. Widespread presence of microcapsules based on animal proteins such as gelatin, casein or albumin contrasts with a very limited use of plant proteins. Wheat gliadin was one of the rare plant storage proteins used for encapsulation of dispersed oil phase by simple coacervation method. The microparticles made from soy protein isolate (SPI) were mainly fabricated by using spray-drying, coacervation, and cold gelation techniques [11, 14, 27]. The table 1 provides an overview of nanoparticle types and methods of their preparation.

TABLE I
OVERVIEW OF PLANT-PROTEIN BASED NANOCAPSULES AND TYPE OF PREPARATION [14]

Type of particles	Preparation
Zein microparticles	Spray drying or supercritical antisolvent method
Zein microparticles	Spray or freeze drying
Zein nanoparticles	Liquid–liquid dispersion method
Zein nanoparticles	Phase separation or liquid–liquid dispersion method
Zein nanoparticles	Liquid–liquid dispersion method or electrospraying
Zein nanoparticles	Supercritical anti-solvent
Zein nanoparticles	Liquid–liquid dispersion method or electrospraying
Zein-chitosan complex nanoparticles	Low-energy phase separation method
SPI-zein complex microparticles	Ca^{2+}-induced cold gelation method
SPI/FA-conjugated SPI nanoparticles	Ethanol desolvation method
SPI nanoparticles	Ca^{2+}-induced cold gelation method
Soy protein nanocomplex	Ligand binding properties
SPI-CMCS complex nanoparticles	Ca^{2+} induced co-gelation method
Soy protein-soy polysaccharide complex nanogels	High-pressure homogenization and heating procedures
Soy lipophilic protein nanoparticles	Ultrasonic treatment
Gliadin nanoparticles	Antisolvent precipitation method

IV. CONCLUSION

Natural polymers show great potential for developing promising delivery vehicles to incorporate and protect various bioactive ingredients, and control their release behaviour under the different conditions. It could be used to produce a wide range of delivery systems, such as micro- and nanoparticles, fibers, films and hydrogels, all of which can be tailored for the design of innovative functional foods. As the interest in functional foods is rapidly growing, the development of advanced plant protein-based delivery systems will expand the possible applications. Nanocapsules outperform most other colloidal carriers because of their small size, greater encapsulation potential, greater encapsulation power, and targeted action. Nevertheless, the delivery of functional ingredients in the complex food systems is rather challenging as it is essential to evaluate not only the impact of complex food matrix on the storage stability and bioavailability of the encapsulated ingredients, but also the effect of the delivery systems on the food product functionality, such as stability, texture, taste, appearance and bioavailability of the ingredients.

The work also has a wide application from forensics to herritology.

Kvantne generativne suparničke mreže za generisanje naučnih rezultata

Vladimir Arsoski

A stra t*—Već dugi niz godina smo svedoci da je veli i broj publi acija efi asno sredstvo za priznavanje izuzetne ompetentnosti i talenta u nauci, što može omogućiti pojedincu veli u moralnu i finansijs u satisfa ciju. Čuvena fraza u a adems im rugovima "objavi ili nestani" postaje surova realnost. U želji da objave senzacionalna otkrića, pojedinci pokušavaju da lažiraju naučne rezultate, a o bi stvorili privid izuzetnosti. avremeni programi za analizu sli a, zasnovani na veštačkoj inteligenciji, su se po azali ao efi asno sredstvo za razotkrivanje lažiranih pri aza naučnih rezultata i doveli su do povlačenja velikog broja sumljivih publi acija iz časopisa u poslednjih ne oli o godina. ovi algoritmi veštačke inteligencije zasnovani na generativnim suparničim mrežama pružaju mogućnost za generisanje sli a oje mogu biti lasifi ovane ao verodostojne. Implementacija ovih algoritama na vantnim računarima se po azala ao potencijalno superioran metod generacije sli a, te predstavlja realnu opasnost da slučajevi lažiranja naučnih rezultata ostanu neprimećeni. Ovo nameće potrebu da se u blis oj budućnosti razvije disciplina oja bi se mogla opisati kao forenzika naučnih rezultata i oja bi se bavila razot rivanjem primena ne samo klasičnih, već i vantnih algoritmima za generisanje rezultata.

***Ključne reči* — generativne suparničke mreže; veštačka inteligencija; kvantni računari.**

I. UVOD

Proces publikovanja naučnih radova u časopisima je započeo sredinom 17. veka kada je na inicijativu Henry Oldenburg-a, prvog sekretara Kraljevskog društva, pokrenut prvi naučni časopis *Philosophical Transactions of oyal Society* [1]. Pre toga su naučnici razmenjivali ideje i rezultate na naučnim skupovima i putem privatnih korespondencija, što je ograničavalo pristup najnovijim saznanjima široj populaciji. Koncept publikovanja radova u časopisima zasnivao se na ideji diseminacije i verifikacije novih ideja, saznanja i rezultata u cilju progresa nauke. Vremenom je razvijena metodologija bavljenja naučnim radom, koja je standardizovala i formalizovala istraživačke metode, kao i način prezentacije naučnih radova i zacrtala osnovna moralna načela, koja su vezana za akademski integritet i čestitost.

Od početka devetnaestog veka, mnogi poznati univerziteti u Evropi su počeli da pridaju podjednak značaj podučavanju i naučnom radu [1]. U poslednje vreme, rasprostranjeno je mišljenje da naučni rad ima mnogo veći značaj od nastavnog rada. Mnogi univerziteti vrše selekciju kandidata na osnovu broja publikacija, što može da usmeri nastavnike i saradnike da se intenzivno bave naučnim radom zapostavljajući nastavne delatnosti i mentorski rad. Neretko se dešava da nastavnici organizuju intenzivne prezentacije svojih naučnih dostignuća, čak i na predavanjima, kako bi privukli što veći broj potencijalnih kandidata za bavljenje naučnim radom u nadi da će povećati produktivnost publikovanja. Pritom, zbog sopstvenog angažovanja u nastavi i naučnom radu, često nemaju vremena da se dovoljno posvete mentorskom radu. Dešava se da mladi istraživači iz neznanja produkuju nedovoljno kvalitetne radove, sa pogrešnim ili modifikovanim rezultatima i bez citiranja korišćenih referenci.

Povećanje produkcije radova na godišnjem nivou dovodi do porasta broja naučnih časopisa [2]. U poslednja tri veka, rast broja aktivnih naučnih časopisa godišnje u procentima je približno konstantan i varira oko srednje vrednosti 3.46 %, što odgovara udvostručenju broja časopisa na svakih 20 godina [3]. Poslednjih godina, ovaj trend se povećava, te smo svedoci skoro svakodnevne pojave raznih časopisa čiji je naziv povezan sa oblašću, koja je u žiži naučnog interesovanja. Većina časopisa proverava originalnost, kvalitet prezentacije i značaj razmatrane problematike, tako što vrši selekciju radova pomoću ocenjivanja od strane dva ili više stručnjaka iz oblasti rada (engl. peer-reviewed). Iako se naučna zajednica i broj znalaca u većini oblasti rapidno povećava, postavlja se pitanje njihove raspoloživosti za recenziju rada, što je često vezano za veliko angažovanje samog recenzenta na produkciji radova. Velikom broju naučnih radnika se dešavalo da rad bude predložen za publikaciju ili bude odbijen bez detaljnijeg i konkretnog objašnjenja od strane recenzenta.

Sve veća ulaganja u istraživanja i nauku, kao i velika konkurencija istraživačkih grupa, dovela je poslednjih godina do pojave slučajeva tendencioznih prevara pri akviziciji i prezentovanju naučnih rezultata. U praksi su postale standardne prevare poput *plagijari ma* (prisvajanje tuđih naučnih rezultata), *autoplagijari ma* (objavljivanje istih rezultata u više naučnih časopisa), "*seckanja salame*" (prezentacija jednog naučnog dostignuća kroz seriju radova pod izgovorom obimnosti problematike), "*autora duho a*" (dodavanje na rad autora koji nisu dali značajan doprinos radu) i raznih drugih neetičkih radnji [4].

Statistika je pokazala da samo oko 45 % radova objavljenih u vrhunskim naučnim časopisima iz oblasti biomedicine imaju citate u prvih 5 godina, a od tog broja 5-25% su autocitati i/ili kocitati [4]. Posebno neetički aspekt prevara odnosi se na časopise iz ove oblasti, gde dolazi do obmanjivanja naučno-stručne javnosti, a posredno i pacijenata, o mogućem brzom i

Vladimir Arsoski – Elektrotehnički fakultet, Univerzitet u Beogradu, Bulevar kralja Aleksandra 73, 11020 Beograd, Srbija (e-mail: vlaimir.arsoski@etf.bg.ac.rs).

 ISBN 978-86-7466-930-3

efikasnom izlečenju. Falsifikovanje naučnih rezultata obično je vezano za mikroskopski prikaz slika biomaterijala, ćelija i tkiva [5] ili za grafički prikaz "rezultata merenja" [6]. Neki od ovih radova su dostupni u bazi matičnog časopisa [5], dok na drugima stoji oznaka da su povučeni [6]. Ovi [5,6] i slični slučajevi "dorade" naučnih rezultata, otkriveni su primenom savremenih metoda i programa za analizu slike zasnovanih na veštačkoj inteligenciji. Neka softverska rešenja su besplatno dostupna na internetu, poput *Forensically* [7]. Postoje organizacije koje prate i javno objavljuju podatke o povučenim radovima [8] jer se često dešava da časopisi, zbog čuvanja reputacije, netransparentno uklone rad iz svoje baze podataka. Prema podacima sa sajta [8], do trenutka pisanja ovog rada, povučeno je čak 219 naučnih radova vezanih za COVID-19 pandemiju.

Dosada otkrivene prevare, vezane za objavljivanje lažiranih naučnih rezultata, uglavnom su se zasnivale na korišćenju softvera za odbradu slike, gde su nedoslednosti u vidu kloniranja delova slika, nepravilnog gradijenta boje, osvetljenja, šuma i defekata na slici, mogli da budu detektovani pomoću metoda zasnovanih na mašinskom učenju [7]. U skorije vreme su se pojavili generativni modeli mašinskog učenja, poput varijacionog autoenkodera (VAE) koji predstavlja veštačku neuralnu mrežu koja pripada familiji probabilističkih grafičkih modela [9]. Ovaj model formuliše problem statističkog zaključivanja (na osnovu slučajne veličine zaključak je druga slučajna veličina), kao statistički problem optimizacije. VAE je usmeren model, trening (obučavanje) se može obaviti primenom modela zasnovanih na gradijentu i lako se može generalizovati za rešavanje raznih problema [10]. VAE model, vezan za generisanje slika, uspešno je implementiran u programskom paketu *eras* pod programskim jezikom *Python*. Nedostatak VAE ogleda se u inherentnoj osobini, koja leži u samoj postavci modela, da produkuje relativno "zamućen" izlaz (engl. blur), kada je reč o treniranju za generaciju slika [10], što softver za forenziku može označiti kao mogući problem.

Potencijalno superioran model generativne mreže je generativna suparnička mreža (engl. Generative Adversarial Network - GAN), koja se zasniva na teorijskom scenariju takmičenja između mreže koja generiše uzorke (*generatora*) i mreže *diskriminatora*, koja pokušava da napravi razliku između realnih podataka iz skupa za trening i generisanih podataka [11]. Najbolje performanse modela se postižu za scenario u kojem generator pokušava da poveća vrednost logaritma verovatnoće da diskriminator pogreši, umesto da smanjuje vrednost logaritma verovatnoće da diskriminator dâ tačan odgovor [10,11]. Kada se trening završi, diskriminator sa podjednakom verovatnoćom klasifikuje generisane slike kao prave ili pogrešne i može da se apstrahuje. Na ovaj način, generator je naučen da prevari sistem veštačke inteligencije. Demonstrirano je da duboke konvolucione GAN mogu da generišu izuzetno verodostojne slike [12], što ih čini potencijalno opasnim za generisanje slika u naučnim publikacijama koje može da prođe nezapaženo.

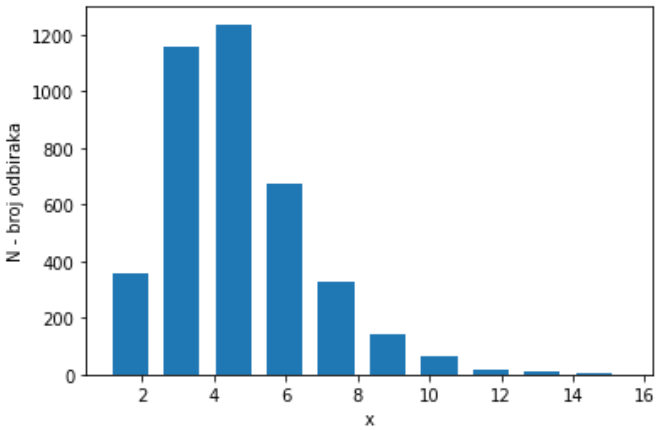
Razvoj kvantnih računara obećava veliki napredak u oblasti hemije, biomedicine, rešavanja kompleksnih matematičkih i fizičkih problema, kao i implementacije naprednih sistema veštačke inteligencije. Efekti inherentni za kvantnu mehaniku, poput superpozicije, interferencije i kvantne zapletenosti (engl. entanglement), mogu dovesti do veće efikasnosti kvantnih algoritama u odnosu na klasične [13]. Za razliku od kvantnog sistema, koji je po prirodi probabilistički, klasični sistemi ne mogu efikasno generisati slučajne veličine (već se govori o pseudo-slučajnim veličinama). Zbog toga su kvantni sistemi, koji su vezani za stohastičke algoritme, značajno jednostavniji i ujedno efikasniji od klasičnih probabilističkih. Takođe je poznato da je za predstavljanje vektora u N-dimenzionom prostoru potrebno $\log_2 N$ kubita, kao i da je vreme manipulacije kvantnog sistema nad retkim matricama složenosti u vremenu reda $(\text{poly}(\log_2 N))$ [13]. Sve ovo dovodi do potencijalne prednosti kvantnih u odnosu na klasične algoritme, pogotovu kada je reč o visokodimenzionim prostorima i stohastičkim procesima. Uprkos činjenici da je kvantni hardver u svom ranom povoju i da su trenutne implementacije podložne dekoherenciji, spoljašnjem šumu i imaju ograničene mogućnosti povezivanja kubita, postoje indikacije da će kvantno mašinsko učenje biti jedna od prvih značajnih primena na kvantnom hardveru. Veliki broj algoritama mašinskog učenja je već adaptiran za rad na kvantnom računaru [14], a od skora i GAN pod nazivima QGAN i QuGAN [15,16]. QGAN je, između ostalog, našao primene vezane za generisanje realističnih raspodela [17,18] i slika [19], gde je demonstrirao jednostavniju implementaciju i eksponencijalno ubrzanje u odnosu na klasičnu GAN.

Sl. 1. Šematski prikaz kvantne generativne suparničke mreže. Ulazni podaci za diskriminizator su kvantna stanja iz generatora G (čiji ulaz pobuđuje stohastički vektor |z>) ili iz realnog izvora podataka . Izlaz diskriminatora je kvantno stanje |lažni> ili |realni> i odnosi se na procenu porekla ulaznog podatka. Slika je adaptirana na osnovu rada [15].

II. Model kvantne generativne suparničke mreže

Šematski prikaz kvantne generativne suparničke mreže je dat na Sl. 1. predstavlja izvor realnih podataka koji za zadatu kvantnu labelu $|\lambda\rangle$ generiše realne podatke. Svrha QGAN-a je da definiše generator G koji imitira izvor realnih podataka . G predstavlja varijaciono kvantno kolo, čiji su gejtovi parametrizovani vektorom $\boldsymbol{\theta}_G$. Na osnovu stanja $|\lambda\rangle$ i dodatnog stohastičkog stanja $|\ \rangle$ generator produkuje stanje na svom izlazu koje treba da bude slično stanju koje daje . U

 ISBN 978-86-7466-930-3

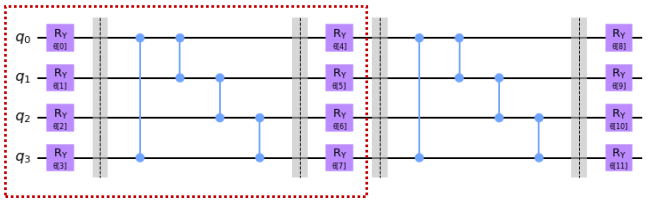


opštem slučaju, dodatno stanje $|\ \rangle$ je stohastičko i ponaša se kao nestruktuirani šum koji dovodi do porasta entropije raspodele generisanih podataka, te se za jednu istu labelu $|\lambda\rangle$, može generisati više izlaznih stanja. Podaci za obučavanje generatora se dobijaju od diskriminatora koji predstavlja kvantno kolo parametrizovano vektorom $\boldsymbol{\theta}$. Uloga diskriminatora je da proceni da li ulazno stanje potiče od realnog izvora ili generatora, dok je uloga generatora da "prevari" diskriminator, tako da podatke koji su generisani označi kao realne. Cilj optimizacije QGAN obučavanja je da se definišu parametri diskriminatora koji će da maksimizuju verovatnoću da je diskriminator pravilno označio ulazni vektor, a ujedno i parametri generatora koji minimizuju ovu verovatnoću. Za nominalno prebrojivu vrednost Λ, labela $|\lambda\rangle$, ovaj problem se formalno definiše izrazom [15]:

$$\min_{\boldsymbol{\theta}_G}\max_{\boldsymbol{\theta}}\frac{1}{\Lambda}\sum_{\lambda=1}^{\Lambda}P\{[(\quad(\boldsymbol{\theta}\ ,|\lambda\rangle,\quad(|\lambda\rangle))=|\text{realni}\rangle]\cap [(\quad(\boldsymbol{\theta}\ ,|\lambda\rangle,G(\boldsymbol{\theta}_G,|\lambda,\ \rangle))=|\text{lažni}\rangle]\}. \tag{1}$$

U iterativnom postupku se određuju parametri kvantnih kola, tako da generator može što uspešnije da prevari diskriminator [15].

III. Rezultati i diskusija



Za implementaciju modela je korišćena biblioteka *iskit* [20], koja radi pod programskim jezikom *Python* u virtuelnom okruženju *Anaconda*. Realizovana je QGAN za generisanje log-normalne raspodele, koja se može sresti u biomedicinskim primenama. Primer jedne realne raspodele je dat na Sl. 2. Realizacija QGAN-a na samo 2 kubita pomoću jednostavne kvantne mreže korišćene za realizaciju kvantnog generatora postoji kao primer u tutorijalima *iskit*-a [21].

Sl. 2. Prikaz histograma za jedan vektor realnih podataka. Za korišćeni sintetički skup od 4000 ulaznih podataka je fitovanjem dobijeno da podleže log-normalnoj raspodeli sa srednjom vrednošću μ=1.5 i standardnim odstupanjem σ=0.4.

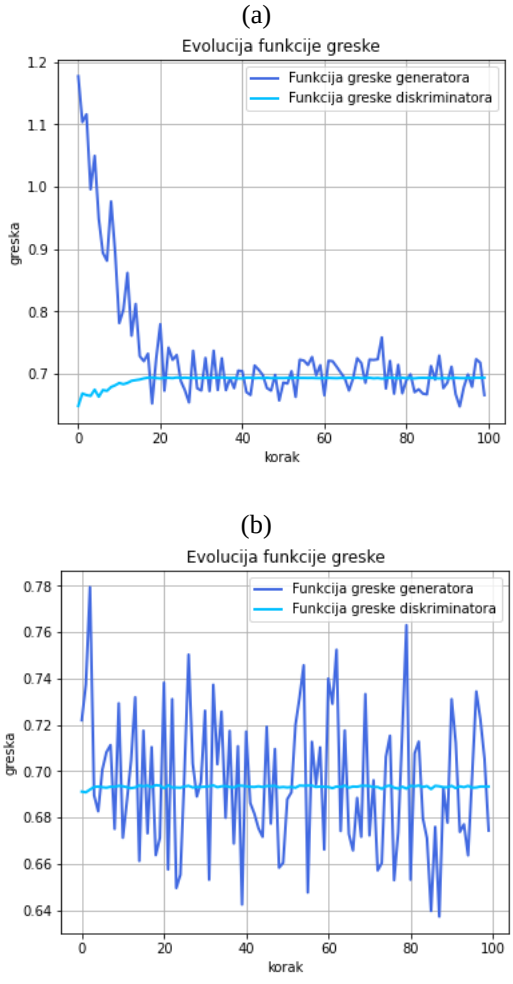
A. Pretpostavka kvantnog kola

Za realizaciju osnovnog sloja kvantnog kola generatora je usvojena *pretpostavka* (engl/nem. *ansatz*) definisana na 4 kubita. Ponavljanjem ovog bloka se postiže veća efikasnost obavljanja zadatka od strane kvantnog kola, ali se produžava vreme obučavanja usled povećanja dubine kvantne mreže. Svaki blok se sastoji od parametrizovanih jednokubitnih operacija primenjenih na svaki kubit i dvokubitnih C_Z operacija, kojima se ostvaruje međusobno *kvantno spre anje* (engl. *uantum entanglement*) svih susednih stanja kubita. Poslednji kubit je dodatno spregnut sa prvim kubitom. Ovakvo povezivanje je vezano za pojam kružnog umrežavanja. Za implementaciju kvantne mreže je korišćena ugrađena biblioteka *Two ocal*, gde je atribut željenog sprezanja *entanglement* = "circular", dok je parameter ponavljanja *rep* uzimao vrednosti 1 ili 2. U ovakvoj konfiguraciji, kvantna mreža ima samo 8 i 12 varijabilnih parametara, za mrežu formiranu od jednog i dva osnovna bloka, redom. Varijabilni parametri se podešavaju pri obučavanju mreže. Šema pretpostavke kola generatora je data na Sl. 3.

Sl. 3. Šema pretpostavke (engl/nem. ansatz) kvantnog kola generatora. Osnovni blok/sloj je uokviren crvenom isprekidanom linijom.

Diskriminator je implementiran pozivanjem funkcije *Numpy iscriminator* i predstavlja klasičnu neuralnu mrežu sa 3 *sloja* (engl. *layer*), koja koristi *eaky e* aktivaciju u *skri enom sloju* (engl. *hidden layer*) i aktivaciju sigmoid funkcijom u izlaznom sloju. Na ovaj način ćemo ustanoviti uslove, pri kojima bi kvantni generator "prevario" klasični diskriminator, koji je zadužen za testiranje prezentovanih rezultata. Za optimizaciju varijabilnih parametra generatora i diskriminatora je korisćen predefinisani *Adam* algoritam [22], koji predstavlja metodu za stohastičku optimizaciju.

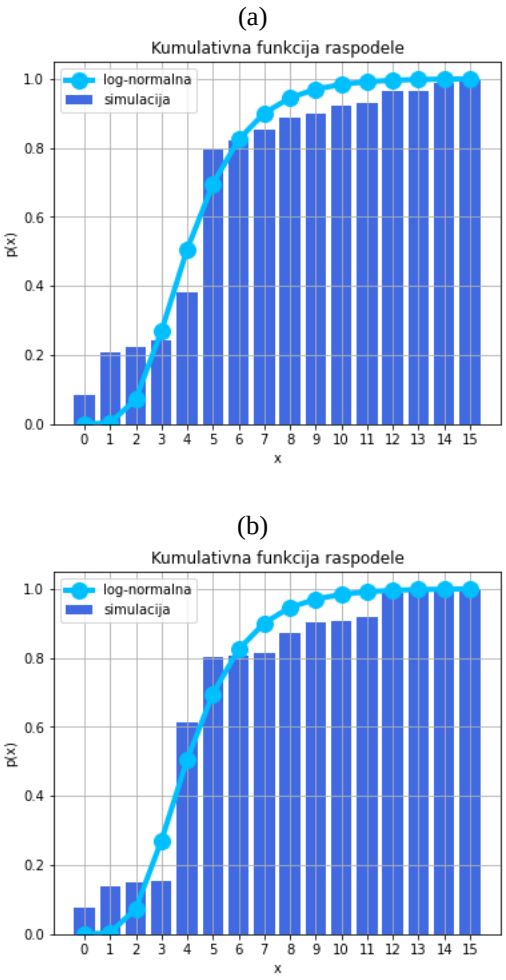
B. Obučavanje mreže



Obučavanje je najpre testirano na simulatoru raspoloživom u programskom paketu *iskit*. Trening mreže je obavljen korišćenjem 100 *u oraka u s akoj iteraciji* (engl. *batch si e*). Najpre je korišćeno kvantno kolo sa samo jednim blokom (oblast uokvirena isprekidanom linijom na Sl. 3) koji ima samo 8 varijabilnih parametara i računata je lokalna *funkcija greške* (engl. *cost loss function*). Parametri mreže su inicirani na pseudo-slučajan način. Broj *prola a kro trening skup* (engl. *epoch*) je bio 100 puta. Zatim je dodat još jedan blok, tako da je dobijeno finalno kvantno kolo prikazano na Sl. 3. Dobijene vrednosti varijabilnih parametara (zaokružene na 2 značajne cifre) za deo kvantnog kola koji je prethodno treniran su uzeti kao inicijalni, dok su parametri za blok koji

 ISBN 978-86-7466-930-3

je dodat izabrani nasumično. Postepeno građenje finalne pretpostavke kvantnog kola je urađeno kako bi se pri obučavanju izbegla pojava *ra nih platoa* (engl. *barren plateaus*) funkcije greške [23-25]. Pri rešavanju problem vezanog za prepoznavanje rukom pisanih brojeva (MNIST dataset) [26], ovaj pristup je pokazao i značajno manju grešku generalizacije u odnosu na standardne šeme obučavanja, koje se primenjuju na celu mrežu [25]. Trening je urađen u 100 prolaza sa 100 uzoraka u svakom trening skupu. Dobijeni su vektori varijabilnih parametara za mreže generatora satavljene od jednog i dva osnovna gradivna bloka, redom:



(a) $\boldsymbol{\theta}_G$ = [5.3857293, 4.28779218, 4.24118702, 0.51582692, 2.21546187, 1.08074945, 4.08073098, 4.46537089].

(b) $\boldsymbol{\theta}_G$ = [4.13100272, 0.63322951, 5.16027858, 2.0964577, 4.03147984, 4.69264686, 5.54824841, 5.96373602, 1.69386018, 4.81546402, 1.1501217, 3.24610254].

Sl. 4. Evolucija funkcije greške (engl. cost/loss function) diskriminatora (svetlo plava linija) i kvantne mreže generatora (tamno plava linija), sastavljene od (a) jednog i (b) dva osnovna gradivna bloka.

Da bi analizirali tok obučavanja mreže, treba razmotriti promenu funkcije greške u toku treninga. Evolucija funkcije greške u funkciji rednog broja koraka za mrežu sastavljenu od jednog i dva osnovna bloka je prikazana na Sl. 4 (a) i (b), redom. Za mrežu sastavljenu od jednog osnovnog bloka, vrednosti greške generatora i diskriminatora postaju uporedive posle dvadesetak koraka obučavanja. Pritom, razlika je najveća na početku treninga, što je očekivano, jer su parametri mreže inicirani na pseudo-slučajan način i mreža, inicirana na ovaj način, ne daje odgovarajuću raspodelu. U slučaju mreže koja je sastavljena od dva bloka, greška nije velika ni na samom početku treninga. Ovo je posledica postepenog građenja kvantnog kola generatora, gde smo za deo mreže inicirali skup parametara, tako da se na zadovoljavajući način reprezentuje tražena raspodela. Uočava se da u toku obučavanja greška diskriminatora približno ulazi u zasićenje, dok greška generatora "osciluje" oko neke srednje vrednosti. Razlog za ovakvo ponašanje je izbor metoda za optimizaciju Adam, koji je računski efikasan i brzo nalazi optimalno rešenje, ali ne adaptira korak na adekvatan način, tako da se postigne bolja konvergencija.

Sl. 5. Kumulativna funkcija log-normalne raspodele (svetlo-plava linija) i histogram kumulativne raspodele dobijen usrednjavanjem 10000 raspodela koje je generisao realizovani kvantni generator sastavljen od (a) jednog i (b) dva osnovna sloja kvantne mreže.

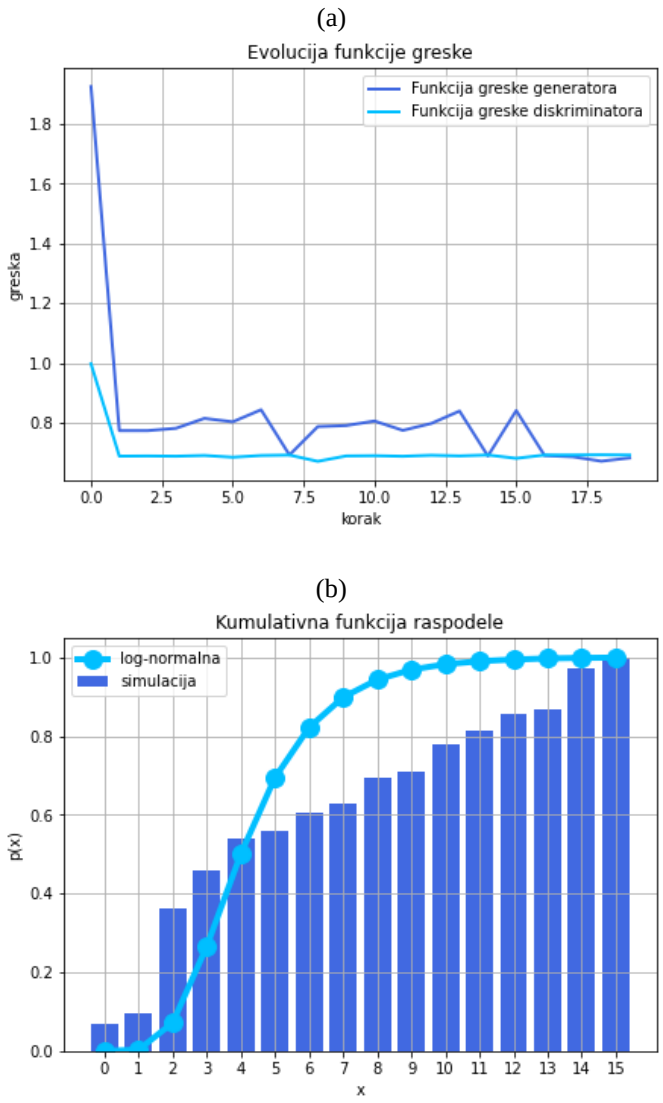
 ISBN 978-86-7466-930-3

Za dobijene parametre kvantnih generatora, postavljena su kvantna kola i generisano je po 10000 raspodela. Za svaku generisanu raspodelu je nađena kumulativna funkcija raspodele i rezultati su usrednjeni. Dobijeni rezultati su upoređeni sa kumulativnom funkcijom idealizovane log-normalne raspodele, koja je ustanovljena za polazni skup i rezultati su prikazani na Sl.5. Poređenjem raspodela na Sl. 5 (a) i (b) se može ustanoviti da jednostavnija mreža daje nešto lošije rezultate u oblasti gde postoji veliki gradijent log-normalne raspodele. Mreža generatora koja se sastojala iz više slojeva je bolje reprodukovala "strmiju" raspodelu. Pretpostavlja se da bi razlike između dubljih mreža (sa više od dva osnovna kvantna sloja) i mreže sa jednim slojem bila još veća u slučaju generisanja raspodele, koja ima više lokalnih maksimuma (multimodalna raspodela). Ipak, povećanje broja slojeva bi značajno produžilo trening mreže. Treba naći ravnotežu između kompleksnosti implementacije mreže (u cilju povećanja realističnosti raspodele) generatora i vremena potrebnog za obučavanje mreže. Takođe, pretpostavlja se da bi još realniji opis proizvoljne raspodele mogao da se dobije ukoliko bi se koristila kola sa više kubita, što bi dodatno usložnilo svaki sloj kvantne mreže i značajno produžilo trening i jednoslojne i višeslojne (duboke) mreže.

Sl. 6. Šematski prikaz kvantnih operacija korišćenih za implementaciju koda na kvantnom računaru ibmq_lima. Sistem ima 5 kubita raspoređenih u T geometriji, tako da je kubit q1 povezan sa tri kubita (q0, q2 i q3), kubit q3 sa dva kubita (q2 i q4), dok su ostali "ivični" kubiti (q0, q2 i q4) povezani samo sa jednim najbližim susedom.

Na kraju je metoda testirana na realnom kvantnom računaru. Kôd je izvršen na najmanje opterećenom sistemu **ibmq lima** [27]. Ovaj sistem je zasnovan na Falcon r4T arhitekturi kvantnog procesora sa svega 5 kubita i *k antnom apreminom* (engl. quantum volume) koja iznosi 8. Iako predstavlja jedan od najskromnijih IBM-ovih sistema po pitanju performansi, dovoljan je za izvršavanje postavljenog problema. Osnovna kvantna kola (engl. gate) u ovoj arhitekturi su jednokubitne I (jedinična; engl. Identity gate), , Z (rotacija oko -ose na Bloch-ovoj sferi), S (koren iz ; $S\ rt(\ ) = \sqrt{\ }$) i dvokubitna C (kontrolisana operacija). Realizacija jednog koraka programa odgovara implementaciji datoj na Sl. 6. Korišćena su prva 4 kubita (označeni q0-q3), pošto zadovoljavaju uslov najbolje međusobne povezanosti. Zbog ograničenog broja iteracija, koje jedan korisnik može odraditi u jednom procesu, broj epoha pri obučavanju je ograničen na 20. Ovaj broj je pet puta manji od onoga što je korišćeno u kvantnom simulatoru, pa se ne očekuje da će rezultati dobijeni na realnom kvantnom računaru biti bolji od onih na simulatoru. Kao rezultat optimizacije generatora dobijen je vektor varijabilnih parametara:

$\boldsymbol{\theta}_G$ = [2.34593012, 2.40548665, 6.16308627, 0.64978231, 3.46996776, 6.22740227, 5.06966893, 2.22040949].



U cilju poređenja sa rezultatima, koji su dobijeni pomoću klasičnog programskog simulatora kvantnog kola, na Sl. 7 su redom prikazani evolucija funkcije greške u funkciji rednog broja iteracije (epohe) i histogram kumulativne funkcije raspodele, dobijeni na osnovu rezultata koje je generisao realni kvantni sistem. Čak i za ovako mali broj epoha pri obučavanju kvantne mreže na kvantnom računaru, kvantni generator je u stanju da "prevari" klasični diskriminator. Ovo je očigledno na osnovu Sl. 7 (a), gde je funkcija greške generatora manja od diskriminatora posle obučavanja. Sa druge strane, poređenje kumulativne funkcije greške za log-normalnu i raspodelu dobijenu usrednjavanjem 10000 generisanih raspodela (videti Sl. 7 (b)) mogu se uočiti značajna odstupanja. Takođe, rezultati su lošiji od onih koji su dobijeni pomoću softverskog simulatora (videti Sl. 5), što je i očekivani rezultat obzirom da je obučavanje realnog hardvera bilo značajno kraće. Ono što je očigledno je da je u realnom hardveru funkcija greške pala na malu vrednost već posle par iteracija, za razliku od klasične simulacije kvantnog računanja, gde je značajan pad ostvaren tek posle 20 epoha. Ovo bi moglo da navede na pogrešan zaključak, da obučavanje kvantnog generatora realizovanog na kvantnom računaru traje kraće od vremena (broja iteracija) koje predviđa simulacija, gde nisu uračunati efekti šuma i dekoherencije. U skorašnjim publikacijama [25] se kao razlog za ovakvo ponašanje navodi prisustvo dekoherencije i šuma u kvantnom hardveru, koji su uzrok brže konvergencije ka optimalnoj vrednosti parametara.

IV. Zaključak

U radu je razmotreno kvantno kolo generatora raspodele koji bi se mogao iskoristiti za generisanje rezultata koji odgovaraju realnim eksperimentalnim rezultatima u mnogim naučnim oblastima. Kolo je dobijeno algoritmom kvantne generativne suparničke mreže, gde se u konkurentnom postupku takmiče kvantni generator, koji generiše raspodelu, i klasična neuralna mreza, koja treba da klasifikuje generisanu raspodelu kao realnu ili lažnu. Za razliku od originalne postavke algoritma, diskriminator je klasičan i treba da

 ISBN 978-86-7466-930-3

reprodukuje slučaj, gde kvantni sistem treba da nadmaši klasični sistem mašinskog učenja koji se upotrebaljava za otkrivanje računarski generisanih rezultata. Ustanovljeno je da je moguće realizovati kvantnu mrežu koja bi sa velikom verovatnoćom mogla da generiše raspodelu, koju bi klasični diskriminator ocenio kao realističnu. Kao primer je uzeta log-normalna raspodela, mada bi princip bio identičan i u slučaju proizvoljne raspodele.

Sl. 7. Za realni kvantni generator koji se sastoji iz jednog sloja i klasičan diskriminator prikaz: (a) evolucije funkcije greške diskriminatora (svetlo plava linija) i kvantne mreže generatora (tamno plava linija); (b) kumulativna funkcija log-normalne raspodele (svetlo-plava linija) i histogram kumulativne raspodele dobijen usrednjavanjem 10000 generisanih raspodela dobijenih pomoću kvantne mreže generatora (tamno plava linija).

Najpre je izvršena simulacija kvantnog algoritma na klasičnom računaru. Za konstrukciju generatora su korišćene kvantne mreže sa jednim i dva sloja. U svakom sloju je ostvareno kružno kvantno sprezanje kubita. Analizom evolucije greške tokom treninga i kumulativne funkcije raspodele realizovane jednoslojne i dvoslojne mreže je ustanovljeno da mreže sa više slojeva verodostojnije generišu traženu raspodelu. Ipak, sa povećanjem broja slojeva se povećavao broj varijabilnih parametara, a samim tim i vreme potrebno za obučavanje mreže. Ustanovljeno je da obe mreže, sa velikom verovatnoćom, mogu prevariti klasičan diskriminator, koji bi vršio klasifikaciju rezultata. Zatim je algoritam izvršen na realnom kvantnom hardveru. Analiziran je kvantni generator koji se sastoji iz jednog kvantnog sloja. Obučavanje je izvršeno u malom broju koraka. Dobijeni su rezultati koji su ukazali na dobre performance razmatranog algoritma i u slučaju simulacije na realnom kvantnom računaru. Za realizaciju analiziranog algoritma nije potreban veliki broj slojeva u kvantnoj mreži, pa se obučavanje može izvesti u relativno malom broju iteracija, čak i na trenutno dostupnom kvantnom hardveru koji je podložan dekoherenciji i šumu. Analizirani algoritam bi se mogao usložniti na slučaj raspodele u više dimenzija, tako da daje rezultate koji su veoma slični onima koji bi se dobili u eksperimentalnim biomedicinskim merenjima poput citometrije, DNK analize, radioloških, ultrazvučnih i drugih biomedicinskih mernih metoda. U daljem radu bi bilo interesantno razmotriti kako bi se model pokazao na slučajevima složenijih jednodimenzionih i višedimenzionih raspodela, kako bi povećanje broja kubita uticao na poboljšanje performansi generatora, kao i slučaj različitog sprezanja kubita u osnovnom kolu na kvalitet rezultata i vreme konvergencije parametara mreže.

ZAHVALNICA

ABSTRACT

For many years, we have witnessed that many publications are an effective means of recognizing exceptional competence and talent in science, which can provide an individual with great moral and financial satisfaction. The famous phrase in academic circles "publish or perish" is becoming a harsh reality. In their desire to publish sessional discoveries, individuals try to falsify scientific results to create the illusion of exceptionality. Modern image analysis programs based on artificial intelligence have proven to be an effective means of exposing false representations of scientific results and have led to the withdrawal of many suspicious publications from journals in recent years. New artificial intelligence algorithms based on generative adversarial networks provide the ability to generate images that can be classified as credible. The implementation of these algorithms on quantum computers has proven to be a potentially superior method of image generation and poses a real danger that cases of falsification of scientific results will go unnoticed. This imposes the need to soon develop a discipline that could be described as forensics of scientific results, and which would deal with unraveling the application of classical and quantum algorithms for generating results.

Forenzički aspekt prostorne i vremenske komponente

Snežana Stojičić, Radovan Radovanović, Milesa Srećković, Nikola Radovanović

Apstrakt—**Dinamičnost realnih sistema uključuje neizostavno vremens i o vira i prostorno referenciranje, što je u direktnoj vezi sa davanjem nalaza i mišljenja sa forenzičkog aspekta. U određenim događaima i slučajevima primene forenzičkih metoda, posebno se mora dati značaj redosledu, sledu dešavanja u okviru određenog događaja, jer on može značajno uticati na zaključivanje. Prostorno referenciranje se, može razmatrati od osnovnog navođenja mesta događaja do dovođenja u kontekst uticaja elemenata prostora na uzrok i posledicu događaja, oji se obrađuje. Ukoliko je moguće obezbediti referentne vremenske podat e, podat e u jedna im vremens im intervalima oni mogu biti posmatrani i analizirani ao vremens e serije. radu su dati primeri uključivanja vremenskog okvira i prostornog referenciranja, imajući u vidu da značajno mogu doprineti ciljevima forenzičkog inženjerstva.**

***Ključne reči*—Forenzički aspekti; prostorno referenciranje, vremens i o vir;**

I. UVOD

Zaključci o uzrocima nastanka incidentnih događaja se zasnivaju na činjenicama i analizi u kojoj mogu biti primenjene i metode forenzičkog inženjerstva. Nalaz i mišljenje do kojih se dođe u toku analize može, prema prethodno navedenim aspektima primene stručnih znanja, veština i specifičnih znanja, mogu biti usmereni ka poboljšavanju bezbednosti proizvodnog procesa, poboljšanju performansi i efikasnosti rada mašina i uređaja, kao i ka primeni nalaza i mišljenja kao stručne pomoći u sudskim i drugim postupcima pri utvrđivanju činjenica, koje se odnose na nesreće ili krivične stvari. Generalno se sa forenzičkog aspekta procenjuje stanje pre događaja, posle događaja, postavljaju hipoteze o mogućim načinima i uslovima koji se mogu dovesti u vezu sa nastankom stanja posle događaja, pronalaze dokazi koji negiraju ili potvrđuju postavljene hipoteze i primenjuju znanja i veštine za povezivanje različitih činjenica i dokaza u koherentni scenario, vezan za nastanak događaja i sačinjava nalaz i mišljenje u formi koja odgovara daljoj primeni i/ili procesuiranju slučaja [1].

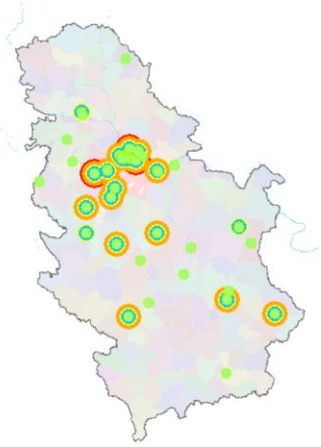
Primena metoda forenzičkog inženjerstva se vrši od strane pojedinaca ili stručnih timova koji obavljaju forenzičke istrage u sprovođenju aktivnosti na otkrivanju uzroka koji je doveo do incidenta. Prostorni kontekst je jedna od osnova za referenciranje događaja, pojave ili procesa koji se analizira, kao i vremenski okvir koji je potrebno dati sa najvećim mogućim stepenom preciznosti [2,3]. Međutim, nije uvek jednostavno ustanoviti veze vremenskog okvira i prostornog referenciranja [2, 4-7].

II. PROSTORNO REFERENCIRANJE



Jedan od primera koji će biti obrađivan odnosi se na prostorni kontekst događaja koji su uzrokovani požarnim ili eksplozivnim procesima [8], odnosno jednim aspektom koji se odnosi na dejstvo štetnih materija na okruženje, što pak uključuje potrebu za omogućavanjem utvrđivanja koncentracija zagađujućih materija u vazduhu [9]. Određivanje koncentracije zagađujućih materija se može vršiti na osnovu postojećih mernih stanica. Za to se mogu koristiti merne stanice automatskog monitoring kvaliteta vazduha u Republici Srbiji[1]Za određivanje lokacija mernih mesta za uzimanje uzoraka za merenje koncentracija zagađujućih materija, a u svrhu ocenjivanja kvaliteta vazduha u zonama i aglomeracijama, primenjuju se kriterijumi dati u Uredbi o uslovima za monitoring i zahtevima kvaliteta vazduha („Sl. glasnik RS“, br, 11/2010, 75/2010 i 63/2013). Posebno, makrolokacije za fiksna merenja, određuju se u cilju zaštite zdravlja ljudi, vegetacije i prirodnih ekosistema, a u neposrednoj blizini tačkastih izvora, s obzirom na gustinu emisija, očekivanu raspodelu zagađujućih materija u vazduhu i potencijalnu izloženost stanovništva.

Određivanje lokacija mernih mesta, vrši se tako da se može pratiti primena standarda i najboljih dostupnih tehnika u skladu sa propisima u oblasti sprečavanja i kontrole zagađivanja vazduha (Sl.1). Sam postupak određivanja lokacija zahteva prethodnu analizu na osnovu dostupnih podataka u odnosu na prostor, uz primenu svih propisanih kriterijuma i analizom dobijenih procena. Posebno, imajući u vidu da izbor mernog mesta i lokacije za uzimanje uzoraka, je potrebno proveravati periodično ili protokom određenog vremenskog perioda, u cilju potvrđivanja validnosti kriterijuma koji su prethodno korišćeni i u zavisnosti od

[1] АЗЗЖС - ОБЈЕДИЊЕНИ ПРИКАЗ АУТОМАТСКОГ МОНИТОРИНГА КВАЛИТЕТА ВАЗДУХА У РЕПУБЛИЦИ СРБИЈИ (sepa.gov.rs)

 ISBN 978-86-7466-930-3

promena nastalih okruženju nalaženja novih predloga i rešenja [2].

Sl. 1. Prikaz lokacija mernih stanica iz Sistema automatskog monitoringa kvaliteta vazduha sa podataka o koncentracijama PM2.5 izmerenih u periodu 18-25.04.2022. godine – satni podaci.

Različite vrste fizičkih dokaza mogu pružiti opšte informacije o prostornim odnosima između objekata, ljudi i događaja. Pored toga, primena forenzičkih metoda ispitivanja i analize može doprineti tumačenju i potencijalnom rasvetljavanju krivičnog dela.

Forenzičke metode koje se primenjuju za ispitivanje, komparacije i identifikacije uzroka i posledica, kod eksplozivnih i požarnih procesa, kao i drugih dokaza u istražnom postupku, olakšavaju rasvetljavanje krivičnih dela. Kod razrešavanja krivičnih dela u kojima se pojavljuju eksplozivni i požarni procesi uključivanjem prostorne komponente, može značajno doprineti davanju kvalitetnije prezentacije i vizualizaciji događaja sa ciljem davanja mišljenja i nalaza o dejstvu ovih procesa sa aspekta forenzičkog inženjerstva. Upotrebom softverskih alata za rad sa prostornim podacima omogućava se postavljanje upita u odnosu na podatke o lokaciji događaja kao i primena metoda za analizu podataka u odnosu na prostor. Ovi alati omogućavaju vršenje merenja, analize i izradu prikaza, koji pored sadržaja koji se odnosi na prostorne podatke, organizovane po tematskim slojevima, mogu sadržati elemente koji su određeni prema parametrima koji su definisani faktorima relevantnim za posmatrane događaje i procese. Mogu se ostvariti simulacije dejstva, analize koje se mogu vršiti i u odnosu na prostor, kao i testiranje hipoteza i rekonstrukciju događaja u cilju utvrđivanja relevantnih činjenica. U postupku utvrđivanja relevantnih činjenica koriste se instrumentalne i komparativne metode za modelovanje procesa, vizualizaciju i dokazivanje dejstva eksplozivnih i požarnih procesa. U radu je dat prikaz mogućnosti korišćenja podataka sa mernih stanica u sisitemu automatskog monitoringa kvaliteta vazduha u Republici Srbiji i mogućnosti analize i detekcije i vizualizacije stanja za slučajan uzorak, u izabranom vremenskom periodu od 18-25.04.2022. godine. Sa mernih stanica preuzeti su satni podaci kako bi se izvršila njihova analiza. Dalja razmatranja mogu biti usmerena ka analizi eksplozivnih i požarnih procesa u odnosu na lokaciju dešavanja procesa i distribuciju u odnosu na prostor, čime forenzički inženjering može dati neutralan i objektivan doprinos da istraži jedan od načina da se jedna kompleksna problematika dejstva eksplozivnih i požarnih procesa obradi uz uključivanje prostorne komponente, i da se pruži potpuniji izvor informacija o ovoj temi u prostornom kontekstu. Praktičan značaj je ukazivanje na mogućnost uključivanja komponente prostora uz komponentu vremena u forenzičkom inženjerstvu, u odnosu na forenzičke identifikacije eksplozivnih i požarnih procesa u cilju sprečavanja i suzbijanja kriminaliteta i opšte bezbednosti.

Razmatranja podataka iz sistema automatskog monitoringa kvaliteta vazduha data su u odnosu na granične vrednosti suspendovanih čestica PM10 i PM2.5, date u Tabeli I, kao zagađujućih materija, čija koncentracija može biti povećana i u slučaju pojave incidentnih situacija izazvanih požarnim i eksplozivnom procesima.

TABELA I
GRANIČNE VREDNOSTI ZA PM10 I PM2.5

Zag. Materija (1h)	Odličan	Dobar	Prihvatljiv	Zagađen	Jako zagađen
PM10 (ug.m-3)	0-25	25-50	50-90	90-180	> 180
PM2.5 (ug.m-3)	0-15	15-30	30-55	55-110	> 110

III. PRAKTIČNI PRIMER ANALIZE VREMENSKOG OKVIRA I PROSTORNOG REFERENCIRANJA

Za prikaz praktičnih aspekata, preuzeti su podaci sa mernih stanica Sistema za automatsko praćenje kvaliteta vazduha u Republici Srbiji, koji su dostupni na satnom, nedeljnom i mesečnom nivou, i koji su dostupni za analizu i korišćenje kao otvoreni podaci. Podaci su preuzeti u period od 18-25.04.2022. godine na satnom nivou, prema stepenu dostupnosti i stanju mernih uređaja na mernim stanicama. Preuzeti skup podataka je dalje obrađivan, kao slučajan uzorak. Prema lokacijama mernih stanica, podaci su pripremljeni za korišćenje u alatima za rad sa prostornim podacima i omogućavanje prikaza i dalje analize u odnosu na prostor.

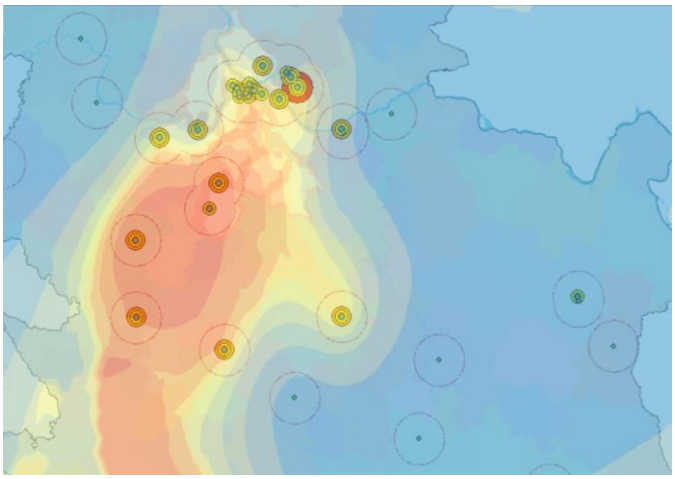
Na osnovu deskriptivnih statističkih podataka, prikazanih u Tabeli II, u posmatranom uzorku identifikovane su lokacije sa pojavom ekstremnih vrednost i vremenski period nastanka i trajanja prisustva povišenih vrednosti (Sl. 2). Identifikovane ekstremne vrednosti su dalje analizirane sa ciljem utvrđivanja dužine trajanja visokih koncentracija i prostorne distribucije.

Sl. 2. Prikaz podataka o koncentracijama PM10 za lokaciju sa identifikovanim ekstremnim vrednostima u posmatranom uzorku, kao vremenskoj seriji.

Analizom je dobijeno da je prisustvo ekstremnih vrednosti identifikovano u kraćem vremenskom interval i da u odnosu na posmatrani period nije ostvaren značajan uticaj na distribuciju posmatranih vrednosti (Sl. 3).

Sl. 3. Prikaz statističkih podataka o koncentracijama PM10 izmerenih u periodu 18-25.04.2022. godine na mernim stanicama za monitoring kvaliteta vazduha.



U cilju procene prostorne distribucije na osnovu posmatranog uzorka, korišćene su geostatističke metode dostupne u okviru alata za rad sa prostornim podacima i to na lokacijama, u odnosu na vreme i u odnosu na sve posmatrane lokacije in a njima izmerenih vrednosti sa prediktivnom procenom. Korišćena je prostorna ocena za PM10, kao promenljive, na osnovu doprinosa tačaka u kojima je vrednost poznata (Kriging).

Rezultati analize pokazuju da značajnije dejstvo ostvaruju povišene vrednosti u dužem vremenskom periodu i ako su nižeg nivoa, od ekstremnih vrednosti, koje se pojavljuju u kraćem vremenskom periodu (Sl. 4). Potrebno je svakako imati u vidu da u analizu nisu uključeni ostali element iz okruženja i karakteristike terena za izvedeni zaključak, što svakako ukazuje na potrebu dajeg istraživanja i uključivanja drugih elemenata realnog okruženja, odnosno, ukoliko isti nisu dostupni u vreme sprovođenja analize identifikacije elemenata i generisanje modela sa mogućnosšću variranja vrednosti i procene uticaja.

Svakako, sprovedenom analizom je potvrđeno da komponente prostora i vremena mogu biti značajno doprineti

 ISBN 978-86-7466-930-3

pri analizi događaja koji dovode do emisije zagađujućih materija u vazduh i procene dejstva.

Sl. 4. Prikaz podataka o koncentracijama PM10 izmerenih u periodu 18-25.04.2022. godine na mernim stanicama za monitoring kvaliteta vazduha sa zomama i predikcionom mapom u odnosu na prostor.

IV. ZAKLJUČAK

Uključivanje prostorne i vremenske komponente, uz korišćenje alata za rad sa prostornim podacima, proširuje mogućnosti analize i primenu metoda sa forenzičkog aspekta. Izložena razmatranja i praktični prikazi na datom na slučajnom uzorku, ukazuju na mogućnosti koje mogu biti dalje razmatrane i istraživane u korelaciji sa određenimi, događajima koji su predmet primene drugih forenzičkih metoda, kao što su između ostalog i požari i eksplozije, koji za posledicu mogu imati povećanu koncentraciju suspendovanih čestica u vazduhu.

ZAHVALNICA

Aurori se zahvaljuju organizacionom odboru konferencije ETRAN 2022 na prepoznatom značaju oblasti forenzike, prostoru i vremenu datom za izlaganje i diskusiju.

ABSTRACT

The dynamic of real systems inevitably includes time frame and spatial referencing, which are directly related to giving findings and opinions from the forensic aspect. In certain events and cases owhere application of forensic methods might be appropriate, special importance must be given to the sequence of events within a certain event, because it can significantly affect the conclusion. Spatial referencing can also range from the basic indication of the place of the event to bringing into context the influence of the elements of space on the cause and effect of the event being processed. If it is possible to provide reference time data, the data in equal time intervals can be observed and analyzed as time series. The paper gives examples of including time frame and spatial referencing, bearing in mind that they can significantly contribute to the goals of forensic engineering.

A space and time from forensic aspects

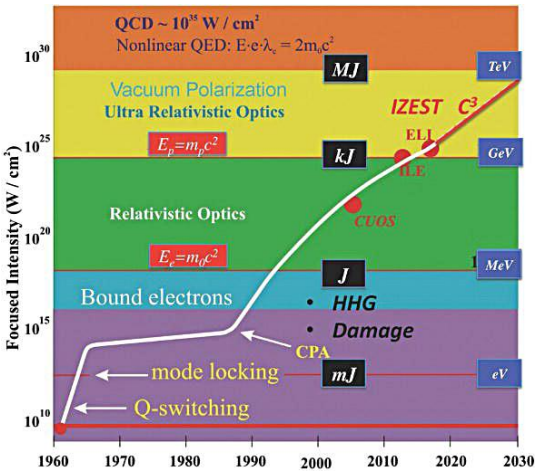
Različiti režimi rada kvantnih generatora kao instrument za modifikacije u stomatologiji

Aleksandar Bugarinović [1,2], Željka Tomić [3], Sanja Jevtić [4], Aleksander Kovačević [5], Svetlana Pelemiš [6], Zoran Nedić [7], Dragan Družijanić [1]

Apstra t - potrebom vantnih generatora u raznim oblastima, a i u stomatologiji, bavi se veliki broj istraživača sa perspektivom da taj broj bude i veći. Ciljevi su različiti: od dobijanja materijala za dalje formiranje do učešća u formiranju modifikovanih materijala, modifikacije osobina već tradicionalnih materijala do postizanja zadata a oji se pojavljuju u vezi sa zahtevima heritologije forenzi e ili za masmedija primenu. Specijalno, dijagnostičke tehnike na bazi jačih ili slabijih intera cija elions ih snopova sa materijalom, postaju sve više tražene merne tehnike zbog vremena same dijagnostike i mogućnosti ispitivanja karakteristika uzoraka i u malim lokalnim površinama, a skeniranjem po potrebi i u većim. Podrazumevaju se i kvantitativne i valitativne analize, a rad sa više od jednog snopa (manje i veće gustine snage), pored mogućnosti praćenja interakcije sa teoretske strane, pruža i praktičan deo aplikacije laserske ili uopšte elionske tehnike, koji je ušao u praksu ili je od potencijalnog interesa za protetičke i druge svrhe. Šta bi onda moglo biti generalno novo u ovoj oblasti? Novi dinamički režimi rada kvantnih generatora, oblici impulsa, njihovo trajanje i fre vencija, donose novi valitet, koji može proizvesti drugačije efe te pri intera ciji lasers ih snopova sa materijalom, uspostaviti nove standarde i ili potisnuti stare. ad se bavi intera cijom lasers ih snopova, u različitim režimima rada, sa odabranom klasom materijala. Dis utovani su modeli za opis i rezultati intera cija, analizirana se oštećenja i dat je osvrt na trenutna i potencijalna polja primene i izabrane paralele sa drugim snopnim tehni ama.

Ključne reči - kvantni generatori, režimi rada, interakcije, modeli, polje primene.



I. Uvod

Primena laserske tehnike ili, u širem smislu, kvantnih generatora, treba da, na prvi pogled, menja značenje *modifikacije* sa kvantifikacijom od minornih uticaja na materijal mete do totalne ili lokalne destrukcije mete, zavisno od režima rada sistema kojim se vrši tretman.

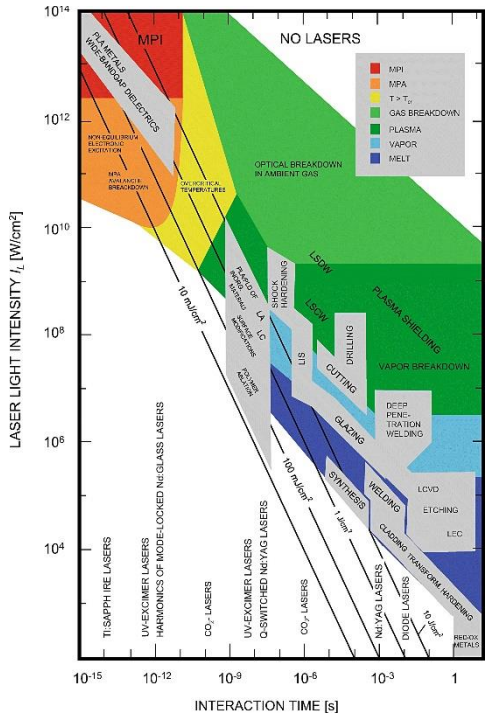
Pošto je stvarnost omogućila da se interakcija koristi: a) u dijagnostičke svrhe, b) u strogo *modulacione* svrhe c) za spajanje materijala iste vrste ili različitih tipova d) za razdvajanje materijala, to postoji i grupisanje gustina energije, snage, primena *cw* ili impulsnog rada sa različitim parametrima, slike 1 i 2.

Vremenska baza impulsa (širine impulsa) je u rasponu od prvih milisekundnih impulsa sa stotinak spajkova [1] do *fs* režima.

U pogledu materijala, koji su od interesa za stomatologiju, veoma je široka njihova paleta, zato što se danas koristi laserska tehnika u svakodnevnoj kliničkoj praksi: (a) za saniranje *biološkog aparata*, uključujući i meka i tvrda tkiva, (b) u protetičke svrhe.

Slika 1. Istorija i predviđanje razvoja fokusiranog intenziteta od prvih demonstracija lasera (sa različitim režimima rada).

U svim tim procesima, postavljali su se i postavljaju se i dalje objektivizacije opisa procesa, pored toga što se veliki broj interakcija koristi u svakodnevnoj praksi, s obzirom na višedecenijsku primenu lasera u stomatologiji, zavisno od zemlje i njene regulative. To znači da su uključeni skoro svi glavni tipovi materijala: metali, dielektrici, specijalne klase keramike i dr. Posebno su važne i primene za paradentozne tretmane u kojima su korišćeni laseri malih snaga (reda mW) i gde se radilo samo o ozračavanju tkiva u vremenu predviđenom protokolom (kada je odobrena ta terapija u pojedinoj državi). Za simulaciju procesa interakcije prema očekivanom izlazu, koriste se modeli od termalnog do modela teorija sličnosti i zavisno da li se radi o proceni naponskog stanja protetske konstrukcije, do holografskih studija lokalnog opterećenja tačaka od interesa.



Slika 2. Procesi ablacije izazvanih laserima i neki procesi uz slojeve materijala od površine.

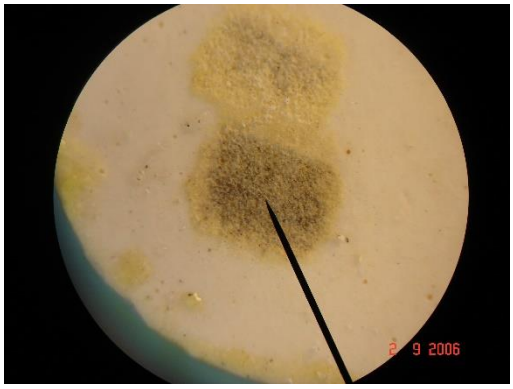
 ISBN 978-86-7466-930-3

U ovom radu je odabrano nekoliko režima rada kvantnih generatora u režimu slobodne generacije ili Q-*switch* i dati su rezultati interakcije.

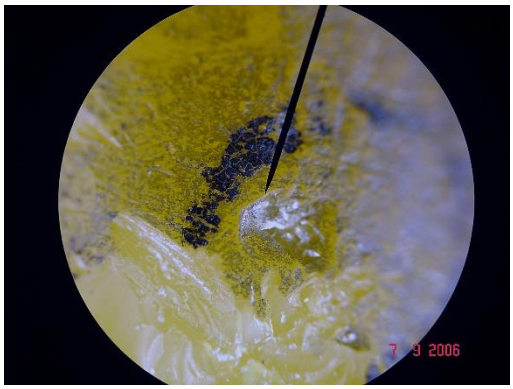
Slika 3. Karakteristična vremena interakcije, intenzitet lasera i mogući procesi sa često korištenim laserskim sistemima. (PLA/PLD – impulsna laserska ablacija / depozicija, LA – odgrevanje, LC – čišćenje, LIS – separacija izotopa, MTA – višefotonska apsorpcija / jonizacija, LSDW/LSCW – detonacija / sagorevanje podržana laserom, LCVD – indukovana hemijska CVD, LEC – elektrohemijsko nanošenje prevlaka / nagrizanje, RED/OX – redukcija / oksidacija indukovana sa dugim impulsima ili *cw* CO_2) [11].

II. Rezultati rada i diskusija



Jedna od standardnih šema eksperimenata sa izlaganjem materijala od interesa, za određenu oblast stomatologije, podrazumeva rešavanje optike ulaznog snopa, položaja mete sa odgovarajućim *support*-om za promenu geometrije upada snopa lasera u materijal i prema mogućnosti laboratorije, podrške za promenu polarizacije snopa, uključivanje drugog tipa kvantnog generatora i kontrolu izlaznog snopa, uključujući mogućnost kvantitativnih opisa u vremenskom i prostornom domenu. Kako se pri impulsnom radu, najčešće rešava samo vreme ekspozicije, to je potrebno vršiti i kontrolu vremena. Ovaj deo aparature, sam po sebi, ne bi predstavljao specifične probleme, ali za stomatološke procese je od specijalnog interesa, jer je upravljanje snopom ručno.

Idealni eksperiment bi podrazumevao mnogo drugih različitih kontrola samog procesa, sakupljanje izbačenog materijala, kontrolu sastava izbačenog materijala (nastanak novih jedinjenja) i geometrijske putanje izbačenog materijala, jer se simulira, odnosno predviđa situacija stvarne upotrebe. Za slučaj primene lasera kod žučnih i bubrežnih kamenova, prvi eksperimenti su vršeni uz sakupljanje razvijenih gasova, da ne bi došlo do neželjenog trovanja organizma, a to podrazumeva i razne vrste operacija u stomatologiji (čišćenje kamenca i dr.).



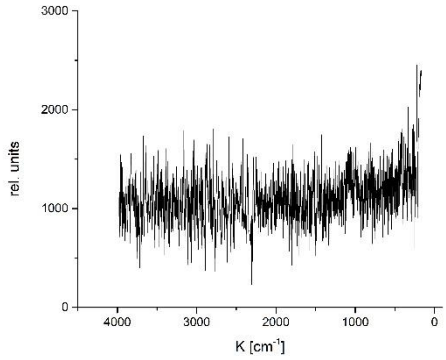
Bez obzira na simulaciju iz raznih oblasti posmatranja dinamike procesa u izabranom režimu rada, dobro je posmatrati materijal mete sa više deskripcionih tehnika nedestruktivnog tipa za ulaz u eksperiment i ponoviti ih posle interakcije, kad dolaze u obzir i destruktivni postupci merenja, kakvi su zahtevi u SEM i drugim elektronskim tehnikama.

Za date rezultate interakcije dati su i IC spektri tretirane površine. Za tretiranje LAZ-a (Laser Affected Zone), u primeni u stomatologiji, traži se minimum zahvata tkiva ili bar strogo kontrolisan. Odnos LAZ-a i HAZ-a (Heat Affected Zone) je uvek pitanje, koje je podložno diskusiji.

Na slikama 4 i 5, dati su rezultati sprovedenih analiza stanja povreda na nekim materijalima od interesa za protetiku i za zubno tkivo. Na slici 6 je izabrani uzorak HAP-a, koji se već duže vremena primenjuje za ojačanja bioloških tkiva, privremenih ili stalnih.

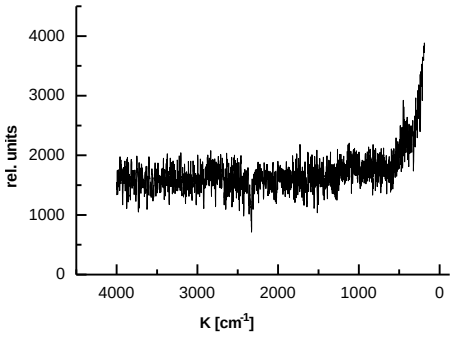
Slika 4. Mikrograf analize optičkim mikroskopom belog gipsa izloženog laserskom snopu. (Nd^{3+}:YAG, E = 35 mJ, površinski reljef, OM 40 x)

Slika 5. Analiza optičkim mikroskopom interakcije Q-*switch* tipa lasera na uzorku žutog voska. (Nd^{3+}:YAG, τ = 15 ns, E = 35 mJ, 3 impulsa, OM 40 x, površinski reljef)



Prema režimu rada, očekivalo se da bude proizveden krater koji ima više ili manje nagomilavanje materijala po obodu, pri čemu bi veće nagomilavanje materijala bilo vezano za režim slobodne generacije. Krater sa manje izbačenog materijala (po obodu) bi, sa druge strane, trebalo da služi i inverzno, za raspodelu gustine energije po preseku snopa ili prikaz nehomogenosti materijala mete. Zato je i bilo govora na početku eksperimentalnog dela, da bi u idealnom slučaju bilo dobro imati, paralelno, analizatore laserskog snopa direktno ili bar povremenu kontrolu gustine energije / snage, kojoj je meta bila izložena. Jednostavan prilaz bi bio i da se pri toj vrsti eksperimenata, pre serije impulsa na nekom materijalu izvrši isti režim na materijalu koji je predložen kao kontrolni materijal, a koji je pogodan za datu talasnu dužinu.

 ISBN 978-86-7466-930-3



Slika 6. Mikrograf povrede na uzorku HAP-a. (Nd^{3+}:YAG, Q-*switch*, E = 35 mJ, površinska modulacija, OM 40 x)

Na slikama 7 i 8 dati su IC spektri za uzorke gutaperke i HAP-a.

Slika 7. Infracrveni spektar (IC) uzorka gutaperke u dijapazonu 4000 - 180 cm^{-1}.

Slika 8. Infracrveni spektar (IC) uzorka HAP-a u dijapazonu 4000 - 180 cm^{-1}.

Idealno bi bilo da se spektri uvek rade pre i posle interakcije, zato što bi zavisno od površine povrede mogao da se sprovede formalizam za dobijanje optičkih konstanti materijala, kao što su koeficijenti refleksije, koeficijenti dielektričnih osobina, vezano za optičke osobine i kompleksan zapis. Ovde bi od koristi bio i *aman*-ov spektar, koji bi i samim poređenjem sa IC spektrima dao neki kvalitativan odgovor bez sprovođenja primene algoritama za analizu strukture materijala.

Pretpostavka o novim materijalima, čiji broj raste u stomatologiji, je uvek potrebna, a za poznate materijale potrebna je iz razloga kontrole postojećih podataka i izbegavanje razlika u tehnologiji izrade protetskog materijala. Čini se da je dobro ponoviti uvek provere i za poznate materijale.

Od interesa bi bila i tehnika termovizije, koja je skoro dve decenije bila prisutna sa prvim primenama lasera u stomatologiji, u vreme kada je ekonomska strana nabavke te kontrole predstavljala veći problem. To su eksperimenti koji mogu pratiti proces za određene dinamičke dijapazone kvantnih generatora, kad se radi o dugim impulsima ili srednjim vrednostima, pri većim repeticijama, kao kontrolna relativna tehnika.

Važna oblast bi bilo i određivanje boje kod zuba ili protetičkih materijala, gde bi moglo biti od interesa vezivanje sa trenutnim stanjem deskripcije boje, u kojima glavne boje pripadaju kategoriji lasera (za televizijske svrhe HDTV, odavno je razvijen tip RGB lasera).

III. Simulacija

Kako je u uvodu konstatovano, posle izabranog modela, za određene režime rada kvantnih generatora [9] se konstatuje da i više modela mogu da se koriste za određene režime, koji odgovaraju tipu grejanja materijala do tačke ključanja. To su slučajevi izlaganja patogenog tkiva (paradentoza) koje se već više od deceniju koristi za saniranje stanja. Slučajevi bušenja (otklanjanja materijala), zavisno da li se problemu prišlo sa redosledom grejanje-topljenje ili grejanje-sublimacija i sl., bi morali da koriste odgovarajuće algoritme kod programa kod kojih su oni razvijeni [5].

Pošto je za bušenje najbitnije pitanje dimenzija (dubina, širina), onda se za preliminarnu ocenu koriste formule koje zavise od parametara izlaganja, termodinamičkih i optičkih osobina materijala.

U širokoj paleti materijala, čini se da je situacija *Status uo* i da se može naći mnogo praktičnih korekcija za izabrane režime rada, gde će se za promenu koeficijenata u formulama za standardne uslove rada približiti simulacija eksperimentu. Pri interakciji je jedna od važnih činjenica pitanje maksimalne gustine snage / energije, koja neće dovesti do praga za „lom". Sve to pripada složenoj problematici „laser damage", gde se uključuje statistika malih brojeva i statistika velikih brojeva, koje se različito modeluju.

IV. Zaključak

U današnjem stepenu laserske tehnike postoji nekoliko definisanih režima rada kvantnih generatora, koji potencijalno mogu da se primene u biomedicinske svrhe. U praksi, iako postoji dosta dobro razvijena industrija laserskih sistema okrenutih medicini, pokazalo se da, generalno, postoji niz pozitivnih novih pravaca za primenu lasera. Ipak, od stanja same države i stepena njenog instrumentarijuma, vezano za klasičnije metode (mehanička bušilica, rentgenografija, poznate klase protetskih materijala sa komercijalnom podrškom), zavisi koliko će u njoj biti brzo uklapanje novih „optičkih" metoda u sve četiri uslovno podeljene oblasti: dijagnostika, modulacija u užem smislu (tkiva ili materijala), invazivna interakcija (hirurgija) i saniranje i formiranje ispuna i pravljenje mostova i dr. U ovom radu je pokazana interakcija sa tipovima odabranih materijala (keramičkog tipa i dr.), izvršene su analize sa strane optičke i elektronske mikroskopije, definisanje materijala mete putem IC spektroskopije. Ukazano je na

 ISBN 978-86-7466-930-3

potrebu daljeg eksperimentalnog rada, vezano za stanje uzoraka i za, potencijalno, organizaciju daljih ispitivanja ili primena holografskih i tomografskih tehnika za definisanje dinamike opterećenja, uključujući tehnike brzog starenja materijala, koje bi služile za ocenu, vek trajanja protetskog nastavka i pravac traženja, kroz krojenja novih vrsta materijala od interesa za protetiku i prihvatanje „stranog tela". Po pitanju samog HAP-a, bile su razvijene dve teorije koje su primenjivane na mehanizam stapanja sa organizmom.

ABSTRACT

The use of quantum generators in various fields, as well as in dentistry, is dealt with by a large number of researchers with the perspective that the number will be even higher. The goals are different from obtaining materials for further formation to participating in the formation of modified materials, modifying the properties of already traditional materials to achieving tas s that appear in connection with the requirements of heritology forensics or for mass media application. In particular, diagnostic techniques based on stronger or wea er interactions of elion beams with material are becoming more and more sought-after measurement techniques due to the time of diagnostics and the possibility of testing sample characteristics in small local areas, and scanning if necessary in larger ones. uantitative and qualitative analyzes are included, and wor with more than one beam (lower and higher power densities), in addition to the possibility of monitoring the interaction from a theoretical point of view, provides a practical part of the application of laser or elion techniques in general, which has entered into practice or is of potential interest for prosthetic and other purposes. What, then, could be generally new in this area ew dynamic modes of operation of quantum generators, pulse shapes, their duration and frequency, bring new quality, which can produce different effects when laser beams interact with material, establish new standards and or suppress old ones. The paper deals with the interaction of laser beams, in different operating modes, with the selected class of materials. odels for the description and results of interactions are discussed, damages are analyzed and an overview of current and potential fields of application and selected parallels with other beam techniques are given.

ey words - quantum generators, modes of operation, interactions, models, field of application.

Different modes of operation of quantum generators as an instrument for modifications in dentistry

Оптичка влакна у периметарским системима техничке заштите

Слађана Пантелић[1], Бранка Радојчић[2]

***Апстракт*— Тема рада је реализација система техничке заштите у оптичком домену, тј. упознавање са основним концептима примене оптичких влакана у разумевању сензорских система за периметарску заштиту објеката и оптичких мрежа у другим системима техничке заштите (видео надзора, контроле приступа, алармног система,....), који се могу и интегрисати. Периметар је појам који означава затворену линију унутар које се налазе штићени простор и штићени објекти. Дат је пример пројектантског решења имплементације периметарског система техничке заштите, применом оптичких компонената. На тај начин, упознајемо карактеристике оптичких елемената система, а са циљем максималног искоришћавања њиховог потенцијала у савременим комуникационим системима. Сврха овог рада је била у опису најчешће коришћених оптичких сензора у системима периметарске заштите објеката, са нагласком на сензоре вибрација, који изазване промене у оптичком сигналу претварају у електрични сигнал погодан за даљу обраду и препознавање алармног стања. Детекција и тачна локализација места притиска, оштећења или прекида оптичког влакна, могућа је применом оптичких мерних метода, што омогућава техничку контролу имплементираног система техничке заштите.**

Кључне речи — оптичко влакно, оптички сензор вибрација, периметарска заштита, алармно стање

I. Увод

Сталне претње од напада свих врста доводе до важности јачања мера заштите људи, имовине и пословања, као и критичне инфраструктуре објеката од државног интереса. Упркос веома јакој цубер сигурности, објекти морају бити заштићени јаким физичким баријерама, како би се спречили физички напади. Системи за детекцију упада у периметар често су први бедем одбране, па се периметарска заштита пројектује као заштитни обруч, који штити улазне тачке објекта. Наведени системи су напредовали усвојивши новије технолошке трендове, као и интеграцију с другим сигурносним системима (нпр., сензори за ограде и паметна сигурносна расвета). Паметна сигуроносна расвета је важан додатни алат у пројектовању целокупне заштите периметра [1].

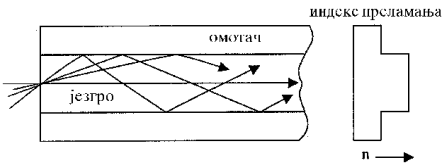
II. Оптичка влакна и оптички сензори

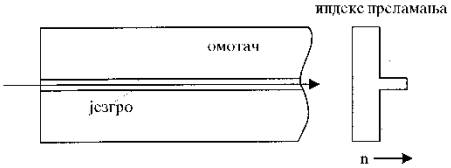
Развој оптичких влакана је ишао у правцу проналажења нових технологија за обезбеђивање све мањих оптичких губитака и могућности производње све дужих и флексибилнијих влакана, као и у правцу повећања брзина комуникација и смањења цене. То је све пратио брз развој извора светлости – ласера и пријемника светла – фотодиода. По цени, оптичко влакно је данас најјефтинији медијум за пренос информација [1-3].

Простирање светлосног снопа кроз оптичко влакно засновано је на принципу преламања светлости. Када светлосни сноп из средине већег индекса преламања (језгро) прелази у средину мањег индекса преламања (омотач), долази до његове рефлексије назад у средину са већим индексом преламања. Деле се на мономодана и мултимодна оптичка влакна.

Мономодна оптичка влакна се користе за реализацију далеких веза, а све више и у локалним мрежама. Пречник језгра им је од 3,5 μm до 10 μm (у зависности од таласне дужине која се користи) а пречник примарног омотача је 125 μm [4]. Због малог пречника језгра код мономодног оптичког влакана не долази до појаве модалне дисперзије, тако да има велики пропусни опсег, који је ограничен само хроматском дисперзијом, Сл. 1. Недостатак му је мали пречник језгра, па захтева извор са компатибилном емитујућом површином и одговарајућим угаоним дијаграмом зрачења.



Сл. 1. Простирање светлости кроз мономодно оптичко влакно: изглед пресека влакна, путање и профила индекса преламања.



Код мултимодних влакана примарни омотач је направљен од материјала чији је индекс преламања мањи од индекса преламања језгра. Могу бити са степенастим и градијентним индексом преламања, Сл. 2. и Сл. 3. Влакна са степенастим индексом преламања имају пречник језгра од 50 μm до 1000μm. То су јефтина оптичка влакна, једноставна су за употребу, али су ограниченог пропусног опсега. Не користе се за потребе преноса података. Градијентно мултимодно оптичко влакно има

 ISBN 978-86-7466-930-3

параболичан профил промене индекса преламања у материјалу језгра.

Сл. 2. Простирање светлости кроз мултимодно оптичко влакно са степенастим индексом преламања: изглед пресека влакна, путање и профила индекса преламања

Сл. 3. Простирање светлости кроз мултимодно оптичко влакно са градијентним индексом преламања: изглед пресека влакна, путање и профила индекса преламања

Предност мултимодних оптичких влакана је велики пречник језгра, тако да је знатно олакшано убацивање светлости у њих, као и њихово међусобно спајање. Недостатак мултимодних оптичких влакана је појава модалне дисперзије. Она настаје када се оптичка снага убаченог светлосног импулса распореди на све модове у влакну, који се крећу благо различитим брзинама, што доводи до кашњења неких модова на излазу из оптичког влакна, па долази до развлачења импулса. Модална дисперзија се смањује употребом градијентних влакана.

Оптичка влакна се примењују у оптичким сензорима још од 1977. год., и представљају главне елементе у специјалним сензорима за мерење: акустичких величина, магнетских величина, температуре, притиска, брзине, убрзања, итд. Сензори на бази оптичког влакна се деле на интерферометријске (мерена величина изазива интерферентне ефекте) и амплитудске (мерена величина модулише интензитет светлости).

Оптички сензори се састоје од извора светлости и пријемника. Као извори светлости најчешће се користе полупроводничке светлеће диоде - ЛЕД и ласерске диоде - ЛД. Оне дају довољно велику и просторно усмерену оптичку снагу а димензије су им прилагођене димензијама оптичких влакана. Пријемник светлости претвара оптичку енергију у електрични сигнал, а најчешће се користе фотодиоде, фототранзистори и фотоотпорници. Оптички сигнал може бити у подручју видљиве светлости или инфрацрвене и ултраљубичасте светлости, у невидљивом делу спектра [5].

Мерена физичка величина је у вези са одређеним параметром оптичког сигнала, који је у ствари електромагнетски талас фреквенције 1013–1015 Hz. Промена параметара оптичког сигнала сразмерно амплитуди мерене физичке величине, представља модулацију тог сигнала. Основни параметри оптичког сигнала су: амплитуда, фреквенција, фаза, поларизација и расејање светлосног сигнала. Оптички сензори се могу употребити у условима деловања јаког магнетног поља, високе температуре, електричних шумова и корозије, па су много флексибилнији и поузданији од класичних сензора. Лоше особине су им: сложеност израде, обраде сигнала, захтевају оптичку видљивост између пријемника и предајника.

III. Примена и инсталација оптичког влакна у периметарском алармном систему

Алармне системе чине уређаји, који упозоравају на нека задата нежељена стања. Постоје различите врсте аларма, светлосни, звучни, вибрирајући, или у облику електронске информације и упозорења од ниске или високе температуре, упозорење на присутност разних плинова, дима, SOS дојаве, затим противпровални и противпрепадни аларми. Алармни системи се углавном имплементирају у комбинацији са савременим системом видео надзора. Најчешћи облик аларма је противпровални, где алармни уређаји светлосно и звучно, разним телефонским, радио, IP или GSM, GPRS, 5G дојавама узбуњују раднике обезбеђења или власнике неке имовине. Један од тих система је и сензорски систем периметарске заштите са оптичким влакнима.

Систем периметарске заштите, који се у основи састоји од једног или више оптичких влакана у улози сензора, већ је добро познат на тржишту техничке заштите. Њихова примена заснована је на провереној поузданости и квалитету перформанси,

Чињеница да оптичка влакна као сензори система, за пренос информација и детекцију аларма не користе електричне сигнале, већ светлост на посебним таласним дужинама, омогућава њихово коришћење на већим удаљеностима при чему су отпорни на мување, високу температуру, корозију, електромагнетне сметње или друге електричне сигнале.

Постоје два главна типа система ране детекције провале на бази оптичких влакана: зонски систем, са традиционалним хардвером и новији, осетљивији, интерферометријски систем који, на основу технике коју примењују, може прецизније и поузданије одредити провалу на огради. Иако су оба наведена система заснована на оптичким влакнима, фундаментални принципи, који стоје иза њих су сасвим другачији, а самим тим и њихове перформансе и примена у пракси.

Како се кроз оптичко влакно преноси светлосни сигнал, било какво савијање или покретање истог, доводи до промена његових преносних особина. Принцип рада је да се, током редовне ситуације у систему периметарске заштите, ласерски емитује једносмерни монохроматски светлосни талас, који се шаље кроз каблирано оптичко влакно, уграђено дуж ограде (на врху ограде или у њеном средњем делу). Након рефлексије, рефлектовани светлосни талас се враћа до пријемника ради утврђивања мирног стања, односно стања без аларма. Када дође до илегалног напада тј. када неко покуша да се попне уз ограду, оптички кабл почиње да се физички помера, при чему се особине светлости, која путује оптичким влакном мењају. Тада се у систему, тј. пријемнику, детектује промена интензитета пренешене светлости, па ако иста пређе неки, унапред постављени, праг или се поклопи са одређеним дефинисаним критеријумима, подиже се стање

 ISBN 978-86-7466-930-3

аларма. При томе се у обзир узимају и прате најважније карактеристике рефлектоване светлости, чије промене подразумевају снагу, фазу, таласну дужину, поларизацију и дисперзију [6].

На основу наведеног може се рећи да су ови сензорски системи подложни утицају најразличитијих сметњи (ветар, микросеизмичко подрхтавање тла, град, пролазак возила, итд.). Да би се у великој мери онемогућиле појаве лажних аларма, за повећање отпорности на буку користе се сложени алгоритми за препознавање, имплементирани помоћу уграђених микропроцесора.

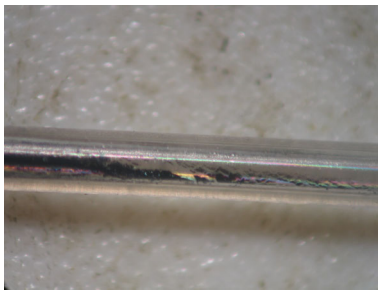
Могућа алармна стања периметарских сензора са оптичким влакнима, сврставамо у четири категорије:

- аларм за упад: покушај илегалног уласка који изазива вибрације оптичког влакна;
- аларм за прекид жице: прекид оптичког кабла сензора;
- аларм за растављање: незаконито растављање или уништавање на местима спојева оптичких влакана;
- квар у комуникацији: комуникацијски оптички кабл је искључен.

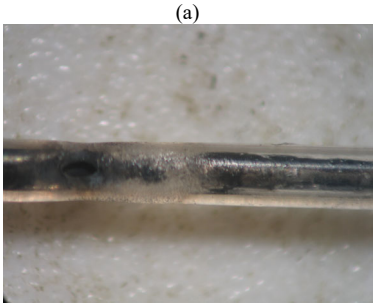
На Сл. 4., је као пример приказан изглед периметарске ограде, изграђене крајем 2018. год., између Крима и Украјине. Ограда је дужине 60 километара и састоји се од неколико типова барикада, различитих типова сензора, видљивих и скривених система видео надзора, укључујући и инфрацрвену опрему. Уграђен је и систем сензора осетљивих на вибрације [7].

Сл. 4. Ограда опремљина сензорима између Крима и Украјине

IV. Утицај ласерског зрачења на мономодно оптичко влакно које се користи у периметарској заштити



У експерименталном делу, извршено је испитивање утицаја ласерског зрачења на комерцијално мономодно оптичко влакно (9/125 μm), које се користи у периметарској заштити. Израђени оптички спојни кабл, са постављеним оптичким конекторима, приказан је на Сл.5.



Сл. 5. Оптички спојни кабл од мономодног оптичког влакна са FC/PC конекторима на крајевима.

Комерцијална оптичка влакна могу бити сачињена од различитих материјала. Један од типова оптичких влакана су вишекомпонентна стаклена оптичка влакна, чије језгро и омотач чине стакла различитог хемијског састава. Добијају се стапањем ултрачистих прахова. Стакла, која чине омотач и језгро одвојено се стапају, а затим спајају у компактно влакно у специјално конструисаном двоструком тиглу. Најчешће коришћена оптичка влакна су такозвана PCS (polymer coated silica), коју чини влакно од допираног кварцног стакла са заштитном полимерном превлаком [8-10].

Приказани оптичко влакно је изложено Nd^{3+}:YAG импулсном ласерском снопу. Ласер је комерцијалног типа са могућношћу промене и енергије импулса и густине снаге (од неколико J, понављањем од 1 до 10 Herz). Генерално, средња снага је била у опсегу kW. Интеракција снопа и узорка изведена је у ваздушној атмосфери (обични услови) са упадним углом од 90°. Интеракција је вршена са једним (Сл. 6. (а)) или више импулса у једној тачки (Сл. 6. (б)).

(а)

(б)

Сл. 6. (а) Микроскопски снимак интеракције оптичког влакна са једним импулсним снопом Nd^{3+}:YAG ласера; (б) Микроскопски снимак интеракције оптичког влакна са више импулсних снопова Nd^{3+}:YAG ласера.

На основу приказаног на Сл. 6. и видних оштећења на оптичком влакну, може се закључити да оптичка влакна нису отпорна на утицај ласерског зрачења. Околност, која ову чињеницу олакшава је да су мономодна оптичка влакна изузетно малих пречника језгра, па је вероватноћа да се влакно погоди на периметарској огради, и на тај начин оштети, је мала.

V. Закључак

На основу наведеног, може се очекивати да ће напредак технологије оптичких сензора у будућности довести до

 ISBN 978-86-7466-930-3

раста сектора заштите периметра. Међутим, оптички сензори су већ међу најпопуларнијим технологијама на тржишту система за заштиту периметра, било да се ради о онима који се постављају на ограде или технологији за детекцију вибрација. Интеграција оптичких сензора за ограде с другим системима техничке заштите, као што је на пример паметно осветљење, омогућава и нове функције и апликације. Интелигентно осветљење може реаговати на периметарске упаде прилагођавањем интензитета светлости или стробирањем у угроженим зонама, чиме се повећавају могућности одвраћања и процене претње. Једна од најважнијих предности оптичких сензора за заштиту периметра је да су идеални за уградњу у већ постојеће-изграђене периметарске ограде, тј. за надоградњу већ имплементираних система, што значајно утиче на смањење финансијских трошкова инвеститора.

Експерименталним радом је утврђено да оптичка влакна нису отпорна на утицај ласерског зрачења али су изузетно малих пречника језгра, па је вероватноћа да се влакно погоди на периметарској огради, и на тај начин оштети, је мала.

Abstract

The topic of the paper is the realization of technical protection systems in the optical domain, i.e introductions to the basic concepts of optical fiber application in the understanding of sensor systems for perimeter protection of buildings and optical networks in other technical protection systems (video surveillance, access control, alarm system, ...). These systems can also be integrated. Perimeter is a term that denotes a closed line within which there are protected areas and protected objects. An example of a design implementation solution is given. In this way, we get to know the characteristics of the optical elements of the system, with the aim of maximizing their potential in modern communications systems. The purpose of presented paper was to describe the commonly most used optical sensors in perimeter security systems, with emphasis on sensors (for vibration), which convert induced changes in the optical signal into an electrical signal suitable for further processing and alarm detection. Detection and accurate localization of the place of pressure and damage or interruption of the optical fiber are possible by applying optical measurement methods, which enables technical control of the implemented technical protection system

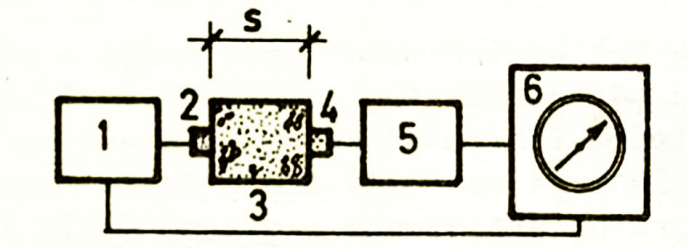
FIZIČKA I NEDESTRUKTIVNA ISPITIVANJA KERAMIČKIH MATERIJALA ZA OBLAGANJE SA ASPEKTA TRAJNOSTI

Zoran Stević[1], Aleksandar Savić[2], Milica Vlahović[3], Sanja Martinović[3], Tatjana Volkov-Husović[4]

Apstrakt— U radu su prikazane osnovne metode ispitivanja materijala, koje mogu poslužiti prilikom prve faze procene kvaliteta materijala, nakon degradacije usled vremena ili drugih faktora koji mogu izmeniti fizičko-mehanička svojstva materijala. Nedestruktivna metoda ispitivanja pomoću praćenja brzine prostiranja ultrazvučnog impulsa upotrebljena je radi ilustracije mogućeg pristupa pri proceni kvaliteta različitih tipova keramičkih materijala za oblaganje.

Ključne reči— *keramičke pločice, metoda ultrazvučnog impulsa, zapreminska masa, korelacija*

1. UVOD



Pod pojmom keramika se podrazumeva veliki broj raznovrsnih proizvoda koji se dobijaju pečenjem gline, kao osnovne sirovine [1]. U pogledu kompaktnosti mase, keramički proizvodi se mogupodeliti na: proizvode sa poroznom masom i proizvode sa polustopljenom masom. U slučaju da je upijanje vode kod keramičkog proizvoda veće od 5% u pitanju su proizvodi sa poroznom masom, a u slučaju da je upijanje vode manje od 5% proizvodi se karakterišu kao proizvodi sa polustopljenom masom. Za proizvode sa polustopljenom masomje karakterističnaviša temperatura pečenja, a koja se kreće u intervalu 1200-1400˚C.

Tehničke karakteristike keramičkih materijala za oblaganje prvenstveno zavise od njihove primene. Zahtevana svojstva i njihove vrednosti mogu varirati u funkciji od toga da li se radi o unutrašnjim ili spoljašnjim oblaganjima, odnosno u zavisnosti od toga da li se oblažu zidovi ili podovi [2]. Ova svojstva uključuju zapreminsku masu, stalnost geometrije, boju, teksturu, otpornost na pojavu vlasavosti, otpornost na delovanje razblaženih kiselina i baza, čvrstoću pri savijanju, tvrdoću i sl. Ispitivanja ovih materijala zahtevaju specifičan pristup i poznavanje šireg spektra standardne i nestandardne metodologije, između ostalog i nedestruktivnih i destruktivnih postupaka ispitivanja [3]. Posebno su od interesa ispitivanja kada se radi o materijalima koji su u svom eksploatacionom veku izloženi visokim temperaturama [4].

Zapreminska masa, čvrstoće i mehaničke otpornosti nekog materijala, kao i njegova trajnost i promena svojstava sa vremenom mogu se pratiti i povezati sa odgovarajućim nedestruktivnim metodama ispitivanja, u koje spada i metoda ispitivanja brzine ultrazvučnog impulsa kroz materijal. Treba naglasiti, međutim, da se kod ispitivanja svojstava materijala putem metoda bez razaranja traženo svojstvo unajvećem broju slučajeva ne meri direktno, već se postupak svodi na merenje neke druge fizičke veličine kojaje u funkcionalnoj vezi sa datim - traženim svojstvom.

Kao što je poznato, pod ultrazvukom se podrazumevaju vibracije iste prirode kao i zvuk, ali vrlo visokih frekvencija - koje ljudsko uho nije u stanju da registruje. Ove vibracije, koje u suštini imaju mehanički karakter, odlikuju frekvencije > od 20000 Hz (20kHz).Za dobijanje ultrazvuka najčešće se primenjuje piezoelektričnimetod, koji se zasniva na sposobnosti pojedinih kristalnih tela da pod dejstvom električne struje menjaju svoje dimenzije i na tajnačin proizvode visokofrekventne impulse.Ovi kristali imaju i sposobnost ispoljavanja suprotnog efekta: da pod uticajem visokofrekventnih impulsa dolazi do njihovog naelektrisanja (piezoefekat).

U praksi(slika 1), ultrazvučni impulsi se dobijaju primenom specijalnih generatora impulsa (1); za unošenje impulsa u element koji seispituje služe posebni predajnici (2); primenom ovih predajnika provode se UZ impulsi kroz ispitivani materijal (3) do prijemnika(4), pri čemu dolazi do prenosa podužnih, poprečnih ili površinskih ultrazvučnih talasa; primljeni impulsi pojačavaju seputem pojačivača (5) i šalju na indikator vremena (6).

Slika 1: Osnovni princip funkcionisanja ultrazvučne aparature

Promena svojstava materijala usled uticaja spoljašnje sredine najčešće je degradacionog tipa, što znači da se svojstva najčešće pogoršavaju sa vremenom. Osim što je moguće pratiti i porediti svojstva jedne vrste materijala i njihovu promenu primenom nedestruktivnih metoda ispitivanja, moguće je pratiti i promenu tj. pad svojstava materijala sa vremenom, ili utvrditi odstupanja izmerenih vrednosti u datom trenutku u odnosu na pojedinačne poznate i očekivane vrednosti za taj materijal u datom trenutku, primenom matematičkih, u prvom redu statističkih metoda [5]. Pravovremeno ispitivanje i praćenje svojstava već ugrađenih

 ISBN 978-86-7466-930-3

keramičkih materijala je posebno važno ukoliko se radi o objektima od velike važnosti za zajednicu [6]. Nakon eksploatacije u konstrukciji, keramički materijali se mogu ponovo upotrebljavati, što je veoma važno sa aspekta ekološkog i održivog pristupa u građevinarstvu [7]. U tom slučaju njihovo praćenje i karakterizacija u eksploataciji postaju prvi korak za prvu upotrebu ovih materijala u drugom, recikliranom, obliku.

U radu je prikazana metoda merenja brzine propagacije ultrazvučnih impulsa kroz pet različitihkeramičkih materijala za oblaganje, u okviru modela materijala koji je upotrebljavan ranije. Prikazani rezultati predstavljaju početnu fazuobimnijeg istraživanja.

2. MATERIJALI I METODE ISPITIVANJA

Ispitivani materijal predstavljajukeremičke ploče za oblaganje, starosti preko 20 godina, izrađene sa različitim pigmentima (slika 2). Pomenute ploče nisu izlagane eksploatacionim uslovima. Pre ispitivanja je svaki od uzoraka pregledan u cilju utvrđivanja vizuelnih tragova destrukcije ili drugih nedostataka. Konstatovano je da su uzorci kompaktni, pravilnih ivica i očuvani.

Slika 2: Ispitivani uzorci keramičkih materijala za oblaganje

Za ispitivanje zapreminske mase korišćeni su digitalno pomično merilo marke MESSZEUGE nemačke proizvodnje, opsega 150 mm kao i vaga KERN kapaciteta 35 kg i podatka 0,1 g.Rezultati ispitivanja dimenzija i mase prikazani su u tabeli 1. Prikazani rezultati merenja dimenzija predstavljaju prosečne vrednosti dobijene na osnovu najmanje tri merenja.

Za ispitivanje brzine ultrazvučnog impulsa upotrebljena je ultrazvučna aparatura italijanske proizvodnje, proizvođača MATEST. Pre samog ispitivanja je na ispitivane uzorke naneta odgovarajuća količina kontaktnog agensa, kako bi se eliminisao sloj vazduha na kontaktu uzoraka sa sondama ultrazvučne aparature, nakon čega je izvršeno merenje. Prosečne vrednosti merenja dobijene na osnovu četiri merenja (po dva na dva upravna pravca) prikazane su u tabeli 1.

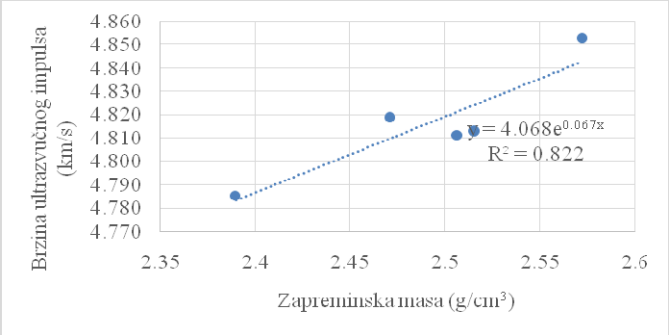

Tabela 1. Vrednosti dimenzija, mase, zapreminske mase i brzine ultrazvučnog impulsa kod ispitivanih keramičkih materijala

Uzorak br.	1	2	3	4	5
Masa (g)	240,7	250,2	247,7	242,2	253,7
Dimenzije a×b×h (mm)	80,86× 81,21× 14,57	81,53× 81,10× 14,71	81,31× 81,35× 14,94	81,83× 82,13× 15,08	81,44× 80,90× 15,58
Zapreminska masa (g/cm^3)	2,516	2,572	2,507	2,390	2,472
Brzina ultrazvučnog impulsa (km/s)	4,813	4,853	4,811	4,785	4,819

3. ANALIZA I DISKUSIJA REZULTATA ISPITIVANJA

Na osnovu ispitivanja koja su sprovedena na ispitivanim uzorcima utvrđeno je da zapreminske mase uzoraka variraju u relativno malim granicama od 2,390 g/cm^{3}do 2,572g/cm^{3}sa prosečnom vrednošću od 2,491 g/cm^3. Takođe, utvrđeno je da brzine ultrazvučnog impulsa dobijene na ispitivanim uzorcima variraju u relativno malim granicama od 4,785 km/s do 4,853 km/s sa prosečnom vrednošću od 4,816 km/s.

U cilju procene korelacije i trenda promene svojstava, izvršena je regresiona analiza korelacije zapreminske mase i brzine ultrazvučnog impulsa kroz ispitivane uzorke. Pomenuta korelacija prikazana je na slici 3.

Slika 3. Korelacija između zapreminske mase i brzine ultrazvučnog impusa kod ispitivanih keramičkih materijala za oblaganje. Iz priložene slike se može zapaziti da korelacija relativno pouzdanog tipa može omogućiti praćenje trenda promene svojstava. U ovom slučaju, za ispitivano svojstvo može se usvojiti zapreminska masa, te se na osnovu konkretne metode nedestruktivnog ispitivanja može dati načelna procena gubitka (pada) zapreminske mase usled degradacije materijala kroz vreme i dobiti prva procena ispitivanih uzoraka u funkciji od vremena.

ZAKLJUČCI

U radu su prikazani rezultati početne faze šireg istraživanja, koji se bave nedestruktivnim ispitivanjima keramičih materijala veće starosti, sa aspekta praćenja svojstava u eksploataciji, sa vremenom ili usled dejstva agresivne sredine u kojoj se ti materijali mogu naći.

Napominje se da bi svakako pri ispitivanjima trebalo proceniti i očekivane vrednosti merne nesigurnosti, kako bi se sagledao karakter i stepen pouzdanosti samog merenja. Veliki stepen merne nesigurnosti u različitim slučajevima merenja može dovesti do značajnog pada pouzdanosti rezultata ispitivanja. Iz tog razloga je u svakom ispitivanju potrebno identifikovati i uzeti u obzir sve faktore merne nesigurnosti.

Konačno, treba napomenuti da nedestruktivna ispitivanja građevinskih materijala ne mogu dati jednoznačne odgovore na pitanja njihovog kvaliteta, odnosno da se ne mogu uzeti kao merodavna kod izvođenja zaključaka o trajnosti ili

 ISBN 978-86-7466-930-3

stepenu degradacije koji je nastupio kod bilo kog tipa građevinskih materijala.

Međutim, iako je konstatovano da ispitivani uzorci imaju relativno ujednačen kvalitet i da se može dati generalna ocena da njihova svojstva nisu značajno degradirala sa vremenom, ukazuje se na mogućnost praćenja i približne inicijalne procene svojstava sličnim metodama u laboratorijskim ili *in situ* uslovima. Na ovaj način se u većem skupu ispitivanih uzoraka može utvrditi oblast od interesovanja ili odgovarajući podskup uzoraka za detaljniju i opsežniju analizu sa aspekta trajnosti, uključujući neke od destruktivnih metoda ispitivanja.

Суб-микрометарске паралелне површинске структуре индуковане фемтосекундним ласерским снопом у форензици

Александер Ковачевић, Сузана Петровић, Марина Лекић, Борислав Васић, Бранислав Салатић, Јелена Поточник

***Апстракт*— Један од ефеката интеракције ултра-кратког ласерског снопа са материјалима је формирање паралелних структура на површини (laser-induced parallel surface structures - LIPSS), чији је период мањи од таласне дужине снопа. Уколико се ради о вишеслојним танким филмовима метала, квалитет формираних структура је бољи. Узорак од пет двослојних танких филмова Al и Ti на супстрату Si смо изложили фемтосекундном снопу и запазили формирање две врсте структура које се разликују по облику. Обе су врсте вероватно узроковане појавом површинског плазмона-поларитона на површини најгорњег слоја. Појава плазмона поларитона на површини танких металних филмова и наночестица може да ограничи простирање електромагнетног поља и да појача флуоресцентни сигнал из молекула хемикалије на површини. У зависности од структуре интерфејса за одређивање циљне хемикалије на металној површини флуоресценција побољшана плазмоном (plasmon-enhanced fluorescence, PEF) је привлачан метод за скраћење времена и појачање осетљивости разних аналитичких технологија које се користе у форензици.**

***Кључне речи*— фемтосекундни ласер; вишеслојни танки филмови; периодичне површинске структуре; флуоресценција.**

I. Увод

Интеракција ласерског снопа са површином проузрокује многе ефекте, међу којима је у последње време пажњу заокупило формирање паралелних структура (LIPSS – laser induced parallel surface structures) под дејством ултракратких снопова [1]. Због карактеристике да им је периодичност мања од таласне дужине снопа, поље примене је веома широко [2]. Интеракција са металима може побољшати триболошке карактеристике, а на ламеларним материјалима, као што су вишеслојни танки метални филмови, формирани LIPSS има добар квалитет и може да побољша особине површине [3-4]. Снопови различитих карактеристика (флуенца, таласна дужина, дужина импулса, поларизација, ...), разни материјали (диелектрици, полупроводници, метали, ...), али и стање амбијента током интеракције – све то утиче на карактеристике LIPSS [5]. Генерално, уочена је појава две врсте структура, са нижом просторном учестаношћу (LSFL – low spatial frequency LIPSS) и са вишом просторном учестаношћу (HSFL – high spatial frequency LIPSS) [6].

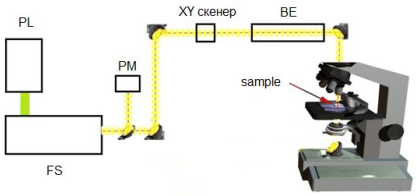
II. Експериментална поставка

Узорци који су коришћени су добијени депоновањем Al и Ti на подлогу од Si (1 0 0) помоћу Balzers Sputron II апарата који користи 1,3 keV аргонске јоне и са 99.9% чистоће Al и Ti мета. Две врсте узорака су подвргнуте интеракцији са фемтосекундним снопом. Први тип је био силицијумска подлога на којој је депоновано пет Al/Ti двослоја чиме је достигнута укупна дебљина од ~130 nm (сваки слој од ~13 nm). Други тип је такође био силицијумска подлога, али на којој је био депонован један слој Al дебљине ~130 nm.

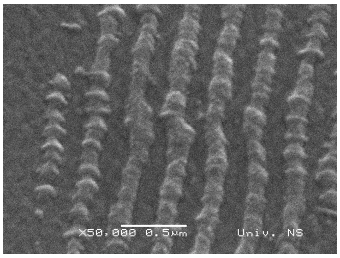


Сл. 1. Дијаграм експерименталне поставке за статичну интеракцију; PL – ласер за пумпање, PB – сноп за пумпање, FS – извор фемтосекундног снопа, FB – фемтосекундни сноп, SHG – удвајач учестаности, BE – проширивач снопа, FL – фокусирајуће сочиво, MPX/MPY/MPY - микропозиционери, SM – спектрометар, sample - узорак.

Извор фемтосекундног снопа је био Coherent Mira 900F систем чија је фреквенција удвојена са Inrad 5-050 ултрабрзим генератором другог хармоника. Карактеристике снопа су биле: таласна дужина 390 nm (удвојено) и 800 nm (основни хармоник), дужина импулса ~150 fs, репетиција 76 MHz (период између импулса ~13 ns), снага на мети 160–260 mW, линеарна поларизација у

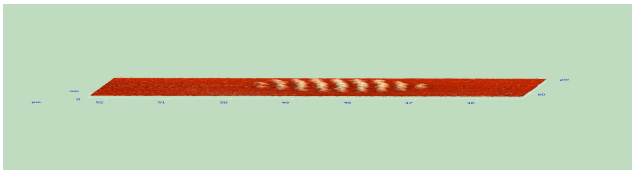
 ISBN 978-86-7466-930-3

хоризонталној равни, Гаусов елиптични профил. Експозиције су биле од 1 до 10 s. Таласна дужина снопа је контролисана фибер-оптичким спектрометром Ocean Optics HR2000CG-UV-NIR. Интеракције су обављане у ваздуху фокусирањем фемтосекундног снопа под нормалним углом на површину првог слоја узорка (Al), сл. 1. Резултати су анализирани скенирајућим електронским микроскопима (SEM) JEOL JSM 6560 LV који има Oxford Instruments EDS анализатор и FEI SCIOS2, као и помоћу микроскопа атомских сила (AFM) NT-MDT NTEGRA Prima.



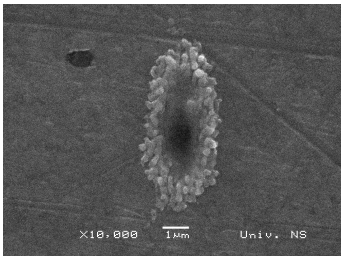
На сл. 2 је дијаграм поставке модификоване за потребе скенирања снопа преко узорка. Изостављен је удвајач учестаности, чиме је интеракција пренесена у блиску инфрацрвену област, ради скенирања се сноп уводи у огледални 2D скенер и у проширивач снопа, а фокусирање се обавља објективом модификованог микроскопа (40×, NA=0,65).

Сл. 2. Дијаграм експерименталне поставке за интеракцију уз скенирање снопом; PL – ласер за пумпање, FS – извор фемтосекундног снопа, PM – мереље снаге снопа, XY скенер – скенер снопа, BE – проширивач снопа, sample - узорак.



III. Резултати и дискусија

На сл. 3 је приказ слике SEM дела области интеракције са 5×(Al/Ti). Фемтосекундни сноп таласне дужине 460 nm је имао флуенцу од 13,6 mJ/cm^2 а време експозиције 10 s. У области интеракције се виде паралелне структуре са периодом од око 300 nm. Структуре су формиране у виду издигнућа на површини.



Сл. 3. Приказ слике SEM дела области интеракције са 5×(Al/Ti) на Si; флуенца 13,6 mJ/cm^2 и 10 s време експозиције.

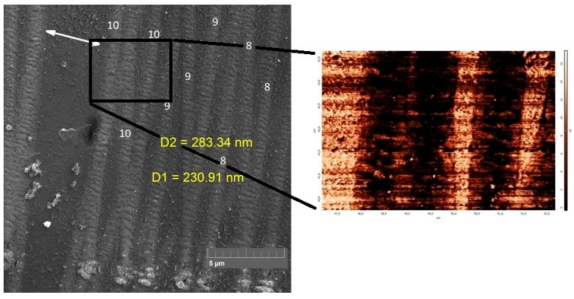
На сл. 4 је приказана AFM слика области интеракције приказаној на сл. 2. Овде се боље види да су структуре формиране као издигнућа на површини.

Сл. 4. Приказ AFM слике дела области интеракције приказане на сл. 2: 5×(Al/Ti); флуенца 13,6 mJ/cm^2 и 10 s време експозиције.

Узорак другог типа – један слој танког филма (~130 nm) Al – је био изложен флуенци од 8,6 mJ/cm^2 исте таласне дужине и времену експозиције од 10 s. Резултати у виду слике SEM дела области интеракције су приказани на сл. 5. У централном делу је дошло до аблације топљењем, а аблирани материјал се распоредио у околини централне зоне интеракције. Дошло је до расподеле у виду LIPSS, али квалитет облика није тако добар као у случају првог узорка. Просторни период структура је око 300 nm.

Сл. 5. Приказ слике SEM области интеракције са Al на Si; флуенца 8,6 mJ/cm^2 и 10 s време експозиције [4].

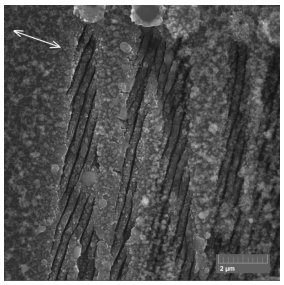
Упадни ултракратки сноп изазива на интерфејсу између металне и диелектричне површине појаву површинског плазмона (SP), а његовом интеракцијом са упадним снопом долази до формирања површинског плазмона поларитона (SPP) [2, 7], који узрокује статичну периодичну расподелу енергије на површини, периода мањег од таласне дужине упадног снопа. Дубина продирања ласерског снопа од 390 nm се израчунава [8] за Al на око 3 nm, а за Ti на око 9,3 nm.



Присуство подслоја Ti узрокује повећање прага оштећења првог (горњег) слоја, Al. Температура решетке се формира кроз два механизма: електронско-фононски (који узрокује локализацију загревања), и транспорт електронима везан за топлотну проводност електрона (који односи топлоту од зоне интеракције) [9]. Разлика у електронско-фононској спрези између два материјала води до стрме промене температуре решетке унутар подслоја (Ti). Као последицу, електрони из горњег слоја (Al) брзо преносе енергију следећем (подслоју) и тиме се термална енергија преноси кроз интерфејс Al/Ti, спреже са решетком и на тај начин односи из зоне интеракције. У првом следећем слоју (подслој, Ti) долази до гомилања термалне енергије периодично у латералном смеру, али због високе температуре топљења Ti не долази до топљења. Праг оштећења првог слоја је тиме повећан јер се енергија углавном гомила у првом подслоју, који већ

 ISBN 978-86-7466-930-3

има висок праг оштећења. Одсуство подслоја Ti омогућава гомилање енергије у слоју Al и изражено топљење (сл. 5).



У поређењу са Al/Ti вишеслојним узорком, оптичка дубина продирања за Al је нижа, што резултује већим вреностима апсорбоване енергије и акумулације топлоте. Топљење и аблација су израженији него код вишеслојног.

Осим статичког озрачивања, вршена су и динамичка, када је сноп скениран преко површине узорка. У овом случају је таласна дужина била 800 nm, а флуенца 153 mJ/cm^2. На одређеним правцима је скенирање извршено вишеструким прелетом снопа преко површине узорка; на сл. 6 је приказана област дела интеракције где је сноп скениран 8, 9 и 10 пута. Просторни период структуре је око 283 nm (мање од половине таласне дужине упадног снопа). У инсету на сл. 6 је приказана AFM слика дела интеракције, формирана по интензитету тунелске струје између врха пробе и узорка. Примећује се да је струја кроз формиране структуре (формиране у виду уздигнућа на површини) мања (еквивалентно тамнијој боји) него струја у деловима који нису трансформисани (светлија боја). То наводи на закључак да је дошло до смањења проводности у тим деловима, за које се може претпоставити да је узрок јача оксидација која је услед већег гомилања енергије.

Сл. 6. Приказ слике SEM (лево) и AFM (инсет-десно) дела области интеракције 5×(Al/Ti) на Si; поновљено скенирање, 8—10 пролаза, флуенца 153 mJ/cm^2; бројеви 8, 9 и 10 представљају број прелета снопа преко истог правца; правац поларизације је означен белом стрелицом.

Модел изложен у [10] предлаже формирање једне врсте LIPSS на металним површинама интеракцијом са ултракратким снопом у ваздуху. У првом кораку расејање на површинским нерегуларностима индукује појаву SPP и периодичне расподеле енергије на површини. У другом кораку, на местима где се енергија акумулира долази до загревања и реакције метала са кисеоником из ваздуха. Због ултракратког импулса је оксидација бржа од термалне дифузије, и дебљина оксида расте на местима акумулиране енергије. Тиме се одржава нанометарска локализација. Како структура расте у висину, расејање се појачава и тиме је остварена позитивна повратна спрега. У трећем кораку – како структура расте – због све већег присуства оксида се смањује продирање кисеоника у структуру и тиме се цели процес зауставља. Трећи корак има негативну повратну спрегу.

Сл. 7. Приказ слике SEM дела области интеракције 5×(Al/Ti) на Si; поновљено скенирање, 10 пролаза, флуенца 215 mJ/cm^2; правац поларизације је означен белом стрелицом.

На сликама 3 и 6 је приказано формирање једне врсте LIPSS, „гребен“, настале оксидацијом и надоградњом материјала. Првац простирања гребенских LIPSS је паралелан правцу поларизације упадног снопа (HSFL). За нешто веће флуенце снопа, сл. 7, долази до аблације материјала, а у аблираној области се појављује друга врста LIPSS, „канали“. Таласна дужина је 800 nm, флуенца 215 mJ/cm2, а као резултат је просторни период од 370 nm. Ширина канала је 80 nm. Аблација је наступила услед топљења/испаравања материјала. Правац каналских LIPSS управан на правац поларизације упадног снопа (LSFL).

Појава плазмона – колективне осилације наелектрисања и придруженог електромагнетног поља на површини металних филмова и наноструктура – омогућава ограничење простирања светлости у мале области и тиме је дало нова решења у оптичким спектроскопијама, као што су површински-побољшана Раманова спектроскопија (in surface-enhanced Raman spectroscopy, SERS) површински-побољшана инфрацрвена спектроскопија (surface-enhanced infrared spectroscopy, SEIRA) и плазмонски-побољшана флуоресцентна спектроскопија (surface plasmon-enhanced fluorescence spectroscopy, PEF), које се користе у низу форензичких аналитичких технологија за детекцију хемијских и биолошких агенаса релевантних у важним областима медицинске дијагностике, контроле хране и безбедности [12]. У PEF се флуорофорни означивачи спрежу са ограниченим пољем површинских плазмона што се може конструисати да веома појача интензитет емитованог флуоресцентног светла ради детектовања врло малих количина аналита са побољшаном границом детекције и скраћењем времена анализе. Просторно преклапање и усклађивање фазе између поларитона води до успостављања спрегнутих симетричних и антисиметричних модова површинског плазмона поларитона. Симетрични тип мода се може побудити на металним површинама са густим решеткама испод нивоа дифракције. Дифракција на таквој периодичној модулацији дозвољава да плазмони поларитони који се простиру у супротном смеру интерагују, стварајући појачане интензитете поља локализоване или у удубљењима (“канали“) решетке или на врховима („гребени“) периодичне модулације.

 ISBN 978-86-7466-930-3

IV. Закључак

Приказано је испитивање површинских модификација индукованих на танким филмовима – узорци од пет (Al/Ti) бислојева (укупне дебљине 130 nm) на Si као и узорци од једнослојног Al (дебљине 130 nm) на Si – помоћу фемтосекундног ласерског снопа таласне дужине од 390 nm и 800 nm и репетиције 76 MHz (~13 ns између импулса). За статичку интеракцију су формиране површинске периодичне структуре (LIPSS) на вишеслојном Al/Ti при флуенци једног импулса од 10,3–14 mJ/cm^2, а на једнослојном Al при флуенци једног импулса од 8,6 mJ/cm^2. Присуство подслоја повећава праг оштећења најгорњег слоја, што побољшава квалитет формираних LIPSS. За динамичку интеракцију (скенирање снопа преко површине узорка) за 153 mJ/cm^2 је дошло до формирања гребенских LIPSS, а за већу флуенцу једног импулса, 215 mJ/cm^2, до каналских LIPSS. На основу правца простирања LIPSS се закључује њихова врста, LSFL (ниске просторне учестаности) или HSFL (високе просторне учестаности). За формирање LIPSS се механизам се види у појави површинског плазмона поларитона који изазива периодичну расподелу енергије. Присуство подслоја одговарајућих термичких карактеристика омогућава лако преношење термалне енергије у дубље слојеве. Код гребенских LIPSS има три корака везаних за продирање кисеоника из ваздуха у материјал (оксидација), док код каналских LIPSS долази до аблације топљењем/испаравањем и уклањања материјала.

Појава плазмона поларитона је важна при неким флуоресцентним техникама, као што је PEF, који је унапредио осетљивост и скратио време анализе процедура за детекцију важних аналита укључујући биомаркере, патогене и токсине. Ова једињења су детектована на ниским фемтомоларним концентрацијама, а анализа је веома скраћена. Једна од плазмона који се појављује је тесно везан са појавом периодичних структура са периодом мањим од таласне дужине (LIPSS). Индуковање LIPSS може бити интересантно у великом броју примена – медицинским, декоративним, триболошким, и др. – због појаве плазмона поларитона којим се светлост конфинира и омогућава побољшање у плазмонски побољшаној флуоресцентној спектроскопији.

Захвалница

Овај рад је спроведен у оквиру реализације научних пројеката, које је финансирало Министарство науке и технолошког развоја Републике Србије под редним бројевима III45016, OI171005, OI171038. Abstract

One of the effects of the interaction of ultrashort laser beam with materials is the forming of laser-induced parallel surface structures (LIPSS), with period less than beam wavelength. For multilayer thin metal films, the quality of formed structures is better. The sample of five bilayers of Al and Ti on Si substrate was exposed to femtosecond beam and noticed the forming of of two types of structures different in shape. Both are most probably the product of surface Plasmon polariton on the surface of most top layer. The occurrence of Plasmon polariton on the surface of thin metal layers and nanoparticles can confine the propagation of electromagnetic field and to amplify the fluorescent signal from molecules of the chemical compound on the surface. Depending on the interface structure for determining the target chemical on metal surface, Plasmon enhanced fluorescence is an attractive method for shortening the time of detection and increasing the sensitivity of various analytical technologies used in forensics.

Sub-micrometer parallel surface structures induced by femtosecond laser beam in forensics

Sinhronizacija mernih podataka u bežičnim senzorskim mrežama

Miodrag Malović

Apstrakt—**Početkom dvadesetprvog veka, unapređenje a posebno pojeftinjenje mikroelektronskih komponenti dovelo je do značajne ekspanzije bežičnih tehnologija. Često imamo potrebu da fizički odvojeni uređaji koriste istu (odnosno, što približniju) vremensku skalu za označavanje veličina i događaja koje prate. Ovo je netrivijalan zadatak budući da su uređaji baterijski napajani i moraju svesti razmenu poruka (koje zahtevaju upotrebu energetski zahtevnog radio interfejsa) na minimum. U tu svrhu osmišljen je veliki broj algoritama i protokola koji se bave problemom usklađivanja satova na bežičnim uređajima u okviru mreže. U ovom radu prikazana su i klasifikovana neka uobičajena rešenja.**

Ključne reči—**sinhronizacija, vreme, frekvencija, bežične senzorske mreže, merenja**

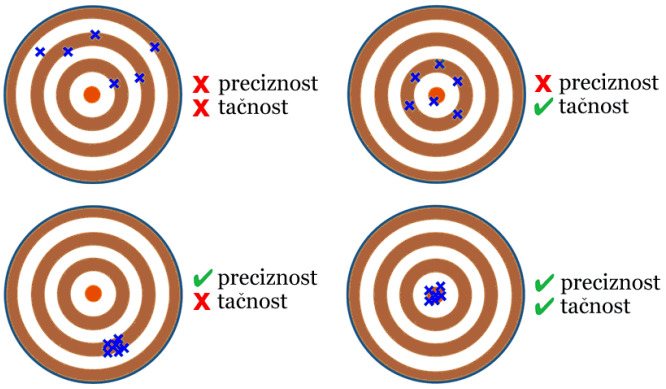
I. Uvod

Bežične senzorske mreže (WSN - *wireless sensor networks*) su sa razvojem mikroelektronskih komponenti niske potrošnje dobile važno mesto u mnogim oblastima nauke i svakodnevnog života. Najčešće oblasti njihove primene su građevina (ispitivanje stanja kapitalnih građevinskih objekata), medicina (daljinski nadzor pacijenata), meteorologija (prikupljanje podataka), saobraćaj (kontrola; nadzor zagađenja), prevencija nepogoda (požara, poplava, raznih havarija), industrijska i kućna automatika, itd. U heritologiji, bežični senzorski sistemi se koriste kako u permanentnom bezbednosnom nadzoru lokaliteta (zaštiti od prirodnih nepogoda i od provalnika) tako i za evaluaciju stanja objekata: snimanje pukotina u zidovima, detekciju vlažnosti i prokišnjavanja, vibracija, i drugih veličina.

Jedan od važnih ciljeva u realizaciji praktično svakog bežičnog mernog sistema jeste postizanje odgovarajuće vremenske sinhronizacije između mernih podataka koji potiču iz različitih tačaka, a koja je primerena za datu svrhu. I dok se kod nekih vrsta merenja, kao što su merenja zagađenja u saobraćaju, praćenje nivoa podzemnih i nadzemnih voda, merenja u meteorologiji, biologiji i sl. ne zahteva velika sinhronizovanost, već je bitno da su podaci obeleženi od strane lokalnog časovnika realnog vremena koji ne mora biti striktno održavan, kod merenja brzih procesa u nekim tehničkim disciplinama kao što su mašinstvo ili građevina, bitna je usaglašenost podataka izmerenih različitim senzorima u različitim tačkama u prostoru, koja mora biti na nivou zanemarljivog dela periode najviših harmonika oscilacija koje se proučavaju. Ove mogu biti reda veličine i preko 100 Hz, mada su najčešće u upotrebi frekvencije od najviše dvadesetak. Razvoj elektronike je zaista omogućio da se ove pojave mogu pratiti sa garantovanom sinhronizacijom znatno boljom od 1 ms, što je dovoljno za opisivanje većine mehaničkih pojava (ne treba zaboraviti da pretvaranje neelektričnih veličina u električne takođe unosi nekakvu dinamiku u proces merenja, te da sami senzori mehaničkih veličina teško mogu da daju odziv sa vremenskom pouzdanošću znatno boljom od milisekunde).

Sl. 1. *Torre Rognosa* u Toskani (centralna Italija), uvršćen u Uneskovu listu svetske baštine (*world heritage sites*), na kome je vršen višemesečni nadzor stanja mrežom bežičnih senzora [1].

Dok kod žičanih mreža sinhronizaciju nije teško izvesti jer se isti signal iz zajedničkog izvora vremena može sa zanemarljivom neodređenošću (reda veličine ns) sprovesti na različite uređaje, kod bežičnih mreža situacija se komplikuje. Ove najčešće koriste kompleksne radio modeme, koji imaju sopstvene procesore i operativne sisteme (*embedded RTOS*) koji unose ne sasvim određeno kašnjenje u prenos poruke, a priroda veze, podložna smetnjama iz brojnih izvora, uslovljava slanje podataka u više paketa čiji prenos može uspeti iz prve ili biti podložan određenom broju ponovnih pokušaja. Takođe, ovi paketi mogu zahtevati isporuku preko relejnih uređaja jer ne postoji garancija direktne veze između pošiljaoca i primaoca (čak, topologija cele mreže može biti podložna rekonfiguraciji u vremenu). Zato je sinhronizacija mernih podataka u bežičnim mrežama senzora postala ozbiljna naučna disciplina.



II. Satovi (tajmeri) i njihove nesavršenosti

Iako se reči tajmer i kaunter ponekad koriste naizmenično, ispravno je za uređaj za merenje vremena koristiti reč koja je

Miodrag Malović – Univerzitet u Beogradu, Inovacioni centar Tehnološko-metalurškog fakulteta, Karnegijeva 4, 11120 Beograd (e-mail: ofiss@malovic.in.rs) (https://orcid.org/0000-0002-0691-4626).

 ISBN 978-86-7466-930-3

izvedena iz reči za vreme, a to je tajmer. Kaunter je po definiciji uređaj za brojanje električnih impulsa (silaznih ili uzlaznih ivica nekog signala). Ukoliko kaunter vežemo sa oscilatornim kolom baziranim na (najčešće) piezoelektričnom kristalu, koje daje takt procesoru i drugim čipovima na mernom uređaju, dobijamo tajmer. Generalno, kategorija „kaunter“ je šira (kaunteri se mogu koristiti u različite svrhe brojanja koje nemaju veze sa merenjem vremena).

Sl. 2. Grafički prikaz razlike između preciznosti i tačnosti.

Sl. 3. Pendulum CNT-91 precizni kaunter/tajmer (prednja i zadnja strana) [2]. Ovaj i slični uređaji se koriste za merenje vremena i frekvencije, kao i generisanje signala stabilne frekvencije, u eksperimentima vezanim za proveru sinhronizovanosti.

Karakteristike tajmera su određene kvalitetom piezoelektričnih kristala (mada se u novije vreme koriste i MEMS oscilatori koji ne moraju biti piezoelektrične prirode) i prateće elektronike koja čini oscilatorno kolo. Pojmovi koji se koriste u opisivanju kvaliteta oscilatora odnosno tajmera se lako mogu pobrkati pa nije na odmet navesti njihove definicije. Greška ili odstupanje predstavlja razliku između tačne i nominalne vrednosti frekvencije. Da bi greška bila definisana, potrebno je da poznajemo tačnu vrednost, što često nije slučaj. Najčešće se pod greškom podrazumeva razlika između nominalne (negde deklarisane) frekvencije i vrednosti koja se izmeri kvalitetnijim (etalonskim) uređajem. Tačnost je inverzno određena ovim odstupanjem. Preciznost se odnosi na ponovljivost frekvencije. Preciznost je sinonim za stabilnost, a ne tačnost. Frekvencija može odstupati od nominalne a biti slabo promenljiva, što uređaj čini preciznim, ali ne i tačnim. Ilustracija ovoga je data na Sl. 2.

Postoje dva glavna izvora greške vremenske sinhronizacije u distribuiranim sistemima. Prvo, vreme propagacije poruka nije dovoljno determinisano kada se koristi radio komunikacija između udaljenih uređaja (jedini način komunikacije kod bežičnih senzorskih mreža, ako ne računamo druge oblasti frekvencija koje ne spadaju u radio, ali je princip rada isti). Drugo, stabilnosti tajmera su limitirane brojnim fizičkim faktorima, pa čak i u slučaju da su njihove frekvencije perfektno kalibrisane u jednom trenutku, pomeranja (driftovi) moraju da se dogode u nekoj meri pre ili kasnije, i odstupanje pokazivanja (ofset) se akumulira sa vremenom, uslovljavajući potrebu za razmenom novih poruka da bi se uređaji međusobno ponovo sinhronizovali.

Mrežni protokoli koji se bave problemom sinhronizacije satova izvode serije akcija koje su bazirane na distribuciji vremenskih žigova iz referentnih izvora, što se naziva ofset sinhronizacija, i štelovanju dinamičkih koeficijenata koji se koriste za kalibraciju satova, što se naziva sinhronizacija brzine [3]. Uobičajena podela ovih akcija ne neke kategorije je data u nastavku, a zatim su predstavljeni neki postojeći protokoli sinhronizacije.

III. Implicitna i eksplicitna sinhronizacija

Kontinualna ili implicitna sinhronizacija znači da se paketi podataka koji su vezani za sinhronizaciju dodaju na postojeće pakete koji se sve vreme (odakle naziv *kontinualna*) šalju kroz mrežu (i nezavisno procesiraju na uređajima, u skladu sa algoritmom rada mreže). Ovo dodavanje sinhronizacionih parametara u regularne pakete se u literaturi označava kovanicom *piggy-backed*, što u doslovnom prevodu znači „na krkače”.

Suprotnost kontinualnoj sinhronizaciji je sinhronizacija na zahtev, koja se takođe naziva i eksplicitna, ili *event-triggered* (inicira se nekim događajem odnosno okidačem ili trigerom, koji može biti automatski detektovan ili dat od strane korisnika). Eksplicitna sinhronizacija zahteva dodatne komunikacione pakete koji služe isključivo (ili barem primarno) u ove svrhe. Ona je zato zahtevnija u smislu energetskih potreba, što je značajno kod bežičnih uređaja, koji su obično energetski ograničeni jer su baterijski napajani, a baterije se moraju ručno menjati ili dopunjavati iz izvora ograničenog kapaciteta, kao što su solarne ćelije, induktivni mikrogeneratori, termogeneratori na bazi termoparova ili piroelektričnih materijala, itd.

IV. INTERNA I EKSTERNA SINHRONIZACIJA

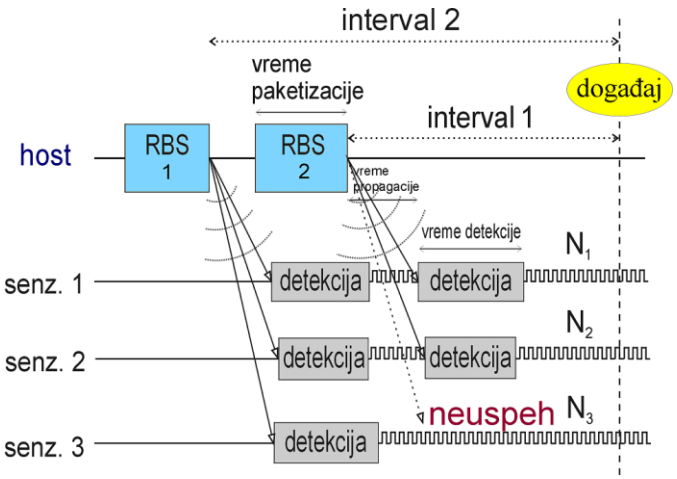
Interna sinhronizacija je algoritam sinhronizacije u kome ne postoji nikakvo spoljašnje referentno vreme. Cilj interne sinhronizacije je da pokazivanja svih satova unutar mreže budu što sličnija [4], a po mogućstvu se vodi računa i o međusobnoj razlici njihovih frekvencija, radi naknadne (tzv. post-facto) korekcije.

Eksterna sinhronizacija se bazira na jednom referentnom satu, bez obzira da li dolazi sa jednog uređaja unutar mreže (u kom slučaju reč eksterna ne treba bukvalno da se shvati) ili ne. Cilj eksterne sinhronizacije je da učini da svi satovi u mreži pokazuju koliko je moguće blizu referentnom satu.

V. UNIDIREKCIONA I BIDIREKCIONA SINHRONIZACIJA

Unidirekciona sinhronizacija je procedura u kojoj se sat ciljnog uređaja podešava prema satu izvornog uređaja, dakle postoji jasan smer kretanja informacije. Tipično transmisiono vreme se oduzima od vrednosti po prijemu. Unidirekciona sinhronizacija ne znači da se ista poruka šalje na samo jednu prijemnu adresu, već samo da nema dvosmerne razmene informacija. Na ovaj način se može sinhronizovati više uređaja u okolini izvora.

Bidirekciona, često zvana i *pairwise* (po parovima, ili parska) sinhronizacija je bazirana na proračunu takozvanog *round-trip* kašnjenja, odnosno vremena potrebnog da poruka otputuje sa izvornog uređaja do ciljnog i da se povratna poruka detektuje na izvornom uređaju (kružno putovanje). Prednost je što se meri stvarno fizičko vreme (naravno, ograničeno preciznošću lokalnog sata), što je inače nemoguće u dve odvojene tačke (kod unidirekcione sinhronizacije). Iako se ne može odrediti tačna raspodela vremena i nesigurnosti vremena putovanja između smerova, za povratnu putanju može se tačno odrediti i srednja vrednost i standardno i maksimalno odstupanje vremena propagacije (round-tripa). Pošto se obično radi sa uređajima istog tipa, za tipično vreme propagacije uzima se polovina round-trip vremena. I drugi uređaji u mreži mogu imati koristi od bidirekcionih sinhronizacionih poruka između dva čvora. Oni mogu da koriste razmenjene vremenske žigove da bi sinhronizovali svoje satove bez bilo kakve dodatne transmisije podataka (utroška energije), samo prijemom, tj. uvidom u otvorenu komunikaciju parova koji se sinhronizuju bidirekciono. Ovakva procedura je česta i naziva se *eavesdropping* (prisluškivanje) [5].



VI. TRANSFORMACIJA VREMENSKE SKALE

Transformacija vremenske skale spada u *backwards*, odnosno post-facto ili naknadne (unazad) sinhronizacione tehnike. Satovi nisu sinhronizovani za vreme događaja koji se posmatra, ali se sinhronizacija skupljenih podataka vrši naknadno u zavisnosti od relevantnih parametara (ustanovljenih frekvencija tajmera i medjusobnih ofseta). Iako zahteva manje energije (manje dodatne komunikacije nego u slučaju sinhronizacije na zahtev), povećava potrebu za procesiranjem podataka, i najbolje je izvršiti je na sistemu visokog nivoa, kao što je PC računar, koji često predstavlja baznu stanicu (hab) bežične mreže. Post-facto sinhronizacija se nekada naziva i reaktivnom ili a-posteriori, što je suprotno od proaktivne sinhronizacije koja se vrši unapred, ili a-priori [6]. Proaktivna i reaktivna sinhronizacija se kombinuju u nekim protokolima.

Kao što ime govori, transformacija vremenske skale je doterivanje vremenskih žigova u skladu sa poznatim odnosima između frekvencija satova na uređajima (doterivanje „nagiba“, odnosno brzine) i poznatim trenucima simultanih događaja (doterivanje ofseta).

VII. RBS, MULTIKAST, I UNIKAST

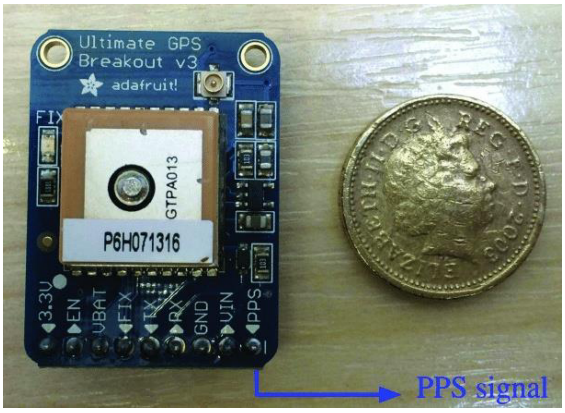
Reference Broadcast Synchronization (RBS) [7] ili sinhronizacija putem referentnog ili prozivnog signala je termin koji se asocira isključivo sa bežičnim mrežama. Spada u unidirekcione sinhronizacione tehnike. Centralni server emituje referentni signal (poznat i pod nazivom *beacon*, odnosno „signal za navođenje“, po analogiji sa signalima koji se koriste u navigaciji) a prijemni uređaji usklađuju svoje tajmere po prijemu. Sl. 4 prikazuje vremenski dijagram povorke od dva RBS-a koji prethodi detekciji događaja od strane više senzorskih uređaja.

Sl. 4. Prikaz uspele i delimično uspele sinhronzacije pri slanju povorke od dva RBS-a; u slučaju uspeha, neodređenost vremena označavanja događaja zavisi od neodređenosti vremena detekcije i neodređenosti frekvencije kojom se mere N_1 i N_2, dok se u slučaju parcijalnog neuspeha (senzor 3) dodaje i neodređenost vremena paketizacije modema hosta [8].

Ovaj tip poruke se naziva *multicast* (šire raspoređen, odnosno za više primaoca), što je suprotno *unicast* porukama (koje imaju jednog pošiljaoca i jednog primaoca). Propagacione neodređenosti, vezane za transmisiju poruke (izlazno vreme kroz fizički sloj, koji se sastoji od interfejsa između procesora i komunikacionog modula, modema ili transsivera, i antene) se potiru jer se radi o istom signalu za sve primaoce. Neodređenosti vezane za prijem poruke su obično za red veličine manje i na ovaj način se ofset između čvorova praktično potire. Logičko vreme je na ovaj način nešto bolje sinhronizovano nego fizičko vreme. Logičko vreme predstavlja „relativno“ vreme unutar nekog posmatranog perioda, kao što je merni ciklus, dok fizičko

 ISBN 978-86-7466-930-3

vreme predstavlja stvarno vreme u spoljnom svetu. Sekundarne RBS procedure se mogu ponavljati u multihop[1] mrežama (gde ne postoji direktna veza između izvora RBS-a i svih uređaja), gde sinhronizovani uređaji služe kao habovi (centralne stanice) lokalnih klastera (grupa u kojima su uređaji „nižeg nivoa“). Pouzdanost sinhronizacije naravno opada sa brojem hopova (novih transmisija RBS-a).



VIII. GPS I PPS

Puls u sekundi (PPS) globalnog sistema za pozicioniranje (GPS) predstavlja odličan izvor vremenskih žigova visoke tačnosti [9]. Kako se očekuje da cene GPS prijemnika padaju u doglednoj budućnosti, ovaj metod će verovatno dobiti na popularnosti. Ipak, u ovom trenutku, osim zahteva da se jeftini bežični senzorski uređaji opreme dodatnim hardverom čija cena nije zanemarljiva, postoji ozbiljan problem dostupnosti signala unutar građevina i drugih zatvorenih prostora, tako da se ovo inače efektno rešenje uglavnom izbegava. Ovaj signal se emituje iz satelita, ograničenom snagom. Čak i malo gušće krošnje drveća mogu da budu prepreka za njega.

PPS signali su odlični za dugoročnu sinhronizaciju vremena. Informacija o protoku vremena se konstantno usklađuje sa referentnim laboratorijama najvišeg nivoa tačnosti na zemlji. Ovaj signal, nažalost, ne sadrži informaciju o fizičkom vremenu (vreme-datum).

U nekim praktičnim realizacijama bežičnih mreža koristi se jedan ili nekoliko referentnih uređaja sa GPS prijemnikom, koji se sinhronizuju putem PPS-a, i dalje prosleđuju informaciju uređajima „nižeg nivoa“ u mreži, koji mogu biti u zatvorenim prostorijama ili ispod vegetacije, ili naprosto nemaju GPS prijemnike radi uštede.

Na Sl. 5 prikazan je GPS modul za platformu Arduino [10].

Sl. 5. GPS modul za Arduino [10], cene $30, 2021.

IX. KLASIČNI MREŽNI ALGORITMI SINHRONIZACIJE

Prve kompjuterske mreže koristile su dve varijacije sinhronizacije putem centralizovanog servera, poznate kao Kristijanova i Berkli sinhronizacija. Hab sistema (centralna stanica) šalje vremenske žigove uređajima u mreži na zahtev. Očekivano vreme propagacije se oduzima prilikom prijema. Alternativno, višestruki paketi sa vremenskim žigovima se šalju u odgovoru na jedan zahtev, i najbrže pristigli paket se uzima u obzir (da bi se izbegla mogućnost povremenih nepredviđenih zastoja). U Kristijanovoj varijaciji algoritma, hab služi kao izvor vremena (njegov sat se uzima kao referentni eksterni izvor), dok se u Berkli varijaciji podaci skupljaju sa različitih čvorova usrednjavaju (opciono sa težinskim faktorima), i usrednjena informacija se šalje nazad.

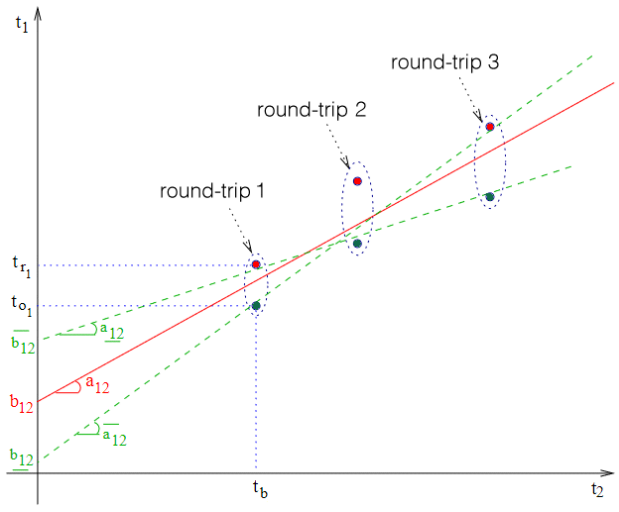
Jedna od najčešće korišćenih metoda u savremenim kompjuterskim mrežama jeste mrežni vremenski protokol ili NTP (*network time protocol*) [11]. Čvorovi mreže se dele u različite slojeve (*layers*), počevši od referentnih satova koji su na vrhu (takozvani „stratum 0” sloj, u koji spadaju nacionalne laboratorije i GPS sateliti). Mrežni čvorovi nižeg nivoa sinhronizuju se na bazi poruka koje primaju sa uređaja istog ili višeg nivoa. Razmena poruka unutar mreže ne sadrži samo vremenske žigove, već i razne druge podatke, kao što su preciznost tajmera na uređaju, vreme njegove poslednje sinhronizacije, pouzdanost njegove poslednje sinhronizacije, i očekivano vreme putovanja poruke. Ciljni uređaj odlučuje da li da izvrši korekciju svog sata, i za koliko, ili ne, bazirano ne samo na zadnjoj primljenoj poruci već ispitujući set poruka pristiglih u dužem vremenskom intervalu. NTP poruke se testiraju na smislenost i one koje izgledaju kao gruba greška se odbacuju u procesu interpolacije, tako da je algoritam robustan.

Precizni vremenski protokol ili PTP (*precision time protocol*), poznat i kao IEEE-1588 [12], je kompleksniji protokol baziran na istom principu. Veći broj tipova poruka se koristi, veći broj parametara se prosleđuje, i uređaji imaju različite funkcije, a ne samo klijent, server, ili klijent-i-server, što je slučaj u NTP-u. Ipak, glavna prednost ovog protokola nisu kompleksne softverske metode već „hardverska asistencija“. To znači da postoji specijalizovani hardver koji se instalira na mrežne kartice i druge uređaje, koji određuje precizna (ispod mikrosekunde) vremena fizičke emisije poruka (tzv. prolaska kroz „fizički sloj“ mreže), koja bi inače bila nedostupna glavnim procesorima mrežnih uređaja. Dok tipičan NTP klijent ostvaruje preciznost sinhronizacije reda veličine milisekunde, kod PTP-a su sinhronizacije reda veličine ispod mikrosekunde.

X. PROTOKOLI SINHRONIZACIJE U BEŽIČNIM MREŽAMA

Veliki broj protokola je osmišljen radi upotrebe isključivo u bežičnim senzorskim mrežama. Navešćemo neke od osnovnih, uz kratak opis načina rada.

Sinhronizacija putem vremenskog žiga ili vremenskog označavanja (*time-stamp synchronization* ili TSS) je metod promene vremenskih žigova poruka koje prolaze kroz multihop mrežu, bazirano na vremenu prijema, procenjenom vremenu puta, i vremenu koje poruka provede u „redu” (lokalnom baferu, odnosno steku, za prijem pristiglih paketa), odnosno *queue*-u, pre nego što se prosledi. Satovi nisu stvarno sinhronizovani tako da se ovde radi o formi *post-facto* odnosno naknadne sinhronizacije. Varijacija na ovu temu je



[1] putovanje paketa u više predajno-prijemnih koraka, odnosno putem releja, kada ne postoji direktna veza između pošiljaoca i primaoca; *hop* označava jedan „skok“ odnosno putovanje poruke između dva čvora

 ISBN 978-86-7466-930-3

RITS (*routing integrated time synchronization*) [13], kod koga se izvodi dodatna kompenzacija zbog razlike u brzinama rada različitih tajmera. Ova razlika se procenjuje na osnovu istorije razmenjenih poruka sa vremenskim žigovima iz bidirekcione komunikacije (gde se mogu uporediti *round-trip* vremena proračunata na različitim čvorovima).

Laka vremenska sinhronizacija (*lightweight time synchronization* ili LTS) i *timing-sync* protokol za senzorske mreže (TPSN) su bazirani na bidirekcionoj sinhronizaciji parova uređaja koji razmenjuju poruke unutar multihop mreže, gde postoji jedna ili više referentnih tačaka (čiji su tajmeri deklarisani kao referentni) [14]. Uređaji na nižim nivoima (više hopova udaljeni od referenci), upućuju zahteve za sinhronizacijom prema uređajima na višem nivou. Kod LTS-a, uređaji proveravaju da li drugi uređaji na istom nivou imaju aktuelne zahteve koji nisu izvršeni (*pending requests*), i sinhronizuju se sa njima umesto da šalju nove multihop zahteve. Kod TPSN-a, uređaji na nižem nivou prisluškuju (*eavesdrop*) sinhronizaciju uređaja na višem nivou, i zatim šalju zahtev za sihnhronizacijom u prigodnom momentu.

Tiny-sync i Mini-sync [15] takođe rade na principu bidirekcione sinhronizacije. Oni koriste statistiku da porede vremenske žigove koji se razmenjuju između parova uređaja. Vremenski žigovi odstupaju sve više tokom vremena, zbog razlika u brzinama satova (koje su dodatno podložne varijacijama usled promene različitih fizičkih parametara), tako da se odnos frekvencija i inicijalni ofset mogu proceniti kreiranjem optimalne prave bazirane na većem broju parova vremenskih žigova sa oba uređaja (tzv. linearna regresija; ilustracija je data na Sl. 6). Različiti algoritmi se koriste da procene najverovatniji odnos frekvencija i ofset.

Sl. 6. Linearna regresija $t_1(t_2)$ gde donje tačke u paru predstavljaju emisiju signala, a gornje prijem odgovora kod round-tripa, u funkciji žiga na drugom uređaju; *a* označava minimalni, srednji i maksimalni odnos brzina satova, a *b* minimalni, srednji i maksimalni ofset [15].

Fleksibilna laka vremenska sinhronizacija (*scalable lightweight time-synchronization protocol*, ili SLTP) [16], koristi metod takozvanog pasivnog grupisanja (*passive clustering*) kao prvi korak, a zatim izvodi sinhronizaciju slično LTS-u. Na zahtev, kreira se topologija mreže (pasivno grupisanje, odnosno trasiranje), pri čemu se uređaji dele na grupe (klastere) i dodeljuju im se funkcije habova klastera (referentnih tačaka, koje dakle nisu fiksne kao kod originalnog LTS-a), članova klastera, ili *gateway*-a odnosno kapija između klastera. Upotrebljava se i linearna regresija, kao kod tiny-synca i mini-synca, za poređenje i usklađivanje satova prilikom bidirekcione komunikacije.

Tsync protokol [17] koristi dve tehnike koje se nazivaju hijerarhijsko referenciranje (*hierarchy referencing time synchronization* ili HRTS) i individualni vremenski zahtevi (*individual-based time request* ili ITR). Glavni uređaj emituje RBS signal koji primaju uređaji najvišeg nivoa (lejera). Jedan od njih se slučajno izabira za bidirekcionu razmenu vremenskih žigova. Propagaciono kašnjenje se procenjuje na osnovu ovog procesa i novi RBS od strane centralnog uređaja se šalje dajući ciljnim uređajima referentnu vrednost vremena i pretpostavljeno vreme propagacije (smatra se da su uređaji hardverski identični te se očekuje približno isto vreme propagacije). Kada se proces završi, uređaji iz prvog nivoa ponavljaju proceduru prema klasterima nižeg nivoa. Proces se rekurzivno ponavlja dok svi uređaji u mreži nisu sinhronizovani. ITR je komplementarni mehanizam u Tsync-u, koji se koristi za sinhronizaciju na zahtev, bilo jednog uređaja bilo grupe. Uređaji koji zahtevaju sinhronizaciju šalju zahtev koji se multihop prenosi do centralne stanice (glavnog uređaja) i referentni vremenski žig se prenosi nazad istim putem. HRTS i ITR u originalnom obliku koriste dva različita kanala za razmenu poruka, ali moguća je implementacija i na jednom kanalu, sa nešto lošijom performansom.

Intervalska sinhronizacija (*interval based synchronization* ili IBS) [18] koristi procenu granica brzine satova (njihovih minimalnih i maksimalnih vrednosti) da odredi granice u kojima se vreme nalazi. Umesto razmene vremenskih žigova, čvorovi komuniciraju razmenjujući podatke o minimalnom i maksimalnom vremenu (tzv. *interval stamps* ili intervalski žigovi, bazirani na najgorem slučaju devijacije frekvencije sata). Ovo se naziva i intervalski model, koji je suprotan instant (tačkastom) modelu. Iako neki autori tvrde da je kombinacija „garantovanih“ granica za lokalne satove optimalnija nego upotreba pojedinačnih vremenskih žigova uz estimaciju njihovog kvaliteta (procenu distribucije verovatnoće i standardne i maksimalne devijacije), suština oba metoda je ista, a u stvarnosti ne postoje stopostotne garancije za granice kod *bounded-drift* modela sata (modela limitarnog odstupanja odnosno limitiranog drifta frekvencije).

Asinhrona difuzija [19] je protokol kod koga svi uređaji periodično šalju signal susedima tražeći pokazivanja njihovih satova (vremenske žigove). Slično kao kod Berkli algoritma, vrši se usrednjavanje ovih vrednosti i one se putem RBS-a prosleđuju susedima (svim uređajima u dometu ili unutar klastera), koji vrše sinhronizaciju na novu vrednost. Proces se ponavlja širom mreže.

Protokol sinhronizacije putem preplavljivanja (*flooding time synchronization protocol* ili FTSP) [20] koristi tzv. preplavljivanje (*flooding*) mreže odnosno slanje velikog broja

 ISBN 978-86-7466-930-3

paketa (slično RBS-u) sa referentnog uređaja, u kombinaciji sa pamćenjem parova vremenskih žigova i linearnom regresijom koja se koristi kod tiny-sync-a. PulseSync je sličan protokol, baziran na plavljenju mreže velikom brzinom, da se ne dozvoli akumulacija nagiba (*skew*) [21]. *Skew* označava akumuliranu grešku sata baziranu na driftu frekvencije tajmera (odstupanju tokom posmatranog vremena). I dok oba protokola imaju preciznost koja opada sa brojem hopova, PulseSync preciznost opada nešto sporije.

Kod protokola vremenske difuzije (*time diffusion protocol* ili TDP) [22], referentni uređaj šalje primarni RBS signal, a susedi u dometu vraćaju informaciju koja sadrži procenjenu stabilnost sopstvene frekvencije tajmera, na bazi ranije razmenjenih vremenskih žigova. Referentni uređaj odlučuje koji susedi mogu da budu izvori sekundarnih RBS signala (centri klastera nižeg nivoa), i šalje sinhronizacioni RBS. Procedura se rekurzivno ponavlja kroz multihop mrežu sve dok svi uređaji nisu primili bar jednu poruku ovog tipa. Uređaji koji su primili višestruke sinhronizacione naredbe sinhronizuju se na srednju vrednost, uz korišćenje težinskih koeficijenata (baziranih na proceni stabilnosti frekvencije i nivou izvora). Sličan protokol pod nazivom GTSP (*gradient time synchronization protocol*) [23] ne zahteva centralni referentni čvor, definisanu topologiju, niti stalnu operaciju svih uređaja. Opisane dvofazne RBS procedure se ponavljaju kroz mrežu bez definisane hijerarhije.

Konsenzus sinhronizacija (*consensus clock synchronization* ili CCS) [24] je tipična interna sinhronizaciona metoda. Svi uređaji emituju unidirekcione poruke sa vremenskim žigovima i primajući uređaji pokušavaju da procene koliko iznosi vrednost „dogovorenog" vremena u mreži. Procena se donosi na bazi pamćenja većeg broja prethodnih poruka sa različitih uređaja.

Kao što vidimo, opisane metode, kao i mnoge druge koje postoje, nisu strogo razdvojene, već se prilično preklapaju i teško je povući granicu između njih i razvrstati algoritme striktno po kategorijama.

XI. Zaključak

Bežične senzorske mreže (WSN) predstavljaju skup (najčešće minijaturnih) elektronskih senzorskih uređaja, koji služe za nadgledanje različitih pojava u fizičkom svetu. Uređaji u mreži komuniciraju putem radio talasa. Ovim putem se razmenjuju i informacije o vremenu, odnosno održava sinhronizacija satova unutar mreže. Sinhronizacija (na nivou određenom mernim zadatkom) je neophodna za ispravno vremensko označavanje mernih uzoraka u distribuiranim merenjima u mašinstvu, građevini, i drugim tehničkim disciplinama, uključujući heritologiju. U ovom članku dat je prikaz uobičajenih algoritama i protokola za minimizaciju razlika pokazivanja satova unutar bežične senzorske mreže.

Zahvalnica

Autor se zahvaljuje za podršku Ministarstvu prosvete, nauke i tehnološkog razvoja Republike Srbije (ugovor 451-03-68/2022-14/200287).

ABSTRACT

Advances in microelectronics in the past decades have lead to widespread use of wireless sensor networks (WSN). Sensor devices in these networks are not connected permanently, but are only able to exchange messages from time to time, using radio interface. In order to preserve limited energy reserves (devices are battery powered), this exchange must be kept to a minimum. Proper fusion of data from different nodes requires certain level of synchronization of their clocks, depending on the particular measurement task. So the clocks synchronization is one of the primary concerns in many WSN. This paper reviews the most common techniques and protocols used for this purpose.

Synchonization of measurement data in wireless sensor networks

Primer kombinovanja raspodela atmosferskih aerosola po veličinama dobijenih metodom merenja električne pokretljivosti i optičkom metodom

Miloš Davidović, Milena Davidović, Sonja Dmitrašinović, Milesa Srećković, Milena Jovašević-Stojanović

***A stra t*—Atmosfers i aerosoli u urbanim sredinama se sastoje od čestica različitih dijametara, oje mogu imati veličinu od par nanometara do par mi rometara. toga je za merenje oncentracije aerosola često neophodno oristiti više instrumenata, sa principijelno različitim metodama merenja. ovom radu su korišćene metode zasnovane na merenju električne po retljivosti čestica, za opseg dijametara od 1 nm do 42 nm, i merenju e vivalentnog optičkog dijametra, za opseg dijametara od nm do 1 um. ao glavni rezultat, pri azani su primeri kombinovanja spektara veličina čestica koji su dobijeni pomoću ove dve omplementarne metode merenja. procesu kombinovanja spektara veličina čestica moguće je modifi ovati raspodelu dobijenu optičkim merenjima traženjem optimalne vrednosti inde sa prelamanja čestica tako da se dobije što bolje slaganje sa raspodelom dobijenom merenjem električne po retljivosti. ao ulazni podaci su orišćeni rezultati merenja iz ampanje mobilnog monitoringa u ovom adu 2 22.**

***Ključne reči* — električna mobilnost; ekvivalentni optički dijametar; ijevo rasejanje; log normalna raspodela.**

I. UVOD

Raspodela čestica po veličinama je jedan od ključnih parametara za određivanje rizika koje mogu nositi po zdravlje, i ovo je utvrđeno u velikom broju studija koje se bave zdravljem ljudi. Videti npr. [1] gde se opisuje mogućnost nanošenja nanočestica u pluća, njihovog jakog upalnog potencijala i prenošenja dalje u organizam, a takođe i njihova pojačana biološka aktivnost usled velike površine u odnosu na masu [2]. Takođe, veličina čestice predstavlja važan parametar koji opisuje česticu aerosola budući da od veličine zavise koeficijenti rasejanja i apsorpcije, sposobnost da čestica veže vodu i dr. što je bitno za karakterizaciju atmosferskih procesa. Usled toga je najčešće i ujedno najznačajnije merenje koje se vrši na aerosolima određivanje raspodele broja čestica po njihovoj veličini.

Sa druge strane, utvrđivanje ove raspodele u nekoj urbanoj sredini nije jednostavan zadatak. Regulatorne mreže za monitoring aerozagađenja često daju informaciju koja je niske vremenske rezolucije, a često postoji i problem malog broja mernih stanica u ovim mrežama. Stoga se ovakvi javno dostupni podaci, moraju dopunjavati kroz dodatne kampanje merenja aerozagađenja.

Za merenje i karakterizaciju čestičnog zagađenja, koje se za aerosole uopšte, i naravno aerosole u urbanim sredinama, sastoji od čestica različitih dijametara, u veoma širokom opsegu dijametara čestica (od par nanometara do 10 um) koristi se obično više instrumenata, pa se njihovi spektri (izmerene raspodele veličina čestica) kombinuju. Neophodnost korišćenja više instrumenata, sa principijelno različitim metodama merenja, proističe iz nemogućnosti pokrivanja celokupnog relevantnog opsega sa samo jednom metodom, npr. optička metoda se ne može koristiti za najmanje nanometarske čestice. Stoga se za ovakva sveobuhvatna merenja i karakterizaciju aerosola koriste i kombinuju metode zasnovane na različitim fizičkim principima kao što su optičke metode, metode zasnovane na merenjima električne pokretljivosti, metode zasnovane na posmatranju uzorkovanog aerosola pomoću mikroskopa, metode zasnovane na merenju aerodinamičkog prečnika čestica i druge. Budući da zbog različitog principa merenja navedene metode imaju drastično različite vremenske rezolucije (od merenja u realnom vremenu do metoda koje podrazumevaju uzorkovanje i naknadnu laboratorijsku analizu) i pokrivaju različite opsege veličina čestica, a da je cilj kampanja merenja koje smo izvršili bila karakterizacija urbanih aerosola u realnom vremenu u ovom radu se kombinuju metoda zasnovana na merenju električne pokretljivosti za opseg dijametara od 10nm do 420nm i metoda zasnovana na merenju intenziteta rasejane svetlosti tj. optičkim merenjima za opseg dijametra od 300nm do 10um,

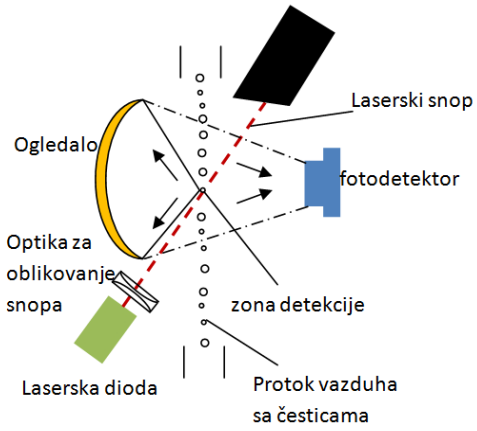
koje omogućavaju visoku vremensku rezoluciju. Teorijska osnova optičke metode je teorija Mijevog rasejanja.

Za analizirane primere kombinovanja spektara će biti korišćeni rezultati merenja iz kampanje mobilnog monitoringa u Novom Sadu 2022.

II. FIZIČKE OSNOVE I PRINCIPI RADA KORIŠĆENIH MERNIH INSTRUMENATA

Sl. 1. Princip odabira čestica na osnovu njihove električne pokretljivosti. Šematski detalj radijalnog diferencijalnog analizatora pokretljivosti (engl. radial differential mobility analizer RDMA)



U ovoj sekciji ćemo ukratko prikazati fizičke osnove i principe rada dva korišćena instrumenta za merenje čestičnog zagađenja. Prvi korišćeni instrument, TSI Nanoscan SMPS 3910, razlikuje čestice po njihovoj električnoj mobilnosti. Na taj način uređaj može da diskriminiše čestice dijametara od 10nm do 420nm u 13 kanala. Za tu svrhu se koristi deo uređaja koji je šematski prikazan na Sl. 1. U sklopu uređaja veličina čestice se procenjuje pomoću radijalnog diferencijalnog analizatora pokretljivosti, koji je zbog kompaktnosti pogodan za korišćenje u prenosivom instrumentu. Čist vazduh bez čestica ulazi u kružni kanal sa donje spoljne ivice RDMAa prethodno je tretiran kako bi se postiglo laminarno strujanje. Sa gornje strane se takođe tangencijalno uvodi vazduh sa česticama različite veličine (uzorkovani polidisperzni aerosol). Gornja elektroda RDMA je uzemljena, a donja elektroda priključena na negativan napon, tako da se između elektroda stvara električno polje. Na pozitivno naelektrisane čestice deluje električna sila usled koje se kreću ka negativnoj elektrodi. Na čestice deluje i Stoksova sila otpora vazduha. Kroz izlazni otvor na katodi za određenu vrednost primenjenog napona prolaze aerosoli klasifikovani po električnoj pokretljivosti (a time i po veličini) i dalje idu ka brojaču čestica. Preostali vazduh i čestice vraćaju se da cirkulišu u uređaju optimizujući laminarnost strujanja. Jednačina kretanja čestice pod dejstvom električnog polja i Stoksove sile otpora, a koja je suspendovana u vazduhu koji struji brzinom $\vec{u}$, je data sa

$$\frac{d\vec{p}}{dt} = m\frac{d\vec{v}}{dt} = \frac{3\pi\mu D_p}{C}(\vec{u} - \vec{v}) + q\vec{E} \qquad (1)$$

gde je m masa čestice, $\vec{v}$ njena brzina, D_p je dijametar čestice, μ koeficijent viskoznosti vazduha, C korekcioni slip faktor, q naelektrisanje čestice, i $\vec{E}$ jačina električnog polja. Terminalna brzina u pravcu električnog polja čestice se postiže veoma brzo, u momentu kada je rezultantna sila jednaka nuli i data je sa

$$\frac{3\pi\mu D_p}{C} v_e = qE \qquad (2)$$

Na osnovu jednačine (2) moguće je napisati izraz za električnu mobilnost kao $\vec{v_e} = B_e\vec{E}$ gde je $B_e = \frac{C\,q}{3\pi\mu D_p}$.

Sl. 2. Princip odabira čestica na osnovu njihovih optičkih svojstava. Šematski detalj optičke komore u kojoj se laserom obasjavaju uzorkovane čestice.

Drugi korišćeni instrument, TSI OPS 3330, razlikuje čestice po njihovim optičkim svojstvima. Na taj način uređaj može da diskriminiše čestice dijametara od 300nm do 10um u 16 kanala. Princip rada je sledeći. Čestice obuhvaćene i vođene strujanjem čistog vazduha nailaze u malu zonu detekcije koja je obasjana laserskom svetlošću. Sistem je konstruisan tako da se u zoni detekcije ne nalazi više od jedne čestice istovremeno, osim u slučaju veoma visokih koncentracija čestoca, pri čemu dolazi do greške koincidencije. Laserska svetlost rasejava se na pojedinačnim česticama i nakon refleksije od zakrivljenog ogledala dolazi do fotodetektora. Veličina čestice se određuje poređenjem izmerenog intenziteta na fotodetektoru i standardne kalibracione krive dobijene merenjima izvršenim sa skupom uniformnih čestica poznatog dijametra i indeksa prelamanja. U optičkim meračima ovog tipa seza kalibraciju najčešće koriste bele polistiren lateks čestice. Teorijske kalibracione krive izračunaju se korišćenjem Mijeve teorije rasejanja na sfernim česticama. Ključni parametri koji određuju rasejanje i apsorpciju svetlosti na čestici su talasna dužina upadne svetlosti, veličina čestice koja se obično uvodi preko bezdimenzionog parametra $\alpha = \frac{\pi D_p}{\lambda}$, gde je D_p dijametar čestice a λ talasna dužina svetlosti i kompleksni indeks prelamanja čestice normalizovan na indeks prelamanja okolne sredine (vazduha) $m = \frac{N}{N_0} = \frac{n+ik}{N_0}$. Iz izmerenog intenziteta svetlosti rasejanog pod uglom θ, $I(\theta, \alpha, m)$ ukoliko nam je poznat indeks prelamanja čestice sferne možemo dobiti njen tačan dijametar. Vrednosti dijametra koje se dobijaju merenjima pomoću optičkih merača veličine bile bi tačne samo ako je indeks prelamanja čestica veoma blizak indeksu prelamanja kalibracionih čestica.

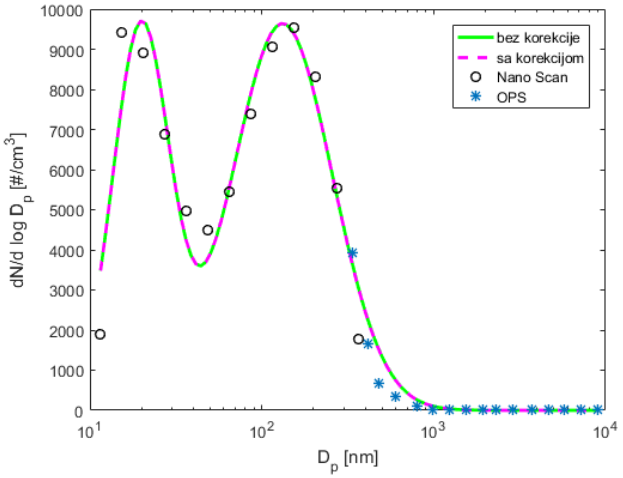
Optički dijametar i dijametar dobijen merenjem pokretljivosti su međusobno usaglašeni za kalibracione sferne čestice, ukoliko čestice nisu sferne ili im se indeks prelamanja razlikuje od indeksa prelamanja kalibracionih čestica potrebno je naknadno usaglašavanje izmerenih spektara.

 ISBN 978-86-7466-930-3

III. METOD

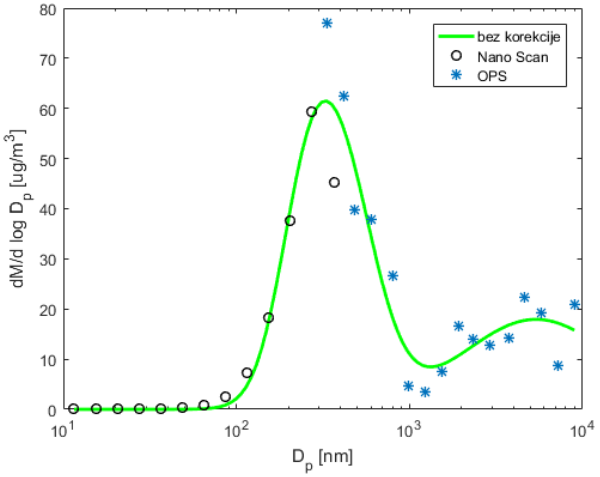
Kombinovanje dva spektra veličina čestica, koji su dobijeni pomoću merenja kvalitativno različitim metodama, podrazumeva određeni nivo modelovanja, tj. uvođenja pretpostavki za modelovanje. Pretpostavka koja motiviše modelovanje proističe iz činjenice da se podjednako i istovremeno koriste obe vrste merenja (sa izabranim težinskim koeficijentima), što je poboljšanje u odnosu na pojedinačno korišćenje metoda, pre svega u minimizaciji greške usled nepreciznosti pojedinačnog instrumenta. U nastavku ćemo opisati dva moguća metoda kombinovanja spektra veličina čestica.

Prvi metod je zasnovan na interpolaciji spektara, pri čemu se za svaki pojedinačni spektar, prikazan u $\frac{dN}{d\log D_p}$ gustini, nameće broj modova od 1 do 2, a za kombinovani spektar se nameće broj modova od 1 do 3. Takođe, kanali dva instrumenta koji se preklapaju, i vrednosti koje su izmerene u tim kanalima se kombinuju u jednu interpolacionu tačku, sa izabranim težinskim koeficijentom. Svaki od modova, koji se koriste pri interpolaciji, je oblika Gausijana, ili zasečenog Gausijana. Ovu metodu je moguće koristiti i za brojčane i za masene koncentracije.



Drugi metod je nešto složeniji i kombinuje dva spektra veličina čestica tako što korekcijama indeksa prelamanja čestica i faktora oblika čestica (engl. shape factor) nastoji da smanji razliku između dva spektra u intervalu njihovog preklapanja. Na ovaj način se dobija uz kombinovani spektar dobija, informacija o indeksu prelamanja čestica kao i faktoru oblika čestica. Oba metoda su dostupna u softveru Multi Instrument Manager 2.0 [3], koji se standardno isporučuje uz dva instrumenta. Ovu metodu je moguće koristiti samo za brojčane koncentracije.

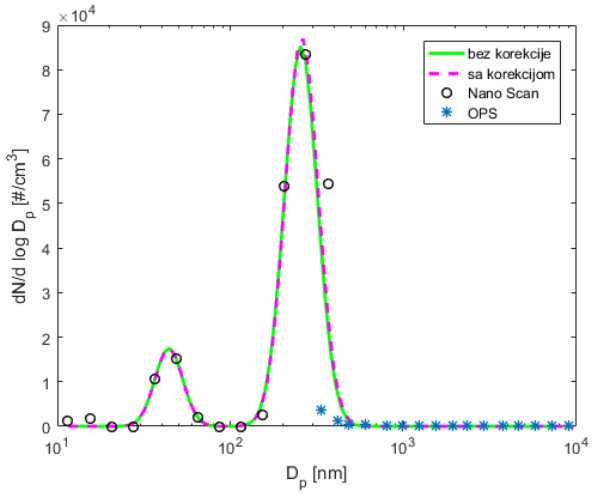
Podaci koje ćemo koristiti za primenu dva metoda su prikupljeni u zimskoj kampanji merenja 2022 na teritoriji grada Novog Sada pomoću instrumenata TSI Nanoscan SMPS 3910 i TSI OPS 3330, iz vozila u pokretu. Svako merenje je bilo geolocirano, a za potrebe ovog rada podaci su usrednjeni na 1 minut.



IV. REZULTATI

U ovoj sekciji ćemo prikazati nekoliko karakterističnih primera spajanja spektara pomoću dve opisane metode. Prva metoda je na slikama označena sa "bez korekcije", dok je druga metoda, u kojoj se vrši korekcija indeksa prelamanja označena "sa korekcijom".

Na slici 3 je prikazan uzorak 6, izmeren 04-Mar-2022 12:03:00. Sa slike 3a je evidentno da dve metode daju gotovo identične kombinovane spektre. Položaj modova je za prvi mod $D_p = 19{,}74\,nm$,$\frac{dN}{d\ log\ D_p} = 9705\,\frac{\#}{cm^3}$ i za drugi mod $D_p = 129{,}5\,nm$, $\frac{dN}{d\ log\ D_p} = 9641\,\frac{\#}{cm^3}$. Brojčani udeo po frakcijama iznosi $PN_{0.1}$: 6217.60, $PN_{0.5}$: 10590.32, PN_1: 10729.67, $PN_{2.5}$: 10737.26, PN_4: 10737.29 i PN_{10}: 10737.30 #/cm^3. Ono što je međutim dodata vrednost drugog metoda je da koristi drugačiju metodologiju, pa da uz kombinovani spektar dobijamo i informaciju o indeksu prelamanja i odstupanju čestica od sferičnih. U ovom primeru (uzorak 6) je indeks prelamanja 1.5941 i faktor oblika 1.0009.



(a)

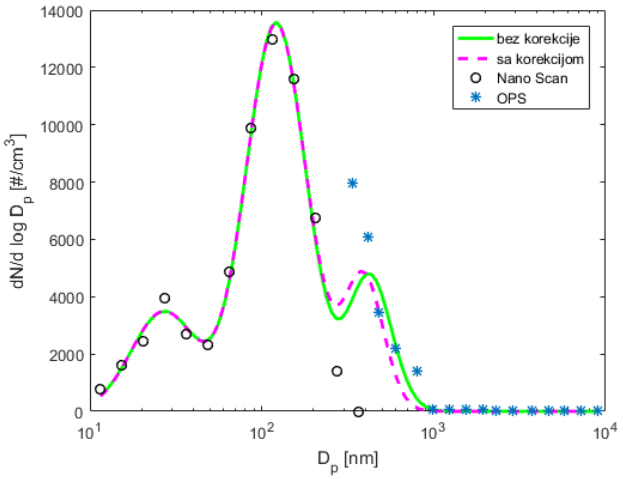
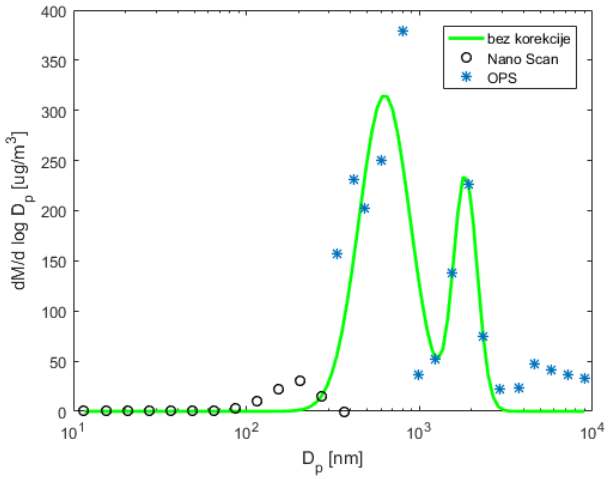
 ISBN 978-86-7466-930-3



(b)

Sl. 4. Uzorak 26: 04-Mar-2022 12:23:00 a) primer spajanja spektara brojčane koncentracije pomoću dve metode. b) primer spajanja spektara masene koncentracije



Na slici 3b je prikazan kombinovani spektar masene koncentracije. Uočljiv je standardni fenomen da čestice većeg dijametra znatno više utiču na masu, pa stoga uočavamo da su dominanti drugi modovi u kombinovanom spektru. Ovo je evidentno i iz masenog udela po frakcijama je $PM_{0.1}$: 0.18, $PM_{0.5}$: 27.15 PM_1: 34.44 $PM_{2.5}$: 38.49 PM_4: 41.70 i PM_{10}: 47.77 μg/m^3.

Na slici 4 je prikazan uzorak 26, izmeren 04-Mar-2022 12:23:00. Sa slike 4a je evidentno da dve metode i u ovom primeru daju gotovo identične kombinovane spektre, ali da su sada dominantna druga 2 moda, naime polozaj modova je za prvi mod $D_p = 44{,}92\,nm$, $\frac{dN}{d\ log\ D_p} = 1{,}743 \cdot 10^4 \frac{\#}{cm^3}$ i za drugi mod $D_p = 263{,}2\,nm$, $\frac{dN}{d\ log\ D_p} = 8{,}691 \cdot 10^4 \frac{\#}{cm^3}$. Brojčani udeo po frakcijama iznosi $PN_{0.1}$: 3510.58, $PN_{0.5}$: 23832.11, PN_1: 23844.91, $PN_{2.5}$: 23844.91, PN_4: 23844.91 i PN_{10}: 23844.91 #/cm^3. U ovom primeru (uzorak 26) je indeks prelamanja 1.4046 faktor oblika 1.05. Na slici 4b je prikazan kombinovani spektar masene koncentracije. Uz standardni fenomen da čestice većeg dijametra znatno više utiču na masu, uočavamo i ograničenja korišćenog algoritma budući da neki modovi nisu uračunati u kombinovani spektar, zbog ograničenja na maksimalno 3 interpolirana moda. Takođe dominantni mod, zbog veće razlike u izmerenoj masi između dva instrumenta u kanalu koji se preklapa u interpolaciji nije blizak sa merenjima dva instrumenta. U ovakvim situacijama, konzervativna procena koncentracije aerozagađenja bi uzela u obzir veću koncentraciju, što bi se u algoritmu moglo primeniti većim težinskim koeficijentom primenjenim na odgovarajući instrument. Maseni udeo po frakcijama je $PM_{0.1}$: 0.18, $PM_{0.5}$: 203.63 PM_1: 203.74 $PM_{2.5}$: 218.22 PM_4: 220.35 i PM_{10}: 220.36 μg/m^3.

Na slici 5 je prikazan uzorak 39, izmeren 04-Mar-2022 12:36:00. Sa slike 5a je evidentno da u ovom primeru postoji razlika između kombinovanih spektara za dve metode, i da u odnosu na prethodna dva primera u ovom slučaju postoje 3 moda u kombinovanom spektru. To su modovi $D_p = 27.1\,nm$, $\frac{dN}{d\ log\ D_p} = 3498 \frac{\#}{cm^3}$, zatim drugi mod na $D_p = 115.1\,nm$, $\frac{dN}{d\ log\ D_p} = 1.344 \cdot 10^4 \frac{\#}{cm^3}$ i treći mod na $D_p = 401.2nm$, $\frac{dN}{d\ log\ D_p} = 4820 \frac{\#}{cm^3}$. Brojčani udeo po frakcijama iznosi $PN_{0.1}$: 3693.81, $PN_{0.5}$: 9591.06, PN_1: 11301.75, $PN_{2.5}$: 11372.78, PN_4: 11372.78 i PN_{10}: 11372.78 #/cm^3. U ovom primeru (uzorak 39) je korigovani indeks prelamanja 1.9577 i faktor oblika 0.8787.

(a)

(b)

Sl. 5. Uzorak 39: 04-Mar-2022 12:36:00 a) primer spajanja spektara brojčane koncentracije pomoću dve metode. b) primer spajanja spektara masene koncentracije

Na slici 5b je prikazan kombinovani spektar masene koncentracije. Uz standardni fenomen da čestice većeg dijametra znatno više utiču na masu, ponovo uočavamo i ograničenja korišćenog algoritma budući da neki modovi nisu uračunati u kombinovani spektar. Takođe i u ovom slučaju postoji znatna razlika između merenja dva instrumenta u kanalu koji se preklapa, tako da bi za konzervativnu procenu bilo potrebno korigovati težinske koeficijente tako da više uzimaju u obzir instrument koji je izmerio višu vrednost. Maseni udeo po frakcijama je $PM_{0.1}$: 0.18, $PM_{0.5}$: 33.16 PM_1: 108.61 $PM_{2.5}$: 156.68 PM_4: 157.26 i PM_{10}: 157.26 μg/m^3.

V. ZAKLJUČAK

U ovom radu je ilustrovana primena dva metoda

 ISBN 978-86-7466-930-3

kombinovanja spektara koji su dobijeni pomoću dve komplementarne metode merenja. Na nekoliko karakterističnih primera je pokazano kako se razlikuju spektri brojčane i masene koncentracije, i ukazano je na prednosti i nedostatke metoda spajanja spektara. U slučaju da dve opisane metode spajanja spektara daju sličan rezultat, korišćenjem metode sa korekcijom indeksa prelamanja se uz konačni spektar može dobiti i sadržajan podatak o indeksu prelamanja i faktoru oblika čestice. Budući da se u praksi prilikom merenja prikupi jako velik broj podataka, spajanje spektara bi bilo najpogodnije automatizovati, što trenutna implementacija algoritma ne dozvoljava, već je neophodno ručno zadavanje broja modova koji je ograničen na maksimalno 3 moda u konačnom spektru, kao i ručni odabir težinskog faktora sa kojim ulaze merenja instrumenata u preklapajućem opsegu veličina čestica. Jedan od mogućih načina automatizacije je automatska korekcija težinskih koeficijenata, tako da kombinovani spektar više uzima u obzir instrument koji je izmerio veću koncentraciju u kanalu koji se preklapa u dva spektra. Na ovaj način bi bilo moguće kreirati mape visoke rezolucije koje bi kao ulazne podatke imale konzervativno procenjen kombinovani spektar.

ZAHVALNICA

Zahvaljujemo se projektima: H2020 VIDIS, br. 952433 u okviru programa Evropske unije za istraživanje i inovacije HORIZON 2020 (https://vidis-project.org/), zatim projektu ‘Prostorno-vremenske varijacije nivoa respirabilnih čestica u urbanoj zoni Novog Sada – mobilni monitoring, modelovanje i kreiranje mapa visoke rezolucije’ delimično finansiranom od gradske uprave grada Novog Sada kao i Ministarstvu prosvete, nauke i tehnološkog razvoja Republike Srbije.

ABSTRACT

Atmospheric aerosols in urban environments consist of particles of different diameters, which can range in size from a few nanometers to a few micrometers. Therefore, it is often necessary to use several instruments to measure the aerosol concentration, with fundamentally different underlying measurement principles. In this paper, methods based on measuring the electrical mobility of particles, for the diameter range from 10nm to 420nm, and measuring the equivalent optical diameter, for the diameter range from 300nm to 10um, were used. As a main result, examples of combining particle size spectra obtained using these two complementary measurement methods are presented. In the process of combining the particle size spectra, it is possible to modify the distribution obtained by optical measurements by searching for the optimal value of the particle refractive index so as to obtain the best possible agreement with the distribution obtained by measuring electrical mobility. The results of measurements from the mobile monitoring campaign in Novi Sad 2022 were used as input data.

An e ample of combining the distribution of atmospheric aerosols obtained by the method utilizing electrical mobility and the optical method

***A stra t*— Primena veštačke inteligencije u zaštiti ulturne baštine, na ovom stepenu razvoja, odnosi se prevashodno na domen a vizicije podata a, koji mogu biti od značaja za stvaranje šire slike o sredstvima i metodama realizacije umetničkih dela. U ovom radu, istražuje se pitanje integracije naučnih znanja u kontekstu primene veštačke inteligencije, u vezi sa delima veli ih formata, i to u domenima specifi uma organizacije materije, diferencijacije omponenti i njihovih elemenata, stru turnih planova i matrica oje daju valitet unutrašnje koherencije i grade performativnu snagu dela. ultidisciplinarna opservacija treba da doprinese procesu obje tivizacije znanja, do oje se, prirodom predmeta istraživanja, može doći samo integracijom elemenata više nauka i naučnih disciplina.**

ljučne reči—**naučna znanja, veštačka inteligencija, heritološki problemi**

I. UVOD

Upotreba lasera i lidara, uz podršku veštačke inteligencije, obeležava naučni rad u zaštiti kulturnog nasleđa na početku treće decenije XXI veka. Reč je o primenama u vezi sa procenama oštećenja površina objekata, putem analiza *oblaka tačaka*, uz korišćenje rezultata dobijenih nedestruktivnim i beskontaktnim metodama istraživanja [1], a takođe je reč i o kreiranju algoritama za klastere *idar Point Cloud* podataka [2], gde se raspolaže informacijama o karakteristikama objekata, do nivoa detalja veličine milimetra [3].

Ove primene već su dale rezultate u istraživanjima zaštite značajnog kulturnog nasleđa, kao što je to *Pala o ecchio* u Firenci (gde je primenjen *PTICS clustering method*) [4] ili katedrala *Notre ame* u Parizu, za koju je laserskim skeniranjem prikupljeno preko milijardu tačaka [5]. Posebno je značajno to, što neuronske mreže pomažu u utvrđivanju defekata upotrebom lidar sistema, uz integrisanje rezultata numeričkih simulacija, u cilju utvrđivanja šteta nastalih na objektima [6, 7] kao posledicama katastrofa koje su zahvatile viševekovno kulturno nasleđe. U okolnostima u kojima se zahteva brza obnova ovih objekata, a bez raspoložive detaljne originalne dokumentacije, u upotrebi su i sofisticirane analize podataka, zasnovane na metodi *linearne regresije*, odnosno na znanjima iz oblasti teorije verovatnoće, matematičke statistike, linearne algebre i multivarijabilnih analiza [8].

Izvan područja detekcije i opservacije oštećenja na predmetima i objektima kulturnog nasleđa, veštačka inteligencija dala je i značajan doprinos u novoj oblasti konzervacije – restauracije, u cilju integralnog razumevanja autorskih dela, gde se veštačka inteligencija koristi za rekonstrukciju delova umetničkih dela koji nedostaju, koji iz različitih razloga nisu sačuvani. Delotvornost ove metode potvrđena je, u do sada najvećem projektu savremenih naučnih muzejskih istraživanja, u restauraciji Rembrantovog remek-dela *Noćna straža e Nachtwacht* iz 1642. godine, koje se nalazi u kolekciji *ijksmuseum* u Amsterdamu. Posle završenog projekta *peration Nightwatch*, u vezi sa ovim umetničkim delom, raspolaže se sa 717 biliona piksela, a veštačka inteligencija pomogla je u spajanju 8.439 pojedinačnih fotografija delova ove slike, snimljenih sa iste udaljenosti od 13 cm. Sve je smešteno na prostoru od 5,6 terabajta. Na taj način su stvoreni preduslovi za rekonstrukciju nestalih delova slike ovog velikog formata (3,63 m x 4,37 m), koji se sada može, prvi put posle 300 godina, videti u originalnoj veličini, budući da je delo 1715. godine skraćivano zbog postavljanja u Gradsku kuću u Amsterdamu, kako bi moglo da bude uneseno kroz vrata (!?!). Tada je na slici odsečeno 60 cm sa leve strane, 22 cm od gornje ivice, 12 cm od donje ivice i 7 cm sa desne strane slike. Na osnovu svih prikupljenih podataka, uz specijalno kreirani softver, a prema kopiji ovog dela, koju je uradio Rembrantov savremenik Gerrit Lundens (1622 – 1686), veštačka inteligencija dala je ključan doprinos u rekonstrukciji *Noćne straže*, ne samo u materijalnom vidu dela, posebno stratigrafiji bojenih slojeva, već i u razumevanju autorske ideje, budući da ova rekonstrukcija pokazuje novo dimenzionalno težište slike, što pomera i konstelaciju prikazanih ljudskih figura koju je umetnik izvorno kreirao [9].

Navedeni primeri ukazuju na složenost upotrebe veštačke inteligencije u savremenoj zaštiti nasleđa, u kojoj rezultati korišćenja laserske tehnike u dijagnostici stanja predmeta i

objekata [10], uz primenu robotike i uz razvoj elektronske ličnosti [11], stvaraju novo polje integracije sa podacima koje daju komplementarne discipline prirodnih i tehničkih nauka, kao i pomoćne naučne discipline povezane za istorijom umetnosti i arheologijom [12]. Imajući u vidu da se najveći obim istraživanja posvećuje pitanju, *šta veštačka inteligencija može da učini u zaštiti nasleđa*, a da postoji izraženi nedostatak istraživanja posvećenih pitanju, *kako u tom cilju integrisati neophodna znanja u primeni veštačke inteligencije*, to je predmet ovog rada upravo pitanje načina integracije znanja, posebno sa stanovišta intenzivnih promena, koje u zaštiti kulturnog nasleđa, inicira primena novih tehnologija [13], u skladu sa duhom tehnološkog vremena [14].

II. Doktrina polifonijskog mišljenja

Heritološko znanje, u kojem se uz pomoć novih tehnologija otvaraju novi pravci istraživanja, pokazuje kompleksnost multidisciplinarnog promišljanja [15,16], baziranog na *polifonijskom mišljenju*, koje danas multidisciplinarno, metodološki, osim heritologije, obeležava i filozofsku granu tehnofilozofije [17]. U dugoj tradiciji razvoja doktrine polifonijskog mišljenja (sa akcentom na različitosti između naučnog znanja i znanja o nauci), gde se doktrina kao sistem učenja razvija praktično od I veka n.e., kada teoretičar Guido d'Arezzo piše traktate *Micrologus* i *Epistola*, polifonijsko mišljenje dostiže vrhunac u vreme renesanse, da bi stupanjem prosvetiteljstva na istorijsku scenu, polifonijsko mišljenje bilo gotovo zaboravljeno u nauci, opstajući prevashodno u umetnosti. Posle perioda viševekovnog razvoja pojedinačnih, uskih specijalnosti u različitim naukama, danas u XXI veku, dostignuta je svest o tome, da je polifonijsko mišljenje zapravo *tehnika*, odnosno kanon (u smislu pravila / normi), čije se funkcionisanje, kako to konstatuje metodičar Pavel Rojko, lako može ustanoviti, ali da i dalje nema odgovora na pitanje, kako je i zašto ta *tehnika* prešla u *umetnost* [18]. Ovo pitanje aktuelno je u svetlu činjenice, da multidisciplinarnost u svojoj suštini praktično nije ostvarljiva bez polifonijskog metodološkog mišljenja.

Keplerovo delo *armonices mundi libri* iz 1619. godine, u kojem je reč o *kontrapunktu uni er alnih harmonija s ih planeta*, primer je koji ukazuje na svu složenost održanja polifonijskog mišljenja u nauci, budući da je za razvoj kanona neophodno permanentno uključivanje novih naučnih dostignuća. Sa druge strane, umetnost, koja svih prethodnih vekova nije odustajala od polifonijskog mišljenja, dostigla je takvu prohodnost kroz vreme, da se univerzalnost polifonijskog mišljenja održava kao standard. Primer je delo Fjodora Mihajloviča Dostojevskog, kao inovatora, čiji opus ukazuje na ideografska i paradigmatička čvorišta u teorijskoj i primenjenoj ravni, značajna u proučavanju linija sinhronije / dijahronije, u prikazivanju načina na koji *celina* oblikuje *strukturu*, i gde, kako to promišlja Bahtin, „…svaki smisao otkriva svoju dubinu kada se sretne i dodirne sa drugim i drugačijim smislom“[19], kao što je to, kako pokazuje istorija, u srednjovekovnoj teoriji ustanovio princip *punctum contra punctum* (kontrapunkt), odnosno u savremenoj upotrebi laserske tehnike, *idar Point Cloud*.

To pokazuje da je neophodno da se polifonijsko metodološko mišljenje u zaštiti baštine, bazira na svim univerzalno konstituisanim normama, koje važe i u naučnom i u umetničkom domenu i bez obzira na tradicionalno distancirane diskurse, imajući u vidu da ta vrsta distance nema značaja u primeni veštačke inteligencije, a što je sasvim u skladu sa revolucionarnim Šenbergovim filozofsko-estetičkim principom polifonije, koji je „…nešto što je heteronomno emancipovanoj harmoniji i što s njom svakom prilikom tek treba da se izmiri“ [20], ili preneto u domen primene veštačke inteligencije u heritologiji, nešto što svakom prilikom egzaktno treba da se potvrdi.

Imajući u vidu navedene postavke, kao i činjenicu da veštačka inteligencija „uči“ na način koji kreira čovek, u ovom istraživanju tragalo se za mogućim razvojnim linijama u izgradnji *polifonijskog mišljenja*, koje bi ukazivale na izvore nauke, odnosno mišljenja o kontrapunktu / polifoniji, na način da mogu da budu pogodne za algoritam „učenja“ veštačke inteligencije. Analiza različitih razvojnih linija, pokazala je da ovakvo učenje treba da se konstituiše polazeći od naučnog dokaza Knuta Jepesna (Knud Jeppesen), da je učenje o kontrapunktu tek u XVI veku dobilo tako čvrstu organizaciju, „…da je svoju egzistenciju nastavilo nezavisno od prakse“ [21], što je i ovde prezentovani model ograničilo na navedeni period. Kao što se može videti, tabelarno su prikazani traktati polihistora, koji u sebi sadrže začetke polifonijskog mišljenja (matematičara, fizičara, muzičkih teoretičara, metafizičara, filozofa, astronoma, kompozitora, pesnika, državnika, diplomata i slikara), upravo zbog rudimentarnosti i nedovoljne konstituisanosti, što u procesu razvoja veštačke inteligencije, omogućava različita tematsko-strukturalna račvanja [22 -37], pogodna za učenje neuralnih mreža.

Za potrebe razvoja veštačke inteligencije u heritologiji, analiza prikazane razvojne linije ukazuje na neophodnost da se u primeni veštačke inteligencije u heritologiji, procesualno i u kontinuitetu razrešava problem fenomena *presupo icije* (termin preuzet izoblasti pragmatike) [38,39], koji polifonijski korespondira sa *implikaturom*, kao i *semantičkom ili logičkom implikacijom*, na polju razumevanja komunikacija između različitih naučnih oblasti i umetnosti. *Presupo icija*, kao tvrdnja uslovljena kontekstom, čija se istinitost ne dovodi u pitanje (u ovom slučaju tehničke provenijencije), a koju odlikuje postojanost pod negacijom, u odnosu na *implikaturu,* kao zaključak o značenju koje nije izrečeno i egzistira van zajedničkog konteksta (u ovom slučaju iz domena izvan empirijskog znanja), zahteva softversku izgradnju modaliteta uzajamnih povezanosti, u težnji ka stvaranju što preciznijih *semantičkih implikacija*.

Na ovom polju, kako pokazuje istraživanje sprovedeno u ovom radu, od pomoći je *aporetika*, kao disciplina u kojoj se prepoznaje usmerenost na *obradu i isticanje dosega problema,* kako to formuliše Hartman [40], gde posebno treba imati u vidu razlikovanje posmatranja slojeva umetničkog dela [41], kao i u širem okviru, stanovište Ingartena, da u istraživanju načina postojanja umetničkog dela treba primenjivati čisto perciptivan način prilaza suštini stvari, dakle „zauzimati stav fenomenologa" [42].

III. Zaključak

U radu su prikazani rezultati istraživanja modusa za integraciju znanja neophodnog u primeni veštačke inteligencije u heritologiji, u funkciji podrške primeni lasera, lidara i drugih tehnologija koje danas čine osnovu za razvoj konzervacije-restauracije kulturnog nasleđa. Istraživanjem doktrine polifonijskog mišljenja, od vremena *artes liberales* i u različitim razdobljima, ovde je u fokusu bio mogući model za razvoj polifonijskog mišljenja, a prema potrebama primene veštačke inteligencije u heritologiji. Sprovedene analize pokazale su, da se to može realizovati pod uslovima uvažavanja pragmatičkih i aporetičkih uzusa, na osnovu čega je i formiran model, kao predlog koji polazi od spekulativnih postavki prikazuje razvojnu liniju ka složenijim zahtevima za analitičko poznavanje kontrapunkta, što ga i čini pogodnim za uvođenje i razvoj veštačke inteligencije. Istovremeno, ovaj predlog treba da pomogne u očekivanom daljem razvoju i promišljanju ovako složene problematike.

Zahvalnica

Istraživanje prezentovano u ovom radu obavljeno je zahvaljujući podršci Ministarstva prosvete, nauke i tehnološkog razvoja Republike Srbije (ugovori 451-03-68/2022-14/200026 i 451-03-68/2022-14/200287), kao i zahvaljujući podršci Ministarstva kulture i informisanja Republike Srbije.

ABSTRACT

The application of artificial intelligence in cultural heritage, at this degree of development, refers primarily to the domain of data acquisitions that may be important for the creation of a wider image on the funds and methods of the implementation of works of art. In this paper, the issue of integration of scientific knowledge is investigated in the context of the application of artificial intelligence regarding the works of large formats. It is the domains of the specifics of the organization of matter, the differentiation of components and their elements, structural plans and matrix that give the quality of internal coherence and build the performative power of the work. Multidisciplinary observation should contribute to the process of objectifying the knowledge, to which the nature of the course of research, can only be reached by the integration of elements of several sciences and scientific disciplines.

Integration of scientific nowledge in the application of artificial intelligence in heritological problems

Problem heritološke abdukcije u vezi sa instrumentalnim analizama materijala kulturne baštine

Suzana Polić, Milesa Srećković, Zoran Stević, Miodrag Malović, Miloš Đurić

***A stra t*—Heritološki fenomeni u oblasti istraživanja kompozitnih umetničkih dela, u vezi sa raznovrsnošću pristupa u valitativnim i vantitativnim riterijumima za izbor materijala, postavljaju složene zadatke u primeni instrumentalnih metoda, oje prethode izradi proto ola za onzervaciju-restauraciju predmeta kulturne baštine. U ovom radu u fo usu je problem heritološke abdukcije, u heurističkoj proceni broja neophodnih analiza, odnosno deficita podata a u fragmentarnim strukturama koje su izraz umetničkog spontaniteta, a sa a centom na fenomen *raem ssa m n r* u traganju za metodološki čvrstom platformom za interpretaciju podata a.**

***čne reči*—spektroskopske analize, kulturna baština, heritološka abdukcija.**

I. UVOD

Savremene metode istraživanja materijala kulturne baštine, koje su uvođenjem laserskih tehnika unapređene u domenu osetljivosti i preciznosti u identifikaciji materijala, omogućavaju analize različitih slojeva umetničkih slika, od podloga, odnosno nosilaca slika, do izvedenih retuša (Tabela I). Ove metode obuhvataju [1-10]:

- XRF (X-ray fluorescence analysis)
- XRD-CT (X-ray diffraction computed tomography)
- PIXE (Particle-induced X-ray emission)
- PIGE (Particle induced Gamma-ray Emission)
- RBS (Rutherford backscattering spectrometry)
- NAA (Neutron activation analysis)
- FTIR (Fourier-transform infrared spectroscopy)
- ATR-FTIR (Attenuated total reflection - Fourier-transform infrared spectroscopy)
- RS (Raman spectroscopy)
- GC-MS (Gas chromatography-mass spectrometry)
- LIBS (Laser-induced Breakdown Spectroscopy)
- SRN (Synchrotron radiation and neutrons)
- HR-ICP-MS (High-resolution inductively coupled plasma mass spectrometry)

Neophodna komplementarnost u primeni ovih tehnika, pomaže u kvalitetu identifikacije pigmenata, veziva i dodataka koji se mogu naći na umetničkim delima u slikarstvu, što ukupno omogućava različite postupke u očuvanju kulturne baštine putem aktivnosti utvrđivanja porekla i datiranosti, otkrivanja podcrteža i preslika, kao i autentičnosti dela i autorskih umetničkih rukopisa.

Složenost problematike heurističke procene, koja se prevashodno zasniva na temeljnom iskustvu u zaštiti nasleđa, odnosi se, kako na pristupe u domenu istraživanja u oblasti tehnologije materijala [11,12], tako i na specifičnu kontekstualizaciju istraživanja na polju izvan empirijskog rezonovanja, u skladu sa istorijskim izvorima i starim recepturama (što obuhvata i u istoriji zabeležene *tajne* ili nikada razrešene slikarske recepture) u primeni materijala tokom stvaralačkih procesa u umetnosti [13]. Budući da nam istorija razvoja oblasti konzervacije-restauracije pokazuje da problemi i dileme u izboru optimalnih materijala i pristupa u zaštiti umetničkih i arheoloških artefakata, čine konstantu u ovoj kompleksnoj oblasti, rasprave o načinu rada, protokolima i metodološkim prilazima, u kontinuitetu traju do danas, zbog činjenice da je reč o jedinstvenosti i ekskluzivnosti zadataka rada na delima visokih umetničkih ili kulturoloških vrednosti.

Imajući u vidu savremenu dinamiku unapređenja instrumentalnih metoda, uočava se da je pitanje primene ovih metoda u kontekstima izvan empirijskog rezonovanja manje istražena oblast, pa je stoga u ovom radu u fokusu upravo tematizacija mišljenja u sferi logičkih nužnosti u postupcima zaštite kulturnog nasleđa, od problema silogizama u pristupima analizi materijala u slikarstvu, do problema heritološke abdukcije u savremenom kompozitnom slikarstvu.

II. Logički pristupi: Meklaren, Verner i Brandi

Oblast istraživanja logičkih pristupa u upotrebi materijala u heritologiji, može se pratiti praktično od vremena prvih receptura u starom slikarstvu, a značajna metodološka prekretnica, dogodila se tokom naučne polemike vođene 1949. i 1950. godine u britanskom *Burlington Maga ine* i italijanskom *Bolletino dell'Istituto Centrale del estauro*. Polemiku je izazvao naučni rad uglednog italijanskog istraživača i direktora Centralnog instituta za restauraciju u Rimu, dr Čezara Brandija, pod nazivom „Čišćenje slika u odnosu na patinu, lak i lazure" [14], na koji su reagovali istraživači *The National Gallery* iz Londona, kustos Nil Meklaren i hemičar Entoni Verner, u tekstu „Neka činjenična razmatranja o lakovima i lazurama" [15]. Ocenjujući da je ova reakcija pokušaj da britanska strana *in articulo mortis*[1] odbrani konzervatorske postupke izvedene u Nacionalnoj galeriji u Londonu, koji su, kako je smatrao Brandi, „doživeli smrtni udarac" njegovim člankom, ovaj istraživač pristupa široj i veoma kompleksnoj razradi polemike, pod istim, britanskim naslovom, *Some factual obser ation about arnishes and gla es*, ovoga puta, u italijanskom glasilu Centralnog instituta za restauraciju u Rimu [16]. Pokazalo se, da je ova neprijatna epizoda za nauku bila veoma korisna u smislu rasvetljavanja suštine naučnog problema, jer je Čezare Brandi pokazao, da se spor samo naizgled odnosio na oblast čišćenja slika, a da je suština u problemu logičkog pristupa, koji čini razliku između dve škole mišljenja, od kojih se jedna zalaže za radikalan pristup čišćenju materijala umetničkog dela, dok druga, kojoj pripada i sam Brandi, zastupa „koncept patine".

Britanska strana, kako je Brandi naglašavao, u stvari je zamagljivala i skrivala teorijske premise problema, koje „opstaju uprkos empirijskom rezonovanju", te da „prećutkujući najveću premisu silogizma", oni veruju da su potisnuli "logičku nužnost" i teže da od nje odvrate pažnju. Ali*, entimema*, koju tako stvaraju, transformiše se ni manje ni više, nego u poznati sofizam „lažne pretpostavke"[2]. Drugim rečima, Brandi je smatrao da je na delu „nepotpuni silogizam", kao skraćeni zaključak izveden samo iz jedne premise, dok je druga premisa bila neizrečena (*syllogismus imperfectus*).

U viđenju britanske strane, reč je o principu: „cilj je konzervacije i restauracije slika da budu prezentovane što je moguće bliže stanju u kojem je umetnik želeo da one budu viđene". Ovo stanovište i do danas zastupaju različite zapadne škole konzervacije, pa se u muzejima neretko mogu videti dela iz prethodnih vekova, koja izgledaju kao da su upravo izašla iz umetnikovog ateljea. A svakako jedan od najsvežijih primera je i velika izložba slika Rembranta i njegovih savremenika, iz njujorške *The eiden Collection*, prikazana u Puškinovom muzeju u Moskvi 2018. godine, na izložbi pod nazivom *The Age of embrandt and ermeer Masterpieces of The eiden Collection* [17], čija je konzervacija – restauracija obavljena u SAD. Čezare Brandi, međutim, ovo „totalno čišćenje" naziva istorijskim apsurdom, kojim se traži, da se delo učini „reverzibilnim u vremenu, kao jedan komad oksidirane materije, kome treba povratiti fizičku čistoću i sjaj prvobitnog stanja". Pozivajući se na logički pristup koji izvire iz „koncepta patine", Baldinučijevog Rečnika (*ocabolario toscano dell'Arte del disegno*) iz 1681. godine, Brandi ističe dve osnovne ideje ovog koncepta: prepoznavanje „znaka vremena" na delu i „estetsku vrednost patine". Konkretno, mora se voditi računa „o istorijskoj strani umetničkog dela, kao istorijskog dokumenta" i treba maksimalno izbeći „one suštinske modifikacije, koje samo *salus publica* ili spasavanje dela, može opravdati kao *suprema le* ", u skladu sa principom da je javno dobro najviši zakon (*salus publica suprema le*).

Ističući razliku između „fizičke boje" i boje „umetničke predstave", gde „materijalnost" boje mora da iščezne utapanjem u umetničku predstavu, Brandi u estetskom domenu koncept patine povezuje sa željom da se priguši „arogancija materije, u korist onoga što nazivamo nematerijalnost umetničke predstave", citirajući reči iz klasične antike, o svođenju boja na mirniju ravnotežu, kao anticipiranje onoga što će se dešavati tokom vremena, a što Brandi eksplicitno izražava Plinijevim rečima *ne claritas solorum aciem offenderet*: „ni da jačina oštrine boja ne vređa". Otuda i ukazivanje da se logički pristup u primeni materijala kontekstualizuje u komplementarnim domenima. Iz veoma obimne Brandijeve argumentacije, ovde je obavljeno analitičko raščlanjivanje baze ovog složenog konteksta, i to na osnovne logičke i komplementarne premise (Tabela II).

TABELA II
Lak kao materijal, u komplementarnim kontekstima, na osnovu Brandijeve argumentacije

Logički iskaz	• Lak nije nužno rastvor smole u organskom rastvaraču
Semantički iskaz	• Lak je samo tečni pokrivač: čak ni transparentnost ne mora nužno da se povezuje sa semantičkim prostorom laka
Tehnološki iskaz	• Tečni lak je usitnjena ambra (čvrsta smola) dodata toplom orahovom ili lanenom ulju
Istorijski iskaz (od kasne antike do srednjeg veka)	• Evstatije u XII veku, u komentarima Homera, navodi da su Grci nazivali ambru *eronico* βερονιχη)
Etimološki iskaz	• βερονιχη → *ernice li uido* (tečni lak)

[1] latinski: u samrtnom času

[2] prevodi Brandijevih tekstova u ovom radu, preuzeti su iz apendiksa br. 6 u „Teorija restauracije" [13], urednik i prevodilac Branka Šekarić

 ISBN 978-86-7466-930-3

(posle sred. veka)	
Konzervatorski iskaz	• *ernice li uido* ne označava jedan stalan tip laka, već razliku između suve rezine i njenog rastvora • stepen rastvorljivosti jednog rastvarača je izmišljen kriterijum, jer, po eksplicitnom priznanju Meklarena i Vernera, „posle jedanaest godina lak od lanenog ulja je isto tako rezistentan na rastvarače, kao lak star 400 godina“

Držeći se filološke determinacije, Čezare Brandi kroz izvođenje paralelne istorije dvaju reči, francuske *glacis* i italijanske *elatura*, demonstrira logiku zaključivanja, ukazujući na činjenicu, da se nazivi koji se ne javljaju u istim epohama, određuju prema autorima „u različitim vremenskim periodima i kulturnim prostorima i različitom lingvističkom upotrebom“, pa tako upozorava i da greškom zanemareni veznici mogu odrediti da je reč o pridevima, a ne o terminima u strogom značenju, sve u vezi sa raspravom o distinkcijama između naziva u različitim starim recepturama (*tečni lak* / *blagi tečni lak* / *običan lak* / *eoma fini i su i lak* / *i anredni svetao i sušiv lak* / *lak postojanog sasta a* / *eoma lep i redak lak* / *lak koji će se odmah osušiti* / *najfiniji lak i najsjajniji od s ih drugih*, i slično , naglašavajući opasnost od dvosmislenih značenja: „jedna stvar je obojenost laka, a druga njegova nečistoća; da bi lak bio transparentan i svetao, ne znači da treba da bude bezbojan“. Za ovu liniju Brandijeve argumentacije, ovde je obavljeno analitičko raščlanjivanje dokaznog postupka u Tabeli III.

Brandi u [14] kaže: „Šta je to *la ura*? Jasno je da je reč o jednoj fazi u dovršavanju slike, tankom sloju boje, koji služi da koriguje ili modifikuje kako lokalni tako i opšti tonalitet slike. To je, ako hoćete, trik, postupak koji se izvodi u zadnji čas, unutrašnji i tajni sastojak. Pošto je trik, nije mogao da bude lako priznat. Izlazi izvan oficijelne prakse slikarstva… Još početkom 19. veka, veoma dobro se znalo šta su to *la ure* i kako su ih koristili Venecijanci i Rubens. Ko onda može, čisteći jednog Rubensa, stavljajući na uvid golu i sirovu boju do kraja, da ne bude potom uveren da ju je zauvek uništio?“

TABELA III
LAZURA [GLACIS (FRA) / VELATURA (ITA) / GLAZE (ENG)[3]]

Izvor	Brandijevi logički iskazi o tereminologiji u starim slikarskim recepturama
Roger de Piles, *Elemens de la Peinture prati ue*, Paris 1766.	• Izrazi ***ac s*** i ***e at ra*** nisu oduvek pokrivali isti semantički prostor • U glagolu ***acer*** fiksira se onaj posebni fizički fenomen tečnosti koja prelazi u čvrsto stanje ostajući transparentna i sjajna • Glagol ***e are*** govori o parcijalnom prepokrivanju • Pravljenje ravnoteže između ***ac s*** i ***e at ra*** pripada savremenom dobu
Andre Félibien, *es principes de l'Architecture*, Paris, 1690.	• Reč ***ac s*** na starofrancuskom jeziku je termin vojne arhitekture (u značenju blage padine ili škarpe nekog utvrđernja) • Termin ***ac s*** nije čak ni zabeležen u de Pilevom malom rečniku slikarskih termina, (*Termes de peinture*) rađenom za „Razgovore o poznavanju slikarstva” (*Con ersations sur la connaissance de la Peinture*) iz 1677.
Pierre Lebrun, *ecueil des essaies es Mer eilles*, 1635.	• „glace(r) je postavljanje završnih ublažavanja i poslednjeg finog sloja koji daje sjaj sjajno-belom, ili sjajno-purpurnom, sjajno-zelenom, sjajno-žutom…”
Dufresnoy, *e Arte graphica*, 1673, prevod Roger de Piles	• „lazurne boje imaju živost koja nikada ne može da se podražava ni najživljim niti najsjajnijim bojama…”
F. Baldinucci, *ocabolario toscano dell'Arte del disegno*, Firenze, 1681.	• U prvom eksplicitnom pominjanju lazura (***e at ra***), postupak prepokrivanja (***e are***) opisan je u odnosu na prijatan efekat koji stvara
Dokazni postupak	
	• Reč ***e at ra*** u italijanskom jeziku nema istoriju različitu od one koju ***ac s*** ima u francuskom jeziku • ***e at ra*** i ***ac s*** imaju suprotna polazišta • Francuskim glagolom ***acer*** ukazuje se na transparentnost gotovo dragog kamena • Italijanskim glagolom ***e are*** podrazumeva se obrnuto – ugasiti zvuk boje, prigušiti ga • Dodirna tačka za francuski ***acer*** i italijanski ***e are*** je transparentnost • Činjenica da dva jezika semantički akcentuju dva različita smisla, ne isključuje drugačije namere u pogledu boje
Praemissa major	
	• Više sa estetskog, nego sa tehničkog stanovišta, ***e at ra*** se mogla povezati sa teorijom i praksom francuskog ***ac s***

Iz navedenog dokaznog postupka, kojim se dominantno tehnološko pitanje izmešta na polje kauzalnosti i transformacije, kojem inače pripadaju, ne samo

[3] *gla e* kada je reč o tamnom sloju na svetlom, odnosno *scumble* kada je reč o svetlom sloju na tamnom [Branka Šekarić]

 ISBN 978-86-7466-930-3

instrumentalne tehnike, već i sam proces umetničkog stvaralaštva, može se uočiti da Brandi demonstrira logički postupak koji je praktično pandan Laplasovoj transformaciji, koja, kako je poznato, kauzalnu funkciju transformiše u drugi (spektralni) domen. Preneto na problem prikazane polemike, Brandi najviše zamera Meklarenu i Verneru, karakterišući kao obmanu, činjenicu da „ni jednog trenutka ne obaveštavaju čitaoca da se ništa ne zna o tome kako su izvođene *elature* ili *glacis,* barem do XVIII veka, ali verni sofizmu „lažne pretpostavke“, smatraju dokazanim ono što treba dokazati, to jest, da je postojala nedvosmislena i stalna praksa lazura…“, zaključujući da britanski autori nisu umeli da pristojno prezentuju, čak ni jedan tekst o metodu primene *glacis* ili *elatura* pre XVIII veka.

Sl. 1. Coppo di Marcovaldo, Madonna col Bambino, 1261., basilica dei Santa Maria dei Servi, Siena [Wikipedia]

Iz perspektive primene savremenih instrumentalnih metoda, u tematizaciji pitanja *merituma* u analizama materijala, značajna je ilustracija, na koji način se takav logički pristup reperkutuje na rešavanje konkretnih problema. Povodom detalja na slici *Madona*, iz 1261. godine, autora Kopa di Markovalda (Coppo di Marcovaldo, s. 1225 – s. 1276, na Sl. 1), gde je primena bojenog i transparentnog laka „koji je postavljan preko lista kalaja ili srebra, da bi se postigao onaj sjaj tona, za koji, četiri veka kasnije, jedan Lebren (Lebrun) i jedan De Pil priznaju da ga je moguće postići - *nunc et semper* - samo sa lazurama“, Brandi prigovara Meklarenu i Verneru, da čak nisu ni zapazili „male ali nesumnjivo prisutne ostatke crvenog transparentnog laka, koji je Kopo koristio kod senki jastuka – *supedaneuma*[4], da bi im dao određenu zaobljenost, bez menjanja kvadratne osnove naslikane tkanine“. Tako je, kako ističe ovaj autor, umetnik lazurama, a ne prozračnim lakovima, naslikao i drugi jastuk, na kojem sedi Madona, kao i nabore tkanina na pozadini trona, na osnovu čega Brandi i upozorava da je ovde jedino reč o tome da je potrebno „znati čitati” sliku!

[4] latinski: podrška za noge na krstu koji se koristi za raspeće

III. ABDUKCIJA I KOMPOZITNA SLIKA

Nekoliko decenija posle ovde prikazane polemike, u savremenom tehnološkom okruženju, u kome razmatramo polje delovanja instrumentalnih tehnika, metodološka problematizacija usmerena je na problem kompozitne slike / instalacije (Sl. 2), koja doslovno terminološki označava kompozitno kao „sasvim drugo”, obeležavajući savremeno doba drugačije vrste kompleksnosti, usled primene novih i brojem neograničenih materijala, kombinovanih bez ikakvih standardno propisanih procedura, a koji i kada su u celini poznati, mogu da budu podvrgnuti različitim, nestandardnim postupcima u procesu umetničke invencije, čiji se ciljevi i dometi mogu sublimirati u promišljanju Sergeja Ajzenštajna: „Dva susedna dela bivaju nužno spojena u jednu sliku, koja se iz njihovog suprotstavljanja razvija kao novi kvalitet“.

Sl. 2. Fabio Mauri, Il Muro Occidentale o del Planto, 1993. (koferi, torbe, zvučnici, kožne obloge, platno, drvo) [www.fabiomauri.com]

Imajući posebno u vidu, da se posredovanje empirijskih metoda, zbog potrebe uključivanja znanja o „čitanju slika” ne može smatrati samoreferencijalnim sistemom distinktivnih oznaka, već pre pomoćnim aparatom za dešifrovanje sredstava transponovanja unutrašnje slike na spoljašnje strukture kompozitnih slika / instalacija, može se govoriti o usklađivanju linija *plastičnog logosa* [18], sa referentnim linijama logičkih analiza, uz prisustvo razumevanja da „autentični umetnički izraz ne poseduje racionalno tumačenje, već emotivne karakteristike, koje ne podležu jednoznačnom dešifrovanju“ kako to formuliše Tarkovski [19], odnosno da postoji „jedan sasvim drugačiji *meritum* od iluzije vlasti nad objektivizovanim predstavama stvarnosti“ [20].

Stoga nas, utvrđivanje operativnog analitičkog instrumentarijuma, bez koherentne metodološke podloge, dovodi na polje *abdukcije*, kao vrste silogizma, u kojem je

 ISBN 978-86-7466-930-3

jedna od dvaju premisa tek *ero atna*, jer je *praemissa minor* objektivna posledica složenosti likovnih problema, u logičkoj ekspoziciji, koja je izvan polja empirijskog rezonovanja. Na polju *strukturalne dualnosti*, o kakvoj piše Rajner Keler [21], stoga je potrebno ispitati moguće usmerenje na *diskur i ne strukturacije*, pre nego na singularne jezičke radnje, koje se uočavaju kod Brandija.

Sa druge strane, uprkos složenosti tumačenja u izazovima brojnih neodređenosti i finesa dinamičkih karakteristika jezika, na koje ukazuje antologijska Brandijeva rasprava (čiji je ovde samo osnovni deo predstavljen za potrebe eksplikacije logičke analize u upotrebi materijala na osnovu opisa iz starih receptura), pitanje merituma u metodološkim zahtevima nešto je što se prepoznaje u kontinuitetu razvoja civilizacije, od sublimacije iskazane u Horacijevim stihovima (Quintus Horatius Flaccus, 65-8. p.n.e), istaknutim i na naslovnoj strani prve Didroove enciklopedije, *Tantum series junctura ue pollet, tantum de medio sumptis accedit honoris* („eto takva je moć celine i sklada, obradom dobrom toliko da i banalna tema zablista!”[5]) [22, 23], pa do jedne od čuvenih teza Praškog lingvističkog kružoka, o jeziku koji nije gotov statički sistem, već stvaralačka energija [24] i tako sve do filozofije Rolana Barta[6], o proizvođenju značenja i strukturisanoj sposobnosti reči i predmeta da istovremeno nešto saopštavaju, u sistemu „varljivog označavanja” [25], što je u našem vremenu kompozitne umetnosti, posebno prisutno. U skladu sa tim, polariteti u terminologiji starih receptura, koje ukazuju na tehnološke osobine materijala, u ovom vremenu prepoznajemo kao pandan ideji polarne suprotstavljenosti i pojačavanja (*Polarität und Steigerung*), u jedinstvenom razumevanju i sposobnosti za otkrivanje frekvencije i semantike pojedinih reči, kao kod kod Džeralda Menlija Hopkinsa[7], koji govori o „razlogu za iznenađenje nad idućom razlikom“, kako nas na to upućuje Edvard Stankjevič [26].

IV. Zaključak

Istraživanje prezentovano u ovom radu, imalo je za cilj da analitički utvrdi način na koji se logički pristup u primeni materijala kontekstualizuje u raznovrsnim, komplementarnim domenima, koji čine metodološku osnovu za primenu instrumentalnih analiza u problemima koje karakteriše obaveza uključivanja mišljenja koje je izvan *empirijskog re ono anja*.

Istraživanje je metodološki sprovedeno na studiji slučaja posvećenoj starom slikarstvu, analizom logičkog postupka i argumentacije za opovrgavanje prakse totalne intervencije na materijalima umetničkih dela, a u korist *koncepta patine*. Na osnovu utvrđenih premisa logičkog postupka, u vezi sa kompozitnom slikom / instalacijom, komparativno je razmotren problem logičkog zaključivanja, prirodom likovnih problema iznuđene *abdukcije*, koja direktno utiče na razumevanje uloge i dometa savremenih instrumentalnih metoda koje se mogu primeniti u analizi materijala umetničkih dela.

Imajući u vidu metodološke instrumente prikazane naučne polemike, utvrđeno je da se rešenje za uočene probleme može pronaći u multidisciplinarnom kontekstu teorija savremenih diskurzivnih i semantičkih transformacija.

ABSTRACT

Taking into account the diversity of approaches in qualitative and quantitative criteria for material selection heritology phenomena in the field of research of composite art works set complex tasks in the application of instrumental methods, which precede the development of protocols for conservation and restoration of cultural heritage. The focus of this paper is on the problem of heritology abduction, particularly in the domain of heuristic assessment concerning the number of necessary analyses, i.e. the deficit of data in fragmentary structures, these being expressions of artistic spontaneity. At the same time, the paper also tackles the phenomenon of minor assumptions while pursuing a methodologically sound platform for interpreting data.

The problem of heritology abduction through instrumental analysis of cultural heritage materials

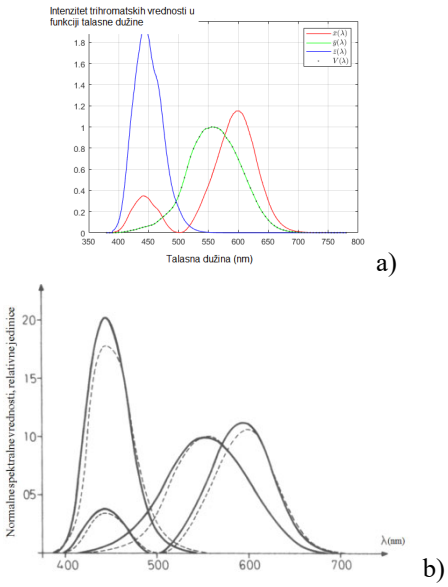
Deskripcija, heritologija i metrologija boje

Milesa Srećković, Veljko Zarubica, Aleksander Kovačević, Milena Davidović, Suzana Polić

Apstrakt—Ljudski osećaj za boje ima mnogo aspekata, počevši od čovekovog poimanja sveta oko sebe, do medicinskih pojmova koji uključuju i daltonizam, ali (u svakodnevici) najpozitivniji, najhumaniji je čovekov osećaj za deo dana ili noći (meseca ili godine), za uživanje u heritološkom blagu, koje su nam ostavili preci, ali ne samo crno-belo. Istraživanja, kojima je procenjivan ljudski vek, postojanje i razvoj humanih bića, kao i nastajanje i evolucija flore i faune, sve ovo mora da bude tretirano multidisciplinarno, bez obzira da li se polazi od stena, stalaktita i stalagmita, morskih dubina, tragova u atmosferi ili potrage za planetom koja je slična Zemlji. U radu se daje nekoliko prilaza boji i kolorimetriji, sa aspekta raznih naučnih disciplina. Prikazuje se uloga lasera u novim problematikama, kvantitativne definicije boje i njenih pokazatelja. U području merenja, daje se prilaz sa aspekta filtera i korektnog opisa stanja i delovanja odabranih filtera sa savremenim izražavanjima rezultata, kao i merne metode. Konstatacija boje i njena deskripcija, ima veliku ulogu u svakodnevnom životu, kao i u pojedinim tehničkim i mass media primenama, uključivši i humanističke i tehničke nauke.



***Ključne reči*— laseri; heritologija; nove tehnologije.**

I. Uvod

Spektroradiometrijska metoda, kao fundamentalna metoda kvantifikacije, deskripcije objektivnog *merenja* boje, prema trenutnom stanju razvijenosti tehnologije izrade prijemnika optičkog zračenja i ostale merno-tehničke opreme, ima kao glavni zadatak postizanje zadovoljavajuće tačnosti i ponovljivosti rezultata merenja, prema postavljenim zahtevima korisnika.

Spektroradiometrijske metode merenja boje, zasnovane su na određivanju spektralne raspodele zračenja, na osnovu čega se formira boja koja se meri. Trihromatske vrednosti boje se nalaze iz poznatih krivih mešanja boja (slika 1). Za primarne svetlosne izvore, veličina koja se meri je spektralna raspodela energije, a za sekundarne se koristi spektralni koeficijent propustljivosti i koeficijent jednog od procesa interakcije, ovde koeficijent refleksije optičkog zračenja (koje se reflektuje ili propušta kroz određene sredine).

U ovom delu rada, izabran je slučaj kada ne postoji poznata raspodela zračenja izvora. Koristi se raspodela zračenja crnog tela i spektralni koeficijent propustljivosti staklenih uzoraka. Na taj način, proračun trihromatskih vrednosti uzima u obzir pored spektralnog koeficijenta propustljivosti i spektralnu raspodelu snage zračenja apsolutno crnog tela (ACT). Spektralna raspodela snage zračenja se množi poznatim spektralnim koeficijentom propustljivosti $\tau(\lambda)$. Na sl. 1 je predstavljena spektralna karakteristika trihromatskih vrednosti u funkciji talasne dužine.

Sl. 1. a) Krive mešanja boja; b) Krive za polje viđenja 100° u odnosu na isprekidane krive za 20°.

Proračun trihromatskih vrednosti u CIE (XYZ) standardnom kolorimetrijskom koordinatnom sistemu, za boje svetlosti, koje se propuštaju kroz posmatrani uzorak, sledi procedura:

$$X = \int_{350nm}^{750nm} E_\lambda \tau_\lambda \overline{X_\lambda} d\lambda \,;\; Y = \int_{350nm}^{750nm} E_\lambda \tau_\lambda \overline{Y_\lambda} d\lambda \,;\; Z = \int_{350nm}^{750nm} E_\lambda \tau_\lambda \overline{Z_\lambda} d\lambda \,. \quad (1)$$

Kod praktičnih proračuna, integracija se svodi na sumiranje proizvoda vrednosti spektralnog koeficijenta propustljivosti i spektralne snage zračenja ACT za nizove talasnih dužina:

$$X = \Delta\lambda \sum_\lambda E_\lambda \cdot \tau_\lambda \cdot \overline{X_\lambda} \,;\; Y = \Delta\lambda \sum_\lambda E_\lambda \cdot \tau_\lambda \cdot \overline{Y_\lambda} \,;\; Z = \Delta\lambda \sum_\lambda E_\lambda \cdot \tau_\lambda \cdot \overline{Z_\lambda} \,. \quad (2)$$

Interval $\Delta\lambda$, bira se 1-20 nm, u zavisnosti od željenih nesigurnosti tipa A i B, koje se zahtevaju za određivanje hromatskih koordinata. Kako su krive mešanja boja specifikovane u obliku relativnih vrednosti na ordinati, trihromatske vrednosti izračunate pomoću njih imaće relativ-

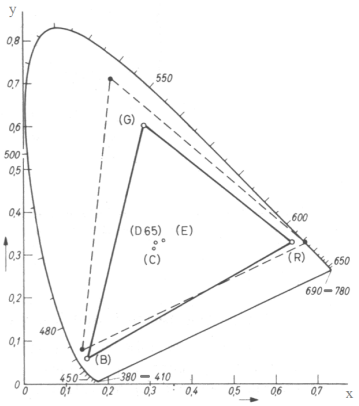
 ISBN 978-86-7466-930-3

ni karakter kao na slici u poglavlju rezultata (sl. 6) (primer proračuna trihromatskih vrednosti za odabrani filtar) [1-4].

Zahtev je da se odrede trihromatske vrednosti i hromatske koordinate boje standardnog svetlosnog izvora tipa *A* sa spektralnom raspodelom energija E_A, posle prolaska kroz uzorak, koji ima određen spektralni koeficijent propustljivosti τ. Posle transmisije kroz uzorak, relativna spektralna raspodela jačine zračenja ima oblik prikazan krivom τE_A. Svaka ordinata ove karakteristike, množi se odgovarajućom ordinatom svake od krivih mešanja boja $\bar{X}$, $\bar{Y}$, $\bar{Z}$. Šrafirane površine ispod krivih, dobijenih posle množenja, proporcionalne su odgovarajućim trihromatskim vrednostima *X*, *Y* i *Z*. Hromatske koordinate *x* i *y* se izražavaju dalje:

$$x = \frac{X}{X+Y+Z}, \quad y = \frac{Y}{X+Y+Z}. \tag{3}$$



Ordinate krivih mešanja boja i ordinate spektralnih raspodela energije za standardni izvor, potrebne za posmatrani metod proračuna, obično se daju tabelarno.

Kod primarnih izvora svetlosti, postavka metode, zasniva se na spektroradiometru koji se koristi za merenje relativne spektralne ozračenosti (iradijancije). Kod sekundarnih izvora, merenje se vrši pomoću spektrofotometara, gde se monohromator sa odgovarajućim sistemom osvetljavanja (u zavisnosti od geometrije merenja), koristi za osvetljavanje datih uzoraka, a reflektovano, odnosno propušteno zračenje se meri fotodetektorom u odgovarajućoj geometriji.

II. Drugi prilaz boji

Boja se može pojaviti kao kategorija ili pojam u vrlo složenim multidisciplinarnim problemima, a često se prema naučnoj discipline, koja se oslanja na doživljaj boje živih organizama (sa medicinske tačke gledišta, sa filozofske tačke gledišta, sa gledišta heritologije, sa ekološkog gledišta i dr.). Šire gledano, radi se o interakciji zračenja elektromagnetne ili druge prirode sa *prijemnim* aparatom. Sa tehničke strane objektivizacije, kolorimetrija ima zadatak da se kroz različite formirane formalizme opisuje boja putem trougla i koordinata, ili na drugi način, kroz drugi formirani sistem višeg ili nižeg nivoa, sl. 2. U tabeli 1 se daju ilustracije nivoa bioloških procesa uzrokovanih zračenjem i vremenskih konstanti odgovarajućih procesa sa odgovarajućim nivoom [5]. Sa obzirom na *mass media* primene (TV, novine, …), kulturne manifestacije, znake opasnosti, dozimetrijska pravila u primeni određene ELIONske tehnike, boja mora da ima dobro definisane koordinate u širem smislu, zasnovane na izvorima (obično tri), čijim se mešanjem postiže efekat određene (željene) boje. Da li će se koristiti odgovarajući softver uz profesionalnu mernu aparaturu, ili će se sve automatizovati kao *user-friendly*, zavisi od trenutnog administrativnog zahteva ili trenutnog nadahnuća umetnika [6].

Prema visini stepena tolerancije, institucije koje se kod nas bave *deskripcijom boje*, kao i njenim promenama, u zavisnosti od izloženosti objekta, odnosno bio-objekta, postoje stroge procedure i sistemi gde se to može izvršiti, a ako nije potrebna

Sl. 2. Normiranje boje putem EBU trougla boja (neprekidno) i FCC (isprekidano) [2].

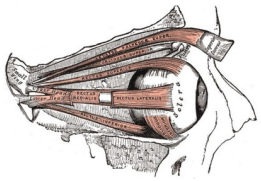


TABELA I

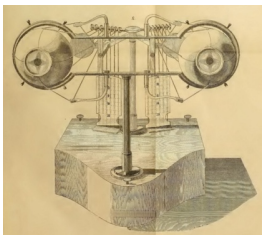
Nivo	Vreme na nivou (s)	Procesi na nivou, modifikacije
Fizički	10^{-18} - 10^{-8}	Eksitacije, jonizacije, elastični sudari, formacija radikala visoke reaktivnosti i kratkoživećih SR u vodi i organskim molekulima
Hemijski	10^{-14} - 10^{-4}	Reakcije SR sa organelama formiraju primarno oštećenje DNA, dimerizacija, modifikacije sa temp. MT, i O_2
Biohemisjki (subćelijski)	10^{-4} - 10^{5}	Reparacija, interakcije oštećenih mikrocentara; mutacije, aberacije, MT i dr. agensi
Biohemijski (ćelijski)	10^{3} - 10^{7}	Deoba ćelija i molekula, Mutacije



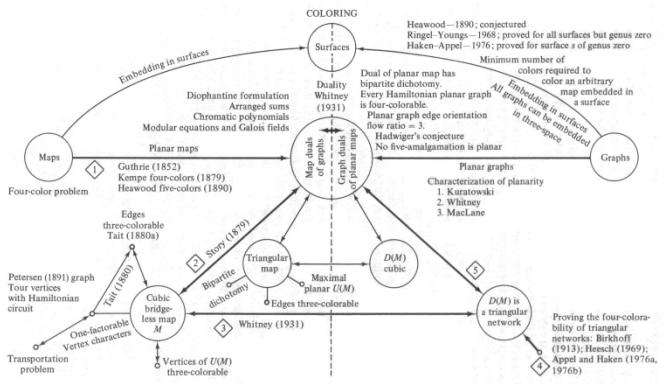
Prema visini stepena tolerancije, institucije koje se kod nas bave *deskripcijom boje*, kao i njenim promenama, u zavisnosti od izloženosti objekta, odnosno bio-objekta, postoje stroge procedure i sistemi, gde se to može izvršiti, a ako nije potrebna velika preciznost, korisnici formiraju svoja sopstvena merna rešenja [7]. U ovim merenjima ima mnogo mesta za definisanje osvetljenosti, u širem smislu, određenog izložbenog prostora i kontrolu stalnog fluksa, koji se, u zavisnosti od mešanja prirodne i veštačke osvetljenosti, mora kontrolisati. U zavisnosti od objekta, mora se obratiti pažnja na mere zaštite od preterane ekspozicije.

Paralelno anatomija oka, njegovog funkcionisanja, mišićnog sistema i osetljivost (kao prijemnika) na definisana zračenja i boje vidljivog spektra su predmet mnogobrojnih istorijskih radova, uključujući i današnja istraživanja na mehanizmima funkcionisanja očnog aparata, modelovanja i kvalitativno/kvantitativno povezivanje sa tehnikama merenja i povezivanja sa *tehničkim uglovima gledanja*, sl. 3 i 4. Poređenje osetljivostu pojma viđenja u oblasti fizike, metrike i psihologije, razlikuje kvantitativnom, kvalitativno i vrednovanje sa tri hromatske kordinate

 ISBN 978-86-7466-930-3

Sl. 3. Anatomija oka, koja je još kod Helmholza imala posebne predstave [8].

Sl. 4. Istorijska slika modelovanja očnog aparata [9].

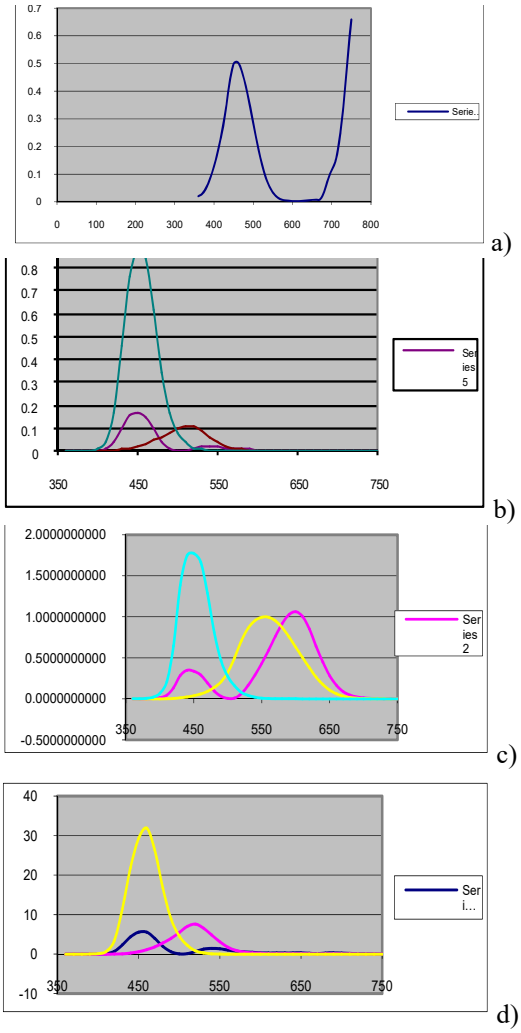


Poređenje osetljivostu pojma viđenja u oblasti fizike, metrike i psihologije, razlikuje kvantitativnom, kvalitativno i vrednovanje sa tri hromatske kordinate.

III. Uloga izvora

Pri definiciji boje u bilo kom sistemu širina spektralnih linija (spontane ili koherentne svetlosti) igra presudnu ulogu. Kao rezultat toga su nastali RGB laseri, od specijalnog značaja za HDTV. Od novijih tipova lasera, pokazalo se da su laseri na bazi polimera pogodni za kalibraciju, odnosno deskripciju boje [5, 10].

IV. Teorema-Problem četiri boje



Klasični problem četiri boje zahteva mnogo raznih pogleda koji su ilustrovani sl. 5 datom u originalu, vezanu za teoremu i problem četiri boje, gde kao dokaz mora da bude uključena i savremena računarska tehnika; to ne uključuje nelinearne relacije i osećaje boje uz velike intenzitete, o čemu su istraživanja morala da se intenziviraju posle razvitka snažnih laserskih snopova [11-17].

Sl. 5. Prikaz deskripcije problematike teoreme četiri boje [17].

V. Rezultati

Merene vrednosti tabele 2 su prikazane delimično i na sl. 6, odnosno $\tau(\lambda)$, $x(\lambda)$, $y(\lambda)$, $z(\lambda)$, prema propisanoj proceduri u postupku određivanja karakteristika staklenog filtra MEL-B-1.

Sl. 6. $\tau(\lambda)$, $x(\lambda)$, $y(\lambda)$, $z(\lambda)$,… su prikazane na a), b), c), d), redom.

Pored merenja u tabeli II, izvršena su merenja i za seriju drugih filtara: MEL-B-2, MEL-G-2, MEL-G-4, itd.

Kao primer merne nesigurnosti za drugu vrstu filtra data je tabela III. Za sva merenja je potrebno dati ocenu nesigurnosti tipa A i B, a za slučaj filtra MEL-Y-2 ocena je u Tabeli III.

Merna nesigurnost ovako dobijenih vrednosti hromatskih koordinata boje propustljivih stakala u boji, svodi se na mernu nesigurnost etalonskog spektrofotometrijskog sistema u pogledu merenja spektralnog koeficijenta propustljivosti i tačnosti zauzimanja talasne dužine, kao i merne nesigurnosti zbog rasipanja rezultata (nehomogenog filtra). Ukupna procenjena merna nesigurnost dobijenih rezultata se pridružuje dobijenim vrednostima hromatskih koordinata; u zavisnosti od opsega hromatskih koordinata komponente

 ISBN 978-86-7466-930-3

merne nesigurnosti će biti različite posebno za svaku od koordinata, *x* i *y*. U ovom radu je predstavljena samo ukupna vrednost merne nesigurnosti. Budžeti merne nesigurnosti za pojedine filtere se proračunavaju na isti način kao u tabelama 2 i 3.

Razvojem spektrofotometrijskog sistema u laboratoriji Analysis d.o.o, ostvarena je cela procedura etaloniranja različitih transparentnih (propustljivih) uzoraka, za različite primene. Poznavanjem svojstva materijala (spektralni koeficijent propustljivosti, spektralna osetljivost detektora, odnosno spektralna raspodela izvora zračenja, može se realizovati još jedna karakteristika materijala – boje. Na osnovu dobijenih vrednosti, moguće je definisati boju datih *uzoraka* u najširem smislu i tako dobiti novu karakteristiku kvantitativno/objektivno.

TABELA III
PRIMER PRORAČUNA BUDŽETA MERNE NESIGURNOSTI STAKLENOG FILTERA U BOJI MEL-Y-2

Komponenta merne nesigurnosti	Tip A	Tip B
Merna nesigurnost spektro-fotometrijskog sistema: -Prosečno rasipanje rezultata -Pomeraj svetlosnog snopa -Orijentacija uzorka u odnosu na optičku osu sistema -Nesigurnost korekcije na inter-refleksiju -nelinearnost sistema -Neuniformnost uzoraka	0,15 %	
Merna nesigurnost zauzimanja λ		0,001 %
Merna nesigurnost izvora zračenja (apsolutno crnog tela) iz literature		1 %
Ukupna relativna merna nesigurnost	1,12 %	

VI. ZAKLJUČAK

Shvatanje boje je složeno pitanje zavisno od prilaza pojedine naučne discipline, ali je multidisciplinaran problem koji zahvata od heritologije i umetnosti do matematike, elektrotehnike, i pojmova osvetljenosti, interakcije sa zračenjima razne prirode. Kad se priđe sa gledišta koherentnosti, unitarnosti izvora osvetljenja i podseti se da se u doživljavanju boje pojavljuju razne terminologije, propisi i uobičajene, ali i specifične merne tehnike, danas se situacija komplikuje sa linearnim i nelinearnim procesima, koje donose laseri velikih gustina snopa i kratkih impulsa, pa se i aberacije hromatske prirode još više komplikuju, a i doživljaji bioloških objekata. Uz klasične aberacije pojavljuju se nove klase.

ABSTRACT

The human sense of color has many aspects, from man's understanding of the world around him to medical terms that include colorblind people, but (in everyday life) the most humane is man's sense of that part of the day or night (month or year), to enjoy heritage , left to us by our ancestors. Research assessing human life span, the existence and development of human beings, as well as the origin and evolution of flora and fauna, all this must be treated multi disciplinary, whether we start from rocks, stalactites and stalagmites, sea depths, atmospheric traces or the search for an Earth-like planet. The paper gives several approaches to color and colorimetry, from the aspect of various scientific disciplines. The role of lasers in new problems, quantitative definitions of color and its indicators are presented, and in the field of measurement, an approach is given from the aspect of filters and a correct description of the condition and operation of selected filters with modern expression of results and measurement methods. The perception of color and its description play a major role in everyday life, as well as in certain technical and mass media applications, including the social and technical sciences.

Key words: lasers, heritology, new techniques/methods.

Proto-konceptualna rešenja u primeni lasera u heritologiji

Milesa Srećković[1], Suzana Polić[2], Zoran Stević[1,3], Veljko Zarubica[4], Stanko Ostojić[5]

***A stra t*—Kritička preispitivanja postupaka koji se delovanjem na materijale primenjuju u onzervaciji-restauraciji predmeta ulturne baštine, obuhvataju opšta i pojedinačna pitanja o upotrebi novih tehnologija, posebno lasera, u odnosu na klasične prilaze problematici zaštite artefa ata, koji imaju arheološku, istorijsku ili umetničku vrednost. Pitanje etičnosti posmatra se sa više aspekata, oji se odnose na materijalna i nematerijalna postupanja prema predmetima zaštite, u smislu ispunjavanja zadate funkcije odabrane tehnike, a pod uslovima najvišeg stepena bezbednosti i ekološke zaštite. U ovom radu u fo usu istraživanja je ara terizacija proto-konceptualnih rešenja u primeni lasera na materijalima predmeta baštine, sa ciljem utvrđivanja eksplikatornih razlika u obrazlaganju potreba za primenu klasičnih pristupa onzervaciji-restauraciji kulturnog nasleđa, sa posebnim osvrtom u domenu tautoloških praksi.**

***Ključne reči*—laseri, heritologija, nove tehnologije**

I. UVOD

Višedecenijski rad fizičara, na čelu sa profesorom Asmusom (John Fredrich Asmus), koji je i prvi autor proto-konceptualnih rešenja u primeni lasera u heritologiji (od laserskog čišćenja skulptura, primena holografije u stvaranju trodimenzionalnih reprodukcija remek-dela svetske baštine, do primena lasera u utvrđivanju autentičnosti dela i restauraciji čuvenih figura od terakote u Kini) [1-4], kao i *digital-chiaroscuro* statistike [5], pa sve do doprinosa u stvaranju laserskih sistema čišćenja (*aser cleaning system*) za primenu u heritologiji [6], predstavlja tehnološki udeo u razvoju nove muzejske teorije i prakse, koju odlikuju zalaganja da „muzej od mesta koje izaziva divljenje i strahopoštovanje, postane mesto kritičkog ispitivanja“ [7].

Reč je o razvoju motivisanom uvidom u praksu konzervacije umetničkih dela, koja je uspostavljena na osnovu subjektivnih izbora kustosa i konzervatora. Sa druge strane, reč je i o uviđanju, da je svako delo organskog porekla, tokom vremena podložno promenama, što neminovno utiče na razumevanje pitanja *autentičnosti* umetnina, shvaćene kao „uzvišeno iskustvo“, odnosno „zračenje aurom“, kako to formuliše Dženet Marstin (Janet Marstine), u uvodu u tematski zbornik *No a mu ejska teorija i praksa* [7].

Međutim, uprkos početnim, istorijski značajnim rezultatima primene lasera u zaštiti kulturnog nasleđa, paradoksalno, do danas nije došlo do očekivanih razmera uvođenja ove tehnologije u muzejsku praksu, u kojoj još uvek dominiraju tradicionalne, čak i viševekovne, metode konzervacije-restauracije umetničkih predmeta, iako se u praksi pokazalo, da su u pogledu nedestruktivnosti delovanja na materijale, bezbednosti i ekoloških kvaliteta, takve metode značajno inferiornije u odnosu na lasersku tehnologiju.

I sam prof. Asmus, uviđajući navedenu situaciju, godine 2003. objavljuje naučni rad *Non-di estment laser applications in art conser ation* [8], kojim je, kako je naveo, želeo da podstakne „…oživljavanje interesa za ove moćne naučno uspostavljene tehnologije, proširenje njihove primene i prihvatanje od strane šire umetničke konzervatorske zajednice“. Kao neke od mogućih uticaja na navedenu situaciju naveo je, da je u vremenu početaka primene lasera u zaštiti nasleđa, postojalo opšte nepoznavanje potencijala laserske tehnologije, ali i uviđanje da je reč o velikim troškovima održavanja i realnim tadašnjim ograničenjima same tehnologije u primeni na umetničkim predmetima (u pogledu dostupnih talasnih dužina).

U međuvremenu, razvoj laserske tehnike obesnažuje ove argumente, a gotovo dvadeset godina posle pokušaja prof. Asmusa da oživi interes za primenu lasera u heritologiji, uvidom u savremenu konzervatorsku praksu [9], uočava se očiglednost, da postoje drugi uzroci fenomena opisane svojevrsne tehnološke regresije, kakva nije zabeležena ni na jednom od polja primena novih tehnologija. Stoga je istraživanje u ovom radu posvećeno rasvetljavanju fenomena tehnološke regresije u odnosu na proto-konceptualna rešenja u primeni laserske tehnologije u heritologiji.

II. AGON I TEHNOLOŠKI PROTAGONIZAM

Pogled na genezu problema agonalnosti u primeni lasera u heritologiji, zahteva utvrđivanje nosioca (*ektora* u

 ISBN 978-86-7466-930-3

doslovnom tumačenju termina) svrhovitog kritičkog promišlja primene laserske tehnologije u zaštiti baštine, pri čemu se *agon,* kao jedan od fundamentalnih pojmova, ovde semantički koristi u širem značenju ***ἀγών*** kao sučeljavanje argumenata u spektru teorijskih nijansi agonistike, koje logički pripadaju konotacijama u ovoj oblasti [10-13].

Te nijanse mogu da direktno ili refleksivno obogate eksplikativnu utemeljenost premise, da laser kao reprezent egzemplarne promene u zaštiti nasleđa, treba da bude razmatran kao subjekt u heritološkom procesu, a ne kao derivat u tehnološkim tumačenjima prirode konzervacije-restauracije. U tom smislu, agonalnost koja stoji u osnovi ovde istraživanog fenomena *tehnološke regresije*, na tako postavljenom semantičkom planu, omogućava da argumentacija različitih provenijencija, od umetničkih, do humanističkih i tehničko-tehnoloških, bude ispitana i na univerzalnoj ravni, pored tehničko-tehnološke, u kojoj je istraživao profesor Asmus.

Jedan od osnova za to daje i uvid koji iskazuje filozof estetike, umetnički kritičar i profesor, Artur Danto (Arthur Coleman Danto), da primena metoda prirodnih nauka na polju društveno-humanističkih nauka ne može biti adekvatna bez razumevanja metodološke autonomije istorijske nauke [14], pa se ispostavlja da potencijale primene lasera u heritologiji, u potpunosti može da aktivira samo istraživač sa odgovarajućom inženjersko – istorijsko - umetničkom kompetencijom, koja predstavlja sublimaciju artikulisanih spoznajnih horizonata i iskustava [15], pri čemu se ima u vidu, kako tehnološko, tako i umetničko spoznavanje fenomena.

Na polju umetnosti, to je mišljenje, da „…slikarstvo ne imitira, kao što [to] Platon navodi, ono ne reprodukuje, već samo smešta svet do sveta. Svet prikazâ je valjan koliko i takozvani stvarni svet.“ [16]. A na polju multidisciplinarnog susretanja tehnologije i istorije, to je pitanje inkluzivnosti istorijsko-umetničkih narativa, koji, budući da neretko ne prelaze naučne norme tehnoloških standarda, zbog svog neformativnog karaktera, izazivaju potrebu da se, kao i u slučaju tradicionalnih nauka, razumeju kao vrednost takozvanih *nenaučnih narati a* [17].

S obzirom na navedeni izraziti nedostatak egalitarnosti perspektiva, kako pokazuje sprovedeno istraživanje, u formulisanju vektora kritičkog promišlja primene laserske tehnologije u zaštiti baštine, neophodno je uvesti i pojam *protagoni am*, u skladu sa etimologijom termina *proto – agon -istis* (prvi borac), koji se ovde odnosi na kvalitet koji laser kao tehnološko sredstvo čini centrom interesa i referencom na polju heritologije, a u demonstraciji prethodno navedenih aspekata superiornosti laserske tehnologije na polju interakcije sa materijalima predmeta kulturne baštine [18].

Sa druge strane, protagonizam je suštinsko obeležje *ektora* kritičkog promišljanja u magistralnoj liniji razvoja primene lasera, koja ima naučnoistorijske osnove i koja cilja na dalekosežnost i široku obuhvatnost svog implementiranja. Otuda ova problemska postavka i omogućava uvođenje naučne deskripcije, koja konotira smenu naučne paradigme.

Istraživanjem različitih puteva parametrizacije, neophodne za sučeljavanje argumenata diferentnih provenijencija, u ovom radu prezentuje se, na koji način se parametrizacija konstituiše u skladu sa metodolgijom Žerara Ženeta (Gerard Genette), u tipologiji narativa [19], koja prebačena u okvir multidisciplinarne heritološke problematike, omogućava širi opseg pitanja o odnosu prema laserskoj tehnologiji, u kontekstu faktora *remena* (tempus), *načina* (modus), *fokali acije* (odnosno odgovora na pitanje *ko idi*) i *glasa* (vox, odnosno pitanj*ako go ori*?).

Pri tome treba imati u vidu da se u lociranju *gledišta* na fenomen koji istražujemo, *differentia specifica*traži u polju distinkcija između fundamentalnih pojmova estetike, mimezisa / μίμησις (ovde u skladu sa navedenim, blisko Aristotelovom shvatanju nagona za učenjem, kao i Lajbnicovom stavu o mogućim svetovima, u korespondenciji sa prethodno navedenim Dantovim mišljenjem), odnosno, na drugom kraju opsega, diegezisa / διήγησις, kao razlaganja u smislu strukturalistički viđenog opozita.

Na ovaj način, polazeći iz različitih oblasti koje konstituišu heritologiju, moguće je pojasniti kako se navedeni parametri povezuju u okviru teorijskih modela (tipologija) primerenih pojedinačnim oblastima, a u cilju multidisciplinarnog saoblikovanja iz preciznije metodološke pozicije, koja treba da obuhvati i iskustvene, neaksiomatske prakse, sistematizovane na nov način argumentacije, a na bazi razlike između univerzalnih i specifičnih vrednosti.

Sa druge strane, potreba usaglašavanja sa duhom vremena koji obeležava primenu svake nove tehnologije, a ovde i u kontrastu sa viševekovnim tradicionalnim tehnikama konzervacije, iskazuje se kao *interdiskurzivno prožimanje*, odnosno, kako to naziva Anženo (Marc Angenot), kao „intertekstualni protok i modifikacija ideologema“, kao istorijski određenog kompleksa vrednosti. Parafrazirajući Anženoovo stanovište, da se „na taj način istorijski uspostavlja granica među onim što se u društvu može zamisliti i izreći i onim što se još ne može ili neće misliti“ [20], ovde govorimo o mišljenju specifične ciljne grupe koju profesor Asmus opisuje kao *širu umetničku konzervatorsku ajednicu.*

Imajući osim navedenog, u vidu, da se čitav proces razvoja primene laserske tehnike u heritologiji odvija u okruženju gnoseološke ravnodušnosti *postmoderne*, koja je „anaučna a ne antinaučna“, kako to precizno formuliše profesor intelektualne istorije Ankersmit (Franklin Rudolf Ankersmit) [21], to je napuštanje tradicionalne predstave u svakoj oblasti, a kako se pokazuje, posebno u konzervaciji-restauraciji, povezano sa obrazovanjem koje treba da izgradi otvorenost prema različitim teorijskim konceptima i praksama.

To je i put za prevazilaženje predmultidisciplinarnih, tradicionalnih gledišta, kakvo na primer prezentuje Šap (Wilhelm Schapp) o svetu prirodnih nauka: „Metafizika prirodnih nauka fokusira se na tezu da je uključenost u svet priča neophodan uslov za rad matematičara i naučnika koji se bavi prirodnim naukama. Oni mogu operisati samo na osnovu tog sveta“ [22].

U skladu sa rezultatima ovog istraživanja je i mišljenje da je u postmodernom „…deontologizovanom svetu decentriranog logosa“, važno istaći značaj problematizacije načina, odnosno aktuelizacije pitanja *kako se misli,* u odnosu

 ISBN 978-86-7466-930-3

na to *šta se misli* [23], zbog čega je i neophodno da savremena pedagogija u oblasti konzervacije-restauracije, uvidi potrebu za analitičkim pristupom u opservaciji *decentriranog mišljenja* [24]. I to iz perspektive mogućnosti sticanja fleksibilnosti u prevazilaženju stereotipija i usvajanja eklektične sistematike. To je i put za mogućnost razumevanja fundamentalnih transformisanja osnova sistema znanja koje je u oblasti konzervacije-restauracije donela primena laserske tehnologije.

Kako sprovedena istraživanja pokazuju, na tom putu značajan je pristup fenomenu *tehnološke regresije* kroz identifikaciju tematizovane agonalnosti sa duhom apologije principu *élan vital* [25], odnosno usmerenosti nastvaralački, umesto na subverzivni pristup. Na taj način *ector* svrhovitog kritičkog promišlja primene laserske tehnologije u zaštiti baštine, može se postaviti na liniju univerzalnog principa stepenovane kompleksnosti, *adae uatio rei et intellectus,* da bi se uspostavio relacioni kvalitet u razumevanju limita tradicionalnih, viševekovnih, unapred zadatih formalno-kompozicionih modela u praksi imitativnog variranja receptura i cirkularnih tautoloških interpretacija. Povećanje tehnoloških kompetencija, čiji bi se karakter u ukupnom istraživačkom protokolu mogao karakterisati kao naučno formativan, omogućilo bi logična razdvajanja relevantnih od irelevantnih pojava, čime bi se i stekli uslovi za adekvatan protagonizam laserske tehnologije, izvan prostora agonalnosti.

III. ZAKLJUČAK

U ovom radu prezentovano je istraživanje paradoksa neadekvatne zastupljenosti primene lasera u heritologiji, kao oblasti zasnovane na značajnim proto-konceptualnim rešenjima. Prikazana istraživanja modela parametrizacije agonalnosti u razumevanju značaja laserske tehnologije, kao i vektora kritičkog ispitivanja, kao integralnog dela nove muzejske paradigme, ukazuju na potrebe uspostavljanja obrazovnih praksi sa formativno usmerenim modelima integracije znanja u konzervaciji-restauraciji, a u cilju eliminisanja subverzivnih shvatanja o upotrebi laserske tehnologije. Prikazani modeli mišljenja predstavljaju osnov za dalje istraživanje načina prevazilaženja specifičnog fenomena tehnološke regresije.

ZAHVALNICA

ABSTRACT

Critical re-examinations of the procedures applied on materials during the conservation-restoration of cultural heritage objects, including general and individual questions about the use of new technologies, especially lasers, in relation to classical approaches to the protection of artifacts of archaeological, historical or artistic value. The issue of ethics is viewed from several aspects related to tangible and intangible actions towards objects of protection, in terms of fulfilling the given function of the chosen technique, and under the conditions of the highest degree of safety and environmental protection. This paper focuses on the characterization of proto-conceptual solutions in the application of lasers on heritage materials, with the aim of determining explicative differences in explaining the need for classical approaches to conservation-restoration of cultural heritage, with special reference to tautological practices.

Proto-conceptual solutions in the application of lasers in heritology

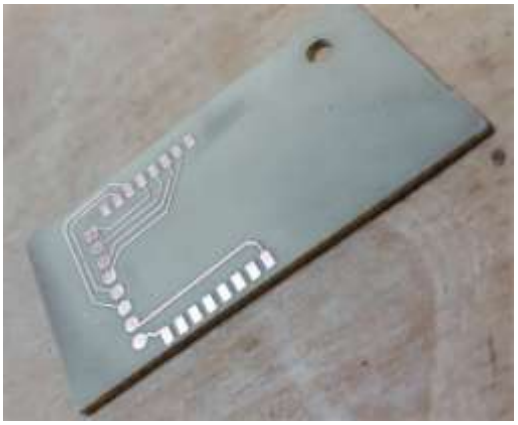
Comparison of 3D printing and galvanic coating of gold in printing circuit board production

Zoran Karastojković[1], Radiša Perić[2], Aleksandar Bugarinović[3], Milan Miladinov[4], Višeslava Rajković[5]

***Abstract*— It became a practice that in printing circuit board (PCB) production is used gold, as an exelent conductor of electricity and highly corrosion resistant (noble) metal. Gold always was an expensive metal, but in great game of electronic decices this metal must be used as a best solution, no matter for the high price. Many processes of gold deposition are available in PCB production, one of them is gold deposition by using electrolytic (or galvanic) process. However, a wide versatility of electrolytic methods were developed for production of circuit boards. In meanwile is established the one more method for curcuit production which is based on so called 3D printing.**

Between those processes existing some differencies, which need furter explanations for better understanding the PCB production, it means the reasons for choosing the proper method.



Key words: Printing circuit board, galvanic coating, 3D printing

1. INTRODUCTION

It could be said that production of PCB on galvanic (electrolytic) manner belogs to two dimension, shorter 2D. When becames clear that production of PCB by 3D printing may be cheaper than traditionally manufactured boards, this new technology has attracted a great attention. Further, 3D technology allows more complex design.

The PCBs consist from different components, depending to the final purpose of this *equipment*. So, resistors could be considered s one of the crucial component in a PCB design. But there are other electronic devices as: transistors, diodes, capacitors, inductors, sensors, etc, Fig. 1. In describing of a PCB is noticed that such board in geometric sence should be flat, other variety of informations about the functionality of this device are available in wide literature sources. In this paper the matter of consideration will be a flatness of gold traces (as a conductive layer), obtained either by galvanic or 3D printing methods.

Fig. 1, Two examples in designing of printing circuit board (PCB): a) monolayer and b) multilayer design

2. SHORTLY ABOUT THE STRUCTURE OF LAYERS

A PCB may contains just one conductive layer, Fig. 1a), or multilayers, Fig. 1b): monolayer is pretty restrictive in function abilities while design with multilayers offers a wide versatilities in making interconnections, etc. So, in designing and terminology of multilayers may be present: the top layer, an internal layer and the bottom layer, above the substrate material. Frequently an insulating layer must be present - if is needed. It must be underline that this vocabular (top, internal or bottom layer) may not be typical scientific but rather engineering terminology, particulary during fabrication of PCB devices. Multilayer, indeed, has an influence on the thickness of such boards. The four layer frequently is recommended, of course when it is possible. It is desired that the top layer is at the same time a corrosion resistant and with excelent conductive properties, as gold does, Fig. 2.

 ISBN 978-86-7466-930-3

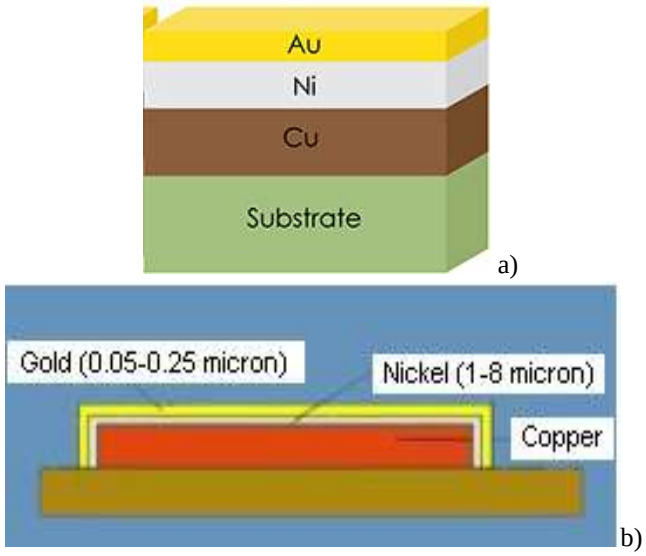

Fig. 2. Composition a) and thicknesses distributions b) at one three-layer structure over substrate material

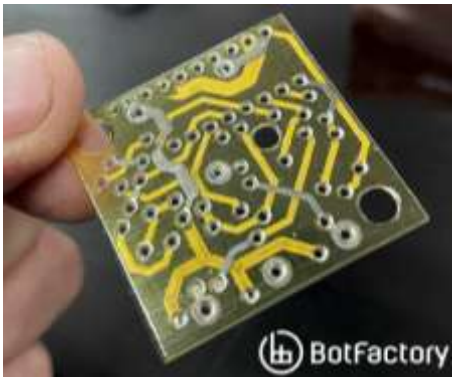
Each layer has a different function. The multilayers are used for improving the PCB performance. From many reasons (structure, hardness, price etc.) the nickel coating also may be used, as indicated in Fig. 2. As the top layer could be chosen a golded layer from one more reason, previously not mentioned, it is a soldering ability with other components from PCB. The golden layer, also called a trace, posses a pretty good soldering ability. Other facilities of (multi)layers are the subject of specialities in designing of PCB, here is the matter on wich way the deposition of gold layer may be provided.

3. ELECTROLYTIC COATING OF PCB

Electrolytic (galvanic) deposition is the well known technology in surface finishing purposes, almost as a method for imrpoving the anticorrosion properties and/or for decorative properties, but also as one of the oldest method in production of traces onto PCB. Next advantage of electrolytic deposition of metals is in possibility to attain a layer over different materials, almost metallic materials but this is not obvious. Principles and technology of such kind of fabrication are well known and applied all over the world. The pure gold could be electrodeposited and than this js known as a “soft gold”. Another tape of gold deposition is provided through an alloy (usuallly with nickel, cobalt or other metals in amount less than 0,2%) when is needed greater hardness, especially at surfaces where the force and than a friction is appeared, so such kind of golden layer is named “hard gold”. The possibilities of mixing the chemical compounds for achieving the proper electrolyte(s) also are pretty well established.

Many metals are available for electrolytic deposition, but not all of them. One of the important advantage in galvanic electrodeposition of golden layer is the possibility to attain thickness of 1μm, even less. This fact has shown a great importance in production of narrow and/or thin circuit boards, every where applied (in computers, mobile phones, TV apparatus, etc.). One example of possible thickness distribution of different layers is shown in Fig. 2b). It is found that the gold layer thickness has shown an influence on the porosity: if thickness is less about 0,40μm than the porosity rapidly increases, further when the thickness of this layer is about 0,75μm than the porosity will be markably low. No doubt that porosity or other imperfestions at the substrate material will produce a kind of porous surface at golden layer, even after the galvanic process is correctly applied.

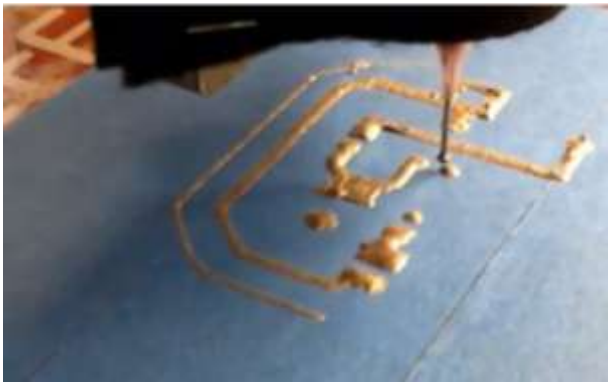
During a longterm heating-up in service periode some electrochemical migrations are possible, which could resulting in metal dendrites formation at the layer between the two adjacent electronic components (electrodes).



It should be noticed that the using of versatility of electrolites may produce a harmfull waste components.

4. 3D PRINTING OF PCB

In last decades the 3D printing as a production method becomes very attractive, especially in modeling and similar demands. In such cases the 3D method is a pretty fast and cost-less method. At many advertisements might be found just a perfect appearance, Fig. 3a). But, not every 3D modeling obviously should be successful, as could be see from Fig. 3b), where the non-uniform thickness is evident.



The printing material, here it is gold metal, should be melted during deposition and this fact represents some kind of risk when the layer is formed on plastic material, because plastic material posses a pretty power melting temperature than gold. The producing of small amount of a kind of gold alloy in the form of wire is technically possible but may be an expensive job. The case from Fig. 3b) is not desired anyway, because the flatness will be destroyed, also with markably increasing the roughness (with unequal surface topography) and a large amount of expencive gold will be unusually spent. At the contemporary level of technics the smaller thicknesses on PCB could be achieved by using a galvanic method of deposition

It seems resonably an expecting that 3D technology does not produce some harmfull components, however it is an important benefit.

 ISBN 978-86-7466-930-3

b)

Fig. 3. Results after applying the 3D printing method with using the golden wire in production of one circuit board: a) correct and b) incorect

CONCLUSION

Flat and thin surface are needed at every production method. The golded traces are wellcome in PCB from one more reason – easy soldering with other components. In galvanic (electro-deposition) is possible to attain a golden layer in thickness of 1μm, even less, but this demand still is impossible if 3D printing method is used. Surface roughness after galvanic deposition is pretty satisfactory while after applying 3D printing the roughnes is greater.

The producing of chemicals for electrolytic deposition of variety metals in the form of (inexpensive) salts or luquids now are present in industry in a great scale and could be supplied relatively eaisy, while the golden wire made from particular alloy (as mentioned with cobalt or similar) in a small amount for 3D printing still is an expensive job.

Thicknesses obtained by using 3D printing fabrication eventualy may reach values above 0,1mm, what is much greater in comparison to galvanic method of deposition. So, the 3D printing method in production of printed circuits is available only at such circuits when the thickness is greater in comparison to galvanic method of deposition.

But, the dissadvanage of galvanic tehnology is in production of variety harmful components, as a waste material, while 3D technology does not.

Apstrakt

Postala je praksa da se u proizvodnji štampanih koma (PCB) koristi zlato, kao izvanredan provodnik struje i jako koroziono postojan (plemenit) metal. Zlato je oduvek skup metal, ali u ogromnom broju elektronske opreme ovaj metal se mora upotrebiti kao najbolji materija,. bez obzira na visoku cenu. Brojni procesi taloženja zlata su primenljivi u izradi PCB, jedan od postupaka je elektrolitičko (ili galvansko) taloženje. Dakako, veliki broj elektrolitičkih metoda je razvijen za proizvodnju štampanih kola. U međuvremenu je razvijena još jedna metoda u proizvodnji štampanih kola, koja je zasnovana na tzv. štampi.

Između ovih procesa postoje izvesne razlike koje zahtevaju dalja razjašnjenja za bolje razumevanje proizvodnje štampanih kola, to znači razloge za izbor odgovarajuće metode.

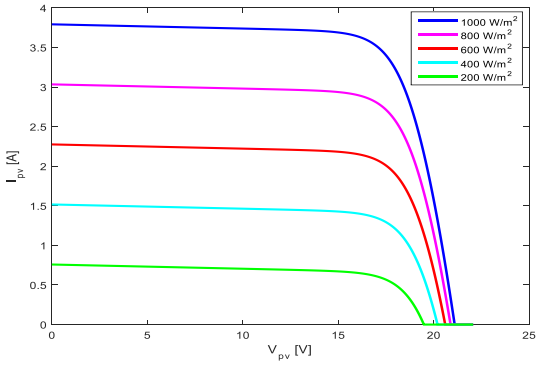
Platform for Rapid Prototyping of Maximum Power Point Tracking Algorithms in Photovoltaic Systems

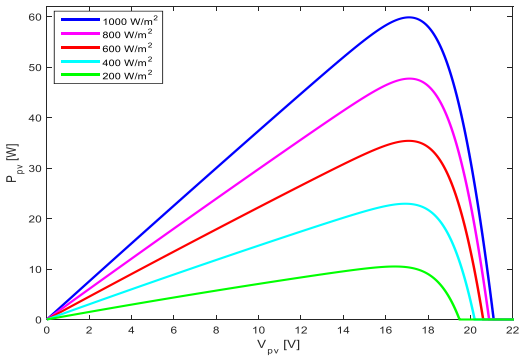


Srđan Lale, Ognjen Petrić, Slobodan Lubura and Marko Ikić

***Abstract*—This paper describes the application of the programmable logic controller (P C), which is software-implemented on the personal computer (PC), for rapid prototyping and testing of ma imum power point trac ing (PPT) algorithms used in photovoltaic (P) systems. The practical results for Perturb and bserve (P) PPT algorithm, which is used to e tract and maintain the ma imum power from the P modules connected to the synchronous buc converter, are given.**

***Index Terms*—P module; PPT algorithm; buc converter; software-implemented P C; rapid control prototyping.**

I. Introduction



RENEWABLE energy sources are becoming an essential part of global trends in the development of low-carbon economy and the so-called "green energy". Among them, the photovoltaic (PV) modules are one of the most important sources. It is well known that the PV modules behave as real (nonlinear) current sources. Their current-voltage (I_{pv}-V_{pv}) and power-voltage (P_{pv}-V_{pv}) characteristics depend on weather conditions, such as intensity of solar radiation and ambient temperature (Fig. 1 and Fig. 2). From the power-voltage characteristics it is obvious that only a single maximum power point (MPP) exists under given working conditions. To find and maintain that MPP, the maximum power point tracking (MPPT) algorithms are implemented.

 ISBN 978-86-7466-930-3

There are numerous MPPT algorithms proposed in scientific literature [1]. Many new MPPT algorithms and their modifications still continuously appear in scientific papers, because this is a very important and popular scientific topic [2]-[8]. To test the performances of the MPPT algorithms, it is very important to develop an appropriate experimental platform, which enables rapid prototyping of the MPPT algorithms in laboratory environment. Various hardware platforms are used for that purpose, for example data-acquisition boards [9]-[12], microcontrollers or digital signal processors [13], [14], field programmable gate arrays [15], [16], etc. All these platforms have their advantages and drawbacks regarding the complexity of programming and manipulation, processing speed, price, etc., so it is hard to determine the optimal platform which satisfies all criteria.

In this paper, the application of the Beckhoff programmable logic controller (PLC), which is software-implemented on the personal computer (PC)/laptop, is proposed for realization of the MPPT algorithms in the PV systems. The utilization of the Beckhoff PC-based PLC for implementation of the conventional voltage control of the DC-DC buck converter is proposed in [17]. The software implementation of the Beckhoff PLC on PC or laptop is enabled with TwinCAT software environment [18], [19]. As it is shown in [17], the main advantages of this platform are modularity, user-friendly operation, high signal processing speed, simple and fast graphical programming, low price, etc. Because of these performances, the Beckhoff PLC is a good solution for rapid prototyping of different converters' control structures, including MPPT algorithms which are subject of this paper.

This paper is organized in the following way. The conventional Perturb and Observe (P&O) MPPT algorithm, which is implemented on the proposed platform, is briefly explained in section II. The proposed platform, which is based on the application of the Beckhoff PLC, is described in section III. The obtained experimental results are given in section IV. Section V represents the conclusion.

II. Perturb and Observe MPPT Algorithm

The MPPT is not possible without the power electronics converter, which must be inserted between the PV module and load. For that purpose, a synchronous buck converter is used in this paper (Fig. 3).

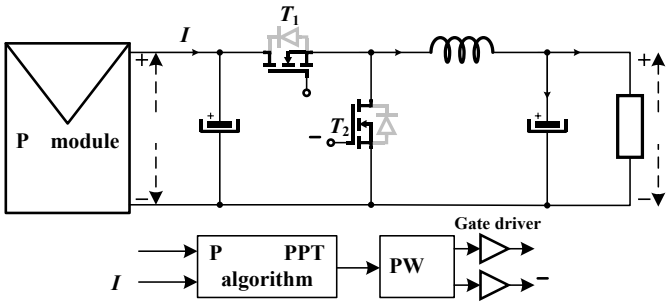

Fig. 3. Proposed PV supply system with MPPT function.

The working point of the PV module is determined by the intersection of the load working line and the I_{pv}-V_{pv} characteristic of the PV module (Fig. 4).

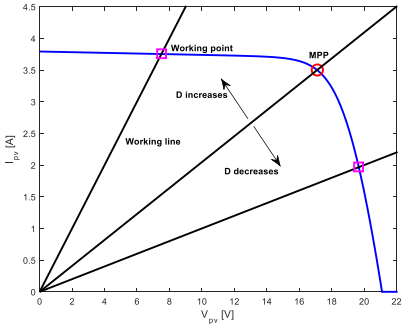

Fig. 4. Dependence of the working point of the PV module on duty cycle .

The load working line for the buck converter from Fig. 3 is equal to:

$$I_p = \frac{2}{p}, \quad (1)$$

where p, I_p, and represent the voltage and current of the PV module, load resistance and duty cycle of the switching signal u, respectively. The slope of the working line and thus the position of the working point, depend on the duty cycle , as it is shown on Fig. 4.

The P&O MPPT algorithm is one of the first developed and the most popular MPPT algorithms. Its operation is based on the permanent perturbation of the working point of the PV module, by automatic change of the duty cycle . Once the MPP is reached, it is maintained by the permanent oscillations of the working point close around the MPP. The size of these oscillations depends on the perturbation value Δ . The well-known flowchart of the conventional P&O MPPT algorithm is shown on Fig. 5.

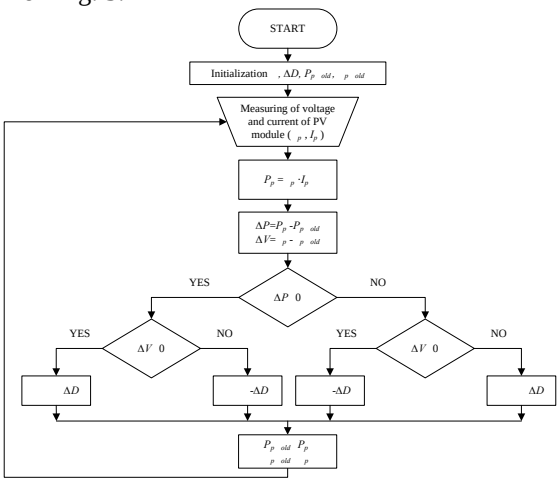

Fig. 5. Flowchart of the conventional P&O MPPT algorithm.

The inputs of the P&O MPPT algorithm are measured voltage p and current I_p. The output of the algorithm is the duty cycle , which is fed to the pulse width modulator (PWM). The PWM generates the switching signals u and $\bar{u}$ for the power switches T_1 and T_2 (Fig. 3).

 ISBN 978-86-7466-930-3

III. PROPOSED EXPERIMENTAL PLATFORM

The block-diagram of the proposed experimental platform, which is used for implementation of the P&O MPPT algorithm, is shown on Fig. 6.

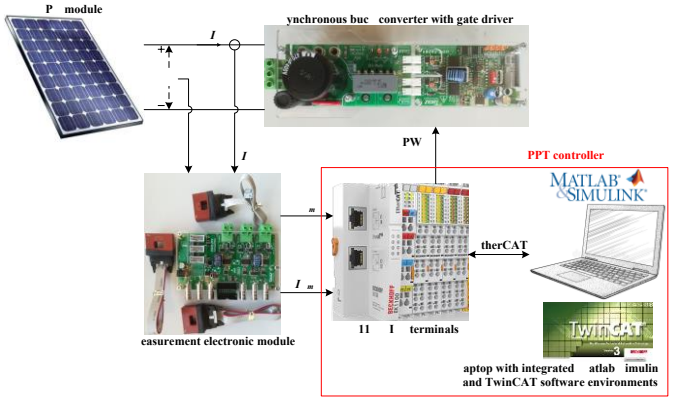

Fig. 6. Block-diagram of the proposed rapid control prototyping platform.

The platform consists of the following main parts.

A. P Module

Two PROSTAR 75W/24V PV modules connected in series, which are placed at the roof of the Faculty of Electrical Engineering in East Sarajevo, were used. These two PV modules can produce about 150 W in standard test conditions.

B. Synchronous Buck Con erter with Gate ri er

SPM-HB SiC half bridge power module [20] is used as the synchronous buck converter, with the connected GDC-2A2S1 galvanically isolated gate driver module [21]. The switching frequency of the buck converter was set to 20 kHz. The other parameters of the buck converter are: input capacitance C_i=470 μF, output capacitance C=1000 μF, inductance =220 μH, and load resistance =4 Ω.

C. Measurement Electronic Module

The measurement of the voltage and current of the PV module is performed with the galvanically isolated electronic module USM-3IV [22]. The measured voltage $_{p\,m}$ and current $I_{p\,m}$ (Fig. 6) at the output of the USM-3IV module are scaled to the ±10 V range, which is necessary for the analog input terminal of the Beckhoff PLC.

. MPPT Controller

The P&O MPPT algorithm is implemented on the Beckhoff PLC. A detailed description of the Beckhoff PLC is provided in [17]. The Beckhoff PLC is software-implemented on the laptop by using TwinCAT software environment. The TwinCAT environment converts the laptop into the real-time controller, which is connected to the input/output terminals via EK1100 EtherCAT coupler (Fig. 6). The analog input terminal EL3164 is used for accepting the measured scaled voltage and current of the PV module, i.e., the signals $_{p\,m}$ and $I_{p\,m}$, respectively. The P&O MPPT algorithm is implemented and executed in real time in TwinCAT software environment. The algorithm calculates and updates the value of the duty cycle, which is used by the output PWM terminal EL2502. The EL2502 terminal produces the PWM control signal, which is fed to the input of gate driver GDC-2A2S1.

The Beckhoff PLC is graphically programmed by using the developed Matlab/Simulink model of the P&O MPPT algorithm, which is a great benefit. This is accomplished thanks to the integration of the Matlab/Simulink and TwinCAT software environments. The created Simulink model of the P&O MPPT algorithm is integrated into the TwinCAT software environment, as it is shown on Fig. 7 and Fig. 8. The discretization period, i.e., the sample time of the model is 1 ms, the perturbation value of the duty cycle Δ is 0.005, and the update period of the duty cycle is 1.5 s.

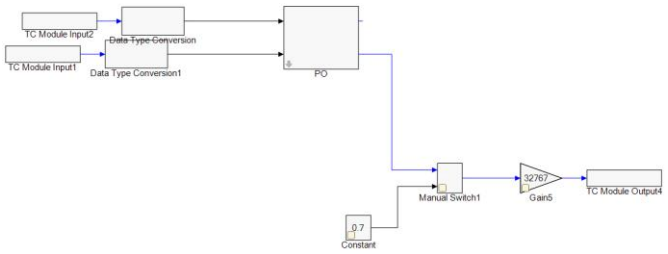

Fig. 7. Implementation of the P&O MPPT algorithm in TwinCAT software environment.

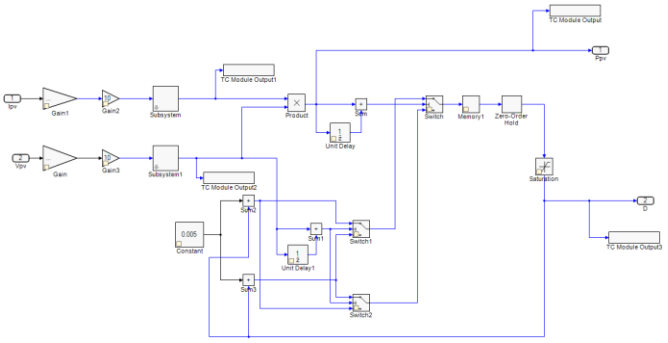

Fig. 8. Implementation of the P&O MPPT algorithm in TwinCAT software environment – scheme of the "PO" subsystem from Fig. 7.

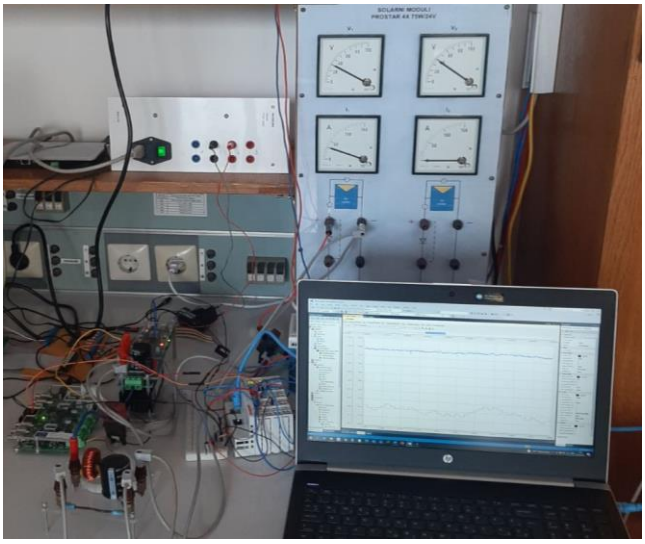

Fig. 9. The experimental setup of the proposed platform for rapid prototyping of the MPPT algorithms.

 ISBN 978-86-7466-930-3

The experimental setup of the proposed platform is shown on Fig. 9. The setup is realized at the Faculty of Electrical Engineering in East Sarajevo.

IV. Experimental Results

In TwinCAT software environment, there is a possibility to observe the signals in real time by using special graphs, i.e., virtual scopes, as well as to record them for later (offline) use.

The experimental waveforms of the obtained power of the PV module and the duty cycle are given on the following figures, which represent the real-time graphs within the TwinCAT environment. The left scale on Fig. 10 and Fig. 11 corresponds to the duty cycle (green signal), while the right scale corresponds to the output power of the PV module (blue signal).

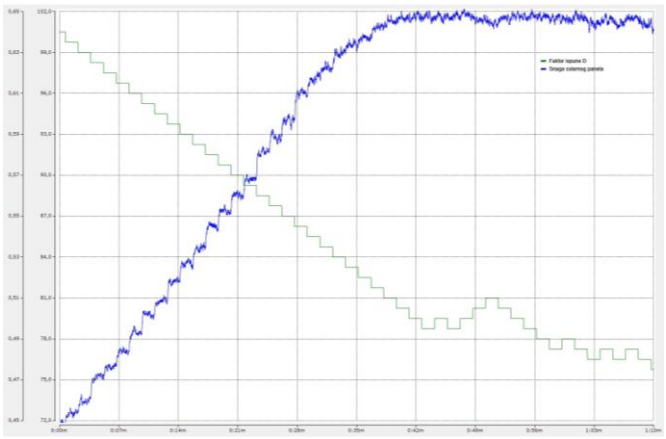

Fig. 10. The experimental waveforms of the duty cycle (green) and the power of the PV module (blue) – reaching the MPP.

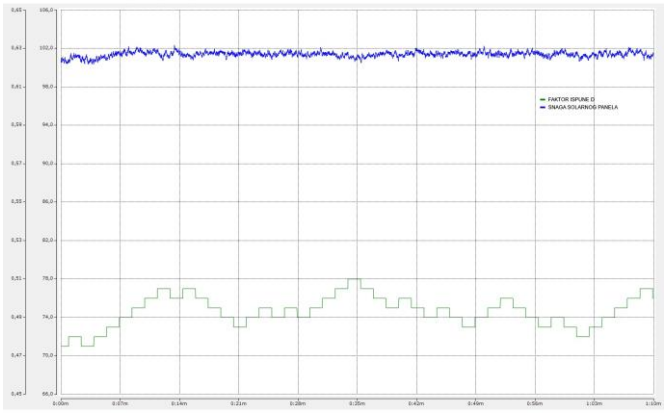

Fig. 11. The experimental waveforms of the duty cycle (green) and the power of the PV module (blue) – maintaining the MPP.

The initial value of the duty cycle was set to 0.65. It is obvious from the given experimental results that the implemented P&O MPPT algorithm successfully reach and maintain the maximum power of the PV module. These results confirm the validity and excellent performances of the proposed experimental platform, which can be successfully used for implementation and testing of the MPPT algorithms.

V. Conclusion

This paper proposes the platform for rapid prototyping of the MPPT algorithms for PV applications. The key part of the proposed platform is the Beckhoff PC-based PLC. There are numerous excellent features of this platform, such as low price, modularity, simple and user-friendly operation, simple and rapid programming by using combination of Simulink and TwinCAT environments, high processing speed thanks to the usage of the computer's processor, possibility of monitoring of different signals in real time within TwinCAT environment, etc. The platform is tested on the example of the conventional P&O MPPT algorithm. However, it can be used for any other MPPT algorithm, by changing the Simulink model and reprogramming the Beckhoff PLC. Also, the existing platform can be upgraded with additional power modules and Beckhoff input/output terminals, so more complex PV systems can be tested. Except scientific research and development, the proposed experimental platform can be very useful for educational purposes.
